SCHOLASTIC APTITUDE TESTS FOR GRADES VIII AND XI.

DEPARTMENT OF PSYCHOLOGICAL FOUNDATIONS, WASH., D.C.

REPORT NUMBER BR-7-1275

PUB DATE

67

EDRS PRICE MF-\$1.00 HC-\$9.76 242P.

DESCRIPTORS- *RESEARCH PROJECTS, TEST CONSTRUCTION, TEST SELECTION, *TESTING, *APTITUDE TESTS, *STANDARDIZED TESTS, GRADE 11, GRADE 8,

THE PURPOSE OF THE PROJECT REPORT IS FOURFOLD--(1) TO PROVE THE NEED FOR SCHOLASTIC APTITUDE TESTS, (2) TO SHOW THE NEED FOR A COMMON TEST FOR A LARGE GEOGRAPHICAL AREA, (3) TO SHOW THAT SCHOLASTIC APTITUDE TESTS ARE PREFERABLE TO TESTS OF INTELLIGENCE, AND (4) TO DISCUSS THE EXPECTED OUTCOMES WITH THE ADMINISTRATION OF SUCH TESTS. THE REPORT IS PRESENTED IN FOUR MAJOR SECTIONS--(1) A STUDY OF THE CRITERIA, DEVELOPMENT, AND SELECTION OF TEST ITEM-TYPES, (2) AN ANALYSIS OF ITEMS AND PREPARATION OF FINAL FORMS, (3) A STUDY OF THE ADMINISTRATION OF FINAL FORMS (WITH DATA ON NORMS AND RELIABILITY), AND (4) THREE EXTENSIVE APPENDICES OF RELEVANT TABLES, GRAPHS, AND CHARTS. SCHOLASTIC APTITUDE TESTS

Chapter I

Introduction

Need for Scholastic Aptitude Tests

There is concern all over the country over the large percentage of failures both in school as well as public examinations. At high school stage, in eighty percent of cases the pass percentages in different boards administering the examinations are less than 70%.¹ The problem of wastage needs urgent attention in our country and from various angles too. The nation cannot afford to waste such large amount of financial and human resources; checks are needed very urgently to stop this wastage. While insufficient and poor instruction may be one of the reasons, indiscriminate admissions and wrong placements of pupils in different courses can be another. It should be possible to reduce the number of failures by improving admissions through the use of tools which have known and acceptable predictive efficiency.

There are two points at which schools and parents have to take decisions about the future course of education of their wards, namely, (a) the end of the middle school (b) the end of the high school. At both these points the educators and parents have to understand whether or not their ward is likely to gain from the higher stage of education and also the kind of courses where his gain is likely to be maximum. Usually the decisions are based on subjective impressions and inadequate information. The decisions are not always correct and some of our school failures may be due to wrong decisions at these points.

Past achievement is generally used to predict success

-
1. Dave, R.H. and P.M. Patel 'Analysis of Results of Board Examinations (Table 10)', A prepublication draft, Department of Curriculum & Evaluation, National Institute of Education, NEW DELHI.

at the next stage. We have been using it without precise knowledge about its overall predictive efficiency or the most useful cut-off points; the cut-off points are often arbitrary. Besides, there are difficulties in the use of raw scores as available from school examinations. These scores are based on essay examinations with their obvious limitations of low reliability^{1,2} due to very limited sampling of content and highly subjective as well as variable scoring on the part of the examiners. Where there are no public examinations, for example, in many cases, at the grade VIII level, the measuring tools also differ widely from school to school making the scores still less usable. Also, there is a widespread feeling among educators and research workers that our examinations are loaded very heavily with rote memory and to that extent are not valid measures of what should be considered as achievement in school.

The reliabilities of prevalent essay type examination cannot be very high, because of limitation of brief content sampling and impressionistic scoring on the part of the examiners. The scores on Scholastic Aptitude Tests would be more reliable information in the hands of teachers and administrators for guiding and selecting students to higher education. These scores will not only be more reliable but also more valid.

If the largely felt impression against our present system of examinations i.e., these tend to measure mainly

1. "The reliability coefficient of the full question paper works out $r_{xx} = .6343$ only." Gayen A.K. and others, Measurement of to be Achievement in Mathematics - Report I - p.71. The question paper under reference is the one for compulsory Mathematics, set in the School Final examination, 1952 by the Board of Secondary Education, West Bengal.

2. "Even as a test of intellectual attainment of the pupils the validity and the usefulness of the present pattern of examinations has been widely questioned. It has been urged that the present system of examining by means of essay type questions will have so much scope for the subjectivity of the examiner that it cannot be relied upon to any great extent" (Report of the Secondary Education Commission - p.118).

• rote memory and very little else is true then we are not selecting necessarily the best students (or all the best students) for recruitment into higher courses of education. The score on the previous examination may give a good prediction for scores in the next examination especially if the ability being measured in both remains the same, that is to say, rote memory to very large extent, accompanied by small amount of other things. But some really good students may be getting eliminated in the process, i.e., the student who is otherwise capable, can think logically and excels in all the higher functions of mind but is not very good in memorizing specially when memorizing is more or less by rote without understanding the meaning very much. By Scholastic Aptitude Tests it is this kind of student that we wish to rescue. It is assumed that the correlation between the scores on Scholastic Aptitude Tests and those on examinations would be fairly high but far from perfect. Therefore, if the scores on Scholastic Aptitude Tests are used in addition to the information available from the examinations, by adopting certain procedures we should be able to select all the best in the student population i.e. those who can excel in the examination on the sheer strength of their memory and also those who are potentially good scholars but do not score as high in the examinations, as some of their friends do.

The Need for a Common Test for Large Geographical Area

The tests as planned are meant for the entire Hindi speaking region which covers four States and the Union Territory of Delhi. There are difficulties in planning and standardizing a test for a large geographical area; also, part of its utility gets limited in the process.

Why should we have a common test at all? For long, many research workers in India have been feeling the need for well standardized tests having wider applicability than

what is available at present. There are a large number of tests of intelligence (which come very close to tests of Scholastic Aptitude) achievement and also some aptitudes available at various places but their comparability in content as well as in scores is not known to anyone. One of the way out could have been to take a given test and find norms for it for different areas and use that as a common test. But many of these are efforts of individuals and small organisations which could not give to these the time, money and expertise needed for the development of a good test. Also it is anybody's guess whether the tests developed in one part of the country would be valid or equally reliable for the other parts in the country.

There are at present many institutions and employment agencies where recruitments are made on all-India basis. Only a few of these conduct their own examinations which form the common evaluating tools for their applicants, others depend on the results available from public examinations held in different places. These examinations are by no means of the same standard - such is the wide spread feeling among educationists, administrators and employers. There are visible differences of cut-off points. The general pattern of scoring in many examinations is to specify various cut-off points to categorise students in 'divisions' which could be compared to 'grades'. For example, at least 33% marks are required for being considered successful in a single examination, at least 50% to be declared to have passed in second division which we may call grade B and so on. These cut-off points are not the same for all the examining agencies. The second division may begin at 45%, 48% or 50% with different Boards. The situation is further confounded in the sense that it is not known whether percentages could be relied upon as

being comparable or whether the broad divisions (grades) should be relied upon for comparative purposes. An examiner may decide in his mind that the script in his hand is by and large a second division script and then assign to it a mark above 50%, 48% or 45% according to the cut-off point for the second division in that particular Board or he may first give the percentage of score regardless of the cut point and let the division get decided by whatever score he gives. It is, therefore, not known as to which of the two kinds of information available to the heads of institutions or employing agencies is more meaningful. A common test could be used as easily available tool, firstly for assessment and secondly for scaling the scores or grades available from different Boards and other examining agencies. The administrators of higher institutions for learning may, for example, on the basis of scaling available on SAT know that a 45% in State X has the same meaning as 53% in State Y and so on. They may then take their decisions which will be more fair to the students coming from different parts of the country. Incidentally, it may be mentioned that the students from some universities and Boards have always had this feeling that their Boards having higher standards have given them lower marks in comparison to some of their counterparts who were clever enough to appear in the examinations conducted by Boards and agencies which have low standards and have, therefore, assigned to them a high mark. The latter category tend always to have a gain in the 'stamp' given to them by the Board or the university.

Lastly a common test of Scholastic Aptitude would be a very useful tool in the hands of research workers in the field of education, psychology and sociology for conducting studies covering large areas. Ideally speaking, the common tests for the entire country should be available to the

aforementioned agencies. At one stage a common test of intelligence was thought of and to some extent also planned in this Department. The difficulties involved in constructing a test mainly verbal in its contents for populations with many different languages were many; some of these get eliminated in the development of a test in the same language but by no means all of these are sorted out. For example, such a test assumes common experiences over the large geographical area. Even this assumption is somewhat more tenable for smaller geographical area having the same spoken language. It is hoped that with the experience developed in this project it may be possible on a latter date to develop tests in other languages which could be considered comparable.

Preference for Scholastic Aptitude Tests over Tests of Intelligence

For the wider use of the tests it would have been better if the tests of intelligence instead of scholastic aptitude were attempted as the former are used more frequently in research studies than the latter but it seemed more feasible to assume a greater standardization of school experiences which would predominate in a scholastic aptitude test in the large geographical area with which we had concerned ourselves than the assumption of comparable environmental experiences which would be required for the tests of intelligence. Also a fair proportion of the age groups under consideration are still out of schools in India and the test of intelligence being supposedly meant for the entire age group will present many more problems of standardization than the scholastic aptitude tests which are necessarily meant only for the school going populations. Incidentally it has also kept us out from the controversial definitions of intelligence.

