Language

Because socialization in terms of language behavior is the pivot for all other socialization, great emphasis is being placed in the linguistic determinants of cognition, and the influence of parents' language on child language and cognition. The same life conditions that foster dialect differences may be presumed to lead to semantic differences. At simple levels of discourse, difficulties in communication may be minimal, but semantic differences, when added to phonological and dialect differences, may have very serious consequences for the reading instruction of young children. Much evidence suggests that from first grade on there are widening gaps between the language of children from poverty environments and those from middle class groups. Word association research suggests specific kinds of deficits. particularly in consolidation of verbs and adverbs. There may be a lack of environmental forces to encourage semantic development which not only causes reading deficits but rules out reading as a source of semantic enrichment. The author describes studies in word association of black and white inner city children, compared with rural Maryland and old order Amish children. She suggests developing semantic structures through schools games which provide drill on particular skills, and more mixing of students in the school and the community. (AMM)

June 1969

The research reported herein was performed pursuant to a grant with the Office of Education, U.S. Department of Health, Education and Welfare. Contractors undertaking such projects under Government sponsorship are encouraged to express freely their professional judgment in the conduct of the project. Points of view or opinions stated do not, therefore, necessarily represent official Office of Education position or policy.

The Johns Hopkins University Baltimore, Maryland

Parts of this report will appear in "Semantic Systems of Children: Some Assessments of Social Class and Ethnic Differences" in Language and Poverty: Perspectives on a Theme, F. Williams (ed.), Chicago: Markham Publishing Co.; and in "Word Association Studies of Amish Children, Comparisons with Other Minority Groups" in Proceedings of the Temple University Conference on Child Socialization, J. Hostetler (ed.).

Topics which are of equal interest in the study of persons and in the study of societies are rare. Language, however, is a functional requisite both of selfhood and of social systems, and the study of language cannot therefore avoid an interdisciplinary emphasis. The process of language acquisition is certainly not yet well understood; nevertheless the new generation acquires its native tongue, whatever it may be, and socialization in terms of language is the central pivot for all other socialization. Such socialization relates directly to social stratification and to social mobility.

Because socialization in terms of language behavior is the pivot for all other socialization, there has come to be lately great emphasis on the linguistic determinants of cognition. Many studies are presently concerned with the influence of parents' language on child language and cognition. A well-known example is the work of Hess and his associates (1968) who observe that when lower class black mothers attempt to instruct their children in simple tasks they use shorter sentences, fewer abstract words, and generally fail to point out alternative actions in comparison with middle class (black) mothers. The lower class black mother presents to her child a relatively undifferentiated view of the world and by this means may shape his cognitive style. If one thinks of upward mobility - "life chances" - it could be that children who are socialized linguistically in such ways are handicapped compared to children from other milieus.

The disadvantaged black urban child's relative handicaps in the first-grade classroom are presently the focus of much social concern, but by no means constitute the entire poverty subculture. Poor whites, Mexican Americans, Indians, and others, actually outnumber poor blacks. The structural conditions of the environment

external to the school - the sociocultural context of the community - no doubt can lead to profound differences in cognitive development for members of many disadvantaged groups and one would not necessarily expect that the differences would be the same from one group to another. The school has the task of enhancing or modifying such development no matter what the community context because now children in most states must stay in school until age 16. The school's task of enhancing development may be unrealizable without detailed knowledge of the cognitive status of various subgroups and of the kinds of actions that can be taken to modify this status. Further, if the school must persist in a task for which it is illequipped, it may do worse than fail in the task per se, i.e. it may alienate the child from other social institutions.

Some parts of the process of language acquisition by minority groups are better understood than others. Data are beginning to accumulate on the phonology and syntax of black urban speakers, for instance. But thorough understanding of the language socialization process requires research on children from many different subcultures. Experiments or laboratory observational sessions that will yield useful data on language are hard to design because experimenters can act for only very insignificant amounts of time compared to time the developing individual normally is producing or witnessing language behavior. Even an heroic effort like Cazden's (1965) where 40 minutes was spent daily with children over a three-month period may represent only a "small" amount of time. In many ways, then, naturally occurring variation among subcultural groups may surpass the "experimental maneuver" as a strategy, or in fact be the only feasible approach.

To chart the area of this report it is convenient to divide linguistic development into three branches: acquisition of phonology, acquisition of syntax, and acquisition of semantics. Here attention will be confined to acquisition of semantics. Emphasis

will be on semantic differences between minority groups.

