A DESCRIPTIVE AND CORRELATIONAL STUDY OF VARIABLES RELATED TO SUCCESS IN THE SAN BERNARDINO VALLEY COLLEGE TWO-YEAR REGISTERED NURSE PROGRAM.
BY- CARLSON, DALE C.

FUB DATE 1 JUN 67

EDRS PRICE MF-\$0.25 HC-\$1.76 42P.

DESCRIPTORS- *JUNIOR COLLEGES, *NURSING, PREDICTIVE MEASUREMENT, INDIVIDUAL CHARACTERISTICS, STUDENT CHARACTERISTICS, CRITERIA, ACADEMIC PERFORMANCE, ACHIEVEMENT TESTS, GRADES (SCHOLASTIC), TEST SCORES, STATISTICAL ANALYSIS, SCAT, NLN ACHIEVEMENT TESTS, SAN BERNARDINO, CALIFORNIA,

THE PRIME CRITERION OF SUCCESS OF A NURSING PROGRAM IS OCCUPATIONAL PERFORMANCE OF GRADUATES. AS AN INTERMEDIATE STEP, THE AUTHOR INVESTIGATED THE RELATIONSHIP OF CERTAIN PERSONAL CHARACTERISTICS (AGE, SEX, MARITAL STATUS, NUMBER OF CHILDREN, NUMBER OF BROTHERS AND SISTERS, FATHER'S AND MOTHER'S EDUCATION, AND SCHOOL AND COLLEGE ABILITY TEST SCORES) AND PRENURSING FACTORS (GRADES IN HIGH SCHOOL AND IN PRENURSING COURSES AND SEMESTERS OF COLLEGE PRIOR TO NURSING TRAINING) TO CRITERION VARIABLES OF SEMESTERS OF NURSING COMPLETED, GRADES IN THE NURSING PROGRAM AND SCORES ON TESTS OF THE NATIONAL LEAGUE FOR NURSING AND THE CALIFORNIA STATE BOARD OF NURSE EXAMINERS. SUBJECTS WERE 81 STUDENTS IN THREE NURSING CLASSES AT SAN BERNARDINO VALLEY COLLEGE. SOME PREDICTORS (AGE, SCAT-VERBAL, PRENURSING COURSES, HIGH SCHOOL CHEMISTRY) SHOWED LOW TO MODERATE CORRELATION WITH STATE BOARD EXAMINATIONS AND NURSING GRADES. GENERALLY, PERSONAL DATA: HIGH SCHOOL GRADES (EXCEPT SCIENCE) AND QUANTITATIVE ABILITY APPEARED UNRELATED TO SUCCESS. OLDER STUDENTS EARNED SIGNIFICANTLY HIGHER SCORES ON STATE BOARD EXAMINATIONS. ANALYSIS OF REGRESSION OF FOUR VARIABLES (SCAT-VERBAL, PRENURSING GRADES, AGE, AND HIGH SCHOOL CHEMISTRY GRADES) ON STATE BOARD SCORES ACCOUNTS FOR ONLY 35 PERCENT OF THE VARIANCE IN SUCH SCORES. THERE IS A NEED FOR FURTHER STUDY, INCLUDING OTHER PREDICTORS. (WO)

INTRODUCTION

In the fall of 1965, the Nursing Department of San Bernardino Valley College, assisted by the Counseling Department, initiated a research program. This project was designed to validate, quantify, and refine the process of selecting nursing students. By identifying those variables most closely related to success in the nursing program and combining them with optimal weights to select students with the highest chances for success, it seems reasonable to expect fewer absolute failures, higher average scores on State Board Examinations, and greater satisfaction with the selection process.

The range of variables under consideration in this initial study is limited to the information routinely gathered as students apply for admission to and proceed through the nursing program. This "ex post facto" analysis is focused upon measures of intellectual ability and corresponding intellectual achievement. Except for identifying information, little attention is given to the exceedingly important, but nebulous area of personality characteristics and traits.

The second obvious limitation of this part of the study is the necessary use of success on the California State Board Examination as a criterion. Important as this subcriterion appears, the ultimate standard for evaluating the nursing program, must be some measure of occupational success.