Outcomes Expected

It was proposed to develop two tests of scholastic aptitude one each for grades VIII and XI/X which ever may be the end point for the high school. It was decided that there would be at least two forms available at both these levels. This decision was taken keeping the requirements of research in mind where two forms are always helpful in various kinds of designs. More than one form of the tests are also helpful if the tests are to be used for grading purposes.

It was decided at this stage that there will be practice booklets to precede the administration of the tests. Practice booklets are particularly important for places and populations which are still not used to these kinds of tests. These were considered very important during the stage of development of tests. To be able to get most valid attempts on the test items, it is absolutely necessary that the children understand clearly the task assigned to them. It is only then, that any meaning can be attached to their attempts. It has been found that at places where objective types of tests are not used very commonly, the scores are rendered more reliable and valid¹ after a sufficient amount of our practice.

It was envisaged that the tests will be ultimately administered by the teachers and school counsellors etc., therefore, a detailed manual of instructions would be necessary.

-
1. G.R. Ortal was faced with the educational selection and guidance of Israeli children from very varied cultural and linguistic backgrounds. Finding that scores on standard tests were seriously affected by such differences, she introduced a period of coaching and on retesting obtained much improved validities in predicting school achievement. Br. Jr. of Ednl. Psy. June 1963 p. 173.

: 8 :

This manual of instruction would include procedures of test administration, Statewise norms, comparability of norms for different groups and other relevant information by way of reliability and validity data as and when available.

A technical report would be made available to those who would be interested in such work.

Chapter II

Study of Criterion; Development and Selection of Item Types

The tests in scholastic aptitude are expected to predict success in future scholastic tasks. One easily available measure of this success is the score in the next higher examination. An attempt was made to understand the nature of the elements (some, if not all) of this criterion with a hope to include such tasks which would measure/predict these elements best. However, the criterion of success in future examinations was not considered sufficiently adequate.

There is large spread criticism of examinations held in India both within the country as well as abroad, the general feeling being that these examinations tend to measure more of memory which is not the sole factor in determining the success in future academic tasks, specially if we consider success broadly and not measure it only in terms of scores obtained in examinations.

Frequently, large number of cases are quoted of pupils who have not been very successful in the examinations but have later made noticeable contributions in creation, assimilation or dissemination of knowledge. It is likely that these are exceptional cases and, being in a sense dramatic, are noticed more and therefore quoted more frequently while a large majority who do not show any such noticeable deviation is forgotten. On the other hand, if there is some truth in the statement that the examinations measure more memory than anything else, this seems to be an inadequate criterion for the development of Scholastic Aptitude Tests.

An attempt was made to consider a second criterion namely, 'scholarship' to the extent it is not measured by the traditional public examinations. It is admitted that the criterion is vague and difficult to define. It will be still

more difficult to demonstrate the validity of the developed tools vis-a-vis this criterion. The first criterion is something concrete and readily available. The validity of the tools developed can be checked against the scores achieved by the students in the next public examination. In the case of the second criterion even if there is some life in it, one will have to wait for years to accumulate data to demonstrate the validity of the tools. The research team, however, was not deterred from considering this criterion, at least attempting the analysis to see if there is anything worthwhile which could be included in the tests. This thinking was strengthened by the fact, that the examination scores being readily available can always be included in any predictions to be made, (provided the reliability is acceptable) and more of 'additional things' should be included in the tests to get best predictive efficiency from combined use of school marks and scores on SATs.

Analysis of Criterion

The first step was to study the two criteria and analyse the underlying variables. For studying the first criterion i.e. scores in the examination two approaches were made. A good school in Delhi was contacted with a view to get assistance from secondary school-teachers in locating the variables which determined high/low scores of the students. The aims and objectives of the Project and the particular task were made clear to the principal of the school and his approval was obtained for carrying out this bit of work in his school. It may be added that the principal was not only agreeable but highly enthusiastic in helping the project team to carry out its work, as he thought this would enhance his own understanding as to what makes the students score high or low. A meeting was held

with the principal and the members of the staff were the Principal Investigator explained the nature of the task to be carried out. The school had been approached soon after the mid-term examinations of November 1963; the teachers were asked to pull out 5% of the scripts assigned the highest and the lowest marks. The scripts were to be used as guides in analysing what determined a high or a low score. It was pointed out to the teachers that very often it was the global impression presented by the answer that determined the score and that most of us, teachers, do not analyse the questions before giving a score into such elements as were desired by the research worker, but the possibilities of such analysis existed and could be explored. It was made clear that in case a teacher thought that a high or low score was really undeserved such a script was to be dropped quietly as our purpose was not checking the reliability of the scoring but understanding the underlying determinants of

high/low scores. A period of 10 days was given to the teachers /investi-to carry out this work. After the lapse of the agreed duration, the g-tor visited this time individually. Many handed over brief written statements, others wanted to discuss their comments with the investigator again and met gator. the teachers.

The high and the low scoring scripts were also collected from the school and studied by the project staff to discern such variables, if any. From the office of the Registrar of Delhi University some scripts of the final public examination held for the degree of Bachelor of Arts in 1963, were borrowed and studied by the project staff. These scripts were drawn from various subjects which the project-staff felt it could study competently, namely English, History, Psychology and Mathematics. The team while studying the school and the university examination scripts kept its notes on what it thought could have determined a high

or a low score and all these elements were considered together.

In spite of the instructions to the teachers that knowledge is to be kept apart, this variable loomed very large with the teachers; it was simply ignored from consideration. The following are some of the variables isolated by teachers and the staff of the project on which scores seemed to get determined: (i) (a) Mechanics of writing, i.e. spellings, sentence structures, paragraphing, sequence of ideas (b) handwriting (ii) Fluency of ideas, (iii) Speed of writing (iv) Brevity of writing, particularly use of single word or a good phrase to express a whole idea; In mathematics and science's avoiding unnecessary elaborations and concrete language (v) Insight into the problems including good understanding of the scope of the task assigned (that is to say, the scope of the question asked), (vi) Reconstructing the problem wherever necessary and ingenuity in solutions (vii) Ability to apply rules, specially in mathematics, (viii) Ability to reason with abstract symbols, (ix) Originality and quality of ideas (x) Comprehension - as evidenced in summarising the material. (xi) Consistency in ideas - in case of low scores inability to stick to a point of view and present an argument consistently. (xii) Ability to state a principle in general terms as contrasted with concrete language.¹

Analysis of Criterion 2

In the school mentioned above, the teachers were asked whether they had met students in their teaching experience, who looked promising to them but who did not get scores as high as some other students did. It may interest the reader that not

¹ For example the condition that the two straight lines given by $Ax^2 + 2Bxy + Cy^2 = 0$ will be at right angles is : the low scoring students tended to mention $A + C = 0$, high scoring students tended to say the coefficient of $x^2 +$ coefficient of $y^2 \neq 0$.

only in this group but in other groups also, to be described later, there was unanimous agreement, that there always were students about whom the teachers had the feeling of good promise in later academic work but who did not show signs of immediate success in terms of high scores. This point was discussed later on in two other groups apart from amongst the research team itself, one was a small group of experienced secondary school teachers from Delhi and the second /most of the students/ of Education (1963-64) run at the CIE, DELHI, was the students of Master's Course/have had experience of in this teaching, this being the requirement for admission to the course. Master's Course There was no exception to the general feeling that such cases are found frequently.

The teachers of the school mentioned above were asked: 'what makes you think that a student was a good scholar when he was not scoring very high?' The same question was posed to the group of teachers from a number of secondary schools and to the students of the Master of Education course. In all these three groups the responses were obtained in writing. The theme was also discussed individually with the teachers of the school mentioned above; in a group with the teachers from other schools, and not discussed at all with the students of the Central Institute of Education. Meaningful variables as mentioned by one or more people are listed below:

- (i) Intelligence
- (ii) good retention
- (iii) interest in the subject/subjects
- (iv) inquisitiveness
- (v) better concentration
- (vi) initiative
- (vii) critical questioning (asks intelligent and probing questions)
- (viii) precision in thinking and expression
- (ix) ambitions of academic work
- (x) logical thinking
- (xi) greater independence in his work
- (xii) quick grasp of things
- (xiii) ability to see relationships
- (xiv) application of generalizations to particular cases
- (xv) clear expression in speech and writing
- (xvi) originality in thinking
- (xvii) capacity

for abstract reasoning (xviii) persistence and swiftness in thinking (xix) good comprehension (xx) quick grasp of subject; quick in response and reactions (xxi) good knowledge of language (xxii) relevance (xxiii) broader interests.

The task before the project-team was to select such variables which were meaningful with regard to the criteria mentioned above. Obviously, our domain was restricted to cognitive abilities. All personality variables like interests, independence, ambitions (greater motivations) etc. were ruled out. After lengthy deliberations and discussions it was agreed to explore the following for inclusion in the tests:

1. Verbal Ability
2. Problem Solving: (a) pertinent questions (b) scope of the problem (c) logical consequences (d) seeing relationships.
3. Concept Formation
4. Expression: (a) conciseness of expression (b) logical sequence of ideas (c) fluency of ideas (d) word fluency (e) speed in writing.
5. Memory - (a) memory for connected ideas (b) memory for discrete ideas.

These were further studied and some were rejected/ limited for reasons of practicability.

In Problem Solving, some of the variables were to be tried in a complex situation i.e. straight on a test of problem solving. However, separate tests were to be developed on 'seeing relationships' and 'discovering the rule'.

Expression was limited to written expression only; 'logical sequence of ideas' was dropped as it was felt that time required in attempting a test with given choices could

not be afforded.¹ On the other hand, the scoring of a free response type situation would be subjective, non mechanical and time consuming. Speed of writing although considered important by many teachers also got eliminated from considerations. It was felt that a pure speed factor was of little meaning here. It was the speed of recall, selection/rejection of pertinent material and writing the same that together mattered. It was felt that a good part of it would get reflected in scores on any test and that a pure speed test was not needed. After elimination of these variables the broad heading was revised from expression to fluency.

