## REFORT RESUMES

ED 015 628

MANUAL OF PROCEDURES AND CRITERIA FOR CAMPUS DEVELOPMENT AND CAPITAL OUTLAY PLANNING.

BY- MASON, THOMAS R. HELDMAN, HERBERT TAYLOR, LIEBERFELD AND HELDMAN INC., NEW YORK, N.Y ASSOCIATION OF STATE INST. OF HIGHER EDUC. IN COLO PUB DATE APR 64

EDRS PRICE MF-\$1.75 HC-\$19.12 476F.

DESCRIPTORS- \*CAMPUS PLANNING, \*CAPITAL OUTLAY (FOR FIXED ASSETS), \*COLLEGE BUILDINGS, \*FACILITY GUIDELINES, \*FACILITY UTILIZATION RESEARCH, CONSTRUCTION COSTS, CRITERIA, EDUCATIONAL COMPLEXES, LAND USE,

THE PURPOSE OF THIS MANUAL IS TO PROVIDE A BASIS FOR SYSTEMATICALLY PROGRAMMING THE REQUIREMENTS FOR PHYSICAL PLANT AND LAND TO ACCOMMODATE THE NEEDS OF AN INSTITUTION UNDER A SPECIFIED SET OF CIRCUMSTANCES. THE MANUAL IS ORGANIZED INTO SIX BROAD ELEMENTS -- (1) ACTIVITY LEVELS OF ENROLLMENT, INSTRUCTIONAL WORKLOADS AND STAFF REQUIREMENTS, (2) PLANNING CRITERIA FOR UTILIZATION AND PHYSICAL FACTORS, (3) SPACE REQUIREMENTS NEEDED FOR ANY FUNCTIONAL CATEGORY OF THE INSTITUTION, (4) BUILDING OCCUPANCY PROGRAMS FOR THE DISTRIBUTION OF INSTITUTIONAL SPACE REQUIREMENTS AMONG PRESENT AND FUTURE BUILDINGS. (5) CAMPUS DEVELOPMENT AND LAND REQUIREMENTS FOR BUILDINGS, PARKING FACILITIES, AND ATHLETIC FACILITIES, AND (6) CAPITAL BUDGETING FOR MAINTENANCE AND ALTERATION OF PRESENT BUILDINGS. COSTS OF NEW CONSTRUCTION AND LAND ACQUISITION. WORKSHEETS ARE PROVIDED FOR A THOROUGH COLLECTION OF DATA AND ANALYSIS IN THE ABOVE NOTED AREAS. (HH)

## COMMITTEE ON

# BUILDING SPACE AND CAPITAL OUTLAY

- Chairman:
- Thomas R. Mason, Planning Director, University of Colorado, Boulder
- D. M. Cummins, Dean of Faculty, Western State College, Gunison
- Mobert W. Marchel, Administrative Assistant, Southers Colorado State College, Pueblo
- Hanshial D. Modray, Coordinator of Flant Pevelopment, Colorado State University, Fort Collins
- Keats R. McKinney, Fall of the College, Adeas State College
- Charles H. E. J., Ur., Directive of Madeinskone and Records, Nath Kawks College, Barrings
- Rechard C. Walsh, Thisetor, Towertional Fishing Salvitos, Colorado State dellege, Greeley
- Curtis Vaight, Eudget Giffent, Colorado School of Mines Colora
- Marry J. Allon, Staff Discussor, Association of Jeats Enstitutions of Higher betweetion in Colorado
- Markert Meldman, Consultant, Waylow, Micherfeld and Millian, Nac., New York City, Mew York

### PREFACE

In recognition of the need for systematic and coordinated planning of building and capital outlay requirements of the state colleges and universities, the Association of State Institutions of Higher Education in Colorado appointed a Work Group in the spring of 1962 to develop a comprehensive procedure for estimating long-range building needs. included representatives from each of the eight existing institutions. The staffs of the State Planning Division, the State Budget Office, and the Joint Budget Committee were invited to participate in all meetings of the Work Group and were supplied with all materials of the Procedure Manual as it was developed. The Association, with funds from the Governor's office, engaged the services of the planning firm of Taylor, Lieberfeld and Heldman, Inc. of New York. This firm has wide experience in planning facilities for higher education, as well as commercial, industrial, and governmental facilities. The firm was requested to supply workable floor area standards for the various types of facilities required by colleges and universities and to criticize the procedures as they were worked out.

The writing of the Procedure Manual began during the summer of 1962. In August, the consultant, the chairman of the Work Group, the staff director of the Association, and staff members of the State Planning Division and the State Budget Office visited all of the eight campuses to review existing facilities and to discuss the procedure with institutional officials. It was agreed that the building requirements would be planned at the levels of classroom and teaching laboratory utilization recommended by A. W. Baxter, Jr., in his 1960 report to the Legislative Committee on Education Beyond High

xxiv

School. During the fall, the chairman of the Work Group, Thomas R. Mason, Planning Officer of the University of Colorado, wrote the Procedure Manual and designed the study procedures in consultation with the consultant and using the floor area standards recommended by the consultant. As each section of the Procedure Manual was completed, it was sent to each institution where members of the institution's staff began carrying out the procedures through a series of planning stages. This effort, completed in 1963, proved us full as a test of the efficacy of the general procedural methods. The Association subsequently asked the consultant to complete a revision of the Manual, prefatory to its final adoption as an official Association document.

This procedure, for the first time, will provide a uniform method of determining the capital outlay requirements of the institutions of higher education. Further revisions of the procedure will be made as experience indicates better ways. In the meantime, it will serve as a comprehensive basis for determining the need and merits of each individual building or other capital project, as well as the basis for a long-range capital funding program for higher education in Colorado.

MANUAL OF PROCEDURES AND CRITERIA

FOR

CAMPUS DEVELOPMENT AND CAPITAL OUTLAY PLANNING

**APRIL** 1964

TAYLOR, MIEBERFELD AND HELDMAN, INC.

PART I
INTRODUCTION

## CHAPTER 1

## CAMPUS DEVELOPMENT PROGRAMMING: A SYNOPTIC VIEW

# A. Perspective

The burden of the Procedures Manual is to provide a basis for systematically programming the requirements for physical plant and land to accommodate the needs of an institution under a specified constellation of circumstances. As such, programming is distinct from design. Programming efforts need not be accompanied by architectural or landscaping design activities. Indeed, a properly prepared set of programming procedures can be used as a basis for evaluating a variety of assumptions in regard to physical planning criteria, institutional activity levels, educational planning assumptions, and so on, prior to the actual initiation of design studies.

Physical plant programming is not a new activity. In the strictest sense, all building and land use schemes are predicated upon a program of requirements that may be more or less fully articulated. However, in the sense used here, programming represents a systematic approach to the determination of physical plant and land requirements. It is an attempt to fill the vacuum in pre-design analysis which in the past has been filled by architects or their clients, as a rule inadequately.

In higher education, wide-spread efforts in the direction of more systematic physical plant programming have been made in recent years.

The intensification of more systematic approaches to determining physical

plant requirements have been a product of many influences, most notable, the recognition of the "rising tide" in college enrollments. In this connection, mention should be made of the early efforts of Russell, Doi, and other pioneers in this field.

The implementation of improved programming techniques has been most noticeable in publicly-supported institutions. The state-supported systems in California and New York may be cited as well-known pacemakers in this field. At the federal government level, the Department of Health, Education and Welfare until recently had given tentative encouragement to programming efforts, but had largely confined its own efforts to providing increased information resources concerning current practices across the broad spectrum of higher education. However, recent legislation passed by Congress, "The Higher Education Facilities Act of 1963", gives renewed emphasis to the significance of adequate programming and the establishment of criteria for determining requirements and priority of need. On the other hand, private institutions are less advanced in this regard. This is understandable. Private institutions can, to some extent, control the pressures on physical plant because they are in a position to make policy decisions setting upper limits to the levels of enrollment they will accommodate; public institutions must, in a relative sense, be open to all comers.

As a by-product of this situation, private institutions have tended to minimize the pressures of the "rising tide" by limiting their enrollments to levels that are consistent with their financial and physical

plant resources. In consequence, pressure on public institutions has been growing throughout the entire post-World War II period. Whereas public institutions formerly accounted for less than half of all students enrolled in colleges and universities, the public sector now accounts for well over 60 percent of total enrollment and the proportion is increasing annually. The next several years will witness an intensification of this pressure upon the public institutions.

The proper assessment of the physical plant and land requirements of a college or university can be enhanced by consolidating into a single procedural outline the techniques for evaluating institutional activity levels and the techniques for converting such information into estimates of physical plant and land needs. Recognizing this, the Association of State Institutions of Higher Education in Colorado undertook the development of a Procedures Manual to be used by its member institutions in the development of a coordinated statement of capital requirements for campus development. To assist in this endeavor the Association retained Taylor, Lieberfeld and Heldman, Inc. a so consultants. The Manual of Procedures

The firm of Taylor, Lieberfeld and Heldman, Inc. was established at a time when increasing recognition was being given to the need for a more systematic approach to meeting the physical plant and land requirements of higher educational institutions. Since its inception, the firm has worked for colleges and universities across the United States and Canada. It has been called upon by public and private institutions, liberal arts colleges and multi-program institutions, specialized professional schools in medicine, engineering, pharmacy, and so on. Moreover, the firm's experience has not been limited solely to physical plant and campus planning. In order to function satisfactorily in these areas, the physical plant and campus programming studies have been augmented with research into the structural characteristics and socio-economic influences shaping the development of institutions of higher education.

developed for the Association is noteworthy. It is the most comprehensive and sophisticated of the approaches currently being used among state-wide systems. It is a tool of the utmost value to administrators responsible for planning for the growth of their institutions and for providing a clear-cut demonstration of the implications of such growth for physical plant expansion and capital requirements.

A preliminary version of the Procedures Manual was developed during the 1962-63 academic year. The members of the Association subsequently had an opportunity to work with various elements of the Manual and tested the viability of the methodology and validity of the criteria set forth therein. This edition of the Procedures Manual uses the first version as a foundation; it incorporates some additional material and includes revisions dictated by the need for certain technical corrections and simplification of some of the computational procedures.

The work of the consultants consisted of the following. First, suggestions were submitted at the beginning of the study concerning the general structural characteristics of the programming effort and the interrelationships among the various components of the Manual. Occasional comments critical of the Manual were submitted in the early stages of its development. Second, the consultants were responsible for providing the physical planning criteria; that is, the recommended square footage

alt was prepared by Dr. Thomas R. Mason, now Director of Institutional Research and Planning at the University of Colorado.

allocations for various functional categories of space to be programmed at the member institutions. The consultants then engaged in a two-fold task: a) a review of the Manual in its initial form, and b) an evaluation of the results of applying the methods outlined therein to the physical plant and campus development problems confronting each of the member institutions of the Association. Finally, the consultants were asked to prepare the revised version of the Manual which this volume represents.

# B. Logical Structure

The Manual is organized in a building block pattern in which six. broad elements are identifiable: 1) activity levels; 2) planning criteria; 3) space requirements; 4) building occupancy programs; 5) campus development-land requirements; and 6) capital budgeting. The accompanying diagram emphasizes the building block nature of the structure. Information concerning activity levels plus physical planning criteria yield estimates of space requirements; these in turn lead to a building occupancy program that specifies the use of existing facilities and the needs for new construction; this permits the articulation of a campus development program expressed in terms of land use; the last two elements are then convertible into a capital budget program for campus development. The feedback characteristics of the system are such that the final results in terms of capital outlay estimates, once computed, may suggest the desirability of re-evaluating the planning assumptions with regard to activity levels or any aspect of the six-component structure

outlined above. A broader discussion of each of these elements follows.

## 1. Activity Levels

. Colleges and universities typically are complex organisms. Institutional activity levels no longer may be defined solely in terms of enrollment. Instruction is only one aspect of the typical college or university scene; as such, it may be measured in terms of total enrollment, total hours of classroom and laboratory meetings, total student contact hours in such class meetings, and so on. However, it is increasingly the case that our higher educational institutions undertake externallysponsored research activity and community service programs which generate substantial workloads. Accurate measurement of the activity level of an institution requires an assessment of all three of these broad activity areas and conversion of the results into carefully articulated and detailed statements of the structure of the student and staff populations and their activities. The student population must be classified by fulltime - part-time status, by class year level, by program of study, and so The staff population must be classified by departmental affiliation and position category. Some of these estimates are in turn the result of institutional policy assumptions regarding such factors as semester credit hours and weekly clock hours of meeting to be associated with particular courses, student-faculty ratios and so on. It is only when the complex and multi-faceted structural characteristics of the institutional population have been so expressed that the planner may proceed to the next stage of programming.

# 2. Planning Criteria

The planning criteria appropriate to the programming effort fall into two broad classes. The first encompasses all criteria that deal with intensity or efficiency of utilization. Included are those criteria dealing with room utilization, student station utilization, single or multiple occupancy office use, turn-over factors in dining facilities, single or multiple occupancy in residential facilities, and so on. The second category reflects the physical aspect of planning more directly. It encompasses such factors as the square footage allocations per student station in classrooms or teaching laboratories, the areas to be assigned to private and/or multiple occupancy office stations, the number of volumes that can be housed per square foot of library stack space, the area requirement per dining station in family style dining halls, and so on. The physical planning criteria emphasize function and, as developed for this study, reflect human engineering considerations and an awareness of the state of present technology.

## 3. Space Requirements

Once having delineated the activity levels and planning criteria to be used in developing an institution's physical plant requirements, it is possible to estimate the amount of space needed to accommodate the projected activities. The resulting space program may be expressed in a variety of ways. For example, it is desirable to have estimates prepared on a departmental basis, indicating the amount of space required for academic departments such as English or Physics and non-academic depart—

ments such as the Registrar's Office and Food Services. It also is desirable to ascertain the amounts of space needed in specific functional categories, such as classrooms, teaching laboratories, offices, research facilities, library space, and so on. Finally, within each major function a category of space (such as office space) it is desirable to express the space needs in greater detail: primary areas, such as private offices or desk stations in multiple occupancy office facilities; and auxiliary service areas, such as supply rooms, file rooms, conference facilities, storage.

# 4. Building Occupancy Program

Upon completing the delineation of the space requirements of an institution in its various permutations, it is then possible to turn to the development of a building occupancy program: that is, the distribution of institutional space requirements among buildings, both existing and new. The total space requirements are derived in step 3, outlined above. If there are no existing facilities to be used in the future, the estimate of total space required represents the amount that must be provided in new construction, and the problem of devising a building occupancy program reduces to one of organizing the distribution of these space requirements among new structures. If there are existing buildings and they are to be used in the future, the existing physical plant must be surveyed and the total amount of space available must be determined. The aggregate of existing space is then subtracted from the total projected space requirements; the resulting deficit represents a first

approximation of the amount of space that must be provided in new construction. Of critical importance in programming is a careful statement of the departmental occupancy pattern, the building occupancy pattern and the cross-classification of the functional distribution of space within buildings and departments in existing structures and new buildings.

## 5. Campus Development: Land Requirements

The programming effort may now move to the evaluation of campus land requirements. Land requirements must be calculated for a number of subcomponents individually. Buildings represent one element of land use. Parking facilities, an increasingly important element in land use, represent another significant subject for analysis. Thorough consideration must be given to athletic facilities for physical education, intramural sports activities and intercollegiate programs.

To some extent, these land requirements can be approached in independence of the particular site upon which an institution is located. But more typically, it is not possible to ignore design and environmental considerations entirely in the development of campus land requirements. The criteria appropriate to an urban setting are inappropriate to rural settings. Similarly, the criteria appropriate to semi-tropical climatic conditions will be totally inappropriate to areas characterized by severe cold and snow conditions.

## 6. Capital Budgeting

Once the building occupancy pattern and campus development programs

have been elaborated, appropriate cost criteria may be introduced for the evaluation of the capital outlay requirements that must accompany the implementation of the physical development program. Consideration must be given to the cost of altering existing buildings, costs of new construction, land acquisition, and a variety of other elements of capital outlay that may arise in the course of institutional development.

## C. Policy Assumptions

The structuring of the programming model requires many assumptions that may be termed educational policy decisions. The level and distribution of enrollment, since these are affected by admissions policies, are examples of such policy planning assumptions. The length of the teaching week, the rate at which rooms should be utilized, faculty teaching loads and faculty-student ratios are other planning assumptions that must be decided at the policy-making level of an institution. In these matters, the programmer's role is limited to exploring the impact of the various assumptions that may be built into the programming model.<sup>a</sup>

Educational policy does not remain static, nor should it. Nor do the conditions underlying the programming considerations at any given instant of institutional development. The Manual provides a basis for a systematic evaluation and re-evaluation of the implications of alternate assumptions with regard to many aspects of institutional organization. The Manual permits development of a coordinated statement of physical plant and land

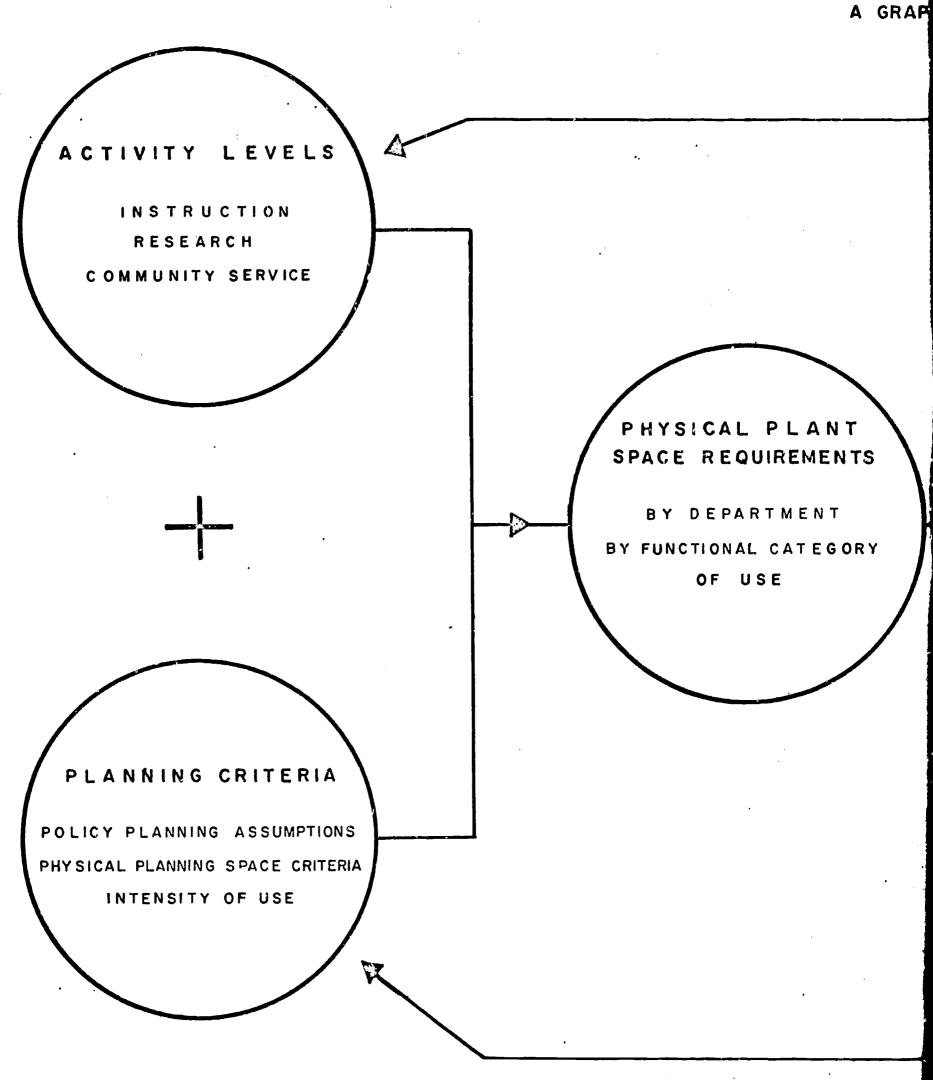

<sup>&</sup>lt;sup>a</sup>It is recommended that the reader examine the questions listed in Appendix A for a quick insight into the range and scope of the policy considerations involved in the programming procedure.

needs for single elements of an institution, an entire institution and a group of several institutions when these are viewed together as a coordinated system. Furthermore, the Manual provides a basis for evaluating the budgetary implications of alternate planning assumptions and the consistency of decisions affecting both the operating and capital outlay sides of the financial picture. The programming system provides a powerful analytical tool for use in both short- and long-term planning of institutional development.