PROCEDURES

The sample for this study consisted of the students who were admitted into the first four classes under the two-year program. These are the 1963 through the 1966 graduating classes and the students who would have graduated at that time, had they completed their course of study. Most of the analyses use only the 81 students of the first three classes, because of the necessary delay in receiving State Board scores for the 1966 class.

The variables included in this study could be placed in the three categories of personal information, predictor or pre-nursing variables, and criteria. Enumerated, they are:

1. Personal Data

- a. age
- b. sex
- c. marital status
- d. number of children
- e. number of brothers
- f. number of sisters
- g. father's education
- h. mother's education
- 1. SCAT score

2. Pre-Nursing Data

- a. high school grades
- b. grades in pre-nursing courses
- c. number of semesters of college prior to admission

3. Criterion Variables

- a. scores on National League For Nursing Achievement Tests
- b. semesters of nursing completed
- c. scores on California State Board Examinations
- d. grades in the nursing program.

RESULTS

Total Sample

Continuous Variables

Descriptive analysis. A description of all students who entered the 1963 through 1965 graduating classes can be found in Table 1. The means and standard deviations are given for all continuous variables studied.

It can be seen that most students are about 26 years old at entrance, average less than one child each, since more than half are single, have at least two siblings, are reared by parents of at least ninth-grade education, spend nearly two semesters in pre-nursing courses prior to admission in the nursing program, and spend about four and a half semesters in the nursing program before graduation.

In scholastic ability, entering students scored slightly higher on the Verbal scale of the School and College Ability Test than on the Quantitative scale. The average scores in terms of national percentiles were 71 and 60 respectively.

On the National League For Nursing Achievement Test, the students scored lowest on the psychiatric section, (41st percentile), and highest on the diet therapy part, (57th percentile).

Average California State Board Scores ranged from 514 on Medical to over 558 on the Obstetrics section with an average of 535.1 for all parts.

In high school they earned a low "8-" average. In courses thought to be important to success in college, the students ranged from a "C" average in chemistry to almost a "8" average in the related science of biology.

In courses taken prior to the nursing program, the group earned grades which averaged between "B" and "C". Since grades in nursing courses were slightly higher, the total grade point average goes up to 2.56. Concordant with the State Board scores, lowest grades were earned in the medical and surgical courses and the highest in obstetrics.

Correlational analysis. The complete matrix of intercorrelations for all continuous variables and sex is presented in Table 2. All correlation coefficients were computed by the Pearson Product-Moment Method unless otherwise indicated. All coefficients printed in red numerals are sufficiently large to be significant at the .05 level of confidence. All others are low enough to have occurred purely by random deviation more often than five percent of the time between truly uncorrelated variables. Since the primary purpose of this correlational analysis is to identify variables, State Board scores and grades in nursing will be considered first. The third criterion, nursing program completion, is considered later where dropouts are compared with graduates.

Searching for relationships with State Board scores, it can be seen that coefficients with age vary in the .30's with an average of .35. Older students score slightly higher on State Board scores. Correlations with sex are very low. However, all are positive, indicating slight superiority for women.

Personal variables, such as number of children, number of brothers and/or sisters, and educational level, attained by parents are not related to success on State Boards. Nor is State Board performance related to the

length of time required to prepare for or complete the nursing program.

Verbal performance on the SCAT bears substantial relationship to State Board performance. The average correlation coefficient is .41. SCAT Quantitative coefficients are negligible. Hence, total score is a poorer predictor of State performance than the Verbal score.

Scores on the National League For Nursing Achievement Tests are highly related to State Boards as expected, since they are quite similar in content and format. The average coefficient is .52.

The average of high school grades is not related to State Board performance, nor are most specific subject grades. The most expected relationship, that of chemistry with State Board scores, averages only
.26.

There is argreater relationship between grades in pre-nursing courses and State Board scores. The average coefficient is .37. Anatomy and physiology grades appear to have the highest relationship of all pre-nursing courses. Not enough students took Chemistry 2 or Math 50 for analysis.

Grades earned in the nursing program are not surprisingly substantially correlated with State Board performance; many coefficients being above .50.

*SCAT-Verbal score was a critical factor in the selection of these students. Since they were a higher-than-average group, their variability in scores was less than it would have been in a random group of college students. When the correlation coefficient is corrected for this restriction in range, it approximated .55.