Semantic Development

Elements of a linguistic code that appear to be the same (neglecting phonological differences), words like "table" or "run", need not have identical semantic implications for speakers from different cultural groups. Differences in semantic structure have received almost no attention, because the topic is an unwieldy one, both in terms of its theoretical underpinnings and in terms of its methodology. Nevertheless the same life conditions that foster dialect differences would be presumed to lead to semantic differences. At simple levels of discourse difficulties in communication may be minimal, but semantic differences, when added to the phonological and dialect differences already mentioned, may have very serious consequences for the reading instruction of young children. Differences in semantic structure could impose a heavy burden upon the minority group child, even though so far little notice has been taken of these structures. And, as McNeill (1965) points out, the semantic component of children's grammar has repercussions for wide areas of cognition beyond language itself.

Research of others testifies that grammatical development is already well along by age 4 and grammatical cues are used efficiently in repetition or memory tasks by children at age 5. Grammatical development is revealed by knowledge of pluralization, verb inflections, and so forth. The preponderance of syntagmatic responses in word association data is another kind of evidence for this early grammatical maturity. McNeill (1965) cleverly demonstrates however, that a great amount of semantic development,

the structuring and elaboration of meanings, must be acquired after age 5. By asking children to repeat sentences immediately after hearing them, and by varying the semantic and syntactic consistency in the sentences, he shows that five-year-old children are not able to profit from semantic consistency whereas 8-year-olds can, although both use syntactical cues equally well.

This same trend in semantic development over ages 5 to 10 is evidenced in word association data by the gradual increase in the number of responses that match the form class of the stimulus word and in the convergence toward a few high-frequency responses. (Entwisle, 1966 (a) (b) (c), 1968 (a) (b)). Instead of giving as responses words that follow the stimulus word in a sentence ("begin" - "to cry"), as children advance in age they give as responses more words that could replace the stimulus word in a sentence ("begin" - "start"). It is particularly noteworthy that these replacement words (paradigmatics) are not limited to synonyms - "begin" has "end" and "stop" as high-frequency adult responses, and most common adjective have antonyms ("black" - "white", "tall" - "short") as high-frequency responses. Paradigmatic responses contain much evidence of semantic structures.

The building of a child's semantic structure is a long slow process. Semantic enrichment probably continues throughout life, but its major phase appears to occur over the elementary school years (McNeill, 1965). Because it is a long slow process, it may be more environmentally dependent than syntactic development. If it is more environmentally dependent, it should show greater subcultural variability than subcultural differences in syntactic development (which appear to be small).

To shed light on differing semantic structures considerable further analysis has been undertaken on word association data collected in 1961-66. This analysis focuses on differences in

semantics among minority groups. Obviously this is a much less straightforward kind of analysis than analyses by form class because the number of possible responses is very large and there is no single dimension along which responses can be compared.

A few words are needed at this point about the nature of semantic development. Very briefly, it is convenient to think of a child constructing a central dictionary where a word is classified by semantic markers. The number of markers is much smaller than the number of words. A word like "flower" may have a single marker "alive", and then acquire other like "small", "plant" etc. as a child becomes older. If the child's associations were sampled at a time when "flower" had the single marker "alive", and words like "mouse" also had that same single marker, the child would use "flower" and "mouse" in the same contexts without finding anything anomalous. For instance, he would say "The flower has babies" and "The mouse has babies". As more markers are acquired, the set of contexts deemed by a child to be appropriate for a word will de-For instance if the marker "plant" is added, the child will now no longer say "The flower has babies" because having babies is a characteristic of (some) animals but not plants. presence of more markers will also be reflected in a reduction in the variety of words given in free association.

Associative structures develop at different rates for rare as opposed to common words and for words of one form class compared to another (adjectives vs. verbs, for instance). Words that occur often like "table" or "he", have associates even for young children that strongly resemble adult associates, and the main differences in associative patterns over age occurs in the convergence toward a single high frequency response. For adults, "table" produces "chair" in 65 per cent of adult respondents, compared to about 30 per cent at kindergarten-first grade, or 50 per cent in later years of elementary school (Entwisle, 1966 a). The word "cocoon" however

yields "butterfly" in 30 per cent of adults, in 15 per cent of fifth-graders or 3rd graders, but is seldom given by first-graders. A low-frequency word, then, is distinguished developmentally by being later to develop strong associates and by approaching a lower asymptote of commonality (the pattern of associations, even for adults, is more varied).