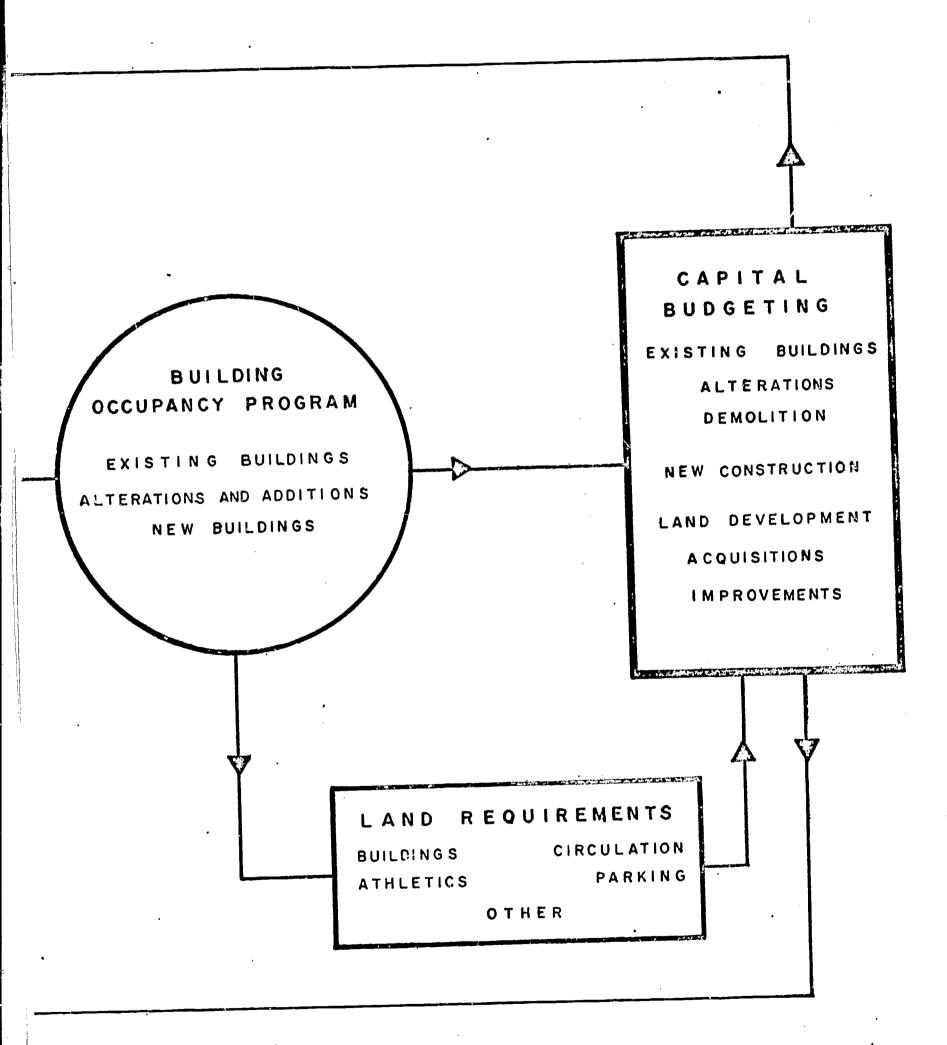

## D. Organization of the Manual

The remainder of this volume is devoted to an exposition of the procedures and criteria appropriate to programming college and university campus development. Part II deals with various aspects of the determination and expression of institutional activity levels. Part III focuses upon the development of physical plant space requirements. In Part IV, consideration is given to the procedures for developing the building occupancy program and physical plant construction program. Part V deals with another physical aspect of campus development: land requirements. The final section of the Manual is concerned with the treatment of budgeting the campus development program.

# EVELOPMENT PROGRAMMING C ANALYSIS

PART II

ACTIVITY LEVELS

#### PART II

#### ACTIVITY LEVELS

Chapters 2 through 4 of the Manual are concerned with delineating key manifestations of activity at the college or university for which the campus development programming study is undertaken. As suggested earlier in the Introduction, institutional activity encompasses instructional programs, research and community service programs. In the final analysis, these activities are in part generated by the student and staff populations associated with an institution, and are in part a result of the number of persons in the student and staff categories at each institution.

In Chapter 2, the focus is on various aspects of student enrollment that are of relevance to the planning process. That is, for the several planning stages that may be considered, it will be necessary to have estimates of the number of students anticipated on both a head count and full-time equivalent basis, classified by residence or non-residence status, classified by sex and so on. The need for these various expressions of student enrollment will be clear as the Manual is developed.

In Chapter 3, the analysis of activity levels is carried a step further. A method is presented for combining estimates of projected enrollment with various assumptions with respect to curriculum content and
the organization of instructional programs in order to produce estimates
of the size and character of the instructional workloads that may be anticipated at an institution.

Chapter 4 proceeds to the analysis of staff requirements at the projected planning stages. The number of staff required is partly a function

of the size and character of the instructional workloads already projected in Chapter 3, planning assumptions with respect to the typical workloads to be associated with various staff categories, and expectations with regard to the size and character of the non-instructional workloads that will be experienced at each institution. While no direct estimating procedures are provided for projecting research and/or community service workloads, it is assumed that the planning analyst at each institution will make such estimates and adjust the staffing patterns generated by the projection of instructional workloads accordingly. Thus, the overall staff requirement estimates should reflect the need for personnel to service all kinds of work and activity expected at each institution at each planning stage.

### CHAPTER 2

#### ENROLLMENT

## A. Student Population

Estimates of the potential student population at a college or university are a prerequisite to programming campus development. The size of instructional workloads, the number of faculty required and the physical plant and land requirements of an institution will clearly be a function of the size of the basic population group which the institution undertakes to service. Moreover, the characteristics of the projected student population must be expressed in such a way as to permit the projection of workloads and physical plant in their several manifestations on campus. Thus, instructional workloads are a function of the level and distribution of full-time equivalent enrollment. Parking facilities and dining facilities are partly related to the level of head count enrollment. The size and characteristics of the physical plant complex devoted to residential purposes are partly a function of the number of students in residence, their sex, and their distribution as between single and married status.

The significance of the planning assumptions underlying the various projections of enrollment is clear. The worksheets associated with this phase of the Manual are designed to permit the expression of these assumptions with regard to total enrollment and its classification among several relevant categories.

For purposes of this procedure, a full-time equivalent student is defined as follows. At the undergraduate level (lower and upper divisions), the FTE student load equals 15 student credit hours per term (30 semester

s.c.h. per academic year, 45 quarter s.c.h. per academic year). At the graduate and graduate professional levels, an FTE student is defined as one fall term, on-campus graduate student registered for degree work. Subsequent differentiation can be made among students at various stages of graduate study.

In most Colorado institutions, fall term undergraduate head count enrollment closely approximates the total undergraduate level student credit
hours divided by 30 semester s.c.h. or 45 quarter s.c.h. Therefore, total
academic year undergraduate FTE enrollment usually will be close to fall
term undergraduate head count. In institutions such as Colorado School of
Mines, where heavier credit hour loads are required, or Southern Colorado
State College, where substantial part-time enrollments are expected, this
will not be the case. But these differences will not affect the basic
measures of the statistical model.

In the future, appropriate data gathering methods should be instituted to permit the direct estimation of student clock hour loads from head count enrollment input. But in order to make use of the existing student credit hour data, gathered for the Association's "Class Size-Teaching Load." studies since 1955, the FTE concept is recommended for use in the procedure at this stage. Further, the FTE concept is well established in budget studies in Colorado and is a familiar term to legislators and state officials.

### B. Planning Stages and Demographic Studies

For planning purposes, it is useful to develop projections of physical plant and land requirements which are independent of the passage of time

and are a function of the level and characteristics of the workload to be accommodated on the campus. This is useful because demographic projections are subject to uncertainty and change. Furthermore, it is possible to combine subsequent analyses of demographic developments with the estimates of physical plant and land requirements at an institution and ultimately express campus development needs in terms of the time scale indicated by the demographic studies as appropriate to meeting these needs. In short, the procedure is so constructed that a series of planning stages, expressed in terms of full-time equivalent or head count enrollment for a given campus, is established. The actual dates at which these planning stages are to be reached may be determined after demographic enrollment projections are completed, and should reflect an analysis of the relationships between projected head count enrollment and FTE enrollment.

Demographic studies of the potential student population of Colorado colleges and universities have been prepared under the auspices of the Association of State Institutions of Higher Education in Colorado. In consultation with Dr. Carl Frisen of the California State Department of Finance, grade progression studies were carried out to determine probable numbers of high school graduates in the state. After determining the probable pressures of demand for college entrance upon existing institutions in the state over the next ten years, the head count enrollment estimates for each institution were developed by applying class progression ratios, adjusted for changing retention rates, transfer input, nonresident student admissions policy, and special conditions for limited professional programs and graduate level enrollments.

The statistical model outlined herein is semi-independent of the demographic student population projections. The model is adaptable to new enrollment projections as they are developed and subsequently revised.

With this method, the traditional use of "high!", "medium!", and "low" enrollment projections to a given year is replaced by a system of determining whether an enrollment of, say, 3,000 FTE students will be reached in 1968, 1970 or 1972. In other words, a given stage of enrollment is fixed and the time scale is varied. When demographic enrollment estimates are updated, analysis of the relationships between head count and FTE enrollments will permit revision of the estimates of when the various planning stages may be reached.

From its current estimates of enrollment growth, each institution should establish a series of FTE enrollment levels covering the forth-coming ten-year period. Rounded figures may be used to express total FTE enrollment, with equal increments of 250, 500, 750, or 1,000 FTE students. The number of planning stages will vary from institution to institution. The first stage should approximate the FTE enrollment in the base year; the last stage should approximate the FTE enrollment expected ten years later. The intermediate stages are arbitrary increments of a given number which should be approximately related to the average rate of growth expected for a one- to two-year interval.

By way of example, the following stages may be established for various types of institutions:

Total Full-Time Equivalent Students

Planning Stage	Large <u>Institution</u>	Medium Institution	Small Institution
I.	10,000	3,000	1 <b>,</b> 250
II	11,000	3,500	1,500
III	12,000	4,000	1 <b>,</b> 750
IV	13,000	4,500	2,000
<b>v</b>	14,000	5,000	<b>2,2</b> 50
VI	15,000		2,500
VII	16,000		2 <b>,</b> 750

The statistical model serves only to provide approximations of future requirements. Therefore, little is gained by an undue effort at precision in the enrollment estimates. Moreover, the labor of calculation is considerably increased if too many stages are attempted. The capital budgets to be derived from these estimates are generally accurate only within the first three years, in any case, and a building program can never reflect ideal annual growth increments. Not only will the building construction program usually lag behind need, especially in the coming years of rapid growth, but individual buildings must be planned to accommodate future growth in the fields they serve. Therefore, the approximations of building space requirements derived from the procedure are sufficiently accurate to provide the basis for moving five-year capital budgets, yet sufficiently flexible to allow for unpredictable changes in rates and magnitudes of enrollment growth.

## C. Outline of Procedure

This section of the Manual consists of five worksheets. Worksheet

2.1 permits the expression of the relationship between the demographic

projections of enrollment and the planning stages that have been established

for purposes of carrying out the campus programming study.

Worksheet 2.2 calls for the expression of enrollment classified by full-time equivalent and head count status and further sub-classified by level. Recent trends and institutional policy will permit determination of the distribution of enrollment by level; that is, lower division (freshman, sophomore), upper division (junior, senior), and graduate. The mix or distribution of enrollment by level should be related as carefully as possible to any institutional programs or policies affecting such distribution. At the graduate level, especially, the expected growth should be reviewed in relation to the program study of the Association's Task Force. This determination should therefore be made in consultation with the Task Force representatives, the chief academic officer of the institution, and the president.

Worksheet 2.3 permits the conversion of the enrollment data expressed in the preceding worksheet to indexes of growth relative to the base year enrollment levels in each category. These indexes will prove useful in subsequent stages of the analysis.

Worksheet 2.4 calls for the delineation of head count enrolls at in several further sub-categories; classifications are provided by sex, by residential status, and by marital status. Worksheet 2.5 permits expres-

sion of the data in worksheet 2.4 in relative terms; that is, as indexes of growth relative to the base year level of enrollment in each category.

It should be remembered that the procedure called for is the construction of a statistical model of future development, not a precise projection of the past into the future. The determination of enrollment mix should therefore be made on the basis of institutional judgment, informed by recent trends, the objectives of the institution, the prospects of new programs, changes in institutional policy, and so on. A written statement describing the reasoning behind the determination of enrollment mix should be prepared and included as part of the technical note section of each table where this is relevant.

## CHAPTER 3

#### INSTRUCTIONAL WORKLOADS

A key step in the campus development programming study is forecasting the volume of instructional activity at the several planning stages under consideration. The size and character of projected instructional work-loads will directly affect faculty and non-faculty staff requirements, the amount and composition of physical plant required, land requirements and the capital budget needed to implement the development program. This chapter focuses upon the technical procedures involved in converting the enrollment estimates presented earlier into instructional workload projections, detailed by department and course. Because of the nature of instructional organization, the analysis will extend in detail to the basic unit of instruction, the individual course offering. While this may generate considerable work in data processing, it is necessary to the adequate exploration of the basic expressions of academic policy and instructional workload.

A. Historical Developments and Subject Field Variations in Instructional Workleads

Colleges and universities are dynamic institutions. Programs of instruction and course offerings rarely remain static for very long periods of time. Not only does an institution modify the character of its offerings in order to provide better quality instruction and more closely meet the needs of the community it services, but students also express varying preferences for programs of study and subject field offerings from year to year. Nevertheless, historical data on the development of instructional

workloads are an indication of the relative strength of particular subject field offerings as well as underlying trends in student preferences.

The first four worksheets in this chapter are designed to provide a basis for analyzing historical patterns in the distribution of instructional workloads. The historical analysis is conducted on two levels of detail: by subject field; and by course level (lower division, upper division or graduate). Workloads may be expressed in terms of student credit hours, full-time equivalent enrollment or head count number of course registrants; the planning analyst must designate the particular form in which the workloads are expressed. However, it should be noted that the last of these measures, head count number of course registrants, is the preferred basis for expressing instructional workloads if the data should be directly available.

Worksheet 3.1 provides for the identification of instructional work-loads by subject field and course level for the past six years. These are the raw data upon which the subsequent analysis is based. Worksheet 3.2 permits the planning analyst to adjust the historical data by eliminating material which may be irrelevant for future planning or adding workload data relating to subject field offerings that may not be included in the historical data. Thus, the basic data can be adjusted so that they are consistent with the scope of offerings anticipated during the planning interval under consideration.

Worksheet 3.3 calls for the analyst to weight the historical distribution of instructional workloads so that the recent years are given relatively greater prominence in the evaluation of shifts in student preferences and curriculum content over time. The weighted distribution contributes to a more reasonable evaluation of the significance of shifts in the distribution of instructional workloads by subject field, giving weight to recent experience without allowing basic curriculum stability to be overshadowed by recent trends.

In worksheet 3.4, a technique is suggested for measuring the shifting pattern of preferences in subject field offerings over the historical period being considered. The resulting measure is designated as the index of trend variance. The index measures in relative terms the extent to which components of total instructional workload vary from the trend characterizing the total; that is, changes in the instructional workloads in individual subject fields relative to changes in the overall workload level of the entire institution. The index thus has a value greater than 1,000 in subject fields experiencing more rapid growth in instructional workload than the average for all subject fields, a value of less than 1,000 where the opposite situation prevails, and a value equal to 1.000 in subject fields in which instructional workloads are just keeping pace with changes in the overall workload level. However, the extreme values that might be generated solely by trend analysis are avoided. Where instructional workloads are increasing more rapidly than the average for the entire institution, the index of trend variance is greater than 1,000 but less than it would be if the weighted average system were not used. The rationale for computing the index of trend variance is explained in the following section.

B. Projection of Instructional Workloads: Course Participation Levels

The procedure now shifts to the projection of future instructional workloads in each subject field. But before explaining methodology, a comment is in order regarding the general logic of the projection procedure.

Consider the instructional workload represented by any given course. In the base year, the instructional workload associated with the course can be measured in terms of full-time equivalent students, credit hours generated, or head count number of course registrants. In turn, participants in the course may be described as lower division, upper division or . graduate level students. Clearly, growth in these enrollment categories. will directly affect the absolute and relative amounts of increase that may be anticipated in the number of students taking the course under consideration at each planning stage. The programming procedure has already called for a projection of the expected growth in full-time equivalent enrollment at each of these levels (see Chapter 2). This information is significant since growth in registrations or instructional workloads in a particular course should certainly reflect the combined influence of the growth patterns characterizing the several classes of students registered in the course in the base period (and who may be expected to take the course in the future).

In a static world in which student preferences did not change and curriculum offerings were constant, enrollment change would be the only influence affecting course workload, as measured in terms of number of participants. Only variations in the patterns of enrollment change

anticipated for the several student groups taking a course would produce a shift in workload other than proportionate to the change in total enrollment.

However, student preferences do change and curriculum structure is not static. For these reasons, the estimating procedure must incorporate a variable to take account of this modifying influence. The measure developed for this purpose has been designated the index of trend variance. As described above, the index measures the relative deviation from the over-all pattern of expansion that may be expected in a particular subject field and course group within the subject field. The index incorporates recent trends in the relative drawing power of various subject fields; it is thus a reasonable basis for modifying the simple growth factor describing the changes expected in the three enrollment groups from which the students taking a course are drawn. Taken together, the index of growth in enrollment and the index of trend variance in subject field course offerings provide a composite index of expansion that will reflect expected changes in the two broad influences affecting course workload: a) changes in emrollment, and b) shifts in student preferences and/or curriculum structure as indicated by recent trends.

Worksheet 3.5 provides the technical format for implementing the method described above. The worksheet implies that the estimating procedure should be carried out at the level of detail associated with a course-by-course analysis. This may involve extensive demands for calculating time. Yet, a course-by-course analysis is essential to estimating the total workloads that can be expected in each subject field, the implicit

faculty requirements generated by these workloads, and the various forms of instructional and non-instructional space that will be needed to service these loads.

Following is an example of the procedure. The illustration demonstrates the mechanics of projecting the instructional workload in a course which has students registered from different enrollment groups.

Illustrative Program for Projection of Instructional Workloads at Specified Planning Stage, by Subject Field, Course and Level of Student Registrants

Instit	ution: State	Subject College Field:	Chemistry		ower Plan ision Sta	ning ge: <u>III</u>

Col. Col. Col.	2: Instituti 3: Instituti	ional records ional records ional records t 2.3	Col	l. 6: Col.	sheet series 4 x Col. 5 3 x Col. 6	3.14

N.B. 1) Total instructional workload at target period is obtained by aggregating projected Lower, Upper and Graduate participation.

2) Instructional workload is expressed as head count number of course registrants.

and column 2 of worksheet 3.5, the level of student registrants refers to the enrollment group from which the students participating in a particular course are drawn. Thus, there may be twenty students from the lower division, ten students from the upper division status, and one student who has graduate status. On the other hand, the index of trend variance in column 5 is associated with the course level of the course being offered. As such, the index of trend variance does not change with the level of student registrants. Rather, the index of trend variance changes only with shifts in the course level at which the particular course is offered; i.e., from lower division to upper division or graduate level.

## C. Policy Assumptions Concerning the Organization of Instruction

The data on instructional workload, as measured by student registrations, are in themselves useful. But various other objectives require the expression of instructional workload in different form. In particular, these data may in turn be transformed into corollary estimates of the number of clock hours of meetings per week or the number of meeting groups per week. This requires certain policy planning assumptions concerning the structure of curriculum offerings and the organization of instruction in these courses. Worksheet 3.6 may be used for systematically recording these assumptions. The program of course offerings in each subject field should be enumerated, together with the planning assumptions regarding the credit hour value per student, the number of clock hours of meeting per week in various types of classroom or special purpose instructional facilities, and the preferred sizes for meeting groups in these facilities. The last may be developed by direct consultation with administrative heads of the various subject fields.

Worksheet 3.7 specifies additional policy planning assumptions which show the basis for converting from the original workload projections to appropriate corollary expressions of instructional workload. Definitions are provided for the transformation relationships among three forms for expressing instructional workload: student credit hours, full-time equivalent enrollment, and head count number of course registrants.

Worksheet 3.8 carries the analysis through the conversion of the instructional workload projections prepared in worksheet 3.5 to the desired corollary expressions. Three measures of instructional workload at each target planning period thus will be available for each course. It should be noted that the programming procedure as outlined later in the Manual only requires that data be developed in terms of head count number of course registrants. Thus, completion of this worksheet may not be necessary if the analysis in worksheet 3.5 has already been carried out in terms of course registrations. The corollary expressions, FTE enrollment or student credit hours, however, may be found useful for other purposes.

D. Projection of Instructional Workloads by Type of Facility Required and Class Size

It is of critical importance to subsequent projections of the requirements for scheduled instructional space that projected instructional workloads ultimately be expressed in terms of type and capacity of facility required. The remaining worksheets in this chapter are to be used for this purpose. The analyses covered by worksheets 3.9 through 3.12 are primarily manipulations of the data already developed.

Worksheet 3.9 focuses upon the class and student periods of instruction associated with each course. The worksheet draws upon data developed earlier for each course: i.e., the projected number of course registrants; and the policy planning assumptions regarding the preferred class sizes and clock hours of meeting per week in each type of meeting facility. These data are then combined to obtain estimates of the total class hours and student periods per week in various kinds of classroom and special purpose instructional facilities.

Worksheet 3.10 summarizes the projections of class hours and student periods per week in each subject field at the specified planning stage. Worksheet 3.11 summarizes the development of projected class hour and student period workloads in the specified subject field over the entire planning interval. In both worksheets, the data are classified by type of instructional facility. Finally, worksheet 3.12 calls for an analysis of the size distribution of projected group meetings by subject field for the specified planning stage and type of facility. These several classifications of instructional workload are similar to some of the material contained in the "Class Size-Teaching Load" studies conducted by the Association.

The worksheets contain sufficient technical material to permit the analyst to move through the successive stages of analysis without difficulty. Institutions may vary in the extent to which underlying data are available for the detailed analysis outlined in this chapter. It will be in the long-range interests of the institutions if future data gathering reflects the needs implicit in the above exposition.

The lack of the historical student credit hour data for Southern Colorado State College and the change to the trimester degree program at Fort Lewis, of course, prevent the direct application of the foregoing procedures by these institutions.