Table 3

Analysis of Regression of Four Predictor Variables
On California State Board Scores

Variable	Mean	Standard Deviation	Correlation with State Board Exam Scores	Beta Coefficients	Regression Weights
SCAT	39.34	7.8	•41	•3028	3.62
Pre-Nursing GPA	2 . 485	•50	•37	.2146	40.04
Age	25.94	9.6	•35	.2150	2.09
H. S. Chem Grades	2.02	.80	.26	.1828	21.32

Table 4

Four Indicators of the Degree of Relationship Between California State Board Scores and the Four Predictor Variables

SE _{1.2345}	76.5
E	15.7
R ²	•326

*After shrinkage correction for small samples

Considering nursing grades as the criterion, it can be noted that age is differentially related to certain courses, ranging from .19 in micro-biology to .51 in obstetrics. As with State Board scores, the other personal information failed to be predictive.

The number of semesters of the nursing program completed is not as correlated as it appears since drop-outs were included in the sample.

SCAT-Verbal bears less relationship to nursing grades than to State Board scores. Quantitative performance is unrelated to scholastic success, bringing correlations for total scores correspondingly lower.

As could be expected, nursing grades are substantially correlated with National League For Nursing Achievement scores, with many coefficients in the .50's and some exceeding .60.

High school performance is unrelated to nursing grades, as well as State Board performance. High school chemistry bears a lower relationship to nursing grades than to State Board scores.

Regression analysis. In July, 1966, the nursing selection committee was forced to select thirty students from over ninety applicants. Since this selection problem was approaching the point where actuarial methods are helpful, the preliminary results of this study were analyzed and applied as described below.

Using an average State Board score as the criterion and the four variables of SCAT-Verbal, pre-nursing GPA, age, and high school chemistry grade as predictors, all applicants were ranked in order of their predicted score. This information was supplied to the committee as they met to select the classes of Fall, 1966 and Spring, 1967.

Table 3 shows the results of this regression analysis. The beta coefficients are found in column five and the raw score regression weights in column six. By applying these regression weights, the predicted average

State Board scores for applicants were computed by the following formula: $X_1 = 179 + 3.62$ (raw Scat-Verbal score) + 40.04 (pre-nursing GPA) + 2.09 (age) + 21.32 (high school chemistry grade.)

The multiple correlation coefficient between State Board scores and the best combination of the four predictor variables is .539 as shown in Table 4. The standard error of multiple estimate is one means of expressing the usefulness of such a coefficient. It indicates about how far the predicted values would deviate from obtained ones. The standard error of any score predicted by the previous formula is 76.5. This means that the chances are 2 out of 3 that the actual average State Board score will be within the limits: predicted score plus or minus 76.5 points. Or to increase the confidence of the prediction, the chances are 95 out of 100 that the obtained score would be within two standard errors or 149.94 points of the predicted score.