Under memory, it was decided to test only immediate recall.

It was felt that 2 and 3 could be broadly summed up under 'Reasoning' leaving us with four broad areas, namely, Verbal Ability, Reasoning, Fluency and Memory to be tested.

Consideration and selection of item types to measure abilities mentioned above

Verbal Ability:

The verbal ability tests included here measure mainly ability to read and comprehend and only indirectly to express oneself; that is to say, these are tests on ability to understand written material; and only to the extent that, richness of vocabulary is predictive of good written expression, these tests can be considered as tests of written expression. The following item types were considered and/or tried out.

Reading Comprehension: A passage was provided for reading and multiple choice questions were asked on the content of the passage. Care was taken not to ask questions as could be answered by picking out phrases and words directly from the paragraph. The questions mainly concentrated on central theme, implied meanings and only occasionally on the meaning of a

1. This variable did seem to have a close relationship with scoring patterns, particularly in reading comprehension.

The questions of the type mentioned above are time consuming both in the preparation of the test as well as in the taking of the test. The evidence obtained in terms of number of items is far too little in proportion to the time spent by the candidate on the test. It is also the experience of some of us that the students feel shy of reading (specially at the trial stages) so much material which is occasionally pretty heavy to read and understand. To supplement this test another type was considered and accepted for try out.

Sentence Completion: An omitted key word from a given sentence or group of sentences was to be selected from given five alternatives, each of which would fit grammatically but only the correct answer would make the sentence meaningful and acceptable in idea. The students could respond to this item type very much faster than to paragraph reading.

Synonyms:- It was felt that a large vocabulary is helpful in understanding any written material and is also indicative of possible good written expression - good in the sense of giving greater power of expression. A multiple choice type of test was prepared for testing vocabulary. Difficulty was experienced in inclusion of abstract words in the test. While the difficulty of language is necessarily associated with the abstract words, in the simple test type which we wanted to adopt i.e. stimulus word followed by five alternatives including one correct answer proved difficult for such words. Hindi language is not at the stage of development where one could find four or five words which would be close enough in meaning to the correct answer to function challenging distractors but not be considered correct answers. An attempt was made to prepare a sub-test giving the meaning of abstract words by

full statements. A draft of sample items was prepared and considered by the research team. Invariably the team found it difficult to agree on the exact statement of the correct answer. The writing of the item was also difficult and time consuming. In view of the first factor mentioned it was decided to drop the item type. Needless to add that this should be reconsidered at some later stage of the improvement of the test.

Antonyms: This sub-test was planned to supplement the test in synonyms. When a word expressed a whole idea, it was found difficult to find a good synonym; it was however easier to get evidence on its comprehension with the help of antonyms.

Four item types then, namely, reading comprehension on the passages, reading comprehension by completing the sentences, synonyms and antonyms were selected for tryout.

Reasoning:

The following were considered for inclusion in the first tryout:

Three types of analogy items were considered (i) Given one pair of relationship, out of the given five relationships the student was to select the one which matched the given relationship. It was felt that this type of reasoning included greater analysis of the relationship of a given pair as expressed in the selection of the similar relationship. It was also felt that the item difficulty can be increased in this type of item than in the simple analogy where the fourth correlate is missing.

1. For example, Fertilizer is to Yield as (i) Education is to Knowledge (ii) Intelligence is to Understanding (iii) Medicine is to Disease (iv) Money is to Research (v) Population is to Poverty.

A draft was prepared and administered to the students of grade XI of some local schools i.e., to a sample of the population on which the test would be applicable later on. It was found to be too difficult. To understand the practicability of this type further, test was administered to a few students and adults individually and they were asked to analyse what led to the correct response. It was found that most students as also the adults, failed to analyse the relationship fully and went invariably on some minor association. On the whole the item type was not considered practical (due to large number of failures) and was dropped. The second type considered in analogy was giving any two of the four words and leaving out the other two providing alternatives for the missing words. This one also proved difficult for high school population. Also the mental processes tested were not liked by the research team. The item type was dropped. The traditional analogy where the fourth correlate is missing was finally accepted for both grades VIII and XI.

Numerical Series: A test of number series in the traditional style where sufficient number of terms of a series are given for understanding the implicit rule and students are asked to write the next two numbers was considered and accepted.

Classification: For grade VIII the traditional classification test of pointing the odd man out was accepted. For grade XI another type was tried and found satisfactory. Here, two groups of words were given each defining a class, or an idea. A list

* For example, Request is to A as B is to Force A1 - Ask, A2 - place, A3 - Argue, A4 - Order, A5 - Tell; B1 - Bother, B2 - Persuade, B3 - Tell, B4 - Punish B5 - Obey

of question words was given to be assigned to class I or Class II.^{1*} To start with, this test was called Concept Formation, but to use the same names it is now named as 'classification' from which it really is not different but only more complex.

Problems in Arithmetic: These were included for both the levels. Computations were kept to the minimum and reasoning was emphasised.

Similarities: Test under this name was included for grade VIII. The students were required to point out (by selecting one out of five given answers) in which way the two given words were similar.

1.* Class I	Class II	Question Words
Mother	Auntie (Father's Younger brother's wife.)	Mother's mother Brother's daughter
Grandmother	Auntie (Mother's brother's wife)	Mother's sister
Aunt (Father's sister)	Sister in law (Brother's wife)	Father's elder brother's wife
Sister	Wife	Daughter in law Sister's daughter

Syllogisms: These were considered for inclusion in test at grade XI. A draft was prepared and tried out on a group of students. It was found that beyond a certain simple groups of syllogisms the students could not work with it. Even from among the adult group the small number on which the test was administered, the test was being answered reasonably and correctly only by those who had had specific training in logic. The item type was dropped.

Another item type under the same head i.e. syllogism was considered with a view to give simple type of syllogism only but by presenting concrete and non-sensical statements.¹ The draft as tried out was found too distracting for the young children who felt very amused at the odd things these statements said and found it difficult to concentrate on the task. They also showed signs to depend on the literal meanings of the statements and strike all absurd relationships given. The item type was dropped. Another item type considered was decoding.² This item type was rejected by the research team itself mainly on the ground that rules were understood by trial and error; certainly it involved hypothesis formation and verification of hypothesis. But opinion was divided on its utility.

Memory:

Under memory the following item types were considered and accepted.

¹ For example 'Some carrots are tables. All tables are buffaloes. Alternatives: (i) No buffaloes are carrots (ii) Some buffaloes are not carrots (iii) Some buffaloes are carrots (iv) All buffaloes are carrots (v) Some carrots are not buffaloes (vi) None of the above.'

² For example, 'following a certain rule the word RESPECT can be written as ECTRES applying the same rule how can the word "BELIEVE" be written in code language?'

Memory for Associated Ideas: A long paragraph was to be given to the students to study with explicit instructions to memorize things given. The passage would be withdrawn and a number of multiple choice questions would be given as test of memory.

Memory for unconnected ideas: (a) A number of sentences unrelated to each other would be given for memorising and the papers would be withdrawn after some time. The sentences were then to be given in a jumbled up form with some words missing in each sentence for which alternatives were to be provided to indicate the correct word. (b) Another version of this very test was that the words in the testing situation were to be written by the children. No choices were given. (c) The fourth test consisted of simple associations between words (names of men and women), objects and numbers, numbers and numbers, each to be given separately for memorizing and then one set given in an order different from the one given for memorising. The student was required to give the associated pair in the blank provided.

Fluency:

Under fluency the following were included.

Fluency for words: Words beginning or ending with a specified letter were to be written by the students.

Idea Fluency: (a) Ideas connected with a particular topic or words which could take a specified adjective or things having a specified shape etc. were required to be written. (b) Another test in Idea Fluency required production of as many ideas as the students could on a given topic like 'Tea Party' etc.

Final Selection of Item Types:

All these item types were retried somewhat systematically

on a small sample of children in Delhi. The objectives of this try out were as follows:

1. To estimate the difficulty level around which the items should be written. It was being experienced again and again by the research team that the exact idea of the level of difficulty of items which would be suitable for the two grade levels was not very clear to the team. It was being argued back and forth without much actual knowledge of the field situation. Existing tests were consulted but many of these were quite old. There was a strong feeling that conditions were changing very fast and the difficulty level presented by these items was not necessarily relevant. Moreover, majority of tests consulted being 'intelligence tests', these represented age levels and not grade levels. It was considered best to go out and find from the prospective respondent what was the ^{for} operative level of difficulty ~~for~~ these children.
2. To test the practicability of the item types accepted. Although some item types were tried out during this interval and rejected or accepted but this was not done systematically for all item-types. Only those on which members of the team disagreed with each other were taken to the field. At this time all the item-types were tried out for testing their workability.
3. To get an idea of the kinds of instructions to be used. The amount of practice required for each item type before the items were administered for item analysis.
4. To get an idea of the predictive efficiency of the variables being tried out viz-a-viz the examination marks as well as assessment of criterion II i.e. good scholarships by the teachers.

Seventeen item types were tried out on approximately 200 students for each of the grades VIII and XI of a local school. On studying the results available from this study it was decided to drop the tests in memory and fluency. At the grade VIII level the four tests in memory did not look very homogenous. Out of six mutual correlations three were nearly zero. With aggregate of school marks, all tests had significant correlations, though not very high (ranging between .24 to .38). The test which was expected to have maximum correlation showed least correlation with the school subjects. A high correlation was expected, as this task namely memorising a long passage looked very much similar to the school work required but for the fact that the memory being tested here was immediate recall. At grade XI, two of these tests had significant but low correlations with the school marks (.27 and .25). In any case, the tests were given up because the administration was found rather difficult, the timings had to be observed very closely, the children did not put down their pencils quickly as required to. It was foreseen that such a test would be still more difficult to administer when the test administration was entrusted to the teachers.