It will be necessary for these institutions to develop constructs of their prospective student load distributions by analysis of their curriculum plans and assumptions about student input and course choices. In

these cases, the direct estimation of instructional workloads may be made by means of a complex statistical model.

The progression of students through the complete degree programs offered by the institutions requires elaboration of the model through the
entire sequence of choices. If this type of analysis can be carried out,
the basis for a comprehensive institutional plan is at hand. The completed
model may serve to predict building space and other physical plant requirements, faculty and staff requirements, the effects of program changes, and
the like from a given student input and a given set of assumptions about
student choices.

A complex model of this sort may be developed in the future for other existing institutions, but for larger, on-going institutions such data can only be handled on large-scale computers and then only after much further study of the multitude of variables at work in each institution. The institutions planning new degree programs should, if possible, introduce this system at the outset when student input into the degree programs will be starting and when planning can be based upon rational assumptions linked to the goals and object res of the institutions.

### CHAPTER 4

### STAFF REQUIREMENTS

### A. Staff Cersus

The projection of faculty and staff requirements at each planning stage is the basis for estimating a large proportion of building space at any college or university. Offices, research area and service facilities of various types are estimated in terms of work area required for faculty members and supporting staff. These projections also are useful in planning connected with long-range operating budgets and serve as a vehicle for improving academic program planning.

Key policy assumptions are involved in estimating faculty and staff needs and these require high level review within each institution. As a starting point for such review, a comprehensive analysis of the actual staffing patterns of the institution should be carried out. It is recommended that the fiscal year used for such analysis be the same as the base year reference for the over-all programming study.

The base year inventory of faculty and staff should cover all departments and divisions of the institution operating on the home campus, including non-institutional personnel such as employees of federal, state, and other agencies. The criteria for inclusion is the provision of office or work space on the campus.

Worksheet 4.1 indicates a format that may be used for such a census or inventory. The worksheet suggests a series of categories into which staff

may be grouped. For purposes of analysis, it is useful to make both head count and FTE tabulations of faculty and staff. Appendix C provides a listing of personnel titles grouped in general categories to illustrate possible methods of classification. Since institutional practices and policies vary widely, it may be necessary to adapt the categories to the classification and record-keeping system of the institution. Thus, the forms and categories listed should be viewed as suggested, not required. The broad personnel categories are as follows: faculty and other professional; student; supporting technical; supporting clerical; other.

Analysis should be made by department and division so that these may subsequently be related to subject fields in instructional departments and to locational groupings. Departments and divisions should then be grouped by functional categories. These functional categories follow the state budget forms and were used in the building inventory established for the 1959-60 Baxter study. A suggested coding of these functional categories is given in Appendix D, table D.1. The broad functional categories are as follows: instruction; research; library and museum; public service; administration and general; plant operation and maintenance; organized activities related to instruction; auxiliary enterprises; housing and food service; non-institutional agencies; other.

### B. Projection of Staff Requirements

The projection of staff needs should be based upon an analysis of the load factors relating to a given department and type of personnel. Worksheet 4.2 is designed for the delineation of the basis for projecting staff needs in each department. The definition of what constitutes an FTE staff

member and how staff is to be estimated should be explained on this worksheet.

For example, in instructional departments faculty requirements will be tied directly to student loads. Non-faculty staff requirements in instructional departments will be made a function of faculty requirements. In other departments or divisions, workloads are not necessarily tied directly to student numbers. But, wherever possible, some relationship between personnel requirements and projectable workloads should be sought. For example, physical plant maintenance personnel may be tied to gross building area, grounds maintenance workers to camous acreage, food service employees to meals served, and so on. In many cases, however, such measures are not available, and in these instances the exercise of judgment in making rough projection assumptions is required.

### 1. Faculty Requirements

Worksheet 4.3 provides a format for the projection of faculty requirements. The projection involves the consideration of two variables: a) an assumption with regard to the average teaching load per faculty member per week; and b) the projection of weekly departmental instructional workloads developed through the analyses conducted in Chapter 3. Worksheet 4.3 provides alternate bases for making the estimates of faculty requirements; it then permits the planning analyst to select or reject any of the formal estimates implied by the relationships suggested therein and specify the set of estimates to be used for planning purposes.

The method of estimating faculty requirements goes directly to the heart

74

of the academic policies and instructional methods of the institution in each subject field and level of instruction. The method avoids the pit-falls of over-generalization entailed by the use of the broad student-faculty ratio concept. The calculation of faculty needs can vary according to changes in the mix of student loads by subjects and levels of instruction as predicted in the statistical model. As a result, shifts in instructional workloads among lower division, upper division and graduate level work will be reflected in changes in the relative number of FTE faculty required.

Worksheet 4.4 permits the conversion of projected faculty requirements into indexes of growth which measure the increases in faculty by any planning stage relative to the number of faculty assigned to each department in the base year. The worksheet also makes it possible to compare the relative rates of growth in faculty requirements among the various instructional departments at an institution over the planning interval described in the worksheets.

### 2. Non-faculty Staff Requirements

Worksheet 4.5 is designed to permit the projection of staff requirements other than faculty for both instructional and non-instructional departments, by position category. Faculty projections already made in worksheet 4.4 would be entered on this worksheet. But staff requirements in all other position categories would be calculated for the first time. The projection of non-faculty staff requirements will involve two previously developed sets of information: a) the data in worksheet 4.1 dealing with the base year inventory of personnel; and b) the planning assumptions specified in worksheet 4.2

regarding the basis for projecting staff requirements by position category in each department.

It should be noted that worksheet 4.4 does not distinguish as to the composition of total full-time faculty. Two possibilities are open to the planning analyst, depending upon the institution's policy with regard to the use of graduate assistants or teaching associates. First, it may be assumed that the projections of faculty requirements include the full-time equivalent student assistants, in which case the entry for student assistants in worksheet 4.5 will require an appropriate downward adjustment of the entry for projected faculty. The other possibility, of course, is that the projection of faculty requirements in worksheet 4.4 does not cover student assistants. In this case, the completion of this component of worksheet 4.5 would thus be carried out according to the general instructions described above.

For other categories of staff, requirements are also based upon anticipations of workload. In instructional departments, non-teaching staff requirements are usually tied to faculty size and ultimately to instructional workloads. Supporting technical and clerical personnel thus would normally be made a function of the total size of the combined faculty and student group in the instructional department. However, adjustments would have to be made to reflect the need for the staff to service anticipated research and community service workloads associated with the department but not specified directly in the preceding analyses. For non-instructional departments, the planning analyst must similarly devise an appropriate basis for projecting staff needs.

### C. Final Staff Estimates

Worksheets 4.6 and 4.7 permit summaries of the staff projections to be developed in varying degrees of detail. These summaries are useful as a basis for quick comparison of the results of the projection procedure among departments, and position categories and planning stages.

The exact method of estimating staff requirements must be left to each institution, but the final reporting is to be summarized on the worksheets indicated in Chapter 4. Common sense should dictate the methods used to develop quantitative estimates of staff requirements. As long as the estimating factors are generally defensible, good judgment is valid for the purposes at hand.

PART III

PHYSICAL PLANT

SPACE REQUIREMENTS

### PART III

### PHYSICAL PLANT SPACE REQUIREMENTS

Institutional physical plant requirements depend upon the projected activity levels of the various operating departments of the college or university and the unit planning criteria adopted for use in physical plant programming. In developing programs of present or future space requirements, the analysis may be conducted along either functional or administrative lines. If the former course is elected, a series of space categories is established and the programming effort focuses on each of these functional components of physical plant in turn. Alternately, each administrative unit may be dealt with in turn, and the analysis of all physical plant requirements associated with the particular unit would be completed before going on to the next department.

For reasons of clarity in exposition, this Manual of space programming is developed along functional lines. Over-all physical plant is divided into twelve broad space categories: classroom space; special purpose instructional space; office space; research space; library space; museum and gallery space; athletic activities space; housing space; food service space; staff and student service space; miscellaneous other space; and physical plant maintenance and operations space. Upon completing the portion of the Manual dealing with any one of these twelve broad categories, the analyst will have obtained the over-all institutional requirements for the particular functional category of space considered. Upon completing the programming of all twelve categories, the analyst can then establish the total space requirements of the institution by aggregation.

In addition, the total space requirements of each department can be determined by reorganizing the data and aggregating the projected departmental needs for the various components of space represented by the twelve broad functional categories.

Chapters 2 through 16 are devoted to an exposition of the method for programming the area requirements associated with each of the twelve broad space categories identified above. Analytically, the Manual takes approximately the same form in dealing with each category. First, the broad category is further subdivided into primary and auxiliary components.

Second, the activity or workload generating the primary space needs is identified. Third, the workload estimates are combined with intensity of use and unit area physical planning criteria to obtain projections of primary space requirements in the particular broad category considered.

Fourth, the primary component is augmented by an estimate of the auxiliary or service space needed to complement the primary allocation and make it completely workable relative to the expected workloads. Finally, by aggregating the primary and service components, the over-all space needs associated with a particular functional category are obtained. Planning stage and departmental assignment are always indicated.

The degree of detail and elaboration involved in the calculation of space requirements varies among the broad functional categories. For some components of physical plant, such as special purpose instructional space, a lengthy and detailed analysis is required. For other components, such as museum and gallery space, the programming method is less complex. In general, variations in the degree of complexity of the procedural outline

are a function of the number of considerations involved in dealing with a particular component of physical plant and the degree of diversity among the space elements included within the broad category.

The physical planning criteria are presented in tabular form immediately following the text discussion of each space category. They reflect an analysis of the amounts of space required to perform the types of functions that may be involved. In some instances, it is the needs of an individual for a work station that determine the physical planning criteria. In other instances, the needs are generated by the characteristics of a particular piece of equipment. In still other types of space, the physical planning criteria reflect consideration of the extent to which supporting space, which varies widely in characteristics and encompasses a variety of elements, is needed to make the primary space allocation associated with individuals or equipment functionally satisfactory. In all instances, the criteria reflect the experience of the Consultants and other planners and institutions throughout the country in planning the typical quantities of space associated with various types of activities. Departures from these criteria may be necessary in the case of particular institutions or operating departments. Such departures presumably can be justified by the characteristics of the activities to be accommodated in the space, and rigid adherence to the recommended physical planning criteria should be eschewed in these cases.

One further consideration should be kept in mind. Implicit in the programming procedure is an evaluation of how intensively the space or capacity is to be used. This concept is most familiar in the case of teach-

ing facilities; e.g., room utilization and student station utilization. However, the same consideration underlies all other components of physical plant. Thus, it is implicit in the decision to program single occupancy or multiple occupancy office space for various categories of personnel. It is implicit in the calculation of the capacity requirements associated with the reader station component of the library. It is also implicit in an evaluation of the turnover factor in dining facilities. To some extent the Manual assumes the adoption of certain planning criteria that have already been established through earlier studies sponsored by the Association. A case in point is the room and student station utilization criteria for scheduled space as developed in the Baxter studies. In other instances, the intensity of use criteria will reflect policy planning assumptions made by the planning analyst or institution involved. It should always be borne in mind that variations in the underlying assumption regarding the intensity of use of a particular space component are of significance and deserve at least as much attention as the actual physical planning criteria that may be used in developing the projections of space requirements.

### CHAPTER 5

### CLASSROOM SPACE

Instructional workloads in classroom-type facilities were projected for each planning stage by the methods outlined in Chapter 3. The general category "classrooms" is subdivided into three types: regular classrooms, seminar rooms, and lecture-auditoriums. This is because these types have different unit area requirements and different scheduling capabilities. This chapter outlines the method recommended for transforming classroom instructional workloads into room and station capacity and square footage requirements for each planning stage, along with the recommended utilization and unit area criteria.

### A. Capacity Utilization Planning Criteria

Classroom utilization studies were carried out by the state supported institutions in Colorado in 1957, 1959, and 1961. These studies have been useful in two respects: a) they measure the efficiency with which available space is actually used; and b) they provide data from which subsequent planning can be carried out. Unfortunately, this latter aspect has been largely neglected in the past. The crux of the classroom utilization study is its value in planning to improve the use of facilities by achieving closer fit between classroom time demand and number of rooms and closer fit between the distribution of class sizes and the distribution of classroom sizes.

Classrooms are merely the physical tools of instruction. The primary objective must be to provide the proper tools to maximize the effi-

ciency of the learning process; the frequency with which the tools are used is secondary to that first purpose. In planning future classroom need, therefore, the goal is to provide the right number of classrooms and the right size distribution to serve the educational program. Serious damage can be inflicted upon the educational program by a shortage of classrooms of the right size and kind. Furthermore, during the next decade, the problem in public colleges and universities will be to have enough classrooms at the right times to provide for the expected doubling and tripling of enrollments; it will not be difficult to improve rates of utilization under these conditions of rapid growth. Finally, it should be noted that while 90 percent of the organized formal instruction takes place in classrooms and teaching laboratories, these facilities compose as little as 10 percent and seldom more than 25 percent of the total floor area of an institution of higher education. Office space, research space, storage, shops, heating plants, warehousing, food service, residential space, libraries, gymnasiums, and many other types of facilities are required to support the instructional programs carried on in college teaching facilities.

Three criteria for intensity of use are relevant when considering the utilization of classroom-type space. The first is the room utilization rate; this may be defined as the number of hours during the teaching week that rooms are in scheduled use or, alternately, the proportion of the teaching week that rooms are in scheduled use. The second is the student station utilization rate, which may be defined as the proportion of available student station capacity that is occupied during the time that class-

room-type facilities are in scheduled use. The third is the capacity utilization coefficient; this measures the average number of periods per week that student stations are in scheduled use, or, alternately, the proportion of total possible student station periods per week that stations are occupied.

To estimate future classroom requirements, levels for these utilization rates must be established as goals for achievement: that is, classroom capacity is determined for a given future instructional load by establishing an average rate of hours of scheduled use per room and a rate of station occupancy as a "standard." The number and size distribution of classrooms are calculated accordingly. The standards of utilization used must be determined from an extremely complex analysis of curriculum structure and class size distributions. The levels of the utilization standards must be such that scheduling conflicts are minimized and the distribution of classroom sizes is fitted to the distribution of class sizes with sufficient tolerance to allow for flexibility in class size and flexibility of time scheduling. If utilization rates are too high teaching efficiency may be impaired; moreover, the risk increases that individual students will not be able to fulfill their degree requirements at the proper time because of course schedule conflicts generated by an inadequate number of To insure that the distribution of classroom sizes does not artificially depress class sizes, classroom capacity must exceed demand most of the time; i.e., the number of stations available must exceed the number of students requiring accommodation.

In 1959-60, A. W. Baxter, Jr. recommended classroom utilization standards or goals for all of the existing state colleges and universities. These were determined after careful study of the existing plants and programs of the institutions against a background of experience in other institutions around the country. The Association has concluded that these classroom utilization standards should be used for the time being for estimating future classroom requirements; within two or three years the standards may be restudied in light of experience. The Baxter criteria are summarized in table 5.1.

In practice, the computation of classroom space requirements is not so simple because it is essential that the distribution of classroom sizes be determined to adequately accommodate the expected distribution of class meeting enrollment sizes. The method recommended in this chapter is designed to take the distribution of class sizes into account.

The utilization criteria recommended by Baxter apply to general classrooms. Seminar rooms and larger lecture auditoriums have different scheduling and utilization capabilities; therefore, station utilization and
room utilization rates for these types of facilities should be adjusted
accordingly. Each institution should analyze the utilization capabilities
of facilities of this type and adjust the utilization criteria accordingly.
Table 5.1 also suggests the criteria recommended for seminar rooms and

A. W. Baxter, Jr., Capital Outlay for Higher Education...for the Public Junior and Senior Colleges and the Universities in Colorado, Report to the Colorado Legislative Committee on Education Beyond High School, June 1960, p. 35.

lecture auditoriums.

The recommended variations allow for the fact that seminar rooms (also used for departmental conferences, honors groups, graduate examinations, etc.) have a lower capacity in scheduled hours per week because of their use for nonscheduled purposes and because graduate seminar-type classes often are restricted to late afternoon because of the teaching duties of a large proportion of graduate students. Lecture auditoriums, because of their size -- determined by maximum class sizes requiring their special facilities and by the fact that they often serve nonscheduled activities as well -- cannot always be scheduled to full capacity; they should be capable of more scheduled hours per week but their station occupancy averages usually are lower.

The utilization "standards" being discussed must be viewed as goals. The rates at which institutions are capable of achieving higher utilization are limited by the nature of existing facilities. This is especially true of station occupancy rates. If the distribution of classroom sizes is considerably larger than the distribution of class sizes, it is impossible to raise the average percentage of stations occupied when rooms are in use without raising class size averages -- a matter of educational policy. If an institution has too many rooms of the wrong sizes, it will have difficulty achieving higher utilization. The object must be to correct these imbalances, but this can be done only over a period of time while new classrooms are constructed, old ones remodeled or converted to other uses. Given better methods of estimating numbers and sizes of classrooms needed by the instructional program and distribution of class size, the

physical obstructions to improved utilization can be corrected fairly quickly (several years) in a period of rapid growth, less quickly when growth is slow. It is therefore recommended that the Baxter utilization standards be established as the standards in the <u>last three</u> planning stages, and that transitional levels be used between current utilization rates and the utilization goals. In other words, lower standards may be used in the earlier planning stages; but by the last stage, the classroom supply should be expected to match demand at the levels of utilization recommended by Baxter.

Worksheet 5.1 is provided for each institution to report the levels of utilization to be used as planning factors at each planning stage. The transitional stages should be such that the amount of classroom space constructed will not exceed the amount required in the last three planning stages. If existing classroom station capacity, given the Baxter utilization standards, is theoretically sufficient to handle the enrollments projected at the later planning stages, this does not mean that no new classrooms should be built, for it is essential that older and more inefficient rooms be replaced by better facilities adapted to the instructional programs and class size distribution of the institution.

of utilization. The normal scheduling week is the number of hours per week during daytime hours (7:00 AM to 6:00 PM) during which classes are normally scheduled. A norm of 44 hours per week is recommended as the measure to be used for all institutions for purposes of comparison. This is based on a normal schedule week of Monday through Friday between 8:00 AM

and 12:00 noon, 1:00 PM and 5:00 PM, and Saturday from 8:00 AM to 12:00 noon; alternately, it may mean scheduling from 7:00 or 8:00 AM to 5:00 or 6:00 PM, excluding the noon hour, or from 8:00 AM to 5:00 PM, including the noon hour, depending upon the manner in which the institution prefers to schedule. By itself, the lill-hour week means little except to serve as a measure of absolute maximum schedule time. Compared with the average room utilization standard of 29 or so hours per week per room, this gives an indication of the degree to which the problem of avoiding scheduling conflicts limits the hours per week in which rooms may be scheduled as an optimum. The "capacity utilization coefficient" is a general measure of the limits of utilization implied by the standards used.

As planning techniques become more effective, as improved data resources are developed, and as the planning of educational programs and practices become more closely articulated with physical planning, it should be possible to gradually raise the standards of classroom utilization. In the next decade, however, with unprecendented enrollment growth and the constant threat that the availability of building facilities will lag behind the need, the utilization levels established by the Baxter study are reasonable and economical goals for achievement.

The classroom utilization standards have a further use which may be noted here: when periodic studies of actual utilization reveal that an institution is approaching or exceeding the levels of utilization recommended, this is a cue that additional classroom capacity is needed to avert the danger of increasing schedule conflicts and artificially depressing desirable growth in the sizes of classes. While this is only one

of many factors that must be taken into account in setting building priorities within and among the institutions, it does justify at least biennial studies of actual utilization as an aid to determining the need for
additional classroom capacity. This statement must be accompanied by the
warning that a relatively small part of the capital construction requirements of the colleges and universities involves classrooms and that utilization rates alone cannot be used to set priorities.

### B. Physical Planning Criteria

Area per classroom station, expressed in assignable square feet

(a.s.f.) per station, varies with the size and type of room and type of
station. Generally, the smaller the room, the larger the area per station
because of the fixed requirements of area for aisles and for the instructor's station at the front of the room. In addition to the immediate area
of the room, allowance must be made for auxiliary service space such as
preparation rooms, projection booths, storage of teaching materials and
the like.

The recommended physical planning criteria for this study are shown in table 5.2. The specific recommendations cover both the unit area allocation per station and the percentage allowances for auxiliary service space. The criteria represent typical figures adaptable to architectural designs in which room widths might vary from 16 feet to 50 feet. Naturally, some variation in the criteria might be required as the room width approaches the extremes of the 16-50 foot range.

Since the projected room size distribution will vary from the specific numbers of stations listed in table 5.2 in some instances, and since different types of stations may be desirable in certain instances, the recommended standards are further broken down on table 5.3. To permit the calculation of area for varying numbers of stations, the program area is broken down into the area immediately occupied by the station furniture and the area per room allowed for internal circulation and the instructor station. The circulation area allowance is actually the mid-point of the room size ranges used in the table, thus constituting an approximate average for the range. (The 8 square feet per station is based on spacing tablet armchairs 3.0 from back to back and 2.8 from centers laterally; in "case study" Type 3 rooms using rows of 24 wide tables and ordinary chairs, an additional 4 square feet per station is required.)