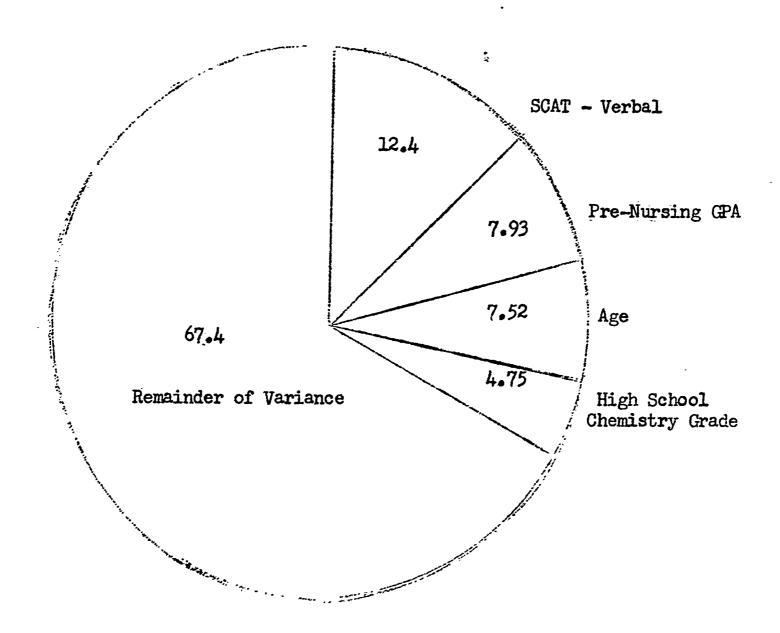

Another statistical tool used to express the value of the four predictor variables is the index of forecasting efficiency, to be seen as "E" in Table 4. "E" for this problem is 15.7, which means that the errors of prediction are only 15.7 percent less than they would be without the knowledge and use of the relationships of the four predictor variables with the criterion.

The coefficient of multiple determination, R², for this problem is .326. This is the percentage of variance associated with or predicted by the four predictor variables with the regression weights used. The proportion of this variance accounted for by each predictor is represented in Figure 1. Only about one-third of all variation in State Board scores can be accounted for by the four predictors, leaving over two-thirds yet

Figure I

Proportion of Variability in California State Board Scores Predictable by the Four Predictor Variables.

to be explained and measured by further research.

Non-Continuous Variables

Table 5 shows the attrition rate and State Board success ratio for the four graduating classes. From 60 to 74 percent of the entering students actually completed the program. Of those students who finished, the proportion who failed any one part of the State Board Examinations ranged from 0 to 11 percent.

The reasons students withdrew from the program are summarized in Table 6. Academic failure ostensibly accounted for nearly one-half of all those who withdrew. It is interesting to see that none of the students listed marriage or financial problems as the main reason. Other reasons were ill health, moving from area, dislike for nursing, and failure in clinical area.

Table 7 classifies all students according to the three non-continuous variables of sex, marital status, and completion of program. It can be seen that nine of the students were men and 72 were women. Roughly, the same proportion of each sex completed the nursing program; six out of nine men and fifty out of seventy—two women.

Observing the single and married students, it appears that a greater proportion of married students completed the program than single students. This hypothesis was verified by a Fisher Exact Probability Test completed on the data in Table 8. The probability of these proportions occuring by chance is slightly higher than one in one hundred.

Sub - Group Analyses

Inter-Group Comparisons

The last step in the search for relationships was a series of subgroup comparisons. Five of these are presented here. The first two groups,

Table 5

1963-1966 Graduating Classes According to Attrition and Failures on California State Board Examinations

Have Completed Program	22	25
Have Not Completed Program	4	19

differentiated by sex and graduating class, are presented with a view to—ward curiousity — satisfaction rather than predictive information. The third comparison, drop—outs versus graduates, forms the main presentation of information regarding this criterion of program completion. The last two sets of dichotomies, age and marital status, are followed by a correlation analysis of each sub—group.

Classes. Table 9 shows the sample size, mean, and standard deviation for each group of entering students, some of whom graduated in the four years of 1963 - 1966. Since differences carry no implication for selection, they were not tested for significance.

Sex groups. Table 10 shows the sample size, mean, and standard deviation of all continuous variables for men and women. The difference between means is given in the right—hand column. If this difference appeared to be substantial, it was tested by the statistic number as Student's tt... If the difference was large enough to meet the .05 level of confidence, it was marked with one asterisk (*). If the difference was large enough to occur less than once in one hundred times in a pure chance situation, it was marked with two asterisks. In comparisons where the size of either sample fell below 20, the difference was tested for significance by the non-parametric Mann Whitney "U" Test and marked as indicated.

Observing Table 10, it can be seen that male applicants were older, had higher SCAT scores, yet scored lower on three parts of the State Board Examination, especially on the obstetrics portion. Men were not unlike women on any other variable.

Attrition groups. The third and most obvious criterion of success in nursing is completion of the program. Table 11 compares those students who completed the program with those who withdrew. The groups are similar

%=P < .05 %%=P < .01

Verbal scores, which were significantly related to State Board scores, failed to differentiate these two groups. Another significant predictor of State Board scores, pre-nursing GPA, does show the graduates to be superior. Significant differences on grades are expected since they are related to a student's longevity.