The tests in Fluency correlated very low with school marks in both grade VIII and XI. The difficulties of scoring were tremendous; administration was not easy either. If little time was given to the children it tended to measure more speed than fluency, if sufficient time was given problems of discipline with young children predominated the classroom; the children got restless, tried to copy each other's material and so on. Scoring was fairly cumbersome and time consuming. Ultimately it was decided to leave all tests under this category.

It was felt, however, that memory for associated material should be considered again at a later stage. If possible, the material should be given in advance so that the memory tested is not immediate recall but similar to what is expected in school tasks. For grade VIII the test in problems in arithmetic looked the best predictor of the school marks followed by reading comprehension tests (sentence completion type) and memory for related material. In grade XI the best single predictor was the test on Concept Formation (Classification) followed by problems and reading comprehension (passage type) and problems in arithmetic. It was also discovered that problems in arithmetic need to be made more challenging, therefore, area of content was extended from arithmetic to algebra and geometry. Since the two tests giving the highest correlation came under the category of reasoning, another sub-test in reasoning namely 'data-sufficiency' for grade XI was included for the tryout at item analysis stage.

With this knowledge the first drafts of items were prepared to be tried out for item analysis in the States.

CHAPTER III

Item Analysis and Preparation of Final Forms

Item Analysis

More items were written for each of the type selected so as to have sufficient number to be able to prepare two parallel forms at each of the two levels. One difficulty which the research team faced and consistently discussed was deciding whether or not a particular word or object being used in test items was known to the other Hindi speaking regions of the Country. Our joint experiences were strongest in knowledge about Delhi and Uttar Pradesh, somewhat limited for Bihar and Rajasthan and practically nil for Madhya Pradesh. To get over this difficulty, the test for synonyms consisting of 600 words and an additional list of words and objects - 61 in all was sent to some schools in the States of Uttar Pradesh, Bihar, Rajasthan and Madhya Pradesh, requesting the teachers to cross out the words which they thought were not known to the age group 13 to 16. These words were avoided in writing test-items.

The items after needed editing were frequently tried out on very small samples for improvement, only in rare cases items went as first drafts for the larger tryout.

Different subtests were printed separately. For each of the two grades VIII and XI, 9 to 10 sub-tests were tried out respectively. The number of items which were administered at this stage was as follows:

Table I
Number of Items Tried Out

	Grade VIII	Grade XI
Synonyms	100	95
Antonyms	75*	84
Sentence Completion	68	75*
Reading Comprehension	70	96
Analogy	70	75*
Problems in Arithmetic/ Mathematics	68	100
Number Series	75*	70
Classification	74*	50
Similarities	70	-
Data Sufficiency	-	63
Problems	-	60
	670	768

The sub-tests were arranged in four groups to ensure that in a single sitting only one and a half to two hours of time is required from the children. The tests were administered in two days' time using four sessions on two consecutive days with a break during the two sessions of a day. The same were preceded by the practice booklets, where for each sub-test, detailed instructions with illustrations were provided and also exercises were given for students to attempt.

In the administration of the practice booklets sufficient care was taken to see that all children understood the nature of the tests. The teachers read out the instructions and illustrations for each subtest, the children were allowed and encouraged to seek clarifications. As they attempted

* In all these tests, considering cost of punching and processing only 72 items were analysed for getting item-statistics.

the practice items, the teachers watched for correct marking of the answers. If necessary, instructions were repeated. When all the items of a practice booklet were attempted, the correct answers were announced. The practice booklets were always administered a day before the tests were and children were asked to take them home and study them, if necessary. They were forewarned that similar tests would be administered the next day but instructions will not be repeated.

In the test booklets the same instructions as were given in the Practice Booklets were repeated on top of the each test but this time the students were left to read the instructions by themselves. No further explanations were offered. The timings for reading the instructions and for attempting the items were given separately. Ample time was provided to the children for attempting all the items. Generous time limits were fixed for each sub-test with instructions to the Supervisors and Test Administrators that the same might be further increased by 5 to 10 minutes or even more in some cases as in the case of test in problems in mathematics so as to ensure maximum number of attempts by the children. It is hoped that the speed factor was eliminated to a very large extent.

Sample for Administration of try-out forms

The samples were selected from each of the four States and the Union Territory of Delhi so as to include boys, girls from both urban and rural areas. No attempt was made to make the sample-design very sophisticated, it was felt to be unnecessary at this stage. However, due to vast expanse of geographical area, it was thought proper to get samples from more than one pocket in a State. At least three to four major centres, fairly widely scattered geographically were chosen in each of the States. In Uttar Pradesh the four major centres were Lucknow, Kanpur, Varanasi and Almora. In Bihar the three

1. Finally tests could not be administered in Almora.

major centres were Purnea, Patna and Ranchi. In Rajasthan these were Bikaner, Ajmer and Udaipur; in Madhya Pradesh, Gwalior, Bhopal and Raipur. In Delhi various areas or localities were included so as to cover all kinds of groups. In and around each one of these centres mentioned, four types of high/higher secondary schools, namely, schools for boys and girls in urban and rural areas were selected without much knowledge about the schools (from the lists of schools available from the various Directorates of Education). The samples for grade VIII have, thus mainly come from high and higher secondary schools, except in the case of Madhya Pradesh where the school structure is such that many high/higher secondary schools did not have the middle classes attached to them and separate middle schools had to be included in the sample. The number of schools in the States where testing was carried out is as follows:

Uttar Pradesh - 12; Bihar - 12; Rajasthan - 10

Madhya Pradesh - 19; Delhi - 12;

The number of children under each of the categories mentioned above are given below:

Table 2
Number of Children Tested in Each State

State	Urban Girls	Urban Boys	Rural Boys	Rural Girls	Total
Delhi	307 229	287 225	300 137	253 107	1,147 698
Uttar Pradesh	558 442	361 431	316 238	20	1,255 1,111
Bihar	528 171	406 338	184 79	139 95	1,257 683
Rajasthan	150 294	407 353	111 35	141 60	809 842
Madhya Pradesh	482 330	496 496	315 339	170 66	1,463 1,231
Total	2,025 1,466	1,957 1,843	1,226 928	723 328	5,931 4,565

In each cell the figure on the top refers to sample size for tests for grade VIII and the second figure to the sample size for tests for grade XI.

Difficulty values and discriminating indices were obtained for each one of these groups i.e. for different strata in different States separately. Only in some cases the data were further reduced at the stage of punching and processing. This was found necessary to cut down the time and expenditure involved but it was felt that it is not likely to affect the selection of the items as the selection was based on a large number of repeated indices available from various groups. The difficulty values were the percentages for the keyed correct answer of the item calculated by the formula $\frac{R}{N - NR}$ so as not to make the item look more difficult because of its placement. The discriminating indices were read from Davis' Chart using percentages of successful attempts of 27% of the high scorers and low scorers for each single sub-test. In determining the upper and the lower group, correction formula was not used for scores as, by and large, the groups would remain the same except for very marginal adjustments. However, since Davis particularly recommends the use of correction formula for the pass percentages for high and low groups for entering the figures in the Chart, such percentages were corrected for guessing by the formula $\frac{R - W}{n - 1}$

$$N - NR$$

Item - statistics were available on two to four groups in a single State. It was earlier planned to get item-statistics on each of the four strata in a State. This did not prove possible because of small sample sizes in some strata. This is specially true of children of grade XI and also of rural-girls samples. In some States the total number of girls studying in grade XI in rural areas in itself is so small that it hardly needs any special attention. The strata were combined keeping in mind the variable and the types of differences which were likely to be prominent. For example,

in test of problems in mathematics the merging of rural urban groups was thought more appropriate but boys and girls were kept apart as the difficulty values of the items were expected to be more widely different for boys and girls, specially in view of the fact that only a negligible proportion of girls offer higher mathematics. At the secondary stage, some have already developed inhibition towards working with figures. When environmental experiences seemed important, rural groups were kept separate, wherever possible.

At the grade VIII level, samples were fairly substantial and much merging was not needed.

On the Use of Information Available on Items

For each stratum in each State the following information was available:

- (i) Percentage of response of high scoring and low scoring 27% as well as the total group for all the alternatives in case of multiple choice items. Proportion for 'non-response' and 'not-reached' were also available. Percentage of correct, incorrect answer, no response and proportion 'not reached' in case of completion type items were available. Incidentally only the number series were the completion type items.
- (ii) The difficulty value in terms of pass-percentage of the total group for the correct response - as available from (i).
- (iii) Discrimination index as read from Davis' Chart.

For each item the data for all the strata in a single State were made available on a single sheet. These were studied to judge the acceptability of difficulty values and discrimination indices (the limits for which will be specified a little later) and also to notice any stratum differences over the items. A difficulty arose here as to what difference should be considered as due to a bias in the item and what

may be attributed to a real difference in the ability level. The data seem to suggest that the assumption of equal ability levels for all strata/States could not be held for whatever reasons it may be. This view was supported by the results available from the sub-tests - that is to say if a particular State or stratum tended to have higher mean scores for practically all the tests one could not stick to the assumption that the differences were due to bias in item writing. It looked more tenable that there were some essential differences in the developed ability of the children. For deciding the direction of these differences the mean scores on the sub-tests for the strata were studied in each case and it was agreed upon that the response pattern similar to the pattern of mean scores would be considered as free from bias in the item. Any deviation from this pattern may be considered as indicative of bias. To illustrate the point concretely, on the test on Antonyms in Delhi the averages recorded for the four strata were as follows:-

Urban Girls	Urban Boys	Rural Boys	Rural Girls	Total
49.10	44.60	41.60	37.55	43.41

It was then accepted that urban girls would have maximum pass-percentage and the rural girls the minimum. The boys' groups fitting in the order as indicated by the mean scores. Any item which recorded a higher pass-percentage for urban girls in comparison with urban boys was not noted for girl-boy difference but if an item recorded higher pass percentage for boys in comparison to girls, a boy girl difference was recorded. Same rule was followed in studying the difference over States from State-data-sheets.