Words of various form-classes have different rates of development. Verbs and adverbs develop later than pronouns and adjectives. Of course different form classes occur with different frequencies and this alone would be expected to produce some differences in associative structuring. Pronouns, for example, occur more frequently than any other form class, particularly in informal discourse (see French, Carter, and Koenig, 1930). Some verbs do occur frequently, verbs like "give", "run", and "sell". It is noteworthy, however, that these most common verbs tend to be irregular verbs, so although they may occur "often" from the point of view of the grammarian, the occurrences in different formats may at first be interpreted by the child to be occurrences of different words. (Over the elementary school years past tenses of irregular verbs--"sell"--"sold", are given as associates for a while and then drop out. Past tenses of regular verbs--"add"--"added", are never given as associates. This strongly suggests that past tenses of irregular verbs are being learned as separate words.) Also verbs are complicated because of auxiliaries. Verbs may not have "high frequency" occurrence in the same sense as other form classes.

Another factor that distinguishes verbs from nouns, adjectives, or pronouns, is in their being less often specifiable by ostensive definition - every noun on the list of stimulus words I used can be defined ostensively ("bird", "fruit", "insect", etc.). This was not intentional.) For this list at least, there is no correlation between this property and the rarity of the word.

"Cocoon" is just as well defined ostensively as "table" although it may take longer to find a cocoon than a table in one's immediate environment. For verbs the same cannot be said. While "run" or "sit", two very common verbs, can be defined ostensively, "maintain" or "restore" cannot (even though according to the Thorndike-Lorge (1944) word count both these verbs occur much more often than "cocoon"). Apparently ease-of-definition is correlated with frequency for verbs. It is not surprising, then, that verbs (and adverbs) appear to develop more slowly than adjectives or pronouns on the basis of conceptual complexity and/or frequency. Our data suggest that adjectives and pronouns are well-developed by third grade but that some verbs and adverbs are still in the process of development at fifth grade.

Much the same point is made by Roger Brown (1968) based on a different kind of data. He compared nouns and verbs of high frequency for adults (among the first thousand for each form class respectively) and not of high frequency for children, and also the converse (nouns and verbs of high frequency for children and not of high frequency for adults.) He concluded that nouns and verbs used by children have more consistent semantic implications than those used by adults. In fact, semantic elaboration may be a lifelong process and even common words may have their meanings altered or extended in adulthood ("soft"--"sell", for example). It may be particularly difficult for the child in an impoverished environment to expand his semantic system. association and other data reinforce this conclusion. Perhaps larger differences in semantic systems prevail between the adult slum dweller and the adult suburbanite than between children of the slum and suburbia. Concrete evidence in this area is badly A little data on associates of Negro college students needed. (Belcher and Campbell, 1968) suggests much lower commonalities for common words, but probably there are too few data to warrant conclusions.

Results

Earlier (Entwisle and Greenberger, 1968) the three most common responses for black and white children who live in the inner city of Baltimore was given. In Appendices A and B of this report similar data are provided for rural Maryland children and for Amish children residing in rural areas around Lancaster, Penna. In Appendix C the response commonality (sum of the percentages for the three most popular responses) is given for the three main lexical classes. Respondents are drawn from inner city, suburban and rural groups equated for IQ (only strata where children are half medium IQ and half low IQ are included, and they are equally represented in every group). These data permit comparisons between urban children and rural children. Similar data for adults (college students) are also given.

Blacks vs. whites. Data for first graders show black inner city children to be not far behind in number of paradigmatic responses compared to white inner city children, and ahead of white suburban children (Entwisle, 1968(a).) At the same time rates based on number of paradigmatic responses, ignore differences in meaning - semantics - between groups. For simple words, "table", "run", "black", etc., where meanings are uncomplicated, there are minimal differences between groups. These are mainly the very common words, the only ones for which any semantic structure at all has been built up by first grade.