Age groups. Since age is correlated with both State Board scores and nursing grades, it is not surprising to find many variables on which students under 21 differ from those over 21 years of age as shown in Table 12. The older students had spent more time studying pre-nursing courses. Although older students did not have higher SCAT-Verbal scores or higher high school or pre-nursing grades, they did score significantly higher on all NLN Achievement Tests and on all State Board Examinations. Their superiority was especially obvious on the obstetrics, psychiatric, and surgical parts.

Marital groups. It was shown earlier that marital status was related to completion of the nursing program. A bi-serial correlation coefficient between marital status and State Board scores reached .43. This seems to indicate the potential predictive value of marital status. However, since marital status is highly related to age (phi = .69), the real relationship between marital status and State Board performance drops to .24 when age is held constant. Hence, marital status is not as fruitful a predictor as would appear.

Table 13 presents a comparison of single and married students. Similar to older versus younger students, married students differ only on one criterion variable, where they are superior to single students.

Intra - Group Correlational Analyses

Since both age and marital status seem to be related to success in nursing, they were given additional attention. Separate correlational analyses were completed for all students under 21 years of age, for those over 21 years of age, for married students, and for single students.

Age groups. Tables 14 and 15 present intercorrelation matrices for students under and for those over 21 years of age respectively. All correlation coefficients not meeting the .05 level of confidence were deleted. Those meeting or exceeding the .05 level are in black print and those meeting the .01 level are in red numerals.

Considering the criterion of State Board scores, it can be seen that the SCAT is a fair predictor for the young students (.40-.50) in comparison to the non-significant coefficients obtained for the older students. High school GPA is equally unrelated to State Board scores for both groups. Grades in high school chemistry is substantially related to State Boards for younger students; whereas, not enough of the older students completed chemistry for analysis. The opposite is true for pre-nursing GPA. Not enough younger students took pre-nursing courses. Whereas, such courses were moderately predictive for older students. Grades in specific pre-nursing courses, especially anatomy and physiology, were even more pre-dictive than an overall GPA.