Thus for each State a note was taken for the acceptability or otherwise of the item; also differences in strata

were noted. If an alternative did not function or tended to distract the high group this was also recorded on the sheet. All this information from all the States were further transferred in a tabular form for each item on a single sheet as illustrated below:

Antonyms:

Item No.2

	UG	UB	RB	RG	
Delhi.	79 35	79 23	63 31	53 28	B/G
Bihar	52 37	60 49	78 25	51 33	B/G
M.P.	47 15	73 35	62 35	47 26	B/G
Rajasthan	65 23	71 34	59 40	---	B/G
U.P.	44 36	69 39	74 49	---	B/G

Favours boys, otherwise acceptable.

The figures on the top left corners give pass-percentages and the figures in the right bottom corner give discrimination indices. A noting like B/G means boys are doing better than girls. In case an alternative was found unsatisfactory it was also recorded against the particular state as alternative A etc. These tables were then scrutinized for final selection or rejection of the items.

Criteria for Selection of items

In case pass percentages showed large variations over State and strata that item tended to get eliminated. For an item the pass-percentages between the range 25 to 75% were considered acceptable. Although this rule was followed generally exceptions were made in a very few cases for values

higher than 75% or lower than 25% in some States or strata. This necessity arose as two of the extreme States, namely, Delhi and Bihar did record quite a few differences. To make available for Delhi children some items of lower difficulty values, it became necessary that items having lower pass percentages than 25% for Bihar were included. Similarly to make available some easy items for the State of Bihar it became necessary that some items which showed high pass-percentages for Delhi also got included. In any case the number of such items is not very large. For discrimination index the general rule was that all values as read from Davis' Chart should be larger than or equal to 20 for the acceptability of a particular item. Since the number of observations for each single item varied from 10 to 18, occasionally one or two lower discriminating indicate were ignored, specially in cases where item difficulties, both in the range and in the central value, looked highly acceptable.

In the selected items, if need was felt to change an alternative it was changed. It is pointed out that the items with changed alternatives have not been tried out again and new item statistics might now be different. The same have been obtained from the data obtained later and are given elsewhere in the report.

Preparation of the Final Forms

Items were selected on a large number of indices both for the difficulty and discriminating values. Although it was considered good by the research team from the point of view of stability of information but for dividing the items into two final forms, this information was too cumbersome to be used. Single indices of item difficulty and discrimination were worked out for each item as follows:

For the difficulty values an unweighted mean of passpercentages was accepted as the difficulty value of the item.1 for the discrimination index the median value was used as the single index.

Using these two indices selected items for each sub-test were plotted on a graph, the closest appearing pairs were encircled and the items were then randomly assigned to Form A or Form B.

It was assumed that items with changed alternatives or those showing strata differences will be and large get divided evenly in two forms. Following is the information (as available from item-analysis) in forms A and B.

Table 3

Division of Different Types of Items as obtained in the two parallel Forms.

	Form A		Form B	
	VIII	XI	VIII	XI
Items which seem to favour urban children	8	-	8	-
Items which seem to favour rural children	1	-	-	-
Items which seem to favour boys as against girls	5	-	5	-
Items which seem to favour girls as against boys	2	2	2	3
Items in which one (in rare cases two) alternative has been changed	37	22	45	29

1. Mathematically one would consider the weighted mean as a better average than the unweighted mean. It was observed that the sample sizes of the data which was actually processed did not vary much and the number of observations being large i.e. varying from 10 to 18, the weighted mean did not differ much from the unweighted mean. A number of concrete cases were calculated to note the difference between weighted and unweighted means. In most of these observations the recorded mean difference was less than 1.00. As in dividing the items in two parallel forms such differences would get ignored it was considered worthwhile to save the effort and time involved in calculating the weighted means.
2. It was found necessary at this stage to divide the total test into two for convenience of administration. Division in V and N forms seemed most practical and sensible.

The number of items in the final form under each subtest are as shown below:

Table 4

Number of Items in Each Subtest

<u>Form V¹ (A and B)</u>	<u>Grade VIII</u>	<u>Grade XI</u>
Synonyms	29	24
Classification	17	14
Analogy	20	16
Reading Comprehension(Passages)	19	22
Antonyms	18	24
Similarities	16	-
Sentence Completion	21	20
<u>Form N² (A and B)</u>		
Problems in Arithmetic/Mathematics	20	20
Number Series	20	20
Data sufficiency	-	16
Total	180	176

Practice booklets did not need very large scale changes. Instructions were revised, wherever necessary. For each administration, practice-booklets are still two in number, with a common answer sheet.

Fixation of Time Limit for the Final Forms

During the initial try out phase it was observed that the Delhi boys and girls worked faster than their counterparts in other States. Bihar boys and girls were found to be slowest of all. In the following tables Bihar and Delhi boys of grade VIII and XI have been compared on two tests i.e. on Antonyms and Number Series.

Table 5 (a)

Data on Differences in Speed of Work of Children.

Urban Boys - VIII	Urban Boys - VIII
Number Series -	Antonyms
Total Time - 100mts.	Total Time 30 mts.
No. of items 72 ¹	No. of items 72

	Delhi	Bihar	Delhi	Bihar
Item No. on which 1st. 'not-reached' case occurred.	34	32	72	52
Percent of 'not reached' cases on last item	12.3%	34.8%	0.7%	4.9%

Table 5 (b)

Urban Boys - XI	Urban Boys XI
Number Series	Antonyms
Total Time - 90mnts.	Total Time - 30 mnts
No. of Items 70	No. of Items 84

	Delhi	Bihar	Delhi	Bihar
Item No. on which 1st 'not reached' case occurred	35	10	66	56
Percent of not reached case on last item	47.4%	42.8%	1.4%	8.3%

1. As available from punched data.

In both tables 5 (a) and 5 (b) it can be seen that first occurrence of not reached case was consistently early in case of Bihar boys as compared to Delhi boys. Beside percent of not reached cases in last item were also higher in case of Bihar boys. In table 5 (b), however, there is one reversal of this trend. There is greater percent of not reached cases in Number Series test among Delhi boys than in Bihar boys. This reversal is more apparent than real. For 65th item, i.e. all but 5, percentage of 'non-reached' is 28.5 for Bihar and 21.6 for Delhi.

Upto this point the percentages are consistently lower for Delhi. Although the above comparisons were made on two tests in each of grade VIII and grade XI only, but the same general pattern was noticed in all other tests.

Assuming that the boys and girls from other States would be somewhat slower than Delhi children, it was decided to fix the time limit of the tests in such a manner as to allow reasonable time to the slowest of the students for attempting a large number of items.

The tests were administered on the boys of a Delhi School (Government Higher Secondary School, Model Town, Delhi-9) for estimating time requirement of the Delhi students. The following procedures were adopted: grade VIII and grade XI of the school was selected for test administration. Practice Booklets were administered strictly in accordance with the procedures as laid down in the manual of general instructions. On the next day the tests were administered. The forms A or B were given to alternative students sitting in a row. Testing procedure was the same as laid down in the manual of general instructions except for a single point, the children were instructed to raise their hand as soon as they had finished answering the questions. Whenever any student raised his hand the test administrator went to his seat recorded the time of submission of the answersheet and collected back the test booklet as well as the answersheet.

The students who received AV in first testing session received AN in the second session and those who had received ^{the} BV in first session received BN in the second.

Total time taken in attempting all the items of AV and BV forms by VIII grade and XI grade students is presented in Table no. 6 (a) below:

Table 6 (a)

Time taken by a Group of Children in Attempting the Tests

Time in Minutes	VIII AV f	V-III BV f	XI AV f	XI BV f
111 - 115	0	0	0	1
106 - 110	0	0	1	2
101 - 105	1	1	0	2
96 - 100	0	3	0	1
91 - 95	8	4	3	3
86 - 90	3	1	8	2
81 - 85	2	3	4	5
76 - 80	8	3	5	3
71 - 75	6	2	3	3
66 - 70	2	7	3	1
61 - 65	1	5	0	2
56 - 60	4	4	0	0
51 - 55	3	1	0	0
N = 38		N = 34	N = 27	N = 25

Total time taken in attempting all the items of AN and BN forms by grade VIII and grade XI students is presented in Table No. 6 (b)

Table 6 (b)

After considering the total time taken by this sample of Delhi boys and keeping our previous experience of comparative slowness of boys and girls from other States in mind total time for each of the forms was fixed as follows:

2 hours for Form V and 1 hour 45 minutes for Form N for grade XI, 2 hours for Form V and 1 hour 30 minutes for Form N for grade VIII.

Chapter IV

Administration of Final Forms, Data on Norms and Reliability

The tests as printed in their final forms consisted of the following for each of the grades:

1. Two practice booklets with a separate but common answer sheet for both the forms.
- 2 i) Form V (A&B) with a separate answer sheet.
 ii) Form N (A&B) with a separate answer sheet.

Although practice booklets had a separate answer sheet, these were categorised as consumable. As mentioned earlier, the practice booklets are left with the children to enable them to study and understand the instructions to the extent they need repetition and/or practice. It was also thought that ultimately, these can become useful handouts to prospective users. The test forms were considered reusable and a smaller number of these were printed in comparison to their answer sheets.

As laid out in the manual of instruction in each case (i) the practice booklets were to be administered by the teachers a day prior to the administration of actual tests (ii) Form V would be administered in the first session next day and Form N during the second session. A school could, if it so desired, administer form N on the third day but rarely was it arranged this way. In fact, we would have liked the N form to be administered on the third day but the procedure was changed because of pressure from schools to get the work done in as small a period of time as was possible.

