     Manpower Development and Training Act (MDTA) programs completed in 1965
were evaluated by benefit-cost ratio and internal rate of return. Initial annual
earnings differential figures at $525,650 and $719,629 were projected into the
future at various rates of promotion and various rates of discount on the benefit
stream. Resulting lifetime benefits (for 30 working years) range from $2,556,110 at a
zero promotion rate and 20 percent discount rate on the first figure to $15,162,977
at a 3.5 promotion rate and a 5 percent discount rate for the $719,629 figure. These
projected benefits may be compared with the total program cost of $3,097,616. On
the other hand, the internal rates of return on the training outlay of $3,097,616
range from 16.29 percent at zero rate of promotion for the $525,650 figure to
26.20 percent at the 3.5 rate of promotion for the $719,629 figure. An alternative
for the cost outlay would have to exceed the rate of return if the training were to be
considered economically unprofitable. It was concluded that, under the circumstances
and assumptions of the study, training conducted under MDTA is worthwhile with
benefits greatly exceeding costs and internal rates of return high. Assessments of
individual programs are also provided. (JK)

PRELIMINARY REPORT.

A BENEFIT COST ANALYSIS OF THE

SOUTH CAROLINA MDTA PROGRAM.

Prepared for and with the Cooperation

Of the Research Department

South Carolina State Employment Security Commission
Research Dept.
Columbia, South Carolina

By

The Bureau of Business and Economic Research.

College of Business Administration

University of South Carolina

PREFACE

The research reported herein was performed pursuant to a $5,000 grant from the South Carolina Employment Security Commission. Points of view or opinions stated do not necessarily represent official South Carolina Employment Security Commission position or policy.

In obtaining and tabulating data for a project of this nature, the cooperation of numerous people is necessary. The following were particularly helpful: James F. Kane, Dean, College of Business Administration, Charles E. Edwards, Director, Bureau of Business and Economic Research, College of Business Administration; Bryan Richey, Chief of Research and Statistics, William Powell, Junior Labor Market Analyst, Mrs. Pinckney Holmes, Senior Labor Market Analyst, Mary Baldwin, Administrative Assistant MDTA, Paul Jarvis, Chief of Manpower Training, all with the South Carolina Employment Security Commission.

James W. Robinson, Associate Professor of Business Administration, Virginia Polytechnic Institute, provided an excellent analysis of individual benefits resulting from the MDTA program under study. Although his analysis does not appear in this report, it has been given to the South Carolina Employment Security Commission. If this study is expanded, his analysis will appear in the later report.

Wendell Smith and Pierce Liles, graduate students at the University of South Carolina, contributed significantly to this study. Their tireless efforts in the frustrating task of compiling various comprehensive tables from sometimes non-comparable data are appreciated. Paul DeQuae did an excellent job with the computer programming. All of the typing was done most efficiently by Flora Lee Kees.

Any errors found herein are, of course, attributable only to the project director.

B. F. Kiker

I.   THEORETICAL MODEL

Investment in area MDTA training is considered an important factor affecting labor productivity and, hence, wages and employment.   The increase in relative earnings affects saving, investment, and thereby the growth of the region.   Through training an individual can increase his productivity, reduce the probability of his being unemployed by increasing his adjustability to changing job opportunities, and, hence, increase his lifetime earnings.

In order to investigate the significance of MDTA training to the structure of relative earnings and economic growth, it is necessary to analyze expenditures on training as a process of capital formation. The process and its results can then be compared with other types of investment in order to develop a better understanding of the special contribution of training to economic growth.

We have chosen to treat all expenditures on MDTA training as investment.   Although a portion of these expenditures may have been responsible for current consumption by the trainees, this portion would have been small.

Our criteria for evaluating the program are (1) benefit-cost ratio and (2) internal rate of return. The former criterion consists of estimating and comparing the benefits and the cost of the training program. The latter criterion consists of estimating the rate of discount (internal rate of return) that equates the benefit stream, that results

from the training, to the cost of the training program and comparing it with the opportunity cost of the investment funds (that is, the highest rate of return on investment opportunities sacrificed). Although there are conceptual difficulties associated with both criteria, each appears to be "correct" in evaluating a "sponsoring agency" program.

The essence of these kinds of analyses lies in their ability to evaluate the total value of benefits of a program against the total costs. Basic elements in these analyses are benefits, costs, time, and the interest rate by which to discount the benefits and costs. The benefits and costs of training usually occur through time--although in the case of the projects under study all costs were incurred in one time period.