The relative position of blacks and whites in terms of number of paradigmatics shifts with advancing age, however, and both inner city blacks and whites show a slowed pace of development compared to suburban (white) children by third grade. Again, however, the rate alone tells only a small part of the story, for while the

semantic systems of white inner city children overlap considerably the semantic systems of white suburban children, semantic systems of black children depart significantly from both white groups, especially for more complex words. Some examples will clarify this point. A common word like "add" suggests "subtract" or "arithmetic" to almost all children, suburban or city, white or black. A much less common word "examine" suggests "test" and "check", both verb synonyms, to suburban fifth-graders. It suggests "test", "x-ray" and "doctor" more frequently (in that order) than other words to white inner city fifth-graders. To black innercity fifth-graders it suggest "x-ray", "operate", and "doctor"—not general words like "test" or "check" that will broaden its meaning beyond the medical examination situation, but words restricted to a very specific context. "Examine" therefore might be viewed as having a constricted semantic structure for blacks.

Amish data. Before considering the Amish data, we need a few words about bilingualism and its possible effects on the linguistic development of Amish children.

Some responses of Amish first-graders are given in Dutch. When this happens the total paradigmatic response rate is unaltered i.e., when the form classes of Dutch responses and English responses are combined the same patterns are present as in form class counts for English-speaking rural Maryland children. Bilingualism might put a brake on semantic development, however, for many reasons. Looking only at the primary responses to the most common adjectives for first-graders, one sees that often the most frequent response is the Dutch equivalent of the stimulus word. By third grade the primary response corresponds with either the primary or secondary response of the rural Maryland group, its frequency usually being lower. (See responses to "cold", "dark",

"hard", "long", "short"). At fifth grade primary responses to a set of words already well consolidated by other groups (Table 2) are in some cases different and in most cases weaker. Further data of the same kind for Amish sixth-graders suggest that convergence toward high-frequency responses of the majority group is continuing but that some noticeable semantic differences are still retained even at sixth grade.

Because collection of Amish data was initially prompted by the hypothesis that Amish children would show syntagmatic response patterns like those of children 50 years ago (Woodrow and Lowell, 1916; Entwisle, 1966a), some prominent syntagmatic patterns--verbs in response to nouns and nouns in response to adjectives--are given for fifth-graders in Table 1. The prevalence of such patterns is low in both rural Maryland and inner city children, and while the Amish show more adjective-noun linkages than other modern groups the rate does not depart drastically from the rates noted for suburban children.

Qualitative differences between associative patterns of the Amish and other groups show several distinct features:

- (1) Effects of a rural environment and a bilingual heritage are visible in the semantic structure. The word "chair" elicits "stool", rather than "table" which is the overwhelming response for other American children. This seems rather obviously traceable to "stuhl" the Dutch word for chair. Also, in reflection of the rural environment one sees "beetle" in response to "bug", "tulip" in response to "flower", "pheasant" in response to "bird". None of these responses is given by inner city children who give "roach" in response to "bug" which likewise reflects their environment.
- (2) There are many syntagmatics still visible at 5th grade, and many past tenses given as associates to regular verbs. Both these tendencies probably signify a slowed pace of development and are reminiscent of the Woodrow and Lowell data. At the same time,

however, there are very mature semantic structures revealed in response to low-frequency verbs like "obey", "inquire", and "examine". The semantic constriction revealed in black inner city children's responses to "examine" has already been dwelt upon. Amish children, by contrast, give general responses like "test" (25 per cent) and "check" (20 per cent). It looks in some ways as if cognitive ability is outstripping verbal facility.

(3) The most obvious characteristic of Amish responses is their decreased commonality. The percentage of responses accounted for by the primary, secondary and tertiary responses is less for Amish than for other groups. The remainder of this paper will elaborate on this, especially in its relation to findings with other minority groups.

Commonality Comparisons. Comparing commonalities (the percentage of total responses accounted for by the three most common responses) between Amish children and other groups has drawbacks. Only 20 Amish children of each grade were interviewed and proportions based on 20 observations are not very stable. On the other hand, if one pays attention to only the most common of the primary responses (when the primary response accounts for 35 per cent or more of total responses) this drawback is less cogent and some suggestions about group differences emerge. Table 2 gives for primary responses of the white inner city children that occur more than 35 per cent of the time, the frequencies of that same response for several other fifth-grade groups. (Before fifth grade the syntagmatic-paradigmatic shift confounds findings based on commonality). Compared to white suburban children, Amish children are giving particular primary responses less often even when the primary response chosen by both groups is identical. For example "subtract" in response to "add", "happy" in response to "sad", and "pepper" in response to "salt". In most cases the

changes occurring between fifth and sixth grades for Amish children increase congruence with suburban responses, either qualitatively ("soft" replaces "stone" as the favorite response to "hard") or quantitatively (the frequency fo "subtract" as a response to "add" goes from 40 per cent to 55 per cent).