The Type 3 "case study" classroom in which rows of tables and chairs are used requires more area per station, but this type facility is increasingly in demand for certain types of instruction, especially in business and engineering where classwork involves more extensive use of books and paper materials. It may be noted that in a room ranging from 550 to 680 assignable square feet, between 26 and 35 stations of Type 3 may be installed compared with 16 to 55 tablet armchairs in Type 1. Experience with Type 3 installations indicates that they are more effective as teaching facilities in certain fields with classes of less than 50, justifying the greater station area requirement.

<sup>&</sup>lt;sup>a</sup>Developed by Dr. Thomas R. Mason, Director of Institutional Research and Planning, University of Colorado.

The percentage increment for auxiliary classroom service space will be applied to the aggregate classroom program space projected for the institution; it constitutes an allowance for such facilities although the exact arrangement of auxiliary space cannot be determined until actual projects are in the architectural planning stage.

### C. Outline of Procedure

Worksheet 5.1 provides for the specification of the room and student station utilization criteria to be used in estimating capacity requirements in classroom-type facilities at each planning stage. The worksheet permits identification of the criteria to be used for lecture-auditoriums, regular classrooms and seminar rooms. The criteria are to be expressed in five ways: room utilization in terms of absolute number of hours; room utilization as a percentage of the normal teaching week; student station utilization as a percentage of the available capacity when rooms are in use; capacity utilization expressed in terms of total student periods per station per week; capacity utilization as a percentage of total potential student station periods available during the over-all teaching week. In completing this worksheet, the final stages should reflect the utilization criteria recommended in the Baxter studies and adopted by the Association. Variations from the Baxter criteria should be explained.

Worksheet 5.2 calls for the analysis of room and student station capacity requirements in classroom-type facilities. First, the workload projections already completed in Chapter 3 are drawn upon for the distribution of class periods per week by class size. For each class size, the

appropriate room utilization criterion is used as a divisor to determine, as a first approximation, the total number of meeting rooms required. This first approximation is then adjusted to eliminate fractional room estimates and to assure consistency with the control total for number of meeting rooms required calculated at the same time. The room size distribution is then obtained by increasing the median class size of each size range by a factor equal to one divided by the recommended student station utilization coefficient. For each room size, total projected student station capacity is then estimated by multiplying the number of meeting rooms required by the number of stations per room. Total student station capacity is obtained by aggregation.

Once the number and size distribution of meeting rooms required in classroom-type space is established, worksheet 5.3 should be used for determining space requirements. Both primary and service space components of classroom-type facilities may be computed on this worksheet. Given the room size distribution indicated in worksheet 5.2, the physical planning criteria recommended in tables 5.2 and 5.3 may be used to determine the room area allocation in each room size class. When multiplied by the number of meeting rooms required, the primary space requirements associated with a particular room size group are obtained. Application of the planning ratio for service space to primary space recommended in table 5.2 will then permit development of the service space allocation associated with each room size range. Simple addition of the primary and service space components will yield total space requirements by room size range and further aggregation will yield the estimated total requirement for all

classroom space.

Worksheet 5.4 is devoted to summarizing the requirements for classroom-type space at each planning stage. All space requirement data can be
drawn from worksheet 5.3. Sub-classifications are provided for by type of
room (lecture-auditorium, regular classroom, seminar room) and space category (primary space, service space). Simple aggregation yields the figures
for total space required in classroom-type facilities at each planning
stage.

#### CHAPTER 6

### SPECIAL PURPOSE INSTRUCTIONAL SPACE.

The heading "Special Purpose Instructional Facility" comprehends those specialized scheduled instructional rooms in which students perform work with equipment and materials, including wet and dry science laboratories, drafting rooms, music and art studios, language laboratories, practice rooms and shops. The key characteristic is the special purpose nature and general absence of interchangeability of these rooms.

Instructional workloads for these facilities were projected in Chapter 3. The procedure recommended in this chapter for projecting the capacity and area requirements allows for considerable variation in approach. Projections should be made on a course-by-course or lab-by-lab basis. This approach yields data which may be used directly in programming new facilities or remodeling.

### A. Capacity Utilization Planning Criteria

Because of their particular and special nature, utilization of special purpose teaching facilities cannot be approached arbitrarily. If a given course requiring laboratory-type instruction is to be offered, the facilities must be provided regardless of utilization. Highly specialized advanced courses with limited enrollments will usually have low utilization in hours per week until the size of the institution is such that multiple laboratory sections are feasible. In order to determine the number of rooms and the number of stations required, however, levels of optimum room and station use must be established for planning purposes. The

facilities are 24 periods per week with 80 percent of stations occupied when rooms are in scheduled use. These are averages, not necessarily valid for particular laboratories. Because laboratory sessions usually are more than one period in sequence, they tend to obstruct larger blocks of schedule time. Overscheduling leads to schedule conflicts. Thus, the utilization rates expected for special purpose teaching facilities are lower than for classrooms.

For planning purposes, optimum room and station utilization criteria must be established to determine the number of rooms and number of stations required. If the course is offered at all, a minimum of one laboratory room must be provided, regardless of course enrollment. The number of laboratory stations should be geared to the number of students desirable in a single laboratory section.

The function of utilization criteria in planning capacity in special purpose facilities may be understood from the following. First, consider room requirements. As course registrations grow, the number of sections of the desired size increases. As the number of laboratory periods per week increases with the number of sections, the hour utilization per week of a single laboratory room will approach a point at which scheduling conflicts increase. At this point, another laboratory room will be needed, so that more than one laboratory section can be held concurrently. Thus, for planning purposes, hour utilization standards should be viewed as scheduling saturation points, signalling the need for another laboratory room. Second, consider station requirements. For laboratories, these

usually are determined by the desired section size plus an increment to allow flexibility. Typically, the desired section size multiplied by 1.25 (the equivalent of 80 percent station occupancy) is used to program room capacity. Thus, a laboratory for sections of 20 students should be designed for 25 stations. This allows a 25 percent increase in the section size before another section has to be set up with accompanying cost of additional instructor time. Any greater increase in section size would impair the quality of instruction; any smaller increment would force the establishment of an additional section of small enrollment before it is needed. For example, say that an advanced science course starts with 15 students; optimum section size is 20 students; 25 laboratory stations are provided. When course registrations reach 26 students, another section must be established. The two sections would average 13 students. But if only 20 stations were provided in the room and a new section were required when 21 students registered for the course, two sections averaging 10.5 student. would be required. The extra station capacity is vital to allow for operational economy of this type.

The average utilization criteria for special purpose instructional facilities are derived from the 1960 Baxter Study. These are tabulated for each institution in table 6.1. Baxter did not make any recommendations for station occupancy rates, but 80 percent is recommended for calculating the average student hours per week per station. The variation among institutions is the result of Baxter's analysis of existing teaching laboratories at each institution. It must be emphasized that these are institution-wide average standards. When dealing with particular laboratories,

the average may be exceeded in cases of multiple-section courses but almost always will fall short in more specialized courses with smaller registration levels.

Baxter set the normal schedule week at 30 hours for teaching laboratories (compared with 44 hours for classrooms) because laboratory time blocks are more difficult to so edule and because most laboratories require "down" time for clean-up, stocking, and set-up of materials. Baxter called the midpoint between the recommended average hour utilization standard and the 30-hour schedule week the "Average Schedule Density Threshold." He used this to gauge the extent to which institutions were suffering from overscheduling of teaching laboratories in certain areas; this measure was intended to serve as a danger signal.

When teaching laboratory needs are projected on a course-by-course basis, another approach is required. Different laboratories will have different optimum scheduling capacities according to the structure of the courses involved. These capacities will vary according to two factors:

a) the mix of class sizes in lecture, recitation and laboratory groups; and b) the mix of meeting periods per week required in lecture, recitation and laboratory meetings. An effort should be made to determine the optimum number of laboratory sections which can be scheduled for the course without having scheduling conflicts between laboratory and lecture-recitation sections of the same course or pair of complementary courses. The longer the laboratory period required and the more lecture-recitation hours scheduled in association, the smaller the maximum number of hours per week of possible scheduled utilization in a given laboratory room.

When these upper limits are approached in programming laboratory requirements, they are cues for the addition of more laboratory units. Whether these will average out at 24 hours per week or all laboratories will depend upon the structure and mix of laboratory courses at a given institution.

#### B. Physical Planning Criteria

Table 6.2 lists the recommended unit area allocation criteria for special purpose instructional facilities in all fields and levels of instruction. Table 6.3 enumerates the recommended planning criteria for programming the service or auxiliary space needed to supplement the primary space component.

The criteria indicate allocations per student station and the proportion that service area is of total space classified under the general teaching laboratory heading. It is impossible to define these criteria for all types of situations. Generally preaking, the unit planning criteria for lower division facilities assume capacities of 24 to 40 stations. Outside this capacity range, the unit standards should be modified; i.e., higher standards for rooms with fewer than 20 stations, smaller allocations for rooms with more than 40 stations. For the upper and graduate division criteria, the assumed ranges a 12 to 24 stations and 4 to 12 stations, respectively. When fewer than four students are involved in laboratory work, it is assumed that the room designation will probably fall in the research space category and the appropriate space allocation criteria will be those that apply to research space. The unit area allocation criteria encompass all storage and service space normally included within the lab-

oratory itself. Wherever appropriate or necessary, different criteria are indicated when the subject matter necessitates such differentiation. The table suggests the subject areas that can be dealt with under the proposed standards. Naturally, the references to course matter coverage are in no sense comprehensive.

The service space coefficient refers to the typical situation in large and small departments. The demarcation point is generally at about 10,000 square feet of total special purpose teaching space, or 7,000-7,500 square feet of primary teaching space. Wherever the large-small distinction was not possible, a single coefficient is indicated.

Naturally, the needs of individual departments might dictate variations from these proposed criteria. It's possible to satisfy the station requirements and service space needs with both higher and lower criteria. However, as in the case of the classroom space allocations, the enumerated criteria are designed to permit comfortable working conditions.

## C. Outline of Procedure

Worksheet 6.1 should be used for recording the room and student station utilization criteria to be used in projecting capacity requirements in special purpose instructional facilities at each planning stage. The worksheet calls for a specification of the following information: a) the length of the teaching week in special purpose instructional facilities; b) the room utilization criteria to be used in calculating the number of rooms required in special purpose facilities, expressed in terms of number of room periods per week and proportion of teaching week which rooms are

expressed as the proportion of available capacity in special purpose facilities to be occupied when such facilities are in use; and d) the overall capacity utilization criteria, expressed as the total number of student periods per station per week that should be expected as well as the proportion of aggregate student station capacity used during the teaching week. The criteria should be consistent with the Baxter recommendations and any expressions of Association policy regarding room and student station utilization goals for special purpose instructional facilities.

Worksheet 6.2 focuses upon the projection of student station capacity in various types of special purpose instructional facilities. A separate worksheet should be developed for each course level group, planning stage and subject field. The first step is the determination of the number of different facilities required to satisfy the instructional workloads at each level. The analyst must use his judgement in this regard for this involves the question of the extent to which facilities may be used interchangeably to accommodate the needs of several different types of courses that may be offered. Consultation with representatives of the individual departments may be necessary for the analyst to implement this aspect of the programming procedure. Upon specification of the number of different facilities required and the courses that can be taught in each special purpose facility, the analyst can draw upon the information developed in Chapter 3 regarding the projected student registrations associated with the specified courses in order to obtain the total registration load in each facility. The data on preferred class sizes developed in

should then be introduced. These figures should be adjusted by the planning analyst to the programmed room size basis, usually by raising the preferred class size figures by a factor which on the average will be equal to one divided by the recommended student station utilization rate. The number of rooms required of each kind can be obtained by dividing the projected student registration load by the programmed station capacity figure that has been established. Projected student station capacity then is simply a function of the number of rooms required and the number of stations in each room.

Upon completing the projection of capacity requirements, worksheet 6.3 may be used to determine the space requirements associated with the projected special purpose instructional facilities. The worksheet parallels the preceding forms and organizes the analysis by subject code, planning stage and course level. For each facility, the primary space requirements are determined by establishing the unit area per room (a function of the number of stations per room and the unit area allocation criteria suggested in table 6.1) and multiplying this by the number of meeting rooms required as determined in worksheet 6.2. Service space requirements then are calculated by applying the planning ratio for service space to primary space as indicated in table 6.2 to the primary space requirements projected for each facility. Total space requirements are then obtained by simple aggregation of the primary and service space components, and total space requirements at each level are determined by aggregation

of the total space requirements associated with each type of facility.a

Worksheet 6.4 should be used to summarize the projections of special purpose instructional space requirements, by subject, facility level, space category and planning stage. Worksheet 6.5 is an even more compact summary form which focuses upon the over-all requirements for special purpose instructional space in each department, by planning stage. Simple aggregation of the departmental requirements at each planning stage will yield the estimate of total institutional needs for special purpose instructional space at each planning stage.

Alternately, the actual projection of service space requirements can be handled as a single calculation dealing with the aggregate primary space projected for each subject field. Total space requirements would then be obtained in a manner paralleling that indicated in the text but would involve only one step: the addition of total primary and service space components.

### CHAPTER 7

### OFFICE SPACE

Projection of office space requirements is based upon the projections of faculty and staff requirements carried out in Chapter 4. These personnel projections must now be analyzed in terms of the work stations required for carrying out the activities associated with each personnel category to determine the office-type building area required. Implementation of this portion of the Manual will depend heavily upon the policies and patterns of the various institutions, and the methods and worksheets used will have to be adapted by each institution to its individual needs.

### A. Primary Office Space (Staff Work Stations)

In determining the requirements for primary office-type space, the procedural steps may take the following form:

- 1. Establishment of unit area allocation criteria;
- 2. Determination of the aggregate number of space units of various types required, and the implied area needs;
- 3. Determination of the locational characteristics of the complex of required space, and the implied area needs.

The first step is consistent with the general planning approach of applying uniform criteria for work station space requirements based upon the functional requirements of the space occupant and independent of his employment position or departmental affiliation. To assist in this regard, table 7.1 provides illustrative unit space allocation criteria. The criteria are those that we and other planners have found useful. For the single occupancy offices, the figures refer to net office space require-

ments, exclusive of such service elements as files, bookcases, etc.; for the units located in multiple occupancy arrangements, the figures include an allowance for immediate circulation and equipment requirements.

As the table suggests, a distinction should be made between office units that are single occupancy or private in nature and those that are in multiple occupancy status. For example, in a multiple occupancy arrangement two or more graduate students or clerks may share space in a single room. The criteria reflect a basic room area module of 120 square feet. The multiple occupancy units are readily adaptable to combination in such a way as to make efficient use of the basic room module. Thus, the basic S-3 unit can also be used to accommodate two M-2 units or three M-3 units.

The work station criteria can, of course, be modified or increased in number and variety if necessary. The 120 square foot basic office unit, however, is one found demonstrably satisfactory for almost all faculty offices except those in which group instruction of over three students is included among the functions that the office space unit must accommodate. Normally, when the size of the small student discussion group is such that a space larger than 120 square feet is required for a faculty office, the group should meet in a classroom or seminar room. Where this cannot be the case for reasons of educational policy, the basic faculty office unit must be larger than 120 square feet.

The second step is the development of the inventory of office unit requirements. The starting point here is the classification of personnel by broad position category for each department (see Chapter 4). By having

personnel and office unit requirements listed on the same sheet, a control device is made available to check that total office unit requirements do not exceed the number of personnel that are to occupy these units. Worksheet 7.1 may be used for this purpose. An examination of the worksheet will show that the personnel classification used for determining office space requirements has been elaborated to reflect budgeted and non-budgeted personnel. This is done for two reasons: first, to underscore the cost of a policy decision to provide space for non-budgeted personnel (e.g., graduate students, students in honors programs, visiting firemen); second, to make sure that the space required to accommodate non-budgeted staff, where such space is to be provided, is accounted for accurately in the estimates.

A third step in the development of the information required at each planning stage would involve the reorganization of the office capacity projections to reflect the general locational distribution of the office work station units. That is, some units should be in predominantly office space complexes; e.g., faculty offices, clerical offices, etc. Other units should be in laboratory areas; e.g., graduate students, laboratory assistants. Still other units might be located in library space (e.g., carrels), laboratory service space (e.g., shops or preparation areas), or other space (e.g., stockrooms). However, this step may be deferred to a later stage of the programming study.

It should be noted that departmental estimates of office capacity requirements can be aggregated by whatever groups of departments are deemed relevant. Thus, social science or humanities departments might be aggre-

gated for purposes of determining the overall number of offices necessary to accommodate them as a group. The needs for new structures or the adequacy of existing structures can more readily be evaluated for those departmental groups that are primarily office space users.

### B. Service Space

Naturally, these reference criteria co not by themselves permit estimation of that portion of departmental office space that falls in the "service" or "auxiliary" category. Included in the service category are such elements as files, reception areas, supplies, conference areas, and so on. The basic allocations to staff stations, however, can be used as a point of departure.

Two approaches to auxiliary office space needs are possible. One approach, that for which a computational format has been provided in this Manual, involves the use of rule-of-thumb estimates of the ratio of office service space to a) total office space requirements or b) total primary office space requirements. In either case, once primary office space requirements are estimated, the service space needs are readily calculated by use of the appropriate planning ratio. Although the proportions will vary with the size and character of departmental office operations, experience indicates that office service elements account for approximately 20 percent of total office space needs. That is, for every 100 square feet of office space, 80 square feet are used for staff work stations and 20 square feet fall into the supporting space category. Naturally, greater sophistication is possible even when using rule-of-thumb measures. Thus,

different factors should be used for academic and non-academic departments. Within these categories, further subclassifications by size and character of operations are possible. The procedure that is ultimately adopted will probably depend upon the resources and time available for making more detailed estimates. Table 7.2 summarizes some of the rule-of-thumb factors worked up from experience with more detailed studies.

The second approach is optional and no computational procedure is outlined here. It would involve studies in greater depth of the office service space category. In the same way that activity levels (in the form of staff estimates) are used as the basis for calculating primary office space needs, appropriate indexes of need would be used for calculating the various sortice space elements. Thus filing, conference, and storage heads would each be projected only after initially studying the intensity and character of the needs for each element. Then the estimate of the number of units needed of each service space component (whatever the relevant form that these units may be measured in) would be combined with the appropriate unit space allocation criterion to arrive at the estimate of total space needed to accommodate that specific office service element.

Consider, for example, file space. Estimation of space requirements would require a projection of the number of file drawers required at some specified level of departmental activity. This would in turn depend upon the rates at which records are accumulated, record retention policies, and the number of file drawers required for the quantity of records that have been calculated to require housing at the subject planning date. If consideration is restricted for purposes of this discussion to letter and

186

legal files, the next step is converting the file drawers estimate into estimates of the number of file cabinets needed. This will, of course, vary with whether 2-, 3-, 4-, or 5-drawer file cabinets are used. The average floor space requirement per drawer declines as the cabinet increases in drawer capacity; and, from a space planning viewpoint, the 5-drawer cabinet is to be preferred. Experience indicates that letter-size file cabinets require 10 square feet of space, while legal-size cabinets must be assigned 12 square feet. Combining the estimated requirement for file cabinets (letter-size and legal-size separately) with the appropriate file cabinet unit space allocation criterion results in the total file space requirement estimate.

An analagous procedure can be developed for each component of the office service space complex. The procedures for determining the activity
levels or unit requirements will not be discussed any further at this juncture. Clearly, these can be of greater or lesser complexity. However,
recommended unit space allocation criteria for selected service space elements are enumerated in table 7.3. They can be incorporated into an office
space planning model even if the procedure for estimating the number of
units required must be limited to r atively simple organization. Further
observations on this subject will be offered if the detailed programming
approach is adopted.

### C. Outline of Procedure

where 7.1 should be used for indicating the office capacity requirements of each department at each planning stage. The worksheet calls for the use of information developed in Chapter 4 regarding the number of personnel projected for each department. Within each personnel category, a specification should then be made of the number of office work stations required, classified by type of station. That is, the number and kind of single occupancy offices and the number and kind of work stations in multiple occupancy offices should be indicated for each staff category. Aggregation will yield the figures for the total number and distribution of work stations of various types required for each department.

In worksheet 7.2, the total office space requirements for each department may be calculated. The worksheet calls for the separate determination of primary and service space components. Drawing upon the data developed in worksheet 7.1, the number of different types of office work stations required may be enumerated. Each type of station is then multiplied by the appropriate unit area allocation per station suggested in table 7.1. This yields the aggregate program area requirements for primary office work stations, classified by type of station. Simple aggregation of these figures will yield total primary space requirements for office space. By then applying the planning ratio for service space to primary space indicated in table 7.2, the amount of service space required to supplement the primary office space allocation can be determined. Aggregation of the primary and service space components will yield the total space requirements for the department at the specified planning stage.

Worksheet 7.3 is to be used for summarizing the institution's office area requirements at the specified planning stage, broken down by department and program area classification (primary, service, total). Aggregation will yield the total office space requirements projected for the specified planning stage.

Finally, worksheet 7.4 may be used to enumerate all departments and summarize projected office space requirements at each planning stage.

### TABLE 7.1; OFFICE SPACE

#### CHAPTER 8

#### RESEARCH SPACE

The determination of research facilities required by each institution must correspond with the institutional function in research defined in the <u>Program for the General Differentiation and Coordination of Functions Among the State Supported Institutions of Higher Education in Colorado</u>, developed by the Association in 1962. Generally, this document intends the concentration of organized research activities and graduate work at the two universities and the School of Mines, except for graduate and research programs in education at other institutions. However, the faculties — especially in the sciences — at all institutions must be given the opportunity to carry on individual research work. Each institution must therefore determine the number of faculty members who will be provided individual research space in the various sciences. Highly specialized and expensive research installations which should not be duplicated at more than one institution in the state will be coordinated through the Association, pursuant to the special emphasis of function at the university-type institutions.

