#### ABSTRACT

Prepared for the Bureau of Labor Statistics by the Bureau of the Census, this report is the 10th in a series of documents on the work experience of the population. The report examines the movements into and out of the labor force as revealed through the 1968 work experience survey and provides a capsule analysis of employment of married men, married women, and teenagers. In addition, the report includes definitions of terms and a series of 27 tables on such topics as the extent of unemployment by age, sex, and color. A major finding of the survey was that 8 out of 10 heads of households worked year around full time. (JS)

# Work experience of the population

Special Labor Force Report examines the necements into and out of the labor force in the 1968 work experience survey

YERA C. PERGELLA

THE WORK EXPERIENCE of the population during the course of a year indicates the mixture of stability and movement in the American labor force. In addition to the millions who are in the labor force year-round, millions move into and out of the labor force over a year's time.

Students who fit work in with their school schedules, women who work as home responsibilities permit, persons who work at seasonal jobs, those who come out of retirement, persons entering or leaving civilian life upon leaving or entering a clitary service are examples of the variety of the people and the circumstances which generate this amount of movement. In addition, there is the normal turnover from death, retirement, disability, and new entrants.

During 1968, for exemple, the combined total of labor force entries and exits was estimated at about 90 million. These figures represent a count of different actions and not of different persons, since many individuals change tatus more than once in the caurse of a year. Further, an entry to the labor force is also an entry into either employment or unemployment. The combined total of entries into and exits from employment status during 1963 was also about 90 million; entries and exits to and from unemployment status were only about half that.

This volume of movement results in a significantly larger number in the annual than in the monthly total of individuals with labor force experience. It accounts, too, for the differing patterns of that experience with respect to weeks of employment and extent and frequency of unemployment over the 12 months.

Vera C. Perrella is an economist in the Division of Labor Force Studies, Bureau of Labor Statistics.

Despite its volume and importance, flux is not of course, the whole picture with respect to work experience, nor even the largest part of it. There is a stable core to the labor force, composed of year-round participants: 7 out of every 10 persons who were in the labor force during 1968 were in it all year. Most men, once they embark upon a work career, are in the labor force year round, and more and more women are working year round.

The latest survey of the work experience of the population shows that 91½ million different individuals were in the civilian labor force at some time during 1968—about 10½ million more than in July, the peak month! This article, based on information obtained in the survey, deals with the work experience of the men and women who were in the labor force at some time during the year and analyzes their employment and unemployment patterns. The discussion includes key figures from the 1968 work experience survey, a report on the overall employment and unemployment situation, and an examination of selected groups whose work experience is typically characterized by stability or movement.

#### Key numbers, 1968

Here, in summary form, are the major findings of the 1968 survey:

90% million persons 16 years old and over worked at some time during 1968 -2.1 million more than in 1967. Two-thirds of the net increase was in full-time jobs.

52% million men and women vorked year round full time—over half a million more than in 1967, although the proportion in both years was roughly 58 percent of all who worked.

As in other years, a smaller proportion of Negro than white male workers were employed all year at full-time jobs--70 percent and 63 percent respec-

. 13

tively in 1968. However, the gap between these two proportions has narrowed somewhat since 1966.

5.8 million men and women worked part time year round in 1968, about the same number as in 1967.

32 million men and women worked part year, compared with about 31 million in 1967; 4 of every 5 gave reasons other than unemployment as the main reason for working part year.

43 million heads of households worked during the year: 8 out of 10 worked year round full time.

22.2 million married women—one half of all married women—worked at some time during 1968; 4 out of every 10 who worked did so year roun! full time.

Almost 9¼ million teenagers—2 out of every 3—worked at some time during 1968. A larger proportion of the white than of the Negro teenage population worked.

11.3 million persons, or 12.4 percent of the total working or looking for work had unemployment at some time during 1968; both the number and the proportion were somewhat lower than in 1967.

19.6 percent of the Negroes in the labor force had unemployment during the year compared with 11.5 percent of the whites.

2.4 million persons had unemployment totaling 15 weeks or more in 1968, 200,000 fewer than in 1967.

#### **Employment**

Economic activity, very high in 1967, was even better in 1968, as evidenced by the smaller number of persons with unemployment during the year at well as the larger number with employment. The number of persons who worked at some time, during 1968 was 2.1 million more than in 1967, largely as a result of population increases (table 1).