A major concern of our analysis is with the determination of benefits (in the sense of social welfare gained) and costs (in the sense of social welfare foregone). Not only must these benefits and costs be identified but they must be measured in monetary terms. Neither of these are easy tasks. Although we are equating benefits to earnings differentials attributable to training, there is evidence that training results in reductions in public assistance and other social services (e.g. crime prevention); training generates tax revenues, provides skills for smooth transitions resulting from structural changes in the labor market, transmits existing knowledge, thereby laying the foundation for the extension of knowledge. Training also provides individual "psychic" as well as social benefits which, of course, cannot be quanti-

fied. (In all of the MDTA training courses under study basic education was offered. Such instruction included topics under elementary arithmetic, personal hygiene, language arts, etc. In view of this, a considerable portion of benefits may not be calculable. In other words, training for a given competence was only part of total training.)

On the other hand, benefits from training depend upon the supply and demand for the trainee's skill. Unless there is a demand for the knowledge or skill acquired by the trainee, his earnings differential stream may be zero. The greater the demand for his skill relative to the supply, the larger will be the earnings differential stream. Moreover, benefits defined as earnings differentials will be overstated if trainees displace other (presumably, untrained) workers. A reasonable assumption for South Carolina, however, is that no displacement occurred. The demand for the skills of those trained under MDTA in South Carolina greatly exceeded the supply.

Costs include outlays for items such as: instructors' salaries, supplies, heat, light, rental values of building and equipment, incidental costs to the trainees associated with training, and earnings foregone while in training--if appropriate.

Albeit the cost of training is incurred in the present, the benefits accrue over time, and since individuals have positive time preferences--that is, future income is valued less than present income--discounting obviously is necessary. Moreover, the interest rate used in discounting represents the opportunity cost of investment funds. It may

also represent in part a risk factor. Certainly risk and uncertainty reduce the value of any stream of future benefits, and it is possible to account in part for this by employing a discount rate that includes a risk factor.

One of our approaches to assessing the area MDTA training program is to find the total benefit resulting from the training and relate it to the total cost of the training. The total benefit (B) is determined by discounting the annual benefits (b) at the appropriate interest rate (i). The formula for determining B is:

$$B = \frac{b_1}{(1+i)} + \frac{b_2}{(1+i)^2} + \cdots \frac{b_n}{(1+i)^n}$$

where:

$$b_1 = b$$

$$b_2 = bv \left[1 - \frac{P(2)}{2}\right]$$

$$b_3 = bv^2 \left[1 - \frac{P(3)}{2}\right] \left[1 - P(2)\right]$$

$$\vdots$$

$$b_n = bv^{n-1} \left[1 - \frac{P(n)}{2}\right] \left[1 - P(n-1)\right] \cdots \left[1 - P(2)\right]$$

and

b_t: Annual benefit measured at the end of the appropriate year t.

b: Annual benefit at the end of year one; therefore, the promotion rate and mortality factor are included, i.e., $b_1 = b$.

v: Annual rate of promotion (promotion is synonymous with an increase in productivity and, hence, real remunera-

tion).

P(t): Proportion of persons alive at the beginning of the year who die during the year. For example, P(2) = proportion of persons alive at beginning of year two who die during the year. Since individuals die throughout the year, we have assumed that on the average they will die in the middle of the year. Hence, we assume that half of the annual earnings of those who die will remain in the benefit stream during the year of death.

n: The age at which the trainee retires from the labor force.

The benefits (B) must be compared with the total cost of training (C) to determine the "profitability" of the training projects. If $B > C$ or $(B / C) > 1$, we may assume that the area MDTA program was "economically profitable." If, on the other hand, $B < C$ or $(B / C) < 1$, the program was "unprofitable." This may not mean, however, that the training was not worthwhile; it may mean that it was carried on inefficiently. Even if the training program was conducted efficiently and $B < C$, attendant uncalculable psychic and social benefits may yet justify the training.

Our other approach to evaluating the area MDTA program is to find that rate of discount (r) that will equate the annual benefit stream (b) back to the cost of the training program (C). This internal rate of return (r) can be determined from the formula:

$$C = \frac{b_1}{(1+r)} + \frac{b_2}{(1+r)^2} + \cdots + \frac{b_n}{(1+r)^n}$$

The program may be termed "profitable" if $r > i$, where i is the oppor-

tunity cost of investment funds.

In assessing the "economic profitability" of programs, these approaches usually give the same results. We have chosen to present both criteria so that the reader may compare the B/C ratio and/or internal rates of return which have been calculated for the program under study with other comparable B/C ratios and internal rates of return that have been estimated.