The procedure for estimating research facilities recognizes three broad space components: a) individual work space for faculty and professional research personnel and students engaged in research; b) space for large scale specialized equipment and technical services used in supporting research programs; and c) auxiliary service areas required to support research work.

#### A. Staff Project Research Space

Table 8.1 lists the recommendations for unit area allocations to

personnel engaged in research in selected subject matter areas. points should be noted. First, the criteria are typical, and cannot be expected to work without exception at every institution. Second, there is considerable uniformity in the criteria for allocating space per individual work station. This derives from a human engineering phenomenon; i.e., the amount of bench space or work area a person can utilize effectively is a function of the physical limitations that characterize all individuals. This implies that wherever the individual is not the dominant element on the research space scene, as is the case cocasionally in engineering processes or large animal studies, the development of research space estimates cannot be based upon standards that are oriented towards human characteristics only. Third, in a few broad discipline areas the service space coefficient is expressed as a uniform percentage of total research space, reflecting the wide range of variation that is possible in organizing research activities in these subjects. For example, sometimes, the research space is dominated by equipment; at other times equipment may be miniaturized and the human being is the dominant factor.

With these comments in mind, the unit area criteria should be treated as averages per person, valid in aggregate totals but subject to considerable variation in actual design of research facilities.

## B. Large Scale Equipment and Technical Services

Research facilities not directly related to individual work area requirements must be dealt with separately, with area determined by the nature of the facility. Among the types of facilities requiring this special treatment are the CSU hydraulics laboratory, certain parts of the School of Mines

metallurgy laboratory, and the cyclotron at the University of Colorado.

Institutions which participated in the 1962 National Science Foundation study of projected scientific and engineering physical facility and apparatus needs may use data compiled for that study. Only those facilities should be listed which are in themselves primary pieces of equipment or of a nature not normally included in individual-oriented research laboratories. Since such facilities vary widely in character, an enumeration of recommended physical planning criteria cannot be developed.

### C. Service Space

Research activities in the sciences and engineering usually require extensive supporting area for shops, storage, stock rooms, animal rooms, and the like. In this procedure, the service area requirements are determined generally as an incremental percentage of the primary research area for a given subject field. The recommended percentage allowances for service space are listed in table 8.2.

#### D. Outline of Procedure

Worksheet 8.1 permits the computation of staff project research area requirements according to the number of persons — faculty, professional research persons, and students — expected to be engaged in research. The number of persons should be derived from the faculty-staff and graduate student projections for the given subject fields carried out in previous portions of the study. The institution must determine and be able to justify the number of faculty, professional staff and students for whom research space is to be provided. Since service space is computed as a

function of the allocation to the primary component of research space, the service space portion of staff project research space is projected directly on this worksheet.

Worksheet 8.2 is analogous to the preceding worksheet, but deals with the space generated by the need for large scale specialized equipment and technical services in the research program. After enumerating the items involved and the space required to accommodate them, the auxiliary service space needs are calculated as a function of the primary research space allocation.

Worksheets 8.3 and 8.4 provide for summary statements regarding research space requirements. For each department and at each planning stage, the former shows the amount of primary and service space associated with staff project activities, large scale equipment and technical services, and both combined. The latter provides for an enumeration of each department's research space needs at each planning stage.

It should be noted that the worksheets focus upon the research space as a functional category. In this sense, it makes little difference whether the research activity is sponsored or university-supported, conducted in university installations or in on-campus space owned by non-university agencies. In short, the emphasis is on the aggregation of total research space requirements on campus.

However, each worksheet makes provision for a departmental designation. By sorting processes, the research space allocations associated with various groups of administrative units can be identified. Thus, although

the emphasis is on research space requirements in the functional sense, this will not preclude the identification of who controls the space and, to a lesser extent, who the sponsoring agency is.

#### CHAPTER 9

#### LIBRARY SPACE

The library is the heart of a college or university. Although the content and nature of the library will vary widely with the nature, size, and character of the institution, the basic units of building space required to house the readers, books and services of the library are sufficiently uniform to permit the use of common planning criteria. The combination of these units, however, will take many different forms according to the needs of the institution. The purpose of this chapter is to provide a method for calculating floor area requirements; the design, functional organization and layout of a library is a matter to be worked out by the experts; i.e., the architects and professional librarians. It is important that the institution's librarian be consulted when determining how existing facilities should be used in the future and the types of additional facilities that will have to be built.

A number of significant technological changes in library services are in the offing and should be kept in mind: e.g., the growing use of microfilm, reproduction equipment, and recordings; the prospects of improved techniques of facsimile transmission; the use of "teaching machines" and closed circuit television; improved design of reader station furniture; development of group study methods; the use of computers in cataloguing and circulation services; centralized technical services.

See, e.g., Ralph E. Ellsworth, <u>Planning the College and University Liberary Building: A Book for Campus Planners and Architects</u> (Boulder, 1960).

All of these will affect library space requirements. It will be many decades, however, before books are replaced by electronic memory storage systems, and only in rare cases will these developments actually reduce space requirements. The reader must always be served, and books are still the most efficient means of storing and transmitting knowledge.

## A. Planning Criteria for Library Facilities

The general unit area criteria for library facilities are shown in table 9.1. These were recommended by the consultants to the Association, with supplementary recommendations for faculty library studies and for open stack book storage (i.e., stacks open to library users in general as against closed stacks which are open only to library staff and limited users) supplied by Dr. Ralph E. Ellsworth, director of libraries of the University of Colorado.

The reader station floor area allowances for different types of stations have been tested by the consultants in actual floor layouts and found to be adequate and flexible. The book storage unit area standards per volume are averages for common types of shelving. The percentage allowances for library service space vary according to the size of the library. No attempt has been made to break down the various types of service space. This is dependent upon the design and type of library. However, provision has been made in the procedure for the specification of the composition of library service space, if desired.

#### 1. Reader Stations

It is recommended that the general standard for determining the number of library reader stations be 25 percent of projected student enrollment plus some proportion of projected faculty and other professional staff. The student allocation basis is somewhat lower than the standard recommended by the Association of College and Research Libraries, which is 30 percent of enrollment. Some institutions are striving to achieve as much as 50 reader stations for every 100 students enrolled. Since few institutions now achieve as much as 20 reader stations per 100 students, and since rapid growth in the next decade will make it difficult to attain and hold even the 25 percent ratio, the recommended proportion is realistic. Subsequent studies of intensity of library usage will determine whether a higher proportion of reader stations is needed. In certain special cases, where the nature of a library unit clearly requires a higher allocation ratio for reader stations due to intensive use, higher proportions of reader stations should be planned. The declining use of textbooks purchased by the students in favor of more extensive reading lists in many courses requires greater use of multiple-copy reserved book facilities which in turn require the student to spend more time reading in the library. More extensive use of library research by students is a clear trend in most institutions.

Given the aggregate reader station capacity estimate, a determination should be made in consultation with the institution's librarian of how the required reader stations will be allocated among the various types. General reading rooms are large open areas with 60 or more reader stations.

Special reading rooms include those with 40 or fewer stations: e.g., periodical and reference rooms; microfilm or listening stations; rooms equipped with table-top dividers. Carrel stations are those equipped with dividers and some book locker equipment; they may either be grouped together in a room or distributed through stacks. The category "other" is included to allow for unique features for reader stations not included above, such as group study rooms, typing rooms, and the like. Institutions also should allow for a limited number of private faculty studies for faculty members doing scholarly work in the library. This is an important provision in the research libraries of the universities. A small number (usually not exceeding 10) should also be allowed in the college libraries. The number allocated is to be determined by the institution and should be fully justified.

#### 2. Book Storage

The growth in the number of library volumes to be housed must be projected for each planning stage (according to a reasonable time scale) in consultation with the institution's librarian. This requires an accurate inventory of existing holdings and determination of the expected annual rate of growth.

Some empirical rules-of-thumb may be helpful in this respect. Nationally, library collections have tended to double in size every sixteen years, science collections have been doubling every decade. Within this

<sup>&</sup>lt;sup>a</sup>See Council on Library Resources, <u>Annual Report</u>, 1959, p. 7; Derek J. Price, "The Exponential Curve of Science", <u>Discovery</u>, June, 1956.

general pattern, small institutions usually have higher growth rates, while large institutions have smaller growth rates. A critical factor is the degree of maturity of the library collection. Nevertheless, the general historical trends may be tested on semi-logarithmic graph paper by the individual institution, using historical data describing the growth of the institution's own library, if such data are available, and projecting the number of volumes forward so that they double in sixteen years. The rate of growth may then be measured off the graph and fitted to each planning stage. At the rate of doubling every sixteen years, the book collection will increase by a factor of 1.55 in ten years, 2.00 in sixteen years and 2.35 in twenty years.

The size of book collections normally is measured in terms of numbers of volumes, but some institutions use the more accurate measure of lineal feet of shelved books. Generally, scientific books average 4 or 5 volumes per lineal foot and other fields about 6 volumes per lineal foot. On the average, and in standard stack shelving, 0.6 assignable square foot is required for each lineal foot of shelved books (equivalent to 0.10 assignable square foot per volume). However, the unit area allocation will vary with the type of book storage facility adopted. The distribution of collections by type of storage facility should be determined in consultation with the institution's librarian; that is, the proportion of the collection to be shelved in closed stacks, open stacks, volumes in reading rooms, or other type of storage.

#### 3. Service Facilities

Library service facilities generally fall into two broad categories: reader services, and technical services. These in turn encompass a wide range of types: public catalogues; circulation control and processing; purchasing, cataloguing and processing; microfilm processing; reproduction equipment; record and tape listening facilities; and general storage. The amount of space required for these service elements depends very much upon library organization and type and the physical design of facilities. Therefore, the projection of space needs is carried out by means of a percentage allowance for service of the area required for books and readers. These allowances are given in table 9.1, varying according to the size of the library.

#### B. Outline of Procedure

As suggested earlier, the first step in the calculation of library space requirements is the projection of reader station capacity needed in library facilities. Worksheet 9.1 may be used for the specification of such capacity requirements at each planning stage. A separate worksheet is to be used for each library unit; that is, the main library and all branch library installations. The worksheet calls for the calculation of reader station capacity as a function of the population groups that will be the principal users of the specific library unit under consideration. Reference should be made to table 9.1 for determination of the planning criteria for the ratio of reader stations to total users, students and staff, for whom library space must be provided. The percentage distribution

of capacity requirements by type of station must be decided by the planning analyst, presumably in consultation with the director of library services. The numerical distribution of reader stations will then be a function of the total reader capacity required and the planning assumption regarding the preferred distribution of this capacity among various types of stations.

Worksheet 9.2 should be used for determining the space required to accommodate projected reader station capacity in each library unit, by planning stage. The space requirements are to be projected by type of reader station. Thus, reference must be made to the data developed in worksheet 9.1 regarding the numerical distribution of reader station capacity programmed in library facilities at each planning stage. These workload estimates then should be combined with the recommended physical planning criteria for unit area allocations to various types of reader stations shown in table 9.1; the total program area requirements associated with each type of reader station can be obtained by multiplication. Aggregation of the program area estimates for the various types of reader station facilities will produce total space requirements for library reader stations at each planning stage.

Worksheet 9.3 shifts attention to the requirements for book storage capacity in library facilities. The first portion of the worksheet focuses upon the growth in the size of the collection (number of volumes, rather than titles) in the specified library unit at each planning stage. The worksheet then calls for a delineation of the probable distribution of the collection among various types of book storage facilities; e.g., closed

stacks, open stacks, various types of reading rooms, reserve books and other types of storage. Conversion of these data into an estimate of the numerical distribution of the collection by type of storage facility then is a simple arithmetical operation.

Worksheet 9.4 should be used for converting the projection of book storage capacity requirements into the corollary estimate of book storage space requirements. For capacity requirements, the data developed in worksheet 9.3 may be used. The unit area allocation criteria appropriate to each type of book storage facility are suggested in table 9.1. Combining the projection of capacity requirements with the unit area allocation criteria will produce estimates of the total space required in each type of book storage facility. Aggregation of the estimates will yield the total book storage space requirements at each planning stage.

As the next step, the space required for library service facilities and the summary of total library space requirements may be calculated. Table 9.1 suggests that library service space may be calculated as a function of the total allocation of space to reader stations and book storage. Therefore, provision is made in worksheet 9.5 for a) aggregating the program area estimates for reader stations and book storage, and b) applying the planning ratio for service facilities to this aggregate to obtain the allocation to service space. Total library space requirements then may be obtained by adding the estimated allocations of space to reader stations, book storage and service facilities. Worksheet 9.5 when completed provides information regarding total library space requirements and the distribution of these requirements among the three major categories of

library facilities at each planning stage.

Worksheet 9.6 can be used for analyzing the service space allocation in greater detail. Service facilities are divisible into two broad categories: reader service space, and technical service space. Within each of these broad categories are further sub-divisions. Reader services may be sub-divided into space for public catalogues, circulation centrol and Technical services may be sub-divided into processing space, records and reproduction space and other facilities. To calculate the allocation of space to these various components of the service facilities category, a planning assumption regarding the percentage distribution of service space among these various sub-categories must be developed. Application of this relative distribution to the program area estimate for service facilities developed in worksheet 9.5 will yield the estimated distribution of service facilities, in area terms, among the several subcategories delineated. It should be noted that worksheet 9.6 is optional and completion is not critical for the implementation of the broad objectives of the programming study. The worksheet, however, will be found useful if a more detailed analysis of the service space component of library facilities is found necessary at a later date.

Worksheets 9.7 and 9.8 should be used for the development of summary statements of the program area requirements for library facilities. In worksheet 9.7, the focus is upon the aggregate amount of library space required at a specific planning stage, and a separate worksheet must be completed for each planning stage. The worksheet calls for the delineation of the distribution of program area requirements among the three

broad library facility categories in each library unit. Aggregating the allocations to each library unit will yield an estimate of the total space required for all library facilities, by broad library space category.

Worksheet 9.8 calls for an enumeration of the total space requirements of each library unit, by planning stage. The data for the summary are drawn from worksheets 9.5 and/or 9.7. Aggregation of the total allocations of space to each library unit will yield the estimated over-all space requirements for library facilities at each planning stage.

### CHAPTER 10

### MUSEUM AND GALLERY SPACE

Museum and art exhibition facilities do not lend themselves to direct treatment. Floor area requirements will vary widely with the types of institutions, the magnitude of collections, and the nature of the museum or gallery operation.

All institutions need to have collections of mineral, botanical, zoo-logical, and archeological specimens for instruction in the sciences. These are generally part of the supplies and equipment of the teaching laboratories and are not to be included under the museum category.

When significant collections are exhibited by the institution for public as well as student use, they may be considered as museum collections. Similarly, space used for art exhibitions beyond those normally part of the teaching of the fine arts may be classified as museum space.

In smaller institutions, a limited number of exhibit and storage rooms or perhaps the use of a large corridor area may be used for exhibition of special collections of specimens, artifacts and art.

A full-scale museum operation, with full-time curatorial staff and large collections generally will exist only in the universities.

The amount of floor space allocated to museum and gallery facilities must be determined in light of programs at each institution, but table 10.1 suggests some generalized rule-of-thumb measures for programming museum and collection space. Worksheets 10.1 and 10.2 may be used for this purpose.

# TABLE 10.1; MUSEUM AND GALLERY SPACE

Recommended Planning Criteria for the Allocation of Space to Museum and Gallery Facilities

	l	Planning (Assignable Solumber 2	Criteria Square Feet Percent 3
1	Unit area allocation per FTE student a, b	1.80

3	Total <sup>b</sup>	1.80	100
4	Display	1.50	83
5	Service	.14	8
6	Storage .	.16	. 9

This planning criterion should undoubtedly vary with the size of the student body, the character of the curriculum, and the "mix" of the collections. These variables do not lend themselves to simple planning treatment. The criteria, therefore, should be treated as a point of departure only; suitable modification in the light of particular institutional and departmental circumstances and resources will be required.

bOther space components which might be included in over-all museum and gallery facilities, such as office or research space, are not accounted for in this tabulation. Such elements would be accounted for at a separate stage of the calculating procedure and be included in the summaries of Chapter 17.

### CHAPTER 11

### ATHLETIC ACTIVITIES SPACE

Indoor facilities for physical education and athletics serve several types of programs important to the "sound body, sound mind" principle:

a) required (or elective but organized) physical education activity classes; b) intercollegiate athletics; c) free-time physical activity and intramurals sports; and d) degree program training of physical education instructors for schools and colleges. All of these use gymnasium, swimming pool, fieldhouse and other indoor facilities. Classrooms, specialized teaching laboratories, and faculty offices required for degree program instruction in physical education should be dealt with separately by the methods described in the chapters dealing with those types of space. This chapter deals with floor area requirements for activity areas and supporting service facilities.

### A. Activity Levels

Athletic plant comprehends a wide variety of specific facilities.

The activities involved may range from swimming to basketball, fencing to general exercise. Moreover, the needs for space are generated by a variety of programs. Required physical education produces a certain combination of workload and facilities requirements. Professional programs, intramural programs, casual needs and intercollegiate programs also generate varying workloads, both in total and by type of activity station. The size and distribution of workload by type of station and generating program also vary with the sex of the participants and the season of the year.

As a point of departure in projecting future space requirements, a tabulation of workloads in the base period, classified by type of activity and generating program, is necessary. Worksheet ll.l may be used for this analysis. However, this worksheet also should incorporate adjustments that reflect the analyst's estimate of the workloads that would have been experienced at the base year enrollment level where the absence of facilities or special conditions have artificially depressed these workloads. In so doing, the subsequent projection of future activity levels will more accurately reflect the need for athletic plant capacity.

Worksheet 11.2 permits the assembly of needed information for calculating future activity levels. A worksheet should be completed for each planning stage showing the anticipated index of growth in activity expected between the base year and the specified planning stage, classified by type of activity and generating program. For example, the analyst would record the growth factor anticipated in the workload associated with basketball facilities as generated by the required physical education programs; a similar entry would be made to cover the growth generated by the various other programs using this type of athletic facility. A similar index of growth should be entered for each type of activity enumerated and/or expected at the specified planning stage.

The workload projection can be developed by using worksheet 11.3. This may be accomplished by multiplying the base period workload in a particular activity by the index of growth appropriate to that activity program.

# B. Capacity and Space Requirements for Athletic Activities

It is now possible to project the capacity and space requirements for each type of facility that might be included in the athletic plant. However, in doing so it must be recognized that there is considerable overlapping in the extent to which various types of activities may be accommodated in a single type of space. For example, basketball and volleyball are two types of activities that use the same type of floor area. But handball and squash usually require a different kind of space than that associated with basketball or volleyball. There also tends to be variation in the intensity of need for various kinds of facilities, depending upon the season of the year considered. Thus, an analysis of capacity requirements for athletic plant should incorporate two adjustments: a grouping of activities that may be considered interchangeable from the point of view of type of facilities required to reduce the number of different special purpose facilities to a minimum; and an identification of the peak period of the year and related workload to be accommodated when such facilities are needed.

Capacity requirements then can be determined by dividing the projected workload for each separate activity station by the planning criterion for the maximum number of persons that may be accommodated at such a station during the interval to which the workload projection applies.

Once capacity requirements are known, these may be combined with the recommended physical planning criteria to obtain the desired estimate of program area requirements associated with each kind of activity station.

To be sure, this analysis demands considerable judgement on the part of the planning analyst. He must determine which types of activities may be grouped for purposes of analyzing capacity requirements. He also must select the peak load figure to be used when estimating the maximum workload to be accommodated at any one time. This may require consultation with the persons responsible for implementing the institution's athletic activity programs. But complicated and difficult though the procedure may be, it is preferable to a rule-of-thumb criterion regarding the over-all amount of athletic plant space required per specified number of enrolled students.

# C. Spectator Seating

The requirements for spectator seating also can be subjected to systematic study. In worksheet 11.5, such an analysis is outlined. For each separate seating installation, the procedure involves the following steps: determining the amount of spectator seating used in the base period; establishing the appropriate index of growth in spectator seating relative to the base period; making a first approximation of spectator seating required, subsequently adjusted on the basis of an evaluation of the reliability of the initial projection; selecting the unit area allocation per spectator seat; calculating the program area requirements by multiplying the projected capacity requirements by the unit area allocation criterion.

# D. Auxiliary and Total Space Requirements for Athletic Facilities

The projections thus far have covered only the primary space requirements in indoor athletic facilities. In order to complete the estimates,

the primary requirements associated with activity areas and spectator seating must be augmented to cover lockers, shower and toilet facilities and other types of space. Worksheet 11.6 may be used for this purpose.

As is the case elsewhere in the Manual, auxiliary or service space is made a function of the total allocation to primary activity area.

Worksheet 11.6 contains a planning assumption regarding the relative size of athletic plant components. This distribution may be used to expand the space requirements already projected for the primary components of athletic plant to obtain total space requirements for all athletic facilities.

Worksheet 11.7 should be used for summarizing the results of the preceding analysis. Aggregate space requirements for athletic activities at each planning stage may be summarized here. Sub-classifications for allocations to men's and women's facilities and activity and auxiliary spaces are provided for in the worksheet.