If these were all the data at hand it would be tempting to assume that generally minority group culture led to language socialization with less stereotyping than that characterizing the majority group. But just a glance at similar data for black (and white) inner city children (Appendix C) shows that almost the reverse apparently also occurs. Inner city black children, another minority group, show greater convergence to popular responses (Table 2) and less variety of response generally than blue collar suburban children at grade 5. Table 2 shows that generally both black and white inner city groups at fifth grade exceed the suburban group in strength of primary responses (see "bird", "black", "bright", "chair", "clean", "cold", etc.). The next question is: does this occur only for stimulus words like those in Table 2 that have especially strong primary responses, or only for very common words? Table 3 shows that convergence on a few popular responses by inner city children occurs for all categories of nouns and adjectives. With verbs, which generally develop later, the picture is not so clear-cut because some of the rarer verbs (maintain, restore) are still yielding large numbers of anomalous responses at fifth grade. (If "no response" is a frequent "response" category, analysis in terms of the "three most common responses", is not sensible). Even though there is not much difference in paradigmatic response rates across groups at fifth grade, as noted earlier (Entwisle, 1968), an overwhelming convergence in a few responses (average commonality for high frequency adjectives is 86 per cent for black and 88 per cent for white inner city children) may signify a failure in semantic

enrichment. This fact, together with the higher commonality for inner city children, points to a conclusion highly relevant to the elaborated-restricted code ideas proposed by Bernstein (1964): the same paradigmatic rates across fifth grade groups noted earlier (Entwisle, 1968 b) reflect rather different kinds of response distributions. The variety of responses for inner city children is less. This would lead one to guess that their semantic structures are not as rich as the suburban childrens. This guess seems reasonable also in view of the finding that commonality does not continue to increase between fifth grade and college for high SES persons and in many cases actually decreases. Semantic enrichment may imply the opposite of a strong convergence on one or two responses.

In summary, then, two varieties of semantic structure appear to characterize two minority groups. One group, the Amish, shows less overlap with the majority in actual associative patterns but, from the small amount of evidence available here, do not appear to suffer from the kind of cognitive impoverishment that may characterize inner city children. Their responses to abstract verbs do not suggest deficits in abstraction. Their responses to specific words suggest a mildly divergent semantic structure ("pheasant" as a response to "bird") but if trends noted between fifth and sixth grades continue, such differences may be minimal by the time children leave school. The other group, the inner city disadvantaged, especially the blacks, display some patterns that suggest deficits in abstraction. The less frequent verbs are not as well elaborated by fifth grade as is noted for suburban children. In addition, there is less variety of response for those words that are well understood by all fifth graders. This can be taken as another concrete piece of evidence in support of Bernstein's hypothesis of a "restricted code" for lower class individuals.

- 13 -

Conclusion

Much evidence suggests that from first grade on there are widening gaps between the language of children from poverty environments and those from middle class groups. association research suggests specific kinds of deficits, particularly in consolidation of verbs and adverbs. Semantic systems are probably elaborated mainly over the grade-school age range, and so may be a particularly fruitful area for study in terms of action programs, although more basic research on semantic structures is clearly needed. In kindergarten and first grade, word meanings, and therefore the cognitive role of words overlap little for the black and the white child. Also whereas suburban children seem to be making orderly progress in expanding their semantic systems to imbed less frequent words over the elementary school years, slum children seem to make only limited progress toward use of language that is conceptually more elaborate than what they started school with ("maintain" produces "can", "retain" and "begin" for suburban third-graders but "no response" is the most frequent reply for both white and black slum children; "seldom" yields "often" and "always" as the most frequent responses in suburban third-graders but "sell" and "no response" as the two most frequent associates in both white and black slum children). One source of difficulties experienced in learning to read by inner city youngsters may be that their backgrounds (most notably television) have provided them with a knowledge of syntax and morphology, and perhaps even with a relatively high degree of linguistic competence in terms of several codes when they reach school, but once in school where reading and cognitive enrichment are supposedly being fostered, there seems to be a deceleration in development. There may be a lack of environmental forces to encourage semantic development which both cause reading deficits and at the same time rule out reading as a source of semantic enrichment.