When these tests would be used for guidance/selection purposes, the same would be administered to the children who have just completed schooling upto grade VIII or X/XI which ever may be the end of high school.¹ It was considered right to administer the tests for Norms as close towards the end of the academic year as was feasible. In most States the annual school as well as public examinations are conducted usually during March - April; therefore, it was decided to administer the tests for norms during December-January. Only in the State of Bihar these were to be administered a little earlier as the students there are allowed to discontinue school and study of their own in preparation for the final examination.

Sample for Norms

In another project, namely, 'A Survey of Secondary Schools in India' being worked at a little ahead of this project, a ten percent stratified random sample of schools was drawn - the strata being rural/urban, government/non-government, boys/girls and high/ higher secondary schools. This seemed to fit in with the requirements that we had in mind and it was decided to adopt this sample for final administration of the tests. The factors that led us to this decision are laid below:

(i) A similar stratified random sample of schools was needed by us for norms.

(ii) As the National Institute of Education had already developed some kind of rapport with these schools, these were likely to respond to our request more easily than a set of new schools.

(iii) It saved time in selecting a fresh set of schools.

(iv) It would give additional information about the student

1. Different States in India have different patterns, e.g. in U.P., high school finishes at grade X while in Delhi, it terminates at the end of grade XI.

population of these schools which could, at a later stage be studied along with the school variables on which data were available on 'A Survey of Secondary Schools in India'.

(v) The Survey Questionnaire had been sent at least a year earlier, if not more, this task therefore would not be additional burden on the same set of schools. Also, the questionnaire was addressed to the headmasters, while the tests were to be taken by the children and administered by the class teachers. Thus, the two groups of individuals being involved in actual work were different from each other.

In the sample mentioned above, complete lists of high/higher secondary schools were obtained as available in 1961 or 1962 with the Directorates of Education of these States. Further information was obtained on whether a school was run by Government or private agencies, was located in urban or rural area, admitted boys or girls.¹ From each of these cells a ten percent random sample of schools was selected. An exception was made for rural girls schools, where, considering the very small number of schools, it was decided to raise the proportion to fifty percent. To illustrate the procedure mentioned above, one of the tabular set of information as available from the files on the sample from which we worked is reproduced below:

State-Bihar

Category of School	Type of School	Boys		Girls		Total
		Urban	Rural	Urban	Rural	
High School	Govt.	16	14	2	-	32
	Non Govt.	2	1	-	-	3
Hr. Sec. School	Govt.	162	1090	43	8	1303
	Non Govt.	16	109	4	4	133
Total	Govt.	3	12	9	-	24
	Non Govt.	-	1	1	-	2
	Total	98	87	10	1	196
		10	9	1	1	21
		279	1203	64	9	1555
		28	120	6	5	159

The list of these schools were obtained. Estimating the number of children who were likely to be available, it was felt that the number of children was much larger than could be accommodated in the time and money available on this project. It was not necessary either. To cut down the work, 25% of this selected sample was dropped by striking off every 4th school from the lists of schools as available from 'A Survey of Secondary Schools.'

This, however, gives the 'model on which the work was started. The drop out from this sample began right with the first letter addressed to the schools. National Institute of Education, and for that matter even the Ministry of Education at New Delhi has no direct control over the schools, or State Directorates of Education. Any directive or request sent out from here is treated according to the judgement and the goodwill of the Director of Education as well as the head of the school concerned. Care was taken to keep the drop out to minimum, in that a personal letter was addressed by the Joint Director of the National Council of Educational Research and Training to the Directors of Education of all the five States to issue instructions to heads of 'selected' schools to help the N.I.E. in administration of tests. Many schools cooperated more than willingly, some had genuine difficulties, Some declined frankly others carried out the work in name and did not follow the instructions faithfully. The worst illustration of the last point is the administration of tests meant for the final year class of the school (i.e. grade XI) to students

-
1. Most schools at this stage are single sex schools. There are a negligible number, if any of co-educational high schools in Delhi, U.P. and Bihar. There are a few in Madhya Pradesh and Rajasthan. There were categorised with boys or girls' schools according to the predominance of children of one sex or the other.

of lower grade to avoid 'wasting of time' of students who have to take a public examination. The data actually used for norms are from a small number of schools, the geographic spread of these schools is shown in the maps.

Data from the State of Bihar were worst hit. Ever since the test material was despatched to Bihar i.e. late in October and early November, 1966, the educational institutions remained closed for one reason or the other. There were riots in the State, students' protests, pre-election disturbances and worst of all, a state of acute draught. The data were received only from five to ten schools. The rest all expressed their inability to complete the work due to perpetual closures of the institutions. Finally, the schools were advised to keep the test materials and administer it to students of new IX (for test for grade VIII) in 1967 and do nothing about the tests for grade XI. That is why no norms are given for grade XI for the State of Bihar. Even for data for grade VIII, the rejection rate was very high. The answers looked like dictated ones in many schools, the scripts were thus rejected.

Sample in the State of Uttar Pradesh also suffered because lots of test material got locked up for Bihar. The original plan of using the non-consumable tests more than once, failed and material could not be sent to all the schools. Detailed information about number of schools selected, number where material was sent and the number of schools from which material has been used in sample for norms is set out in the following table.

Table 7
Number of schools in the Final Sample

State	Number of Schools				
	Delhi	U.P.	Bihar	Raj.	M.P.
Sample adopted	35	144	120	51	72
Where tests were sent for administration.	28	82	95	41	54
Data from which has been used for norms	27	30	34	30	30

Some of the reasons for which data were rejected are mentioned below:

1. Unattempted I Form. Some schools, specially girls' schools returned test material after getting V Form only attempted with the plea that the children find I form too difficult to answer.
2. Small variance in the scores. Although the variances for all school were not calculated separately but scores were scanned roughly, if the children tended to record more or less the same score, such data were considered unreliable.
3. Individual cases where one form was not attempted.
4. The data which were received too late according to our work schedule. If after waiting for sometime, processing of data of a State had started, the data received later than that date were put aside - not even scored.

The scoring at this stage was done by hand. Wherever the sample size looked large e.g., in grade VIII, Madhya Pradesh, the number was lessened by selecting fifty percent of the scripts. No school was completely eliminated in the process. The statistics given are on shrunken samples - wherever they were shrunken.

At this time it was not known whether the forms would prove to be parallel in another sample; it was, therefore, decided to administer both the forms. Ideally speaking, one could have checked the equivalence of forms before rushing in for data for forms but to avoid delay in work this step was shelved. As an alternative both the forms could have been administered in each of the schools to get comparable data but as each form had two parts to be administered separately, this procedure was considered too risky in the hands of schools.

It was decided to send form A to all odd numbered schools and form B to all even numbered schools as available on typed lists. Equivalence of forms is discussed later in the report.

Administration of the Final Forms

It was arranged to have a circular request sent by the Director of Education of the State concerned to all the selected schools.¹ This circular was followed by a request for cooperation - detailing briefly the project and the nature of the task required of students and teachers from the Principal Investigator. A small postcard to be filled in and returned was attached herewith, wherein information about number of children, corr. address of the school, convenient mode of receiving the material (rail or post) and the willingness or otherwise of the school to cooperate in the project was obtained. On receipt of this information, some copies of manual of instructions for administration of tests - both in Hindi and in English and copies of practice booklets along with answer sheets were sent with a request that the same may be studied by the class teachers concerned and doubts, if any, may be referred to us. The test material followed this. Material was packed in two bundles - practice booklets and tests separately as the two had to be opened on two different days. The headmasters were requested to send the material back to us immediately after use. Along with this some relevant information was also obtained (e.g., the number of children who took the test, the code number that was dictated to the children etc.) on a cyclostyled form.

For further details on actual administration of the tests, manual of instructions may be seen.

-
1. In Uttar Pradesh, six schools were reported to be wrongly addressed by us - which were not pursued later.

norms

For each State frequency distribution of scores were obtained for each stratum separately as well for the total sample. The same are given in Table nos 8 to 16 in Appendix 2. The norms were to be calculated on the total sample in each State which in case of absence of non response/rejection would have been representative samples of the States. With such large scale changes in obtained from stipulated sample, the adequacy of proportions was in doubt. In view of differences in means (which quite frequently looked highly significant), simple addition of frequencies over the strata looked unreliable. A solution was found in proportionate weightage (p_i) to data in each of the strata. Estimate of (p_i) was made from information available from 'Second Educational Survey' and 'A Survey of Secondary Schools in India'. After estimating p_i value for each stratum, transformation constants Tci were calculated for each stratum i as

$$Tci = \frac{p_i I}{n_i} \text{ where } I = \text{Total number of cases in all the strata}$$

$$n_i = \text{number of cases in } i \text{ th stratum}$$

Transformed frequency distribution of each strata was then obtained by $Tfij = Tci \times Fij$ where $Tfij$ is transformed frequency of j th class interval in i th stratum and Fij is the obtained frequency of j th class interval in i th stratum.

Transformed frequency of the total distribution for j th class interval was obtained by

$$Tij = \sum_{i=1}^k Tfij \text{ where } k = \text{number of stratum}$$

Tij values were founded up to the nearest integers.

In cases where sum of the rounded frequencies did not add up to exact N , suitable corrections were made in large frequencies to make the N comparable with that of the original distribution.

Where data on a stratum was not available, it was ignored and π 's were proportionately increased to make $\sum \pi = 1.00$.¹ Only in one case (Madhya Pradesh Form B) a small number of cases (sixteen only) in one of the stratum were dropped as it was felt that data from such a small number was getting more weightage in the total transformed distribution than could be relied upon.