It should be noted that the nature of the facilities is such that the projected athletic plant could conceivably serve a wide range of enrollments with varying degrees of efficiency in plant utilization. This is partly because of the minimum requirements associated with particular types of activities, and partly because the plant must serve a shifting composition of athletic activities as the seasons change. In this respect, athletic plant is quite similar to special purpose instructional space in the intensity of utilization that can possibly be realized over the course of the year.

## TABLE 11.1; ATHLETIC ACTIVITIES SPACE

Recommended Planning Criteria for Selected Components of Indoor Physical Education and Athletic Activities Facilities

	Athletic Activities Station or Componenta	Planning Criteria: Unit Area Allocation Assignable Square Feet
	<u> </u>	۲ .
1234567890112114	Basketball courts: Practice court Competition court Combination of 2 practice courts and 1 competition court Baseball diamond (infield for fieldhouse) Football cage (fieldhouse) Indoor track: 1/4 mile, 6 lanes Handball: 4-wall court Handball: 1-wall court Squash: doubles court Squash: singles court Shuffleboard Volleyball (per court) Wrestling (per mat)	4370 6240 8735 16900 19260 33000 1060 680 1125 595 625 3025 1155
15 16 17 18 19 20 21 22 24	Boxing: Ring (1) Punching bag (per bag) Punching bag, heavy (per bag) Pool (Olympic standards - 6 lanes) Exercise room (per person) Rifle range (per point or firing position) Pistol range (per point or firing position) Fencing (per strip) Spectator seating, foldable (per seat)	900 15 35 7130 50 400 320 325 2.5
25 26 27 28 29 30 31 32	Lockers (per locker):    Varsity rooms    General locker room    Tote basket Showers (per head, gang showers) Shower-dressing stall for women (per unit) Ticket booth First aid, training, physical therapy room	10 6.75 .50 16 24 25 750

With the exception of self-contained facilities (e.g., handball and squash courts), the criteria all include allowances for buffer zones or circulation space around actual playing or competition area. Clearly, there is room for variation from these figures since a) competition areas need not be regulation-size, and b) two or more units may be combined, with resulting savings in circulation space needs.

### CHAPTER 12

### HOUSING SPACE

Housing facilities are usually revenue-financed and will be excluded from the computations of state-financed capital outlay. However, housing space is a major element in the institutional plant and also generates a need for certain types of facilities that are financed by internal resources or state funds. Therefore, it must be taken account of in the programming procedure.

### A. Physical Planning Criteria

The physical planning criteria for the allocation of space to housing facilities are summarized in table 12.1. Actual unit area allocations are specified for a single occupancy living quarter unit, a double occupancy living quarter unit, and one and two bedroom units for married students and faculty staff.

However, living quarters are only a portion of the over-all space required for housing facilities. Especially in housing for single students, substantial allocations must be made for toilets, washrooms and showers, and recreational and service facilities. These components of housing space may typically be treated as a function of the unit area allocation per living quarter unit. The planning criteria listed in table 12.1 treat these components accordingly.

### B. Capacity Requirements

The capacity requirements associated with housing facilities must, of course, be established by each institution. Chapter 2 calls for the

specification of the institutional planning assumptions with regard to the number of students to be in residence (i.e., in residential facilities) at each planning stage. These estimates should be even further elaborated at this point in the programming study. Each institution should specify the proportion of its single and married students that will be housed. Of course, this will depend upon the proportions of students expected to live at home and commute to the institution, the capacity of the local community to absorb growing numbers of students in private housing, the extent to which fraternities and sororities will absorb a portion of the housing demand, and the philosophy of the institution with regard to on-campus housing. Further, although the capacity of large, old houses convertible to rooming houses generally is limited, private investors have shown increasing interest in providing housing for students in college communities. The policy of the institution towards such developments should be taken into account.

By the same token, it is necessary that institutional policy be defined regarding the provision of housing for married students and staff. The extent to which such housing is to be provided and the distribution of such housing among one-bedroom, two-bedroom and larger units must be established.

and provision is made in the Manual for fraternity and sorority housing provided by or leased from the institution. This should be treated as residence hall space. If the institution leases land to such organizations on which they may build their own houses, the land requirement will be dealt with in a later section of the Manual.

### C. Outline of Procedure

Worksheets 12.1, 12.2 and 12.3 are devoted to the determination of the requirements for housing capacity by type of occupancy and planning stage. The worksheets call for a specification of the number of living quarter units required in single occupancy, double occupancy and other types of space for male single students and female single students, and the distribution of occupancy by size of apartment unit in the case of married students.

The next three worksheets in the procedure deal with the calculation of the amount of student housing space required. This is accomplished by bringing together the projected capacity requirements in each type of student housing and the unit area physical planning criteria for the type of housing capacity involved. Thus, worksheets 12.4 and 12.5 deal with the housing space required for single male students and single female students, respectively. Worksheet 12.6 focuses upon the housing space requirements for married students. Worksheet 12.7 should be used for determining the capacity and space requirements for housing facilities generated by the institution's staff.

The procedure ends with worksheet 12.8; it provides for a summary of housing space requirements, by type of housing and planning stage.

### CHAPTER 13

### FOOD SERVICE SPACE

Food service facilities, like housing space, are usually revenuefinanced. However, the requirements for food service space may be substantial and the need for such facilities should not be overlooked in programming the over-all physical plant requirements of an institution.

### A. Planning Criteria

Several types of planning criteria must be considered when projecting the space required for food service operations. First, it should be noted that three types of food service facilities may be required, covering the following types of dining arrangements: family style, cafeteria and snack bar. The planning criteria for the allocation of space to various components of the food service operation will vary with the character of the dining arrangement considered. Moreover, different criteria must be applied regarding the intensity with which dining stations may be expected to be used during food service intervals. That is, the turnover factor, expressed in terms of number of sittings per station per meal service, will vary with the kind of food service operation. And, finally, the utilization rate, or the proportion of total dining stations occupied at a single sitting, also will vary with the type of food service operation.

Table 13.1 details the recommended planning criteria associated with the several food service arrangements. The turnover factor, utilization rate and physical planning criteria appropriate for use in programming each type of installation are indicated.

### B. Capacity Requirements

Naturally, the aggregate requirements for food service space will be a function of the amount of capacity required in dining facilities. Worksheet 13.1 should be used for delineating the anticipated food service workload and distribution by type of dining arrangement. The worksheet takes cognizance of the fact that dining facilities may be located in residence halls, the student center and other facilities such as faculty clubs, special dining rooms and so on. The worksheet also permits analysis of the workload to be accommodated in these various types of facilities, as generated by the combination of student and staff populations on campus at each planning stage. The distribution of the peak food service load by type of dining arrangement also can be specified. Worksheet 13.1, when completed, will show the peak number of persons to be accommodated under family style, cafeteria and snack bar arrangements in residence hall, student center and other locations at each planning stage.

Worksheet 13.2 carries the analysis to the determination of the number of dining stations required in food service facilities, by type of arrangement (family style, cafeteria and snack bar) and type of facility (residence hall, student center and other units). The projection of capacity requirements will reflect the preceding analysis of the total number of persons to be served at the peak period, adjusted to reflect consideration of the turnover factor and utilization rate appropriate to each type of dining arrangement.

### C. Space Requirements

Once capacity requirements have been determined, worksheet 13.3 may be used for estimating the space required to accommodate the projected food service capacity needs. Consistent with the preceding analyses, the worksheet is organized to reflect the type of dining arrangement and type of facility involved. The projected number of dining stations required at each planning stage should be combined with the unit area allocation criteria recommended in table 13.1 to obtain the program area estimates for each dining category at each planning stage.

Worksheet 13.4 calls for the development of a summary statement of the program area requirements for food service facilities at each planning stage. The aggregate requirements, taken from worksheet 13.3, are summarized by type of facility and dining category to facilitate comparison and evaluation.

### CHAPTER 14

### STAFF AND STUDENT SERVICE SPACE

Staff and student service facilities vary widely in character and composition. Some of the facilities comprehended by this component of physical plant may be revenue-financed, as in the case of student center facilities, although a substantial portion will be housed in academic and general facilities, such as office-classroom buildings, administration buildings and so on. The projection of staff and student service space requirements should reflect an analysis of the service facilities required for staff and those required for students. Institutional policy will dictate the character of the facilities associated with each of the population groups to be serviced.

Table 14.1 recommends some physical planning criteria for the overall allocation of service space per person in the staff and student population groups. The table suggests that a unit area allocation of four square feet per staff member is appropriate for programming staff service facilities. Presumably, these facilities would be distributed among various buildings on campus; however, the distributional pattern will vary somewhat depending upon whether a faculty club or central staff facility is to be provided.

Similarly, student service facilities tend to be of two types: those located in a centralized facility such as a student center, and those dispersed among other buildings on campus. For student center facilities, the recommended allocation is 8.25 square feet per full-time equivalent

student. This is exclusive of any facilities associated with food service operations or other components of space dealt with elsewhere in the Manual. For facilities located outside the student center, an allocation of 1.5 square feet per full-time equivalent student is recommended.

These general criteria will be adequate to the determination of total service space requirements for the programming study. However, table 14.1 contains unit area allocation criteria for selected student service components, and the planning analyst may elect to use these criteria and program such facilities in detail. In any event, at the time such facilities are being programmed for actual construction, the more detailed approach should be used.

Worksheet 14.1 may be used for the projection of staff and student service space requirements at the several planning stages used in the programming study. The worksheet reflects the desirability of developing the space requirement estimates in two broad categories: staff service facilities, and student service facilities. Within each of these categories, further analyses are suggested. For staff service facilities, it is recommended that the service space needs for faculty and professional staff and supporting clerical and technical staff be dealt with separately. Similarly, analysis of the requirements for student service facilities should be conducted in terms of the two allocation patterns; that is, those located in a central facility such as the student center, and those to be located outside such a facility and distributed among the various buildings on campus. The total program area associated with staff and student service space may be obtained by simple aggregation.

At a later stage, when occupancy patterns are being established for existing and proposed buildings (see Chapter 19), the aggregates developed in worksheet 14.1 may be used as control totals governing the total staff and student service space distributed among the complex of buildings required at each planning stage.

### TABLE 14.1; STAFF AND STUDENT SERVICE SPACE

Recommended Planning Criteria for the Allocation of Space to Staff and Student Services Facilities

	Planning Criteria.
Item	Assignable Square Feet
	. 2
Staff service facilities:	
Unit area allocation per staff member a	4
Student service facilities :	
Unit area allocation per enrolled student: Facilities located in student center Facilities located outside Student center All facilities	8.25 1.50 9.75
Selected student service components: Lockers: per locker (full size, floor standing) Lounges, common rooms; per station Post office: per mailbox (including auxiliary service facilities such as counters, etc.) Meeting room: per station Barber shop: per chair Billiards: per table Bowling alley: per lane Kitchenette Table tennis: per table	6.75 20 .75 20 100 320 575 20 345

<sup>&</sup>lt;sup>a</sup>This covers all lounge and common room facilities for faculty and other professional staff and supporting technical and clerical personnel. Kitchenette facilities are included, but regular food service facilities, such as cafeterias, are not.

The planning criterion of 9.75 square feet per student would apply only in the absence of student center facilities. Should student center facilities be provided separately, the service areas outside the student center could be scaled down to about 1.5 square feet per student. The planning criterion for the allocation of space per student in student center facilities may vary widely since it is largely dependent upon the character and extent of the individual space or activity components that are included. Planning criteria for selected student center elements are listed in the table.

### CHAPTER 15

### MISCELLANEOUS OTHER SPACE

This chapter provides for the determination of miscellaneous building space requirements not accounted for in previous sections, except for physical plant maintenance and operation facilities to be determined in Chapter 16. Under the heading of miscellaneous building space would come special facilities for auxiliary enterprises (e.g., printing plant), infirmaries, armory, non-institutional agencies housed on the campus (e.g., installations of federal agencies), public facilities such as a large auditorium or concert hall, and any other type of facility which cannot be accounted for under any of the eleven broad categories of building space considered elsewhere in the Manual.

Such facilities may even be fully owned by an outside agency, but should be listed if the institution provides land or plant maintenance and operation services to the facility. Worksheet 15.1 provides for the listing of such facilities and the determination of the amount of space required for them at each planning stage.

### TECHNICAL NOTES:

al.e., not covered in Chapters 5-14 and Chapter 16.

bappend statement describing function of facility and basis for program area estimate.

### CHAPTER 16

### PHYSICAL PLANT MAINTENANCE AND OPERATIONS FACILITIES

Building area for the shops, storage, and other facilities required for the maintenance and operation of physical plant, buildings and grounds, and service components of the institution may best be estimated by a general analysis of the requirements of such operations in consultation with the business manager and physical plant superintendent. As a rule, these components are not strongly related to institutional size, but constitute certain minimum fixed requirements. As the total floor area of the institutional plant (including housing) passes certain magnitudes, additional floor area for buildings and grounds service operations may be required.

As a general guideline, table 16.1 lists some empirically established planning criteria for physical plant service building space. These criteria, which are expressed as a function of assignable square feet of all other building area to be maintained and serviced, cannot be applied until the total floor area requirements of all other facilities are compiled. Worksheet 16.1 will permit the development of summaries of the space requirements projected for all other facilities. Worksheet 16.2 may then be used to project the space required for physical plant maintenance and operation facilities.

It should be noted that the space identified by this general category does not include the wide variety of building service elements that are dispersed among campus buildings other than those associated with central maintenance operations. Thus, janitor rooms, mechanical equipment rooms,

elevator facilities, and similar facilities located in individual buildings and serviced by central physical plant maintenance are not included as assignable square feet; the space associated with this building elements is considered to be part of the gross area of campus buildings, but not part of the net area. (See discussion in Chapter 18.)

# TABLE 16.1; PHYSICAL PLANT MAINTENANCE AND OPERATIONS SPACE

Recommended Planning Criteria for the Allocation of Space to Physical Plant Maintenance and Operations Facilities

	Space Component	Planning Criteria: Unit Area Allocation per Thousand Square Feet of Assignable Space to be Serviced Assignable Square Feet 2
7	Maintenance shops	11.0
Ŧ	Maintenance shops	
2	Heating plant	8.6
3	Garages	8.4
<u>L</u>	General storage	12.5
5	Miscellaneous other	2.7
6	Total <sup>b</sup>	43.2

aSince institutional plant varies in size and location, these figures are not universally applicable. For example, heating plant very likely declines relative to total plant as the total size of the plant increases. Conversely, maintenance shops probably increase in relative importance and begin to perform projects that were formerly subcontracted. Once again, these figures should be used as a point of departure and only in this initial phase of gross approximation of future physical plant requirements.

bother space components which might be included in physical plant maintenance facilities, such as office space, are not accounted for in this tabulation. Such elements would be accounted for at a separate stage of the calculating; procedure and be included in the summaries of Chapter 17.

### CHAPTER 17

### AGGREGATE SPACE REQUIREMENTS

At this stage of the programming effort, all space required for all components of physical plant located on campus have been projected. It is now possible to review the results of the programming effort and develop various summary tabulations of projected space requirements. Since the analysis has been conducted along functional lines, this is the first opportunity available to review the over-all physical plant requirements in departmental terms.

Typically, there are several kinds of information required in the summary of space requirements. For example, it is desirable to know how much space is required by each department at each planning stage, by type of space. It is useful to examine the pattern in which the departmental space requirements increase across the several planning stages considered in the programming study, by type of space. It also is useful to compare departments in terms of the growth in total space requirements across the planning interval, by planning stage. Naturally, total institutional requirements, classified by department, type of space and planning stage, can be developed by simple aggregation.

Worksheet 17.1 calls for an analysis of the distribution of physical plant requirements in each department at a specified planning stage, by type of space. A separate worksheet must be completed for each planning stage used in the programming study.

Worksheet 17.2 focuses upon the individual department and its pattern of development. The aggregate space required by each department, by type of space and planning stage, is compiled from an analysis of the results of the programming effort as recorded in the worksheets of Chapters 5 through 16. A separate worksheet must be completed for each department.

Finally, worksheet 17.3 is designed for the enumeration of all departments and the recording of the aggregate space requirements of each department at each planning stage used in the programming study. The worksheet also can be used for aggregating total institutional space requirements at each planning stage, thereby permitting comparison between changes in total institutional space requirements and changes in the space requirement.

### PART IV

PHYSICAL PLANT CONSTRUCTION,

DEMOLITION AND REMODELING PROGRAM

### PART IV

# PHYSICAL PLANT CONSTRUCTION, DEMOLITION AND REMODELING PROGRAMS

The Manual thus far has been devoted to the development and exposition of a statistical model for the projection of college and university space requirements under a specified constellation of workload estimates and institutional policies. The model recognizes twelve broad categories of physical plant facilities and is explicit with regard to projecting the amount of each type of space required to meet the future needs of individual divisions and operating departments. At this stage, with requirements stated and the quasi-theoretical aspects of the model completed, we must turn to the next stage of analysis: determining a) how the institution can best use existing buildings, including demolition and remodeling where this is appropriate, and b) what new structures are required, if any. In short, it is now possible to turn to the elaboration of the building program.

A necessary ingredient in developing a building program is a knowledge of the size and characteristics of the existing physical plant. Such information is of little value or may be unavailable where new institutions are being organized or existing institutions are being relocated to an entirely new campus. But for institutions that will continue to operate on the same campus and use all or a portion of their existing physical plant, a physical plant inventory is extremely important. Consequently, Chapter 18 is devoted to questions involving the physical plant inventory and how it may be accomplished.

With a background of information concerning the present physical plant,

comparison then can be made with the estimates of future space requirements to determine the over-all deficit (or surplus) that may confront an institution at each planning stage. After analyzing the existing buildings to determine which ones are amenable to reuse and evaluating the relative urgency of the departmental needs for various kinds of space, building occupancy programs covering the existing buildings and new construction can be developed for the several planning stages under consideration. Such building occupancy programs are specific with respect to the departmental units cccupying a building and the total amount of each kind of space to be assigned to these departments. Finally, with the present and the proposed configurations of building occupancy and departmental space allocations delineated, the analyst can proceed to the development of a schedule for phasing from the present to the proposed pattern. This schedule will enumerate and indicate the order or priority of the various demolition, construction and remodeling projects required to implement the physical plant modification program. This aspect of the programming procedure is covered in Chapter 19. When completed, the physical plant portion of the campus development programming procedure will have been implemented.

### CHAPTER 18

#### PHYSICAL PLANT INVENTORY

### A. General Remarks

In programming the future development of an institution, a thorough knowledge of existing physical plant resources is necessary. Thus, at some point during the programming study, an inventory of existing physical plant should be undertaken. The inventory should focus upon providing information regarding the following characteristics of the physical plant: a) the amount of space available; b) what kind of space is available (the distribution of total available space by use); c) the location of available space (the distribution of total available space by building and type); and d) who uses the space (the distribution of total available space by department and type of space). This statistical cross-sectional view of the use and disposition of space in the available physical plant will provide the desired point of departure for determining net additional physical plant requirements in the future.

Of course, it should be borne in mind at all times that the statistical record describes the physical plant pattern at a point in time: the interval during which the field survey of existing physical facilities is conducted. Subsequent changes in the amount or assignment of physical plant are excluded from the data. The survey also usually involves the preparation or updating of record drawings of the floor layouts of existing buildings. The use of facilities usually must be established after consultation with representatives of the departments controlling the space so that the

statistical record will reflect an informed interpretation of the functional and administrative assignments of all components of the physical plant.

### B. Space Classification System

Before considering the classification system to be used in the collection of data on space utilization, three broad definitional concepts should be mentioned. The first, gross area, is an aggregate figure which encompasses all floor space delimited by the perimeter walls of a building, including attics and basements, but excluding attic or crawl space with less than six feet of standing room. A second category, occupied area, refers to the floor space of a building, exclusive of the thickness of both interior and exterior walls, duct areas, and all major circulation facilities such as stairwells, corridors, elevator shafts and the like. The third category, net area or assignable square footage, refers to occupied area less all space assigned to building maintenance, such as janitor rooms, mechanical equipment and apparatus rooms needed for the functioning of a building, public restrooms and toilet facilities (except in residential facilities and athletic plant, where toilet facilities are an integral part of the net usable space requirements).

The aggregate referred to as net area encompasses the twelve major categories of space already alluded to elsewhere in the Manual. Included are the following: classroom space; special purpose instructional space; office space; research space; library space; museum and gallery space; athletic activities space; housing space; food service space; staff and student service space; miscellaneous other space; physical plant operation and maintenance

space; and unused or unassigned space. The detailed subcategories of space encompassed by the broad classification system have already been referred to in Chapters 5 through 16 and will not be repeated here. Mention should be made, however, cf the alternate systems that are presented in Appendix D for use in numerical coding of the physical plant inventory. The coding systems are designed to permit the inventory to be processed on mechanical or electronic data processing equipment, should this prove feasible.

### C. Outline of Procedure

Worksheet 18.1 is the basic building data sheet to be used in the inventory of existing physical plant. A separate worksheet is required for each building and each worksheet summarizes the various characteristics of space utilization relevant to the inventory. The worksheet permits the recording of the occupancy pattern within each building as of the date of the inventory; that is, the amount of space allocated to specific departmental units, by type of space used. Worksheet 18.1A is the basic room inventory worksheet from which the summary data in worksheet 18.1 are to be developed.

Worksheet 18.2 is a summary of the physical plant inventory. This worksheet calls for an enumeration of all buildings in the existing physical plant complex, with an indication of four items of information: the gross area of the building; the net area or assignable square footage in the building; and the ratios of gross area to net area and net area to gross area for each building.