II. EMPIRICAL MODEL

Introduction

This study examines only institutional training projects completed in South Carolina during calendar year 1965, though some of these may have begun in the preceding year. No on-the-job training projects were ended in this state under MDTA in 1965. Although about 250 institutional training projects were in progress with about 5,000 trainees in 1965, only 119 training courses were actually completed. Of these, however, there were 28 different types of projects. In other words, this study is concerned with training for 28 different occupations. To each different type of project there corresponds a certain DOT (Dictionary of Occupational Titles) code. When more than one project falls under a particular DOT, it is because nearly identical training was offered in different cities or in the same city at different times.

Many individuals who were offered training during the period under study did not continue to completion. Of the 2,768 to whom an opportunity for MDTA training was tendered, only 2,538 became enrolled by remaining in attendance five days after instruction began. Among those enrolled, 239 trainees dropped out to secure employment and 514 left for unknown reasons. Hence, for the projects covered in this study, 1,785 individuals became MDTA graduates (Graduates II) (Table 1). For each of these persons, the South Carolina Employment Security Commission (SCESC) completed several forms in order to derive statistical data. If one or

more of these forms on a given graduate were unavailable, then that grad-
uate was excluded from this study. Deducting 73 such individuals, there
remain 1,712 graduates (Graduates I) on whom fairly complete statistical
information was available (Tables 1 and 2).

One year after course completion, 1,089 of the 1,712 Graduates I
were contacted. The remaining 623 could not be located by the local ES
offices (Table 2). Apparently, the attempt to contact MDTA graduates
was not a truly diligent undertaking; probably this is a manifestation of
deficiencies in time and personnel rather than of negligence. The
follow-up did, however, reveal that 813 had sought and obtained employ-
ment, 194 were unemployed, and 82 had withdrawn from the labor force
(Table 2). Some 29 of the younger graduates had never been employed
prior to training. For these individuals, obviously, no measure of pre-
training earnings was available. Accordingly, there remained only 784
employed Graduates I for whom both pre-training and post-training earn-
ings were known.

While we are aware that a comparison of post-training and pre-
training earnings is not the best procedure for estimating wage differen-
tials, a funds and time constraint prohibited setting up a control group
of nontrainees. Given adequate funding and a longer period of time with-
in which to complete the study, we would have compared the trainees'
experience with that of a control group of nontrainees. The control
group would have been composed of persons who had been accepted for
enrollment in the MDTA program but who, for various reasons, had not

enrolled.

It is interesting to note that during 1964 and 1965 those who enrolled in MDTA programs were 60 per cent Negro; 53 per cent of the male enrollees and 70 per cent of the female enrolees were Negro. Virtually all MDTA trainees were unemployed before commencement of training (an average of 19 weeks' unemployment before entering training, though 45 per cent had been unemployed less than five weeks). Yet, fewer than one per cent were receiving unemployment compensation or public assistance.

Benefits

Benefits in terms of enhanced earning power may be disclosed by finding wage differentials. This has been done for the 784 employed Graduates I. For this group average straight-time hourly earnings before training was $.93 (Table 3, Column 2). Precisely one year after training was completed, the comparable amount was $1.26 (Table 3, Column 3), an hourly wage differential of $.33 (Table 3, Column 4). Though both the pre-training and post-training figures appear meager, the latter represents a 36 per cent improvement.

It is, perhaps, more useful to view wages from the perspective of the work week. Average individual pre-training wages based on a 40-hour work week were approximately $37 (Table 3, Column 7), whereas after training the comparable figure was $50 (Table 3, Column 8). Assuming a 50-week work year, average individual post-training earnings were $2,528 (Table 3,

Column 10). The comparable figure prior to training would have been $1,857 (Table 3, Column 9). The difference, about $670 annually, is multiplied by the employed Graduates I (784) estimate to obtain a total (or aggregate) earnings differential of $525,650, which is assumed to be attributable to the MDTA training (Table 4, Column 2).

Obviously all of the employed Graduates I were not employed throughout the entire year. In fact, they were employed an average of 83.5 per cent of the 52 weeks following the end of training. According-ly, it might be desirable to reduce the $525,650 estimate of the annual benefit to $438,813 (Table 4, Column 6). (This methodology, of course, assumes that the wages of each employed trainee remained precisely the same throughout the year.) It is apparent that the total benefit to all graduates could scarcely be less than $438,813 during the first year following the training. As shall be posited below, a more realistic estimate of benefits would be much higher.