More than helf of the not employment gain was among women, mostly full-time workers. The gains were greater among women 20 to 29 years old, among whom full-time workers increased by almost helf a million.

Among men, too, the increase in the number who worked during 1968 was concentrated among full-time workers, with the gains preponderantly among the younger men.

Most of the additional women workers were employed in the service industries, particularly in medical and other health services; most of the additional men were employed in durable goods manufacturing and public administration.

Distribution of workers by number of weeks worked and by whether they worked full or part time was about the same as in 1967. About 90 percent of the men and 70 percent of the women with work experience during 1968 worked full time, as in 1967. In both years, 76 percent of the men who worked did so year round (50-52)

weeks) fun time, compared with 40 percent of the women.

The proportion of white men with work experience who worked year round full time continued higher than that of Negro men—70 percent compared with 63 percent. However, among youths under age 25, a smaller proportion of the white youths worked all year at full-time jobs, because relatively more of them were attending school and had to limit their work.

The proportion of women who worked year round full time was the same for Negro and white women (40 percent each). This was also true for those who worked part time (30 percent each).

A few figures sum up the variations in work experience by number of weeks worked during the year:

	Perc	ent of wor	ter:
Employment in 1968	All workers	Fuit- time	Part- time
Total	100	81	19
50-52 weeks	64	58	G
48-49 weeks	4	3	1
40-47 weeks	6	5	1
27-39 wecks	7	5	2
14-26 weeks	8	5	3
1-13 weeks	11	6	5

The distribution has been relatively stable over the sixties to date, except that the preportion of year-round full-time workers is now closer to 6 or t of 10 of all workers that at the start of the decade, reflecting the steadily improving economic situation.

For part-year workers, the distribution by number of weeks worked shows no marked change over the period. Nonetheless, the very fact that there is such a range in the number of weeks worked gives strong indication of the flexible nature of the supply of labor. More than 32 million individuals worked less than 50 weeks in 1968, but fewer than 6 million of them said unemployment was the main reason they did not work a full year. The rest attributed their less than full-year work to personal circumstances rather than inability to find work. This is the element which gives flexibility to the supply of labor and, in the process, generates a large portion of the movement which cheracterizes the labor force.

#### Unemployment

Out of a total 91.5 million persons who worked pocked for work during 1968, 11.3 million or 12.4 percent, had unemployment at some time during the year. In 1967, the total who worked or looked for work was 2 million smaller, but the number who had unemployment was almost a quarter million larger. The continuing increases in the demand for labor in an already tight labor market kept the number of persons with unemployment from rising, despite the 2 million growth in number of persons in the labor force during the course of the year (table 2).

While there were no sharp differences from 1967 in either numbers or proportions of persons with unemployment, whether the figures are examined with respect to sex, age, or color, the proportion of white men who had unemployment decreased 1 percentage point. For women and Negro workers, the proportions with unemployment were not significantly different from 1967.

Overall, the percentage with unemployment continued higher for women than for men, and for Negroes than for whites.

Most of the persons unemployed at some time during 1968 had also worked during the year. In both 1967 and 1968, about 1½ million men and women had looked for work for 1 week or more but had not found jobs. Over half looked for work for fewer than 5 weeks. Among both whites and Negroes, the number of women who looked but did not find jobs was more than double the number of men.

#### Married men

The group of workers from whom the labor force derive its greatest measure of stability is married men. The chances that an individual is in the labor force are highest when the individual is male and married. The married man is also the most likely to have worked continuously over the course of a year.

Practically all married men are household and family heads, with the major responsibility for meeting family financial needs. As a result, the work role dominates to a much greater extent for them than for any other population group. During 1968, 90 percent of the 44.3 million married men in the population were in the labor force at some time during the year. A measure of the stability which characterizes the group's labor force experience is the ratio of the total number of them in the labor force during the course of a year to their monthly average in the labor force. For 1968.

1 Worked 50 weeks or more. 1 Worked less than 50 weeks

this ratio was 103 percent. The ratio of the total number to the number in the labor force during the peak month of the year was 102 percent. These ratios, and more particularly the smallness of the difference between them, are among the simplest and most graphic indicators of the high degree of stability which typifies the married-man labor force. (See chart.) From these ratios, it is clear that the married men who are in the labor force at any given time in the year are also almost certain to be in the labor force at any other time in the year. For no other group of workers may this statement be made with so much certainty.