The preceding two worksheets focus upon the actual pattern of space

allocation on the date of the inventory. But to implement the programming study, there must be a shift in perspective to future utilization of existing physical plant. That is, future building occupancy patterns require that existing buildings be adapted to changes in administrative assignments or space utilization patterns. However, existing buildings are not likely to be 100 percent efficient in absorbing space programs that are based upon the procedures and physical planning criteria recommended elsewhere in this Manual. This is because both the physical and policy planning criteria that underlie the space programs are not likely to be consistent with the architectural configurations of buildings designed for another age. Therefore, it is desirable that the existing physical plant be evaluated with regard to the efficiency with which it can absorb proposed space assignments.

Worksheet 18.3 is to be used for this purpose. It calls for an evaluation of each existing building in order to determine how effectively it can absorb space programs which have been based upon the physical planning criteria and policy assumptions underlying the programming study. For example, some buildings may be 95 percent effective in absorbing recommended programs; others may be only 80 percent efficient. The net available space in each building after allowing for these considerations should be indicated in worksheet 18.3.

Worksheet 18.4 allows for the exploration of another point of view with regard to the size and distribution of available space in the existing physical plant. Instead of using the individual building as a point of departure, worksheet 18.4 calls for an analysis of the current alloca-

tion of net available space to each department, classified by type of space and building location. A separate worksheet is to be completed for each department. The data thus developed provide a basis for evaluating departmental dispersion as well as the amounts of various kinds of space available to individual operating units.

Summary tabulations of the tot 1 amount of space available in the existing physical plant can be developed from the several worksheets described above. The distribution of available space by type of space, department and building are readily accomplished through simple aggregation procedures.

### TECHNICAL NOTES:

- A separate worksheet should be completed for each building.
- e.g., renovation, Indicate any anticipated changes that may affect future use of building: demolition.
- Worksheet 18.1A should be used as the basic data tabulation sheet for the room inventory. The data in worksheet 18.1 can then be developed by aggregation from the detailed room inventory sheets.
  - Specify names of individual departments covered in column headings.

346

TAYLOR, LIEBERFELD AND HELDMAN, INC.

### CHAPTER 19

### BUILDING PROGRAM

velop a program for the use of existing buildings and the construction of new facilities over the planning interval under consideration. The amount and characteristics of space requirements at several planning stages have been projected. Similarly, the amount and characteristics of space available in existing physical plant have been established. These two sets of information can now be evaluated so that the physical plant phase of the campus development program can be articulated.

### A. Size of Building Program

Worksheet 19.1 provides a basis for developing a first approximation of the over-all deficit (or surplus) of space in existing physical plant relative to the space needed at some specified future planning stage. The aggregate space available in existing facilities (as adjusted for absorptive efficiency in accordance with worksheet 18.3) is subtracted from the aggregate space required at planning stage X. An estimate is thus obtained of the approximate total amount of new construction required during the interval that will elapse between the base year and the specified planning stage.

This estimate must be described as an approximation because of the inflexibilities and fixed nature of physical plant facilities. For example, the deficit may be small but not of sufficient size to warrant construction of only a small facility to make up the deficit. A larger building than is necessary to make up the deficit may perhaps have to

be built in anticipation of further growth beyond the target planning stage and ultimate improvement in the effectiveness with which the new structure will be used. Alternately, there may be a surplus of one kind of physical plant and a shortage of another; but the former may not be adaptable to remodeling to compensate for the shortages in the latter. By way of illustration, suppose there are too many pools in the athletic plant; this is likely to be of little use in making up for any space shortages that may be present in the heating plant or in the kitchen facilities associated with residential dining halls.

However, the calculation does provide the basis for a rough estimate of the order of magnitude of the shortage (or surplus) that may characterize the existing physical plant relative to future needs. The actual amounts of construction that may be required can only be determined after completing the analysis outlined in the remaining worksheets of this chapter.

### B. Priority of Need

A more ticklish and difficult aspect of the building program is that of determining the relative urgency of the need to eliminate deficiencies in net area at the department or department group level. Preceding sections of the programming study will have made possible a comparison of future space requirements and net area available in existing physical plant on a departmental basis. This comparison permits the determination of whether or not there will be a deficit in available space at a specified planning stage as well as the order of magnitude of the deficit.

Clearly, the planning analyst must make some judgement as to the relative urgency of the need to offset any projected physical plant deficiencies that may confront the many departments of an institution.

One measure of priority that may be developed can be based on the actual size of the deficit in usable space. That is, departments may be ranked by the absolute size of their expected space deficits, the largest deficit defining the highest priority of need, the smallest deficit defining the lowest. Another measure that might be developed would involve the calculation of the size of the deficit in each department relative to its base period allocation of space. Once again, the order of the ranking would be determined by the size of the relative deficit in each department. The department having the largest deficit relative to the base period allocation would be ranked first in order of priority; the department having the smallest relative deficit would be ranked last in the priority system.

Clearly, neither of these measures will prove faultless. A deficit of 1,000 square feet for a small department may be just as significant to it and the institution as a deficit of 10,000 square feet in a large department. Similarly, a ten percent deficiency in a large department may be as significant as a 50 percent deficiency in a small department. A ranking of priority based either on the absolute size or relative size of the space deficit is not satisfactory in and of itself.

Some combination of these two priority measures is desirable. One possibility is suggested in the technical notes to worksheet 19.2, which is devoted to the analysis of priority ranking in the building program.

This would involve ranking departments in terms of the order of magnitude of the product obtained when the figures designating the department ranks based upon both absolute size and relative size of deficit are multiplied by each other. However, even this system may not prove satisfactory. For example, in some instances a particular department must be accorded high priority status because of the pivotal nature of the department or its present building location in the over-all development program, even though the department may actually have relatively less need for additional space either in absolute terms or in relative terms than other depart-That is, the strategic position or location of the department may be the primary consideration. Quality of existing facilities also must be taken into account. For these reasons, the ultimate decisions on priority of need must be made by the planning analyst in light of a detailed knowledge of the institution for which the programming study has been undertaken. The opportunity for the analyst to record such evaluations is provided in worksheet 19.2.

### C. Building Occupancy Patterns

Against this background of information regarding the departmental space deficits and the priority to be accorded individual departments in eliminating deficiencies, the analyst can turn to developing the desired building occupancy pattern at the planning stages under consideration.

Worksheets 19.3, 19.4 and 19.5 can be used for this purpose.

In worksheet 19.3, the building approach is taken. Each building in the existing physical plant complex is studied and a departmental occupancy

pattern is determined for each planning stage. The departments and the amounts of each type of space required by them are enumerated. Several attempts may be necessary until an approximately good fit is obtained between the space available in a building and the space required by the departments programmed into the building. After programming the use of existing buildings, new buildings may be considered.

In the case of both existing and new buildings, the process of arriving at a satisfactory occupancy pattern may require several efforts. Although this may appear to be a hit or miss proposition, in actual fact the analyst will be able to eliminate many possibilities immediately because of his experience and informed basis for dealing with the development problems at his institution. A separate worksheet must be developed for each existing building that will be retained in the future and for each new building or addition that will be needed to meet the over-all physical plant required at the specified planning stage.

Worksheet 19.4 focuses upon individual departments. It may be used for determining the ideal location pattern of the program area requirements associated with the department under analysis. A separate worksheet should be completed for each department and the conclusions should be consistent with those already generated in completing worksheet 19.3.

Worksheet 19.5 is optional; it is a master worksheet covering the building occupancy and department location patterns for all buildings and departments at a specified planning stage. However, it is useful. The cross-classification of departments and buildings will provide at a glance

what amounts to a panoramic view of the use of physical plant at each planning stage. The location of each department can be readily established; the occupancy pattern of each building also can be readily observed.

### D. Building Program

At this point, it is possible to express the sequence for dealing with the various components of the building program. Worksheet 19.6 focuses on existing structures. All existing structures are listed and their treatment at each planning stage is indicated. The gross area of the building, the planning stage at which the particular project is to be begun, and the character of the project can be indicated. Demolition and major remodeling projects in existing physical facilities should be dealt with on this worksheet.

Worksheet 19.7 calls for the exposition of the new construction portion of the building program. Each new building or addition to existing structures should be listed in order of priority. The planning stages at which new construction must be ready for occupancy should be indicated here. The worksheet also permits conversion of the program area requirements of the new building to gross area. The coefficient to be used in converting from net area to gross area will depend upon the nature of the building project, the amount of construction involved and, ultimately, the design of the new building. However, for planning purposes the conversion coefficients listed in table 19.1 may be used in estimating the gross area of construction involved in implementing each new building project.

### E. Summary of Building Program

Various types of sommaries of the recommended building program will be found useful. Worksheet 19.8 permits the development of summaries of net and gross building area in the base period and at the several planning stages used in the programming study. Sub-studies of the amounts of space in a) academic and general facilities and b) housing and other revenue-financed facilities are provided for in this worksheet. In addition to providing a summary of the total amounts of net and gross area available at each stage of institutional development, the worksheet permits the calculation of the area per student at each planning stage. This is a general index of the effects of the programming procedure, the physical and policy planning criteria used, and the changing mix of instruction, research, and non-academic activities accommodated on campus. However, this is an analytical gauge only; it has no significance for predicting institutional plant capacity and should not be used for estimating building space requirements.

Worksheet 19.9 provides another summary view of the building program. The worksheet is designed to show the changing pattern in the allocation of physical plant by major type of space as the building program progresses through several stages of institutional growth. Net changes in each space component, both additions and reductions, are shown in this worksheet. Thus, another view is provided of the changing mix in the composition of physical plant over the planning interval comprehended by the programming study.

PART V

LAND REQUIREMENTS

### CHAPTER 20

### LAND REQUIREMENTS

Campus resources include both physical plant and land. And in the same way that physical plant requirements are amenable to orderly programming, campus land requirements can also be dealt with in a systematic and comprehensive fashion. The method is essentially the same as that underlying the development of the physical plant program.

Analytically, the procedure for estimating land requirements takes the following form. First, campus land is divided into several functional categories for purposes of analysis. Second, the intensity of land demand associated with each functional category is determined. This is analogous to the determination of the workloads associated with each component of physical plant when programming physical plant requirements. Third, policy planning assumptions are introduced regarding a) intensity of land use and b) unit area physical planning criteria for the allocation of land to different purposes. Fourth, the planning criteria are combined with the workload estimates to arrive at a program of land requirements. Fifth, reference is made to the inventory of current campus land holdings and land evailability is compared with projected land requirements. The existence of a deficit (or surplus) in land resources is ascertained and an approximation of the order of magnitude of the deficit (or surplus) can be established. Sixth, a program is evolved for acquiring additional land resources. Finally, a program for using future campus land resources, both existing and acquired, is developed. This includes the following statements: amount of land required, b) the planning stage at which land acquisitions

TAYLOR, LIEBERFELD AND HELDMAN, INC.

must be made, and c) the use of campus land at each planning stage.

For purposes of this programming study, land use is divided into four broad categories: building sites; outdoor athletic and physical education activity areas; parking; and circulation and other uses. Further sub-classification is possible, but bearing in mind the objectives of the Manual the fourfold classification enumerated above should prove sufficient.

### A. Building Sites

Worksheet 20.1 deals with the projection of acreage requirements for the accommodation of buildings. For each planning stage, the gross floor space of physical plant has already been determined. Therefore, only two further variables must be identified in order to estimate the acreage requirements for building sites. These variables are a) the average number of floor levels per building, and b) the building density factor. The estimate of the average number of floor levels (including basements) that will prevail across the campus should reflect a consideration of a) the character of existing campus architecture, and b) the appropriateness of highrise or low-rise construction for various types of buildings. Thus, it is desirable to keep classrooms and laboratories within three floor levels while offices, dormitories and family apartments may be built in high-rise structures. If no high-rise structures are likely, an average of 3.5 floors is common for campus-type college development. Some presence of high-rise construction may raise the average to 4 floors. A dense urban campus may average 5 but seldom more than 6 floor levels; this is because of the need. at class change time to keep heavy student traffic on lower levels, thereby

avoiding some of the problems of providing for peak load elevator service to classrooms and laboratories.

The density of building coverage refers to the proportion of land area within a building zone actually covered by structures. Excluding parking and playfield areas but including all other open space on campus, the typical "campus" may reach 30 percent ground coverage but usually averages about 20 percent.

In analyzing building density, it should be kept in mind that academic building facilities should be grouped within an area which may be spanned within six minutes walking time (normal class change interval less four minutes) or a diameter of 1,600 feet. This comprehends a zone of about 2 million square feet, or approximately 46 acres, and is a maximum area within which academic buildings should be concentrated. In 46 usable acres, at 20 percent ground coverage, and with buildings averaging 3.5 floors, a total of 1.4 million gross square feet of buildings can be accommodated. Higher density is required to maintain the six-minute walking span for more than 1.4 million square feet of buildings. Parking, physical education and athletic fields, research installations and housing require additional land on the periphery of the central core. The density factor should be determined after considering the degree of compactness required to accommodate academic buildings, housing, special research facilities and other land-consuming facilities within a reasonable distance of one another.

B. Land for Athletic and Physical Education Activities

The second campus land component to be analyzed separately is the

acreage devoted to outdoor athletic and physical education programs. Work-sheets 20.2 through 20.7 are devoted to programming the land requirements associated with outdoor athletic programs. Here the analysis virtually parallels that developed in connection with programming indoor athletic activities space.

Worksheets 20.2 through 20.4 should be used to project the workloads associated with outdoor athletic programs.

In worksheet 20.5, the projected activity levels are first converted to estimates of capacity requirements and then combined with unit area allocation criteria to arrive at estimates of the total land required to accommodate outdoor athletic programs. Physical planning criteria appropriate to determining outdoor athletic activity facilities are provided in table 20.1.

Worksheet 20.6 focuses upon the question of the capacity and acreage required to satisfy the needs for spectator seating at outdoor athletic events.

And worksheet 20.7 summarizes the aggregate campus acreage required to meet the need for playing fields and activity areas and spectator seating at each planning stage.

### C. Parking

The third campus land category separated for analysis is that associated with parking facilities. The acreage required for parking is partly a function of the size of the campus population and partly a function of the rate

at which it uses automobiles and requires parking accommodation on campus.

Of course, parking space for students and staff would have to be augmented to meet the needs of campus visitors as well.

In worksheet 20.8, the number of parking spaces required to satisfy staff, student and visitor needs should be analyzed. Once these workload characteristics are established, the total acreage required for vehicle parking may be obtained by combining the projected load factor with the planning criteria for the number of vehicles that can be accommodated per acre. The last is suggested in table 20.1.

### D. Aggregate Land Requirements

Worksheet 20.9 will permit the determination of the amount of additional land necessary to satisfy aggregate campus acreage requirements at each planning stage. As a first step, the total acreage required for building sites, outdoor athletic and physical education activities and parking should be established. To obtain aggregate land requirements, this figure should then be increased by the amount of land required for circulation and other purposes. This will vary with density characteristics, campus location (rural-urban), institutional policy on parking permits, resident-commuter student mix, and so on. A reasonable assumption would put circulation and other land uses at about 20-30 percent of total acreage on a moderately built-up campus, or about 25-40 percent of the land devoted to the above three land-use components. Then, by comparing available land with projected acreage requirements the net deficit or amount of additional land that must be acquired can be determined.

It should be noted that land must be acquired far in advance of need for perpetual institutions of higher education. Therefore, the land acquisition program to be funded during the planning period under consideration should provide land as much as 20 to 40 years ahead of need, especially if the availability of such land is declining and/or the difficulty of acquiring land is increasing. The enumeration of land acquisition items should therefore be extended to include purchases for long-range growth, regardless of the computed amounts to be actually used within the planning period. A separate justification for these additional acquisitions should be appended to worksheet 21.3 (which deals with the capital outlay projections for land acquisition).

### TABLE 20.1; LAND REQUIREMENTS

### Recommended Planning Criteria for Use in the Allocation of Land to Selected Uses

	•
Item	Planning Criterion
1	2
Swimming pool	.16 acres per unit
Track	4.00 acres per unit

PART VI

CAPITAL BUDGETING

### CHAPTER 21

### CAPITAL OUTLAY PROJECTIONS

The final step in this procedure is to determine the long-range capital outlay requirements of the institution, according to the projected requirements for new buildings, major remodeling and nonbuilding capital projects. The procedure for estimating capital outlay requirements is geared (with some minor variations) to existing procedures of the State Planning Division and the State Budget Office. The Five-Year Moving Capital Budget programs called for in the state's Capital Construction procedure may be directly derived from the estimates made in this chapter. However, since an immediate purpose of this procedure is to provide the basis for a continuing capital funding system for higher education over a longer period of time, the estimates called for here will span up to ten years, depending upon the expected timing of the final planning stage. At this point, a final check should be made that the "enrollment projection-planning stage" correlation made in worksheet 2.1 is still consistent with most recent demographic analyses. If not, appropriate revisions should be made in order that the capital outlay projections reflect the actual dates at which the planning stages are expected to be reached.

### A. Project Scheduling

In scheduling the capital outlay program on a fiscal year basis, major building projects should be funded over a three-year sequence: first year, planning and design funds; second year, construction funds; third year, movable furniture and equipment funds. This means, for example, that a

building needed for the enrollment level expected in Fall 1968 would be funded as follows: planning and design, 1965-66; construction, 1966-67; equipment, 1967-68. The planning and construction schedule would work out approximately as indicated in table 21.1.

This schedule suggests that nearly four years are required from preliminary programming through the completion and acceptance of a major building. If this kind of schedule is to be maintained, it is clear that an institution must have the machinery for developing a "program" for a building project before an architect is hired; this program is needed as the basis for the initial request for planning and design funds which must be filed by July 1, 1964 for a building to be completed by 1968. also is apparent, since at least a full year should be allowed for architectural plans and working drawings, that the first year's appropriation should cover the cost of architectural and engineering services through. the preparation of complete bidding documents, working drawings and specifications, so that bidding on construction may be initiated as soon as construction funds are appropriated. On most larger projects, 18 months should be allowed for the construction period. The timing of this sequence is such that buildings usually will be occupied in the winter; a preferable time would be the summer before the fall term in which the building will be most needed. However, since delays are inevitable under any system, scheduling along the lines outlined above is reasonable. Completion of a building in the winter will leave time during the spring and summer for remodeling of vacated space for new functions and permit occupancy by the following fall term.

### B. Demolition and Major Remodeling Projects

As computations of building area requirements were made in previous sections, the determination was made of how existing buildings are to be used at future planning stages. Changes in the functions of older buildings are an inevitable part of institutional growth as some departments move into new buildings and as other departments grow into vacated space. Generally, extensive remodeling of older buildings is required when such changes occur. Other older buildings simply have worn out and need to be renabilitated with new lighting and electrical systems, improved heating and ventilation, new floor covering, and the like. Finally, for a variety of reasons, some buildings must be demolished. Major demolition and remodeling projects that will be required over the planning period have been compiled in worksheet 19.6. These should be evaluated in relation to the expected cost of the remodeling required and enumerated in worksheet 21.1.

Major remodeling costs will vary according to the extent of interior changes to be made. When a science department moves into space used previously only for offices and classrooms, remodeling for laboratories requires extensive reconstruction of interior partitions, often strengthened floor loading capacities, completely new utilities, extensive ventilation equipment, and fixed hoods and benches. For this reason, and because space requirements in the sciences change more rapidly, it is good practice to assign older space to nonlaboratory functions. Conversely, when science departments move to new space and the areas vacated are converted to nonlaboratory uses, benches and utilities must be torn out, floors resurfaced, and partitions and lighting changed.

aCosting \$25,000 or more and beyond ordinary building maintenance or deferred maintenance costing less than \$25,000.

406

In estimating remodeling costs on a preliminary basis, the square fcotage of floor area to be remodeled serves as a good measuring unit. The cost per square foot may be assessed according to variable factors based upon the extent of remodeling required. Following is an illustration of potential remodeling costs.

Code 1 - Minimum remodeling (painting, now lighting, new floor covering, minor partition changes)

**\$3.00** per s.f.

Code 2 - Extensive remodeling (major partition changes, new floor covering, some utility rehabilitation, new lighting, painting)

\$5.00 per s.f.

Code 3 - Comprehensive renovation (extensive partition changes, interior structural improvements, complete utility overhaul, new lighting, new floors, painting)

\$8.00 per s.f.

It should be noted that these unit costs are illustrative only; actual costs are to be determined from institutional experience in consultation with the State Planning Division staff.

New Buildings and Additions to Existing Structures

No attempt is made here to define the method to be used in estimating unit costs for various types of construction. The worksheets allow each institution to determine the method of estimating the costs of the facilities according to recent experience and professional advice from consulting architects or the staff of the State Planning Division.

Worksheets 21.2 or 21.2A may be used for estimating the costs of major new building projects enumerated in worksheet 19.7. The unit cost would be developed from the institution's recent experience adjusted by an escalation actor to bring these costs up-to-date.

It is recommended that cost estimates be expressed in terms of current dollar values. The estimates of future capital outlay requirements should not be adjusted to reflect anticipated changes in construction industry productivity or long-term inflationary forces. Local industry conditions (e.g., contractor bidding practices) are so significant in determining ultimate capital costs that adjustments in unit costs for national trends in inflation and productivity may introduce greater error than would otherwise be present in the estimates.