It is reasonable to assume that 784 graduates would be employed at all times in the first 50-week year, though not necessarily the same ones. In effect, we would have a revolving pool in which as one person left, another took his place. More precisely, this means that for each of the 784 who was unemployed at some time during the first year there corresponds one other graduate of the unemployed group who was employed (at the same wage) during the former's unemployment. Any graduates who worked some but who are not included above are assumed not to have work-ed at all. Again, a constant wage during the year is postulated. Given

these assumptions, the benefits issuing from training would be the first estimate given above, $525,650. This is, of course, a considerable sum. Again, however, benefits may be understated.

More than 600 of the graduates could not be located. Also, there were 73 additional graduates included in Graduates II. We have assumed, perhaps unrealistically, that the employment experience of these persons (for whom we have no record of success or failure in the labor market) was similar to that of those Graduates I who could be located. About 75 per cent of Graduates I who could be located were found employed (Table 5, Column 2). Hence, it can be concluded that about 75 per cent of those who could not be located and of the additional Graduates II were employed. Thus about 458 and 54 more graduates were probably employed, respectively, in the two categories mentioned above.

A further assumption is that the wage experience of these individuals was similar to our initial group of 784. In other words, hourly wages increased about $.33. Multiplying the hourly wage differential by the number of those "probably" employed, and, again, by 40 hours and 50 weeks, we have additional benefits of $336,386 (Table 5, Column 7). Adding $525,650 and the new amount, the resulting figure is $862,037 (Table 4, Column 3). However, the group of 754 were employed only 83 per cent of the time (Table 4, Column 4). In view of this, the benefit figure has been reduced correspondingly to $719,629 (Table 4, Column 5). This assumes that graduates who were not contacted had the same employment and wage experience as the 754 who were employed. Of course, the benefits to

the 29 who had no pre-training employment experience were ignored.
Benefits are understated further to the degree that training (both gener-
al and specific) assists trainees who did not graduate.

Although three different representations of annual benefits accru-
ing to trainees have been presented, the estimate of $438,813 is unreal-
istically low. Hence, it should not be considered further. Each of the
other two estimates is confined to and couched within certain assump-
tions. The reader must determine for himself those assumptions he deems
most realistic. He may then intelligently appraise the value of the two
estimates.

Since the benefits of training obviously accrue over time, it is
necessary to view benefits from the vantage point of the long run. The
average age of the group of 784 was 35 years when training began (Table
3, Column 1). If they were to retire at age 65, there would remain 30
working years in their lifetime. Hence, it is necessary to estimate
the benefits for graduates over the remainder of their working lives.
It is inappropriate simply to multiply the annual earnings differential
by the number of remaining working years. In projecting an earnings
stream into the future, it is necessary to capture an approximate rate
of increase in worker productivity. Accordingly, various rates of pro-
motion were assumed. The SCESC contrived one of these (3.5 per cent) by
employing a least squares equation on a statistical series for the years
1949 through 1967. The equation, used to anticipate probable earnings
changes of graduates over time, reflected relative variations in earn-

ings of the South Carolina labor force participants. Thus, state average hourly earnings in covered employment became inputs in the construction of the equation. Any other measure of income would not have been directly compatible with the desired earnings increases per trainee. Although this rate is included in Tables 6 and 7, it is unrealistically high since it reflects an inflationary and industry-structure change which may not be repeated in the future. It is assumed that one of the rates given in Tables 6 and 7 will reflect properly the rate of promotion of both graduates and non-graduates since we have no empirical basis for suggesting that MDTA graduates will advance more rapidly than their untrained cohorts. The foregoing assumption is implicit in the fact that benefits were computed over time as the difference between pre and post-training income (one rate of promotion could have been assigned to pre-training earnings, another one to post-training earnings). To each of the two aggregate benefit figures the stated rate of promotion over 30 years was applied.

We cannot merely sum the yearly benefits including promotions. Costs were incurred in the present; benefits did not occur similarly or simultaneously. Hence, for compatibility, it becomes necessary to place benefits in present-value terms. In addition, some of the graduates will die during the ensuing 30 years. To account for mortality, the benefit stream was diminished annually by an amount commensurate with the death rate for South Carolinians at each age level up to 65. Persons who die were assumed to have died in the middle of each year.