Transformed distributions for various States are given in Tables 6 and 7 in appendix II. Graphical representations of these distributions are also given in the appendix. For each State distribution of Form A and B are given on the same graph for easy comparisons. Being on the same scale, these can also be scanned for comparability over the States.

Comparability of Scores

Obtained frequency distributions for various strata in each of the States are given in appendix. Means and standard deviations are set out in tables 8 and 9. Remarks on differences are not based on any statistical analysis but only on such differences as are obvious.

It is not out of place to draw the attention of the reader to the fact that persistent State differences were noticed at the item analysis stage.² In most subtests Delhi children made largest mean scores and children from Bihar, in contrast, the smallest. Rajasthan, Uttar Pradesh and Madhya Pradesh tended to fall in between with Rajasthan

1. Usually, the missing stratum, is the rural girls' schools which are very small in number. Even when 50% of these schools as against 10% of other strata were included, the total no. of girls' schools selected for each of the States were as follows:
Delhi 4; U.P. 6; Bihar 4; Rajasthan 2; M.P. 6.

2. See Tables 1 and 2 (ante p.) appendix I.

coming very close to Delhi occasionally. This observation is particularly true for tests for grade VIII. For grade XI the picture was slightly different, State of Bihar maintained its lowest position but Delhi children showed different pattern for different tests. For tests on verbal ability, they no longer scored highest (in fact the means were lower than the mean scores of children from Uttar Pradesh, Rajasthan and Madhya Pradesh, where Hindi is probably used more) but on tests dealing with numbers, Delhi children were still far ahead of children from other States. Tests on reasoning had somewhat mixed trends depending, perhaps on the admixture of reasoning and verbal factors. This fact is important from the point of view that all data for item-analysis were obtained under personal supervision of the staff of the Department of Psychological Foundations and many interfering variables were under control. No schools could have helped children in locating and writing correct answers, or hurried them through the tests or encouraged them to somehow get through these and begin their serious (?) studies. In the final administration, tests have been administered by school teachers under supervision of their own headmasters. The data seemed to indicate that some, even if few, schools have not quite grasped the purpose or the importance of dependable data from their schools. Some seemed to be really concerned about the possible poor performance of their students and in their anxiety, seemed to have dictated correct answers. Occasionally, the scores from a school seemed more of a measure of the teacher's aptitude rather than the children's. Although such bits of data were largely eliminated but some errors - specially the ones which were not easily detectable on simple scrutiny of the scores - could still have remained. This may be borne in mind while studying the differences.

In table 8 from the column headed by N under "Weighted Total" one can notice that Delhi has maintained its superiority over other States, Rajasthan, Uttar Pradesh and Madhya Pradesh also tend to maintain their (Contd-- on page 62)

position around the same place only Bihar records comparatively higher mean scores. The reader may be reminded that the administration of the tests in Bihar was least satisfactory. It could not be carried out before the examinations. The tests were administered on fresh entrants to grade IX. This, thus is a selected group selected to the extent of failure and drop out at the grade VIII level, figures for which are not known to us. But this is not the entire story. The rate of rejection of data is also highest for Bihar; data from more than 40% of the schools (from which scores were considered for inclusion in sample for Norms) had to be rejected.

The differences are, also somewhat smaller than noticed in data for item analysis. In either form i.e. A or B the maximum difference at grade VIII is approximately 9 points for V and N and 17 and 13 points respectively for forms A and B when total score is considered.

In grade XI, the differences tend to narrow down. The results are once again, consistent with those obtained in sample for item analysis. Delhi children give up their highest position on verbal tests, which is taken by Rajasthan, however, Delhi maintains its superiority on numerical tests. In comparison to the differences on numerical tests at the tryout stage, the differences are now smaller. The differences for girls are bigger than those for boys. On the total

form, Rajasthan leads and this is consistent with previous data.

Over strata, at grade VIII level, except on test in problems in arithmetic, urban girls, in Delhi scored higher in all tests at the tryout stage; they have maintained a similar superiority. Similar persistence of slight superiority of urban boys over urban girls is noticeable for samples from Rajasthan. In Madhya Pradesh urban boys score somewhat higher than girls. This tendency was only dimly visible in item analysis data. In Uttar Pradesh the trend of any such differences was not clear at item analysis stage. In the sample for norms, ignoring the small sample ($N = 58$) of urban girls, urban boys do somewhat better than girls. Although distinctly clear in this administration, this trend could not be considered as in contradiction with the one in item analysis data. Only in Bihar, there is a reversal of trend from rural boys scoring high in comparison to urban boys, at the item analysis stage to the opposite side. Urban girls maintain their closeness to urban boys. This reversal may be due to accidental sampling at the item analysis stage.

In general, then, urban children tend to score somewhat higher than rural children and except in Delhi, boys higher than girls. Urban girls scoring higher than boys is a persistent phenomenon in Delhi. Boys scoring higher than girls fits in more easily with expected behaviour in society. It seems that in Delhi

1. Such is this writer's experience with data on some intelligence tests.

the expectations from the two groups which enter schools remain the same while girls' group, on the average may be somewhat more selected than the boys' groups.

Greater diligence, docility and freedom from temptations of world outside may result in higher achievement in the restricted area of academic tasks for schools girls.

Trends at grade XI level at item analysis stage can be briefly summarised as follows. In Delhi, Urban girls maintained their superiority over urban boys in all but in test on mathematical reasoning; Urban, rural differences were not always available (due to small samples from rural areas) and wherever available the trends were not very persistent. In all other States, urban boys in general scored higher than urban girls with very few exceptions. On the whole, urban children recorded higher mean scores than the rural children but the differences were small.

If small samples are ignored, picture remains the same for final administration. Delhi girls score as high as boys on tests involving numbers as well. Girls' means on N form are much lower than those of boys in Uttar Pradesh and Rajasthan but only slightly lower in Madhya Pradesh.

On Comparability of Forms A and B

Scrutiny of means entered under column "Weighted

: 45 :

"Totals" in tables 8 and 9 leaves one with the impression that the forms may not be parallel; Reader's attention is drawn to the fact that the forms A and B were administered to two different samples of schools i.e., each form to half the schools from the total list of the selected ones. There is, however, no reason for the schools to be systematically different from each other. Therefore, persistent differences need serious attention.

For tests at grade VIII, four out of five sets of means for form V, have larger values for form B, three of these being significantly so. Reverse direction is recorded only in data from Bihar. For form N, differences in all the five pairs are significant, only two of these have higher means for form A and three for form B. As a consequence, in the total score although in four out of five States M_p is higher than M_n , only two of these differences are significant. One difference is significant for the reverse direction. Inspite of a mixed picture there is a serious possibility of form B at grade VIII being easier than form A. Variances are also somewhat larger for form B.

For tests at grade XI, for the verbal form, two out of four means are higher for form B, the other two for form A. But where the differences are significant, the other two are not. For form N, three out of four differences are significant and two of these are in favour of form B. For the total score, two pairs of mean record significant differences both

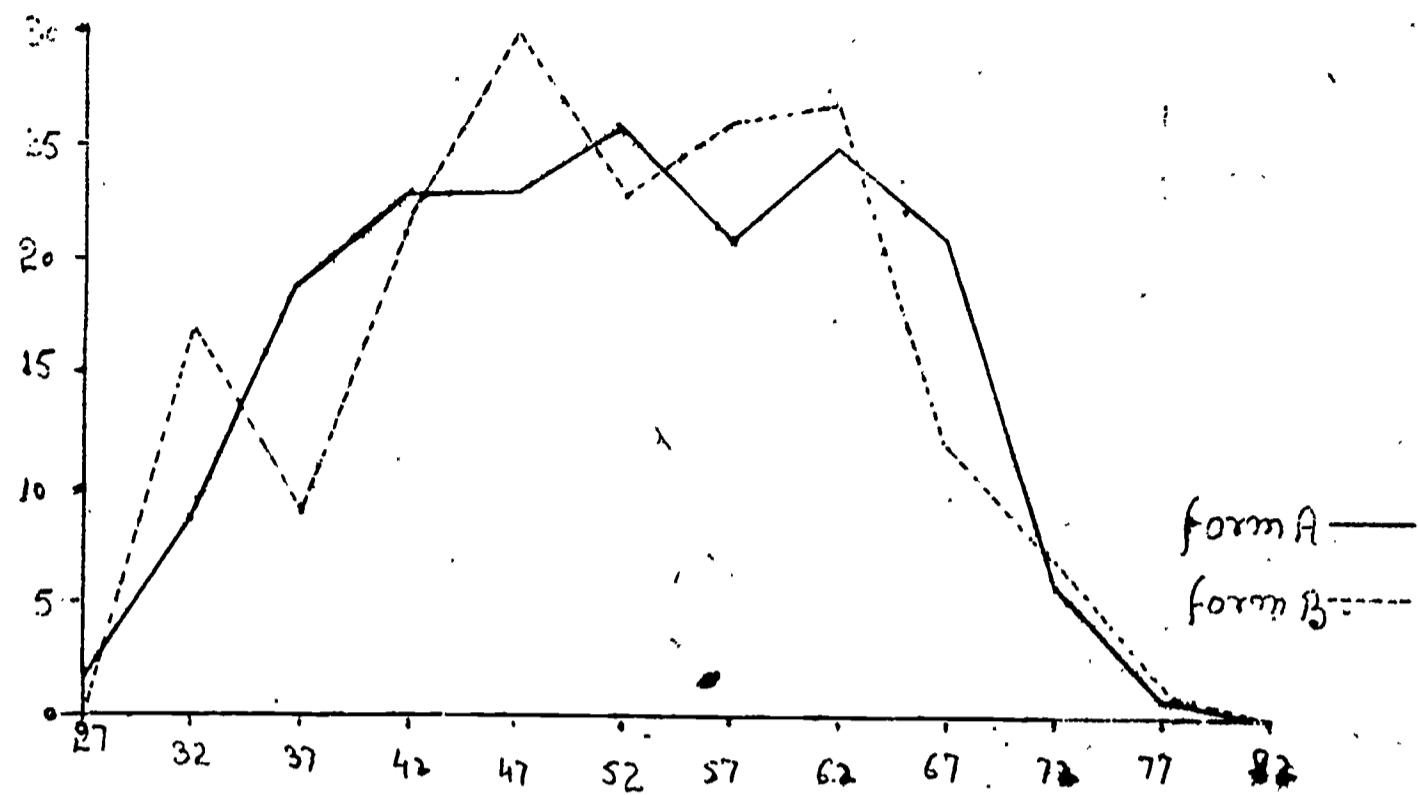

higher for form B. Variances, although at times unequal, do not show any consistency in the trend. It is a somewhat perplexing situation. Items were divided into two forms randomly and the distribution of difficulty values was not considered different from each other. The same is reproduced below for scrutiny by the reader.