No single remedy is likely to be sufficient. A very appealing idea is to invent games to be played in school that provide drill on particular skills, like building semantic structures, without eroding motivation. We have begun some work along these lines. Another remedy, probably the most fundamental, is obvious --more mixing of students in the school and in the community. Different semantic systems are no doubt a direct consequence of residential and educational segregation. With more mixing of students the semantic systems of all groups would tend to converge. This convergence would occur as a result of changes in all groups, not just the minority groups, and would thereby pose less of a burden for the underprivileged child. At present any "differences" between youngsters along social class lines are taken as "deficits" for lower class youngsters and lower class youngsters are expected to modify their behavior to overlap the behavior of the more privileged. In some areas, particularly language, there seems to be small reason to force all the change The benefits from having all groups change in one direction. slightly rather than having one group change greatly are not to be overrated.

Table 1. Comparison of Syntagmatic Response Patterns at Fifth Grade

| | Stimulus | Noun | Adjective |
|---|----------|------|-----------|
| | Response | Verb | Noun |
| Source of Data | | | |
| Woodrow and Lowell (1916) | | 31.0 | 53.1 |
| Middle Class and Blue Collar (1961-63) Same stimulus words as Woodrow and Lowell | | 8.4 | 19.7 |
| Middle Class ^a and Blue Collar (1961-63) | | 10.5 | 14.6 |
| Rural Maryland ^a (1961-63) | | 11.5 | 12.7 |
| Amish ^a (1962-63) | | 12.3 | 20.4 |
| Inner City ^a White (1965) | | 11.7 | 13.1 |
| Inner City ^a Black (1965) | | 11.8 | 12.6 |

a For stimulus words, see Entwisle, D. R., 1966 a.

Table 2. Comparison of Primary Response Frequency for Selected Stimulus Words^a

| Stimulus Word | <u>Response</u> a | Inner Cityb | | Amish ^c | | White Suburban d | |
|---------------|-------------------|--------------|-----------------|---------------------|------------------------|----------------------|--|
| | | White (N=80) | Black (N=80) | 5th grade (N=20) | 6th grade (N=20) | 5th grade (N=280) | |
| Add | subtract | 60.8 | 71.3 | 40.0 | 55.0 | 6 3. 5 | |
| Bird | fly | 38.0 | 32.5 | 30.0 | 25.0 (robin) | 26.5 | |
| | | | | | 20.0 (wing) 15.0 | | |
| Black | white | 78.5 | 65.0 | 35.0 (yellow) | 55.0 | 53.0 | |
| | | | | 20.0 (dark) | | | |
| | | | | 15.0 (color) | | | |

The stimulus words selected are those with a primary response of frequency 35 per cent or more for white inner city children, and the response for that group is the response listed. In cases where this response is not the primary response for another subgroup, its frequency is listed but in addition responses of higher frequency are listed.

The data are taken from Entwisle and Greenberger, (1968), Appendix B. The samples are described in Entwisle (1968). Both blacks and whites have average IQ equal to 90.1.

These data are taken from unpublished materials. For a description of the Amish samples see Entwisle 1966, pp. 95-102. The average IQ of Amish fifth graders is 100.1 and of Amish sixth graders is 96.6.

[&]quot;White suburban" children include 140 middle class (average IQ 115.9) and 140 blue collar (average IQ 89.9) fifth graders (See Entwisle, 1966, p. 17 and Appendix A). These are not the same children as those listed under "Blue Collar" in Appendix C.

| | | T 0.70 | City | Amis | sh | White Suburban |

Table 3. Commonality for Inner-City Blacks and Whites Compared to Suburban Whites (Fifth Graders)

| | Inner | City | Suburban ^b |
|-------------------------------|-------|-------|-----------------------|
| | Black | White | White |
| High Freq. Nouns | 56.8 | 58.6 | 51.4 |
| Med. Freq. Nouns | 65.4 | 64.6 | 57.8 |
| Low Freq. Nouns | 55.3 | 58.3 | 52.9 |
| High Freq. Adj. | 85.8 | 87.7 | 75.5 |
| Med. Freq. Adj. | 62.4 | 64.9 | 59.9 |
| Low Freq. Adj. | 70.7 | 72.0 | 65.1 |
| High Freq. Verbs ^C | 52.7 | 54.5 | 52.7 |
| Med. Freq. Verbs | 35.2 | 40.1 | 38.7 |

a "Commonality" is defined as the combined percent for primary, secondary, and tertiary responses.

b Low SES (blue collar) matched in IQ to both black and white inner city students. Data from Appendix C.

C Low frequency verbs are omitted because large numbers of "no response" make this kind of comparison impossible.