Perhaps at this juncture an example of the procedure for calculating the benefit stream would be helpful. The theoretical model presented above may be written as

$$B = \frac{b}{(1+i)} + \frac{bv\left[1- \frac{P(2)}{2}\right]}{(1+i)^2} + \frac{bv^2\left[1- \frac{P(3)}{2}\right]\left[1- P(2)\right]}{(1+i)^3} + \ldots$$

$$+ \frac{bv^{n-1}\left[1- \frac{P(n)}{2}\right]\left[1- P(n-1)\right] \ldots \left[1- P(2)\right]}{(1+i)^n}$$

where the variables are the same as defined above. B may be replaced by C and i replaced by r, to find r, the internal rate of return. Each numerator on the right hand side of the equation corresponds to b_1, b_2, b_3, ... b_n in the earlier benefit formula.

Assume that one year after completion of training the total earnings differential of all 28 MDTA training projects was $525,650, our low estimate. We found that the average age of the trainees one year after completion of training was 36 years. Further, the rate of promotion is assumed to be 3.5 per cent. Hence, the benefit stream is:

$$b_1 = \$525,650$$

$$b_2 = \$525,650 \ (1.035)\left[1- \frac{.00335}{2}\right] = \$543,136.46$$

$$b_3 = \$525,650 \ (1.035)^2\left[1- \frac{.00360}{2}\right](1-.00335) = \$560,192.88$$

.

.

o

$$b_{30} = \$525,650 \quad (1.035) \left[1 - \frac{.02978}{2}\right] \quad (1-.02771) \quad \ldots$$

$$(1-.00335) \quad = \quad \$985,486.26$$

where   .00335 = the proportion of persons alive at the beginning of year aged 36 and who die between the ages of 36 and 37.

.00360 = proportion of persons alive at age 37 who die between the ages of 37 and 38.

In essence,

b_1 =   \$525,650.00   =   earnings at age 36

b_2 =   \$543,136.46   =   earnings at age 37

.

.

.

b_{30} =   \$985,486.26   =   earnings at age 65.

These earnings have not been discounted and, of course, cannot be summed to obtain the total economic benefits attributable to the 1965 area MDTA training.

As was pointed out earlier, a major difficulty in calculating a benefit-cost ratio is selecting the appropriate interest rate. We have discounted the benefit stream at four rates of interest, five, ten, fifteen, and twenty per cent. The low rate was chosen because it represents roughly the cost of acquiring federal funds. The higher rate was selected to account for the fact that we are more concerned with more immediate benefits than very long-run ones. The most realistic rate is either 10 or 15 per cent. Obviously, the higher the discount rate, the more the emphasis is put on more immediate benefits relative to distant

ones.

Costs

The Department of Health, Education and Welfare and the Department
of Labor, which during the period of this study financed MDTA in
South Carolina, required that the SCESC office estimate and itemize all
costs associated with proposed training programs under MDTA. These esti-
mates are itemized on standard forms (MT-2 and OE-4000). These forms
for approved training projects are the bases of our cost estimates. How-
ever, where actual costs differed from estimated costs, the latter were
made available by SCESC and used. The costs of all the MDTA projects
have been aggregated on a DOT code basis. This was done because our
analysis is predicated upon an examination of costs and benefits by
different types of projects rather than by individual projects (when
more than one project falls under a particular DOT, it is because almost
identical training was offered in different areas in the state or in the
same area at different times). Many of the cost items were itemized in
a useful context and required mere summing by DOT. Other items, however,
were difficult to estimate and had to be imputed. The procedures for
estimation and imputation are presented below.

The total training costs (including allowances) are summarized in
the following categories:

    (1) Allowances (C_e = \$1,566,621)--weekly payment to the train-
ees over the entire training period.

(2) Executive administration cost (C_{ea} = $47,005)--earnings of SCESC personnel engaged in planning, coordinating, and keeping statistics on the MDTA projects.

(3) Allowance administration (C_{aa} = $62,108)--the cost of administering the allowance program.

(4) Selection and placement administrative cost (C_{spa} = $143,520)--the expense of selecting trainees and placing them after completion of training programs.

(5) Instructional supplies (C_{is} = $230,887)--this category includes the cost of items such as notebooks, pencils, rags, brooms, junk automobile parts, various types of lumber, etc. Obviously, items in this category would vary with the nature of the training. No item included in this category was thought to last more than one project.

(6) Instructional services (C_{iser} = $651,888)--cost in this category includes remuneration for instruction and local supervision.

(7) Fixed charges (C_{fc} = $87,062)--this category includes rental charges for non-public space plus the employer share of employee (non-trainees assisting in the training projects) benefits.

(8) Utilities, custodial, and maintenance (C_{ucm} = $82,502)-- charges for telephone, electricity, water, minor repairs, janitorial service, etc. are included in this category.