Table - 10
Distribution of Difficulty values of
Items selected for final forms.

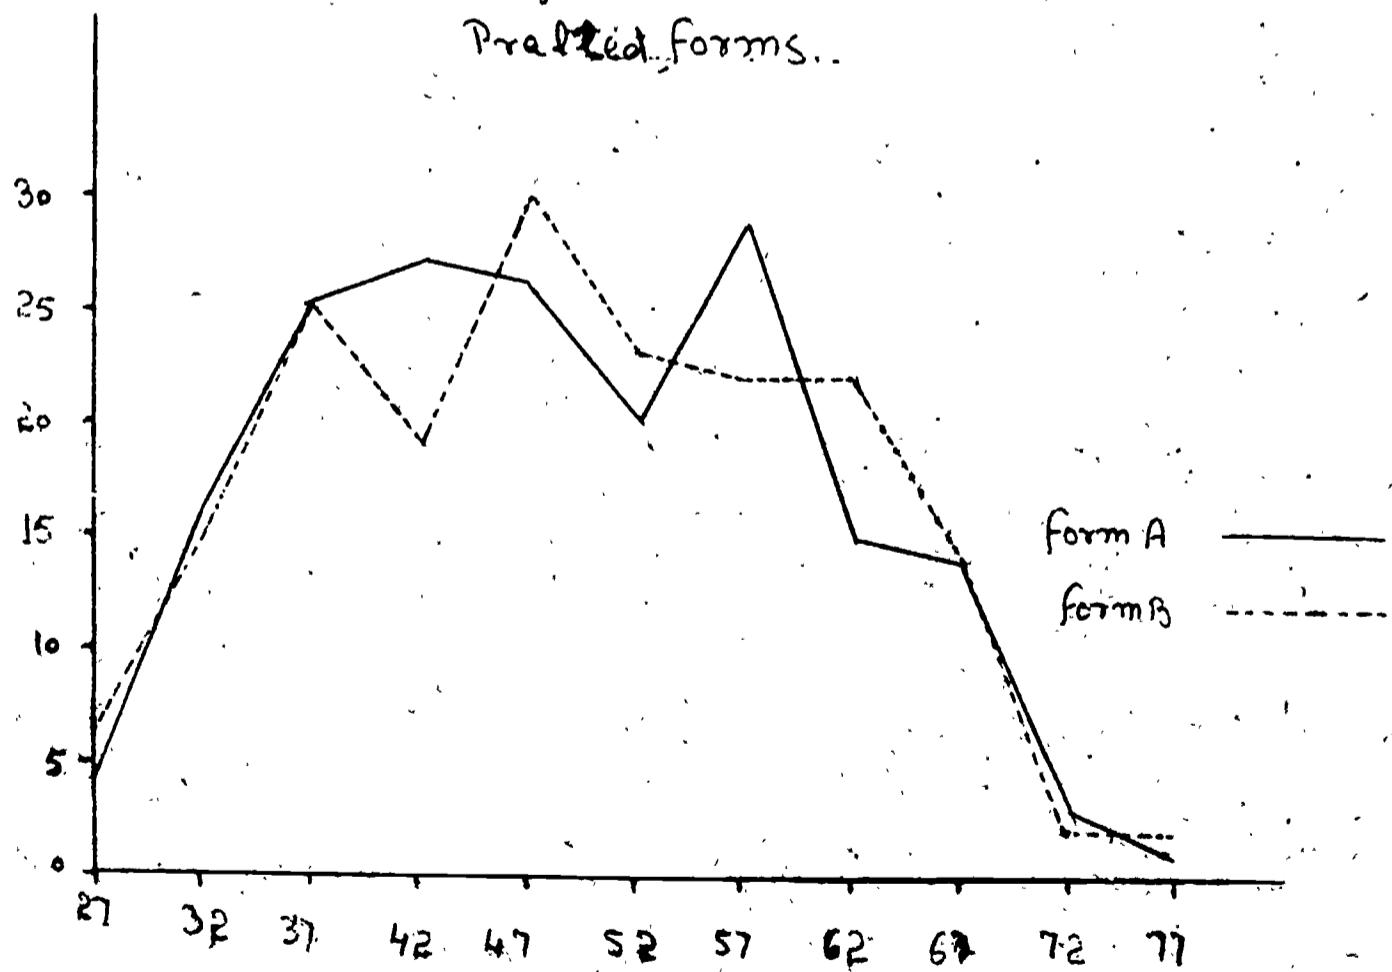

Pass Per- centages.	No. of Items		Grade - XI

Graphs of two sets of distributions though not identical are overlapping in the entire range.

Distribution of Item Difficulties in
Parallel Forms.

Distribution of Item Difficulties in
Parallel forms.

The investigator has found it difficult, with this data in hand to answer the question on equivalence of the forms either positively or negatively. Small studies will have to be conducted in all the five States to check parallelism of the two forms. Since the indices used in dividing the items were overall averages, the chances of forms being different for different States remain. At present only a study conducted in Delhi is being reported. Both the forms were given to children of grades VIII and XI of three Schools in Delhi. In each grade, alternate children were given form A or B. The procedure of administration of the tests as laid out in the manual of instruction was followed. Table 11 (a & b) gives the data available from this study.

Total N Form	30.65	31.03	150.71	145.95	1.57	.35
V + N	98.00	99.35	711.34	599.70	3.33	1.35

$$N_A = 129, \quad N_B = 110$$

Although none of the differences i.e. for forms V, N or total are significant, in all cases means are somewhat higher for form B. This is also consistent with last row of Table-10.

Under the circumstances separate norms have been given for the forms.

Reliability:

From the randomly selected samples of 200 cases from each State, reliability coefficients (by KR-20) were obtained for each subtest separately. The range of these values is listed below:-

Table - 12.
Range of Reliability Coefficients
over the States.

S.No.	Grade - VIII		Grade - XI	
S.No.	Name of the Variable	Range of Values.	S.N. Name of the Variable	Range of Values.

These reliability coefficients were used to estimate battery reliability by Mosier's formula¹,

$$\rho_{ss} = 1 - \frac{\sum w_j^2 \sigma_j^2 - \sum w_j^2 \sigma_j^2 \bar{x}_{jj}}{\sum w_j^2 \sigma_j^2 + 2 \sum w_j w_k \sigma_j \sigma_k \bar{x}_{jk}}$$

1. Mosier, C.I. on the reliability of a weighted composite Psychometrika, 1943, VIII, 161-168.

Table 13

Battery Reliability for Forms V, N and Total

State	Grade VIII						Grade XI					
	A			B			A			B		
	V	N	V+N	V	N	V+N	V	N	V+N	V	N	V+N
Delhi	.94	.90	.95	.95	.93	.96	.93	.96	.95	.93	.95	.96
Uttar Pradesh	.96	.92	.97	.96	.92	.97	.94	.97	.97	.94	.96	.96
Rajasthan	.93	.90	.95	.93	.91	.94	.93	.98	.97	.92	.97	.96
Madhya Pradesh	.95	.90	.96	.95	.93	.97	.92	.94	.95	.94	.96	.96

In some States some schools were persuaded to administer both the forms from which parallel form reliability could be estimated. Since the demand on time made in here was very heavy.

The School administrator in general was reluctant to help. Since the tests were administered on consecutive days, children also felt tired or bored. The data as available are given below :-

: 72 :

Table - 14

Reliability Coefficients from Parallel Forms

States from which obtained.	Grade - VIII				Grade XI			
	No.	V	N	V+N	No.	V	N	V+N
Madhya Pra- desh.	338	.31	.86	.86	246	.36	.80	.91
Rajasthan	106	.31	.41	.81				
Delhi					103	.73	.75	.80
Combined from Delhi Madhya Pradesh and Rajasthan,	581	.80	.73	.83	393	.34	.30	.89

These Coefficients are smaller than the ones set out in table 17(a&b) Appendix II. Fresh investigations need to be made about parallel-form reliability where motivation of the students of the students and teachers could be assured..

21	58	46	53	34	32	40

1. Pass percentages were obtained by dividing the frequency for the correct answer by N-NR. The figure in each column is the unweighted average of percentages available from various strata in a State.
2. Median value of discrimination indices for various strata as read from Davis' chart.
3. The items are given as arranged in the final form.

- Pass percentages were obtained by dividing the frequency for the correct answer by N-NR. The figure in each column is the unweighted average of percentages available from various strata in a state.
- Median value of discrimination indices for various strata as read from Davis¹ chart.
- The items are given as arranged in the final form.

1. Pass percentages were obtained by dividing the frequency for the correct answer by N - NR. The figure in each column is the unweighted average of percentages available from various strata in a state.

2. Median value of Discriminating indices for various strata are read from Davis Chart.

3. The items are arranged as they appear in the final form.