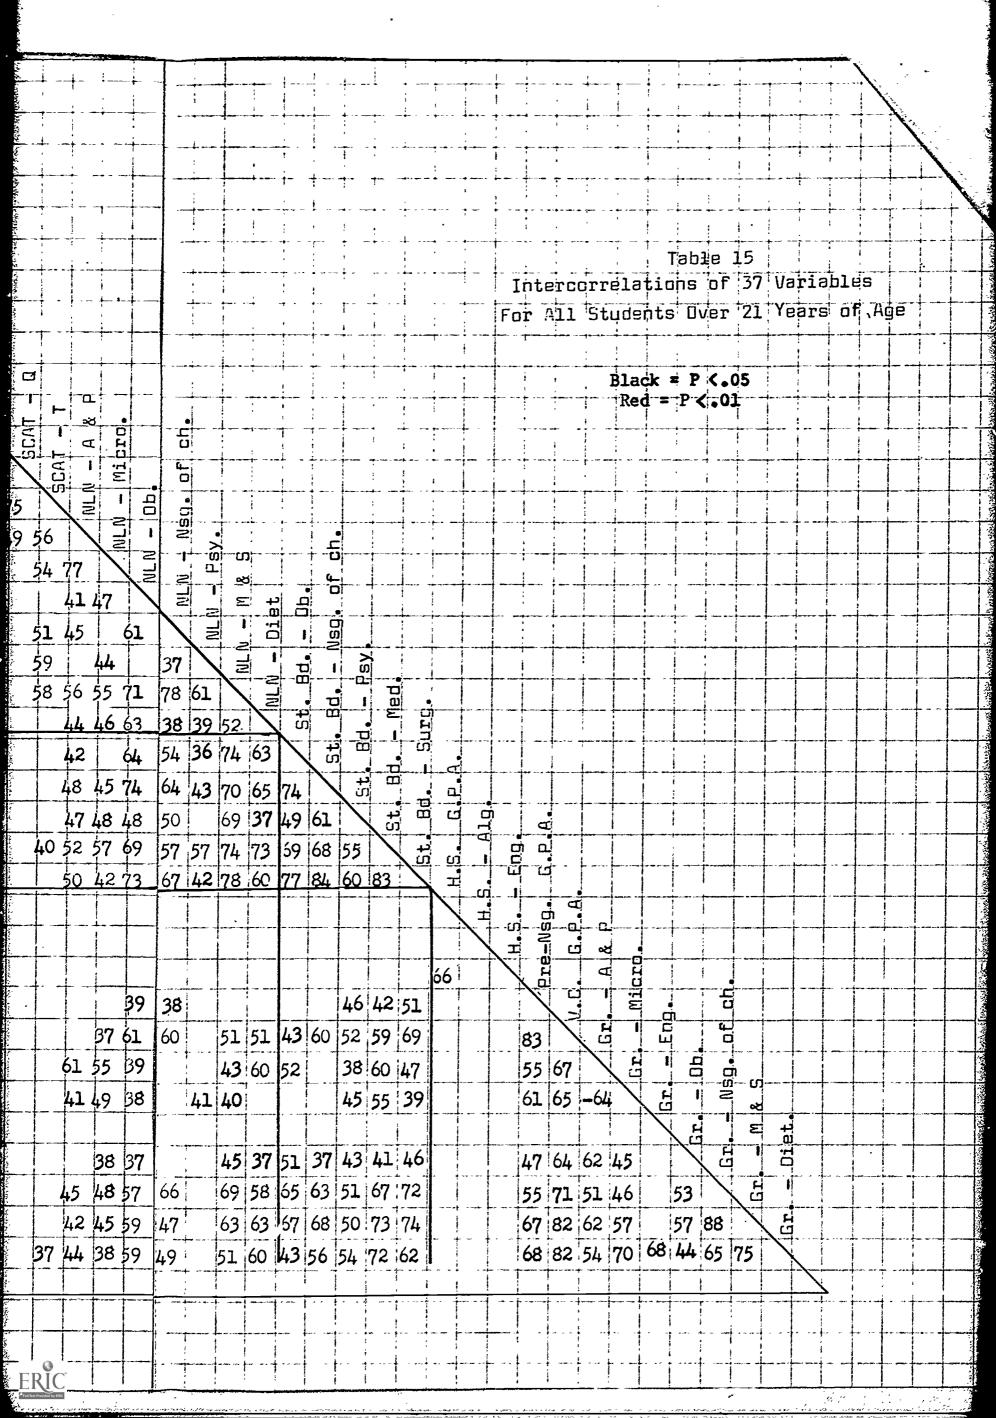

Marital status groups. Tables 16 and 17 present intercorrelation matrices for all variables for single and married students respectively. Remembering the strong relationship between age and marital status, i.e. married students being older, it is not surprising to see that SCAT is much more highly related to State Board scores for single than for married students.

Company of the Company

High school GPA is not predictive for either group. High school chemistry grade is moderately related to State Boards for both groups. Since sub-samples are small, high correlations are needed to reach statistical significance. An average of pre-nursing grades is not predictive of State Board performance for either group. However, anatomy and physiology grades are highly related to State Board scores for the married group.

Summary of Findings

- 1. Moderately high (.40-.60) relationships were found among the criterion variables of State Board scores, NLN scores, and grades for nursing courses.
- 2. Personal data taken from application blanks were unrelated to success in nursing.
- 3. Low to moderate relationships (.20-.50) were found between predictors such as age, SCAT-Verbal, pre-nursing courses, high school chemistry, and the criteria of State Board scores and nursing grades.
- 4. High school grades except in science were generally unrelated to success in nursing courses or to State Boards.
- 5. Quantitative ability showed only a negligible relationship to State Board performance or grades in nursing.
- 6. A significantly greater proportion of married students finished the program than single students.
- 7. Male applicants were older and had higher SCAT scores, yet scored lower on three parts of the California State Board Examinations.
- 8. Nursing school graduates were not significantly different from dropouts in any essential way.
- 9. Although older students did not differ from younger students on verbal ability or pre-nursing grades, they performed significantly higher

on all parts of the State Board Examinations.

10. Married students differed from the single students only on State Board scores where they were superior.

DISCUSSION OF FINDINGS

The above findings are consonant with those reported in the literature on nursing selection. In contrast to this study, most of the studies have been more concerned with grades in nursing courses than with State Board Examinations. In a review of 111 unpublished and 77 published studies related to nursing selection, Taylor (1963) found only one study reporting a multiple correlational analysis using a criterion other than nursing grades.