However, unit costs based upon past projects should be updated to reflect changing cost conditions. That this is necessary may be seen by the reference to published construction cost indexes in various architectural and engineering journals. As an example, table 21.2 lists the F. W. Dodge Construction Cost Index for labor and materials in the Denver area for concrete and masonry type construction since 1955. Between 1955 and 1962, this index showed an increase of 20 percent, averaging an increase of 2.86 percent per year over seven years. In the four-year period, 1958-1962, the index rose by 10.8 percent, averaging an increase of 2.7 percentage points per year. This index may be used to estimate current construction costs

408

by analyzing the actual cost of various types of buildings at an institution in recent years. Taking the basic contract cost (general, electrical, mechanical, special) per gross square foot "recent construction, the estimates may be adjusted at a 2.7 percent increa per year.

D. Land Acquisition, Utility Service, 4. Miscellaneous Other Capital Projects

The capital costs of land acquisition should be developed on worksheet 21.3. Acquisitions should be consistent with the schedule and needs suggested by the analysis in Chapter 20.

The capital costs of extension, enlargement, and rehabilitation of campus utility services which are not funded as part of major new building or major remodeling projects should be analyzed by the institution's staff in consultation, if necessary, with professional engineers and members of the State Planning Division staff. Under this heading would come additional boiler capacity (a completely new boiler plant would be considered a major building project), extension of utility tunnels and/or lines to areas of new development, sewer line extension costs, and major rehabilitation of utility lines. Capital projects of this kind should be enumerated in worksheet 21.4.

Worksheet 21.4 also should be used for listing of all other capital projects for which capital funds will be required: street, curb, and side-walk development not funded as part of specific building projects; parking lot or structure development; landscape improvements; physical education and athletic field construction; and such other nonbuilding capital projects. In compiling these projects, refer to worksheets 20.5 and 20.6 for the compilation of requirements for physical education and athletic fields and to

worksheet 20.8 for parking.

### E. Source of Funds

The source of funding for the capital projects is, of course, significant in evaluating the feasibility of the development program and the appropriateness of reconsidering underlying policy planning assumptions. Worksheets 21.5 and 21.6 are to be used for analyzing each project in the sequence of campus development in regard to the source of funds; that is, whether federal government, state government, or some other source. Funding requirements are still expressed in terms of planning stages at this point, and all projects are included, whether state-funded or otherwise.

### F. Summary of Capital Outlay Projections by Fiscal Year

Worksheet 21.7 provides for the compilation of all capital projects by fiscal year. It is on the same general format as State Form 1.2, the Moving Five-Year Projection Program, except that it extends through ten years. The number of years covered will depend upon how far the final planning stage used in the programming study will carry the institution. In some, the final stage may be reached by 1969, so that the span of funding shown would cover only through 1968-69. In other cases, the final stage may be reached after ten years; but there is no need to carry the funding summary beyond ten years at this time. This listing should include all projects not yet funded, regardless of source of funds.

Worksheet 21.8, which is derived from the preceding worksheet, is more analogous to State Form 1.2. The worksheet focuses on the requirements for

state funds over the first five-year span. Under the fiscal year break-down, only state funds should be shown.

In the future, projections should permit the development of capital funding estimates through at least eight years, even though the official capital budgets will probably continue to span five years; this will provide longer-term data for planning capital financing programs and provide a continuing base for the moving five-year estimates.

All parties should note that these long-range capital estimates are tentative and subject to revision from year-to-year as plans develop, estimating data improve, and priorities change.

### APPENDIX A

CHECK LIST OF SELECTED QUESTIONS ON INSTITUTIONAL POLICIES

AND PLANS RELATING TO CAMPUS DEVELOPMENT PROGRAMMING

### 1. Enrollment and Planning Stages

- 1. What are your estimates of total full-time equivalent and head count enrollments at your institution during the coming decade?
- 2. What series of planning stages should this ten year period be divided into?
- 3. What changes do you expect in the distribution of FTE and head count enrollments among the various levels of instruction (lower division, upper division, and graduate) over the planning period?
- 4. What changes are expected in the distribution of enrollments by sex, marital status, and residential status?
- 2. Instructional Workloads: Programs and Subject Fields
  - 1. What degree programs or fields of study do you expect to add or abandon over the series of planning stages?
  - 2. Will new programs of study require any special facilities?
  - 3. Do you anticipate any changes in the number of semester hours of different courses to be offered per 100 FTE students?
  - 4. Are new joint programs of study among departments, divisions, and institutions being planned? If so, how will these affect instructional loads?
- 3. Instructional Workloads: Types of Facilities
  - 1. What modifications are expected in the number and mix of instructional hours among lectures, seminars, laboratory and other types of meetings in the various fields of study offered at your institution?
  - 2. What are the preferred class group meeting sizes for the various types of subjects and levels of instruction in classroom, laboratory, seminar, studio, and other types of facilities?
  - 3. What changes may be expected in methods of instruction?

### 4. Staff Requirements

- 1. What planning criterion should be used as the typical faculty load, expressed in contact hours per week or semester, in the various fields and levels of instruction?
- 2. To what extent will graduate assistants and undergraduate student help be used in instruction?

- 3. What planning basis is used at your institution to provide clerical, secretarial, and technical staff in instructional departments?
- 4. What is the extent and character of the growth expected in administrative, physical plant, student personnel, library, food service, housekeeping, and other non-teaching personnel?

### 5. Classroom Space

- 1. What is the present number and size-distribution of classroom-type facilities at your institution?
- 2. What is the present level of rocm and student station utilization at your institution?
- 3. What specific scheduling problems at your institution may lead to difficulties in realizing the utilization standards recommended in the 1959-60 Baxter study? What modifications will be necessary to overcome such difficulties?
- 4. Are existing classrooms characterized by any physical limitations which impose restrictions on their utilization at higher rates? What modifications are required to overcome such limitations?
- 5. What modifications do you expect in the equipment used for student stations in classroom and seminar rooms (e.g., use of tables instead of tablet-armchairs)?
- 6. What trends are expected in the distribution of class sizes in classroom-type instruction? Do you expect to increase the use of large lecture sections and/or small independent study groups?

### 6. Special Purpose Instructional Space

- 1. What is the present number and size distribution of teaching laboratories and other special purpose instructional facilities at your institution?
- 2. What new types of teaching laboratories may be needed in the next decade?
- 3. What are the present levels of utilization in the various types of teaching laboratories and other special purpose instructional space?
- 4. Do you anticipate difficulties in achieving the laboratory utilization standards proposed in the Baxter study? Are these due to scheduling problems, small course enrollments, or other factors?
- 5. What changes are expected in the nature of instruction in the various special purpose facilities? Will these affect station area requirements?

### 7. Office Space

- 1. What policies will be followed with regard to providing offices for faculty? Other professional personnel? Supporting technicians? Supporting clerical and secretarial? What proportions of each category will be assigned single or multiple occupancy office space?
- 2. Will desk space be provided for all graduate assistants? Should desk space for graduate assistants be provided in bull-pen type offices?
- 3. What types of desk or study space will be provided for non-teaching graduate students?

### 8. Research Space

- 1. What types of organized research (if any) will be conducted at your institution?
- 2. Do you anticipate any increase in the amount of student research activity required as part of the undergraduate programs of study?
- 3. What changes are expected in the organization of research programs insofar as the use of regularly budgeted university personnel?
- 4. To what extent will future research programs require an expansion in the number of persons employed and reimbursed under separately budgeted research funds?
- 5. Do you anticipate the establishment at your institution of any separately identifiable institutes devoted solely to research activity? Please describe for each planning stage.
- 6. For non-laboratory oriented departments, what research facilities other than private office and library space are required for the accommodation of staff research activities?
- 7. What proportion of the FTE faculty presently engaged in research activity require office or library space?
- 8. What proportion of the FTE faculty presently engaged in research activity require laboratory type space?
- 9. What changes do you anticipate in the volume and departmental distribution of research activity at each planning stage?
- 10. What departments are not presently engaged in research activity but expect to do so in the future?
- 11. What is the present policy concerning the provision of space for the conduct of research activities unrelated to graduate study programs?

- 12. What is the policy of your institution concerning the establishment of research facilities for organizations or institutes that are not affiliated or only indirectly affiliated with your institution?
- 13. Is research space, laboratory or library, now provided on a uniform basis for all graduate students? Honors students? At each planning stage?
- What is the present policy of your institution with regard to centralized or interdepartmental use of various types of research laboratory service facilities: e.g., storage? photography facilities? preparation areas? glasswashing facilities? constant temperature facilities? animal rooms? computer facilities? other? What modifications should be planned for each planning stage?
- 15. How will community service and/or academic extension programs change in relative importance over the course of the planning period?
- 16. What departments at your institution have organized community service and/or extension programs at present?
- 17. What other departments will add such programs over the course of the planning period?
- 9. Library and Other Instructional Service Space

### A. Organization

- 1. What is the policy of your institution with regard to centralized branch libraries?
- 2. What collections (by subject matter) will be housed outside the main library at each planning stage?
- 3. For each separate installation, how many volumes will be involved at each planning stage?
- 4. What will be the hours of operation in the main library and in branch libraries at each planning stage?

### B. Book Stock

- 1. How many volumes does the library presently have in its various collections? If you maintain branch libraries, what is the present size of the book stock at each installation?
- 2. How many periodicals does the library presently subscribe to on a regular basis? Has the number of subscriptions increased in recent years? If so, in what way? How many titles and issues per title are normally kept on open shelves at one time?

- 3. How many volumes are anticipated in the library book stock (at each installation) at each planning stage?
- 4. For each installation, what proportion of the present library collection is housed in open stacks? In closed stacks?
- 5. In the future, will the library be organized on (a) an open stack system? (b) a closed stack system with library personnel providing requested volumes? or (c) some combination of the preceding alternatives? Consider for each planning stage and each library installation.
- 6. Are any technical changes anticipated in the means of storing library material, such as microfilming older periodicals or volumes infrequently called for? What proportion of the collection is involved? Consider for each planning stage.

### C. Reading Rooms

- 1. What proportion of the student body can presently be seated in the library reading rooms?
- 2. What proportion of the student body should be provided with seating at each planning stage?
- 3. For each planning stage, what is the preferred distribution of reader stations among the following categories: general reading rooms, carrels, periodical reading rooms, reference reading rooms, special reading rooms?
- 4. What proportion of present reader stations are occupied at peak period during the day? During the week? During the term?
- 5. What special reading rooms are required, such as microfilm reading rooms, rare book rooms, map rooms, bibliography rooms, etc.? Consider for each planning stage.

### D. Staff

- 1. Will branch libraries be staffed with professional personnel?
- 2. To what extent will student workers in the library be used?

### E. Service Elements

1. What is the ratio of books on reserve to basic book stock at each library installation? Please indicate the ratio appropriate to each planning stage.

- 2. Will technical services (cataloguing, processing, accessions, purchasing, binding) all be conducted in the main library? If not, to what extent will these activities be dispersed among the branch libraries?
- 3. Should space for photostating, photocopying or any other duplicating process for students be provided? What kinds of equipment are involved?
- 4. Are any special meeting rooms required, such as seminar rooms or lecture theaters? In the event that such rooms are provided, can they be assumed to be part of the over-all complex of scheduled space?
- 5. Are any special faculty research rooms required as part of the library accommodation of research activity? If so, how many at each planning stage?
- 6. How many typing stations should be provided for students at each planning stage?
- 7. Is a special room required for the display of library exhibits? Should such exhibits be housed in display cases in a public lobby area?
- 8.. Are any other special areas required? Please specify.

### 10. Museum and Gallery Space

- 1. What provision should be made for organized museum and/or gallery displays?
- 2. Are these facilities to be developed independent of departmental affiliation or as adjuncts to departmental instructional and/or research programs?

### 11. Athletic Activities Space

- 1. Please describe the present scope and character of indoor athletic facilities at your institution.
- 2. What are the physical education requirements for male and female students at your institution at present? Can we assume that no changes will occur in these requirements? If not, please indicate the modifications anticipated for each planning stage.
- 3. What is the present scope, character and extent of participation of students in intramural athletic programs at your institution? If changes are expected, please describe them for each planning stage.

- 4. What is the present scope and character of the intercollegiate athletic program at your institution? Please describe the changes you expect to occur at each planning stage; e.g., (number of teams, size of teams, number of competitions engaged in by each team, etc.).
- 5. What proportion of the staff and student populations should be provided seating space in the various spectator-type athletic facilities? What amounts of seating for public sale should be provided?

### 12. Housing Space

- 1. What is the present capacity of dormitory facilities on campus?
- 2. What proportion of FTE enrollment is presently housed in dormitory facilities on campus?
- 3. What proportion should be housed on campus at present?
- 4. What proportion of FTE enrollment should be housed on campus at each planning stage?
- 5. Is it the policy of your institution to provide single occupancy dormitory rooms for all students? Double occupancy rooms for all students? Some combination of single and double occupancy?
- 6. Are these proportions the same for both male and female residential facilities?
- 7. Will the present distributional pattern between single and double occupancy dormitory rooms continue at future enrollment levels? If not, please indicate the appropriate distributional ratios for each planning stage.
- 8. Do dormitory students presently dine separately from commuting students? What modifications should be planned in the separation of dormitory students and commuting students in dining hall facilities at each planning stage?
- 9. Are dormitory or residential facilities provided for married students and/or staff at present?
- 10. What changes should be planned in the number and/or proportion of married students and staff that will be housed in facilities operated by your institution at each planning stage?

### 13. Food Service Space

1. What is the present capacity of food service facilities: dining halls? food preparation and storage areas? service areas? What should capacity be at each planning stage?

436

- 2. Are present dining facilities designed to accommodate hot meal service three times per day? Hot meal service at lunch hour only? Snack bar service only? Some combination of these?
- 3. What is the prevailing turnover factor in dining hall stations at each meal? i.e., one sitting? two sittings? higher?
- 4. Do present dining hall schedules interfere with use of the noon hour for the scheduling of instructional space? Will this condition be modified in the future? At which planning stage?

### 14. Staff and Student Service Space

- 1. Does your institution presently have student center facilities? If not, at what planning stages should such facilities be provided?
- 2. What kinds of facilities should be incorporated within the student center complex: for example, student lounges? music rooms? bowling facilities? cafeteria facilities? billiards? table tennis? meeting rooms? chapel facilities? arts and crafts facilities? theatre facilities? bookstore? laundry and tailoring facilities? student post office? other?
- 3. Is there presently a faculty club on campus? If not, at what planning stage should such a facility be programmed?
- 4. What elements should be included in the faculty club facilities: dining facilities? lounge facilities? music rooms? billiards? table tennis? meeting rooms? reading rooms? other?
- 5. Is there at present an adequate number of common rooms for male and female staff members distributed among the various buildings of the college?
- 6. What is the present policy with respect to the provision of kitchenette facilities in staff and lounge areas?
- 7. How many clubs or student organizations are presently active on campus? How many organizations do you expect will be active at each planning stage?
- 8. What is the policy of the college with respect to the provision of locker facilities for students and for staff?
- 9. Are mail box facilities provided for all staff? All students? Some proportion of each of these groups?

### 15. Miscellaneous Other Space

1. Are present first aid and infirmary facilities adequate? What is

- the capacity of the existing infirmary (number of beds)? What capacity is deemed necessary at each enrollment stage?
- 2. What facilities at your institution are devoted primarily to community service and/or extension activities?
- 3. Will any special facilities be required for the community service and extension programs of the future as presently conceived?
- 4. How frequently do outside groups use the institution's facilities in connection with the community service and extension programs?

### 16. Physical Plant Maintenance and Operations

- 1. Is the present boiler plant and utilities network at your institution adequate in capacity to your present operating requirements?
- 2. In what way will the increased demand for utility services at each planning stage require modification in the character of your present system: e.g., with regard to capacity? purchase or generation of power? modifications of distributional network? .other?
- 3. Is the present capacity of warehousing and storage facilities at your institution adequate relative to present operating levels?
- 4. Is it the policy of the institution to maintain central warehousing and stockroom facilities with purchasing through a central administrative office?
- 5. Will central purchasing, warehousing and supply systems become standard policy at your institution? At which planning stage?
- 6. Is present capacity in maintenance shops and garages adequate to current needs?
- 7. Are maintenance shops presently housed in structures that are separate from campus buildings devoted to instruction, research, staff and student service, and administration?
- 8. What modifications should be planned in the number, size and character of the maintenance shops and vehicles used at your institution at each planning stage?
- 9. Are facilities for merchandising commodities produced as by-products in normal institutional activities adequate relative to present operating requirements? (meats, milk, etc.). What modifications will be required at each planning stage?

### 17. Physical Plant Inventory

1. Please provide a list of the present buildings in use on your campus,

- with an indication of the gross and net areas of the buildings and the principal use made of each structure.
- 2. Please provide a list of all buildings presently under construction in your campus, with an indication of the gross and net areas of the building and the principal use to be made of the structure.
- 3. Please provide a list of all buildings presently in the architectural design and/or drawing stage, with an indication of the gross and net areas of the buildings and the principal functions for which the buildings will be used.
- 4. Please provide a tabulation of assignable space in these buildings, cross-classified by departmental assignment and function.

### 18. Building Occupancy Patterns

- 1. What functional groupings of departments and divisions do you consider desirable at your institution?
- 2. Is the present building occupancy pattern at your institution satisfactory in the sense of grouping departments and functional activities that are similar or related in nature?
- 3. What modifications in present building occupancy patterns should be adopted for each planning stage?
- 4. Will the functional organization of departments and activities continue and/or be implemented as a general policy in all future construction and building occupancy decisions (functional distribution and grouping of departments and division)?
- 5. Will the space programs for various departments, divisions and activities be satisfied by housing them in buildings in such a way as to approach the ideal occupancy pattern? At each planning stage?

### 19. Building Program

- 1. After comparing physical plant available and projected space requirements, what is the size of the deficit in existing plant at each planning stage?
- 2. Please indicate those structures on your campus that are considered temporary in nature, the priority to be attached to the demolition of temporary and/or antiquated structures, and the planning stage at which such demolition will occur.
- 3. What new structures are required at your institution? What is the proposed size and character of occupancy of the proposed construction?

- 4. What priorities do you attach to the timing of new construction? In what order are the new buildings to be developed? At which planning stage is each element of new construction to be available for use?
- 5. With regard to renovation of permanent structures, please indicate the buildings that require renovation, the priorities attached to
- the renovation programs, and the planning stage at which renovation vill occur.

### 20. Land Requirements and Campus Organization

- 1. Is the present campus adequate to meet the building and open space requirements of your institution at present? At each planning stage?
- 2. Please describe the scope and character of present outdoor athletic facilities at your institution. What will be the impact of changes in the level and character of activity in outdoor physical education, intramural and intercollegiate athletic programs upon land requirements?
- 3. Are present arrangements with regard to pedestrian and vehicular circulation satisfactory? If unsatisfactory, please indicate the modifications you deem necessary to bring the campus circulation system to a satisfactory condition at each planning stage.
- 4. What is the present policy with regard to student operation of automobiles on campus? Can we assume continuation of this policy? If not, what changes in policy will occur at each planning stage?
- 5. What is the present capacity of parking facilities on campus? Are they adequate relative to the capacity requirements indicated by the present operating loads of your institution? What modifications in parking regulations and capacity will occur at each planning stage?
- 6. Is there presently, or do you anticipate the adoption of, a campus master plan under which buildings and activities will be grouped according to function? Can we assume this arrangement will continue to prevail at each planning stage? If not, please describe the manner and planning stage at which changes in any of the above elements of campus organization will affect the requirements of various departments and divisions for space.

### 21. Capital Outlay

- 1. To what extent will implementation of the campus development program be funded by a) federal funds? b) state funds? c) private funds and gifts? d) other?
- 2. Are any revisions required in institutional planning assumptions in light of the availability of capital funds to implement the campus development program?

Following is an alternate numerical classification code for a physical plant space inventory system. The classification system follows the breakdown of physical plant into the twelve broad components separately analyzed in this Manual. As such, an inventory based upon this classification system would be directly comparable to the programming estimates developed by use of the Manual.

This system focuses upon physical plant use to type of space. In order to obtain the kind of information desired (and that would be generated in part by the inventory system suggested in table D.1), it will be necessary to augment the data collection process with a cross-classification by location of space (by building) and administrative assignment of space (departmental control). By including this identifying information together with the space inventory data on the same data collection cards, it will be possible to obtain such information as the following: the amount and distribution of space by functional category within each building; the amount and distribution of space by functional category within each department; the amount and distribution of any category of space by department or building; and so on.

The inherent flexibility in this system eliminates the need to build into the inventory system the kind of identifying information that is implicit in the classification structure covered by table D.l. For example, consider the broad categories of food service space and staff and student service space. Food service facilities may be located in residence halls, faculty clubs, student center and so. Staff and student service space may be located in office buildings, classroom buildings, student center and so

on. But these represent locational characteristics; the amounts of these types of space in each building can be obtained by a simple sorting process followed by aggregation of any particular functional category within the broad space categories. Similarly, a shift in focus to a question of administrative control over space also can be handled by simple sorting and tabulation along departmental lines. Thus, it is possible to determine the amounts of any of the broad categories (or sub-categories) of space assigned to individual departments (instructional or non-instructional), auxiliary enterprises, non-institutional agencies such as state and federal units located on campus, and so on.

The adoption of either of the space inventory systems presented in this appendix will, of course, have to be decided in terms of the information needs of the institution. There are advantages and disadvantages to each system. But each will serve to provide the necessary data with regard to present physical plant utilization and permit the planning analyst to compare future needs by type of space with the present availability of such space.