(9) Rental opportunity cost (C_{ro} = $31,878)--a charge was imputed to each project conducted in public space.

(10) Equipment and repairs (C_{er} = $194,145)--this category includes costs for transportation, installation, and repair of equipment, in addition to an estimate of the cost of any equipment used in the project. Also, rental of equipment (such as farm machinery) is included in this category.

All of these costs are enumerated by training project and aggregated in Table 8.

The categories given above are essentially those used by SCESC or

were easily derived therefrom. Owing to the difficulty of treating numerous categories, we further subsummed these cost items in the categories of administration (C_a), allowances (C_e), instruction (C_i), and plant and equipment (C_p). Total costs (C), of course, would be the sum of these four items. In essence:

$$C = C_e + C_a + C_i + C_p$$
$$\$3,097,616 = \$1,530,995 + \$252,633 + \$882,775 + \$395,587$$

where

$$C_e = C_e$$
$$\$1,566,621 = \$1,566,621$$

$$C_a = C_{ea} + C_{aa} + C_{spa}$$
$$\$\ 252,633 = \$\ 47,005 + \$\ 62,108 + \$143,520$$

$$C_i = C_{is} + C_{iser}$$
$$\$\ 882,775 = \$\ 230,887 + \$651,888$$

$$C_p = C_{fc} + C_{ucm} + C_{ro} + C_{er}$$
$$\$\ 395,587 = \$\ 87,062 + \$\ 82,502 + \$\ 31,878 + \$194,145$$

The condensed categories of costs are presented in Table 9.

Most of the cost items are enumerated by SCESC in a useful manner. The following cost items, however, provided some estimation and/or imputation difficulties: rental opportunity (C_{ro}), equipment and repairs (C_{er}) and administration (C_a).

Rental Opportunity Cost

For many of the training projects, space was available in public facilities in the state. In this event there was no rental figure in the cost profile. Presumably, however, there is an opportunity cost associated with using these facilities. To account for this cost an amount for rent was imputed to each project conducted in public space. If, under a DOT code, any of the projects were performed in public space, the average rental for other training courses under the same DOT code in which rental data were available (that is, when training was done in non-public space) was imputed to the projects. When cost data were unavailable under the same DOT code, rental cost (appropriately adjusted for possible varying lengths of training courses) of a project requiring what we deemed to be similar facilities was imputed to the projects for which rental data were unavailable.

Equipment

Costs for repairs and transportation of equipment (much equipment was transferred from center to center) were well-defined in SCESC records. For many of the programs, however, equipment costs were not distinct and had to be estimated. There were obvious reasons for this: (1) equipment may have been purchased previously for use in MDTA projects; (2) the state may have acquired the equipment under programs other than MDTA; (3) the entire purchase price was included in the 1965 cost profile if required equipment was unavailable at the time of

appropriation request.

Since there is a cost even if equipment was available, it was necessary to devise a procedure for estimating a portion of the institutional price of each piece of equipment utilized (whether newly purchased or transferred). An estimate of the useful life span of each piece of equipment was made by an appropriate state employee. The longevity estimates of the equipment used spanned one to fifteen years, the length depending upon the durability of the item. We, of course, assumed reasonable care and maintenance. Our calculation of the equipment costs proceeded in the following manner.

The length of time in weeks (T_p) that each project lasted was divided into total time (T_t = 52 weeks). In a given project, this number was multiplied by the anticipated life of each piece of equipment (L). To obtain that portion of the total cost (C_{er}) of a piece of equipment to impute to a particular project, the figure last obtained was divided into the item's price (E_p). That is,

$$C_{er} = \frac{E_p}{\frac{T_t}{T_p} \times L}.$$

Employing this technique, we have insured a more substantial equipment valuation for the lengthier project.

Our final modification in our equipment estimates was required. Some of the equipment was not in use perpetually, as the foregoing methodology assumes. Much of the equipment, if not in use under MDTA,

was in use in technical education centers throughout the state. However,
an appropriate source indicated that about 15 per cent of the equipment,
in money terms, was in storage or transit continuously, though not the
same equipment week after week. As a correction of this, 15 per cent
was added to the adjusted cost of equipment for each DOT code.

Administration Costs

Costs were incurred by the local SCESC office for planning, allow-
ance administration, placement, and other administration. Administra-
tion costs on the project level are included under instructional
services.