In studies using academic nursing grades as a criterion, Taylor found that tests of verbal comprehension were the best single predictors, most coefficients being in the .60's. There was great variability between tests and among studies using the same tests. The most stable results were found in studies using weighted nursing selection batteries such as those of the Psychological Corporation and the National League For Nursing. Multiple correlations found in many studies range from .34 to .77; many of these being in the .60's.

In predicting State Board scores, the multiple correlation of .54 reported previously is not necessarily the highest obtainable. Since the regression analysis was completed on preliminary data, the four predictors are not necessarily those which would yield the highest coefficient. Since other studies have not used State Board performance as a criterion in multiple regression analyses, the multiple correlation in this study cannot be appropriately evaluated. However, weighted batteries are reported to be very useful in predicting State Board performance. The best one of these

Test Battery. Most coefficients found with this battery are in the high .60's and .70's. Consideration may be given to the use of such a battery for selection at San Bernardino Valley College.

Whereas high school GPA was the most valid predictor in Garrett's study (1960), it was not related to either State Board performance or with the more logical criterion of grades in nursing in this investigation. The predictive value of high school GPA in nursing is sporadic and unstable at best (Taylor, 1963). It is often true, however, as in this study and as Haney (1962) found, that grades in certain science courses, especially chemistry, are more predictive than average GPA.

The relationship between verbal comprehension and success in nursing has long been recognized. Taylor found that tests such as the Otis ACE Psychological Examination and Coop Total English typically correlate in the .60's with State Board scores. The moderate relationship found in this study using the SCAT-Verbal is typical although coefficients have been reported as high as .69 (Anderson, 1965).

In addition to a verbal comprehension factor, Haney (1959) also found a mathematics factor associated with success in nursing. Garrett's study, alluded to previously, also found mathematics to be a useful predictor. For San Bernardino Valley College students, however, neither the SCAT—Quantitative nor high school mathematics grades were related to nursing success.

It is not likely that the findings and implications of this study would elicit the compliment so coveted recently; that is, "exciting."

Indeed, the strength of the relationships found hardly exceed the expectations of any bonafide pessimistic researcher. Nor is it encouraging to think that this study has dealt with the more measurable and predictable

traits of humans; that is, the cognitive or intellectual. Clinical nursing behavior, probably more highly related to temperment and personality, is not treated here. Attempts to identify predictors of clinical behavior usually meet with failure or dubious success. (Taylor, 1965)

Criticism is usually leveled at tests for failing to predict academic or clinical success more accurately. Much of this critical energy should be channeled into constructing more appropriate criteria. The criteria most often used, grades or State Board Examinations, usually are sorely lacking in the quality demanded of any criterion; i.e. stability or reliability.

The greatest untreated myopia of education, perhaps nursing education to a lesser extent, is the failure to distinguish between actual success in nursing and training standards or progress measures such as State Board scores or nursing grades. This is tragic because grades are generally unrelated to actual job performance ("Hoyt , 1965.) It is not surprising then to see that State Board scores are also unrelated to a nurse's ability to care for patients (Taylor, 1965.)

Therefore, in spite of its appearances of precision, the regression equation reported in this paper is not to be rigorously applied to selection problems. If it were, many potentially good nursing practitioners would not survive the entrance examinations. When combined with other factors such as personality traits, the formula may become useful. The next step, a giant step, is to quantify the personality factors which hopefully will better predict clinical behavior and actual job success.

SUMMARY

This study served the dual objectives of evaluating the performance of the past four graduating classes as well as identify variables which are related to success in the San Bernardino Valley College nursing program.

Means, standard deviations and correlation coefficients for a variety of personal, intellectual, and achievement data for the total sample and subgroups divided on class, age, sex, marital status, and completion versus withdrawal from the program are presented and analyzed. A regression analysis based on four variables found to be moderately related to success on State Boards is presented and interpretated. These variables were SCAT—Verbal score, pre-nursing GPA, age, and high school chemistry grades.

Findings were discussed in the light of other studies. Implications of the findings and suggestions for further research were presented.