During the fiscal year 1965, the services of 9.4 individuals were
required in planning, coordinating, and keeping statistics on the MDTA
programs. Since the salaries of these employees were given for the
fiscal year 1965, an adjustment upward was made to account for promo-
tions and salary increases which were incurred during the ensuing six
months of the calendar year under study. The earnings of the group has
been termed executive administration cost, the sum of which was appor-
tioned equally among the projects. Obviously, the amount apportioned
per DOT code depended upon the number of projects under the particular
DOT code.

An expense to any large employer is that surrounding the issuance
of checks. A great deal of money was expended for allowances to the
trainees during their training. In addition to the actual amounts of

the payment, a legitimate cost consideration is the cost of administer-
ing the allowance program. In many of the project cost profiles an
amount was provided to cover this expense. For each project for which
allowance administration cost was listed, the average (per prospective
trainee) allowance administration cost was divided by the number of
weeks which the project lasted. This gave the average weekly allowance
administration cost. This cost ranged from approximately $1.04 to
$1.44; the average was $1.1466. For some DOT codes no average allow-
ance administration cost was given for any of its projects. In these
cases, an estimate of $1.1466 was used. If a particular DOT code had at
least one average allowance administration cost listed for one of its
projects, this figure was used to estimate average weekly allowance
administration cost for all projects under the DOT code. If under one
DOT code several averages were listed, then the modal one became the
average weekly allowance administration cost estimate. Accordingly, for
each unlisted average allowance administration cost an amount was imput-
ed to each project by multiplying the number of weeks times the appro-
priate average weekly allowance administration cost. Allowance adminis-
tration costs per prospective trainee averaged approximately $22.00
within the duration of each project; the most significant factor in
deviation from this figure was project length.

Allowance administration cost was derived for each project by
multiplying the number of prospective trainees times its particular
average allowance administration cost. The total for all training

embraced in the study was obtained by summing, under each DOT code for all 119 projects.

Selection and placement, finally, are further cost items which were estimated. Some cost prospectuses contained average and total estimates of such costs. The range in the averages was from about $46.00 to $55.00, with no apparent correspondence between this cost and the number of weeks or number of trainees in the project. Hence, no systematic method could be applied to arrive at an average to impute to those projects for which a figure was not listed. Through ad hoc reasoning we obtained an estimate of $52.00, which when multiplied by the appropriate number of trainees, becomes a project's selection and placement administration cost.

III. CONCLUSION

By projecting the annual total benefit estimate (b) of $525,650 into the future at various rates of promotion, appropriately consider- ing the probability of mortality, and discounting the benefit stream at various rates of interest, estimates of lifetime benefits (B) to society resulting from the 1965 MDTA training program under study are deduced and shown in Table 6. If, for example, the rate of promotion is 3.5 and the discount rate is 10 per cent, the benefit estimate is $6,332,203. These benefits can be usefully compared with the total cost of conduct- ing the program, $3,097,616 (Table 9) to determine its "economic profit- ability."

The internal rates of return on the training outlay ($3,097,616), using the annual benefit estimate of $525,650, appropriately adjusted to account for promotion and mortality, are given in Table 10. If, for example, the rate of promotion is 3.5, the internal rate of return is 19.7. Hence, an alternative for the cost outlay would have to exceed 19.7 per cent before the training under study could be said to be "economically unprofitable." If the opportunity costs were five and ten per cent, the sponsoring agency could incur the costs $11,075,733 and $6,332,202, respectively, for training and still "break even."

Treating the annual total benefit estimate of $719,629 in the same manner in which the lower estimate was treated, estimates of lifetime benefit to society resulting from the training under study are calculat-

ed and given in Table 7. If the promotion rate is assumed to be 3.5 per cent and the discount rate is 10 per cent, the total benefit estimate is $8,668,956.

The internal rate of return calculated from the higher benefit stream ($719,629), assuming a promotion rate of 3.5 per cent and accounting for mortality, is 26.19 per cent (Table 11).

It is apparent that under the circumstances and assumptions of this study, training conducted by the SCESC under MDTA is worthwhile. Benefits greatly exceed costs and the internal rates of return estimated are exceedingly high.

Along with assessing area MDTA training completed in 1965 in the aggregate, we have evaluated each of the 28 projects individually. Of these projects the estimated benefits and costs of those with 17 or more graduates are given in Tables 12 through 33. These benefit-cost ratios indicate the "profitability" of individual training programs, e.g., nurses aide and carpenter. Moreover, we are able to deduce from the results the maximum average age ("break-even" age) at which trainees could have begun work and the social benefits still resulted in a benefit-cost ratio greater than unity. For example, we found that the benefit from training 182 individuals with an average age of 36 to be nurses aides was $753,712, assuming a "low" initial earnings differential (i.e., considering only those who were contacted and employed) and accounting for promotion (in this case assume zero rate of promotion), mortality, and time (discounting at 10 per cent). The cost of training these indi-

viduals was $333,841. Hence, the benefit-cost ratio is high and, given these assumptions, society could still have recouped all the cost of training if the average age of the trainees had been approximately 60 years. If, on the other hand, the average age of the trainees had been 21 years, given the assumptions above, the benefit from the training would have been $808,193 (Table 12). The same type information for the 341 nurses aide Graduates I, assuming a "high" initial earnings differential (i.e., considering all those who completed training), is given in Table 13.

The benefit from training 78 carpenters with an average age of 39 was $593,083, assuming an annual rate of promotion of 2.0 per cent, appropriately accounting for mortality, and discounting at 10 per cent. If the average age of these trainees had been 21 years, given the assumption above, the benefit from training would have been $681,313. The cost of training these individuals was $548,067. If we assume a 10 per cent discount rate and a zero rate of promotion for these carpenters, the "break-even" age is 28 years (Table 14). The same type information for the 187 carpenter Graduates I is given in Table 15.

It is strongly recommended that additional work on this project be pursued, for a number of reasons. The project should be expanded to include data for area training conducted under MDTA and completed in 1966. These data should be analyzed in the same manner as the 1965 data.

The benefit-cost ratios which we have determined are, of course, total-benefit - total-cost ratios, whether for all projects combined or for individual projects (training under a particular DOT code). As a

tool for decision making, however, it is necessary to calculate <u>marginal</u> (incremental)-benefit - <u>marginal</u> (incremental)-cost ratios. If it is found that a <u>total</u>-benefit - <u>total</u>-cost ratio is high (or higher than another comparable B/C ratio), one can say that the project under evaluation is "profitable." One cannot, however, say that more funds should be expended on the project with the high (higher) B/C ratio. In order to make policy decisions of this nature, it is necessary to utilize marginal (incremental) data. It will be necessary to determine the difference between 1966 and 1965 benefits (B) and costs (C). In essence, if

$$B_{1966} - B_{1965} = \Delta B$$

$$C_{1966} - C_{1965} = \Delta C$$

and $(\Delta B / \Delta C)$ exceeds unity, more training funds could be profitably expended on area MDTA training.

Given adequate financing, we could determine <u>marginal</u>-benefit - <u>marginal</u>-cost ratios for all of the individual (DOT) training programs for which we have both 1965 and 1966 data. The maximization of social benefits resulting from the training is achieved if the ratio of marginal benefits of the individual training projects is equal to the ratio of the marginal costs of these projects, i.e.,

$$\left[\frac{\Delta B}{\Delta C}\right]_1 = \left[\frac{\Delta B}{\Delta C}\right]_2 = \ldots = \left[\frac{\Delta B}{\Delta C}\right]_n$$

where the subscript refers to the particular training project (DOT Code). If, for example,

$$\left[\frac{\Delta B}{\Delta C}\right]_1 > \left[\frac{\Delta B}{\Delta C}\right]_2,$$

then more individuals should be trained in the training project 1. This can be done by allocating more funds to MDTA training and expending them on project 1, or shifting funds from project 2 into project 1. It would be desirable to expand the study to include marginal analysis of this type.

Finally, with continuation of the project, an attempt could be made to evaluate the relationship between various characteristics of the trainees (age, sex, race, education) and earnings. Also, an evaluation of the relationships among training, earnings, occupations, and industry types could be made. Information on such relationships as the above would be valuable for more complete appraisal of training programs. Thus, expansion of this project to include further work and study is highly desirable and is strongly recommended.

Graduates II = 73 additional graduates included herein who are not included in Graduates I. Complete informa-
tion on the extra 73 was not available. Total graduates = Graduates II.

Enrolled = Still in training after 5 days.

Note: Where letters appear, figures did not add up, and an adjusted figure was inserted to correct this. The
nonadjusted numbers are as follows: a = 28, b = 22, c = 425, d = 224, e = 223, f = 186, and g = 2543.

CNL Benefits = Wage Difference times CNL Employed times 40 times 50
Other Benefits = Probably Employed times Wage Difference times 40 times 50
Employed Benefits = Wage Difference times 40 times 50 times the number of employed Graduates I for whom both
pre-training and post-training earnings were available
% of 52 Week Year Employed = % of 52 weeks following graduation during which employed
Benefits = Column 3 times Column 4
Minimum Benefits = Column 2 times Column 4