In contrast, the comparable ratios for the next most stable group—widowed, divorced, or separated men—were 114 percent and 110 percent, respectively. Fourteen percent more of this latter group were in the labor force during the course of the year than in an average month, and 10 percent more than in the peak month.

NOTE: Because of rouncins, sums of Individual items may not equal fotals.

Married men's employment during the year also shows a high degree of stability. Roughly 80 percent of all those who worked at some time during 1968 worked year round full time. Further, of the 39% million who had worked during the year, less than 10 percent had any unemployment. Among those who did, marly one-half had been jobless for a total of 4 weeks or less. Moreover, about 2 out of 3 had only 1 period of unemployment.

The age distribution of married men has bearing on the labor force experience of the group as a whole relative to that of other men. Single men are heavily weighted in the younger ages in which the amounts of work experience and of tenure are low. Widowed devorced, or separated men are more heavily weighted in the older ages, in which labor force participation is lower than in the middle years.

Other factors han the age differences are undoubtedly also relevant, since age for age,

married men tend to have higher labor force rates than other men. Marriage and labor force participation are selective processes. Physical or psychogenic handicaps may tend to lessen both the likelihood of marriage and of steady employment. Further, in our society, the married man who elects not to work, or to loaf periodically, is subject to greater criticism than are other men, so that his work orientation may be influenced.

Whatever the mixture of demographic, economic, psychological, and sociological factors and the relative importance of each, the labor force effects are clear. Macried men typically are most likely of all population groups to be in the labor force, and to be employed year round fall time. In sum, population change aside, married men constitute the portion of the supply of labor which is least subject to expansion or contraction. The patterns of their labor force, camployment, and unemployment experience indicate that in proportion to their number, they account for only a small portion of the annual volume of movement.

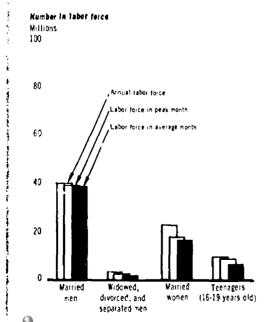

#### Married women

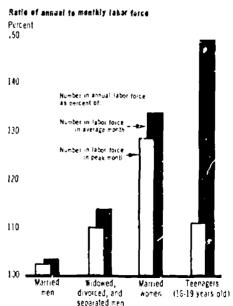

The high degree of mobility, mixed with stability, in the married-woman labor force is indicated by the variations in their labor force participation and work experience. In 1968, about half (22.6 million) of all married women were in the labor force at so the time during the year—about one-third more than were in the labor force in an average month. Almost 6 million more married women worked or looked for work over the course of the year than during an average month.

The women who had work experience were almost equally divided between full-year and part-year workers. Of the 11.3 million women who worked the full year, a very large proportion (8 out of 10) worked full time. Whether they worked full time or part time, the year-round workers were a stable element in the labor force over the course of the year.

The 11 million wives who worked part-year and the 450,000 who looked for work but did not find jobs generated a considerable pertion of the

Chart 1. Annual labor force compared with paak month and average month, selected groups, 1968

total volume of movement over the year. Over half of the part-year workers were in the labor force less than 27 weeks; of the nonworkers, more than 9 out of 10:

	F	Percent of wo	rkers
Weeks in labor force	All workers	Part-year workers	Nonworkers Who looked for work
Total	100	160	100
1-1. weeks	30	27	1 84
14-26 weeks	24	25	1 8
27-09 weeks	19	20	2
40-52 weeks	27	28	6
Number (in thousands)	11, 332	10, 883	449

Data are for interval of 1 to 14 weeks.
Data are for interval of 15 to 26 weeks.

For most of these part-year workers, unemployment was not the major factor in their paryear work, and therefore, not the major factor in the expansion and contraction of the marriedwomen labor force. About 80 percent had no unemployment during the year, and of those who did have any unemployment, almost half had 4 weeks or less. Undoubtedly, much of the unemployment was of the frictional kind which occurs upon entry to the labor force, since 7 out of 10 had only t spell of unemployment. So, while unemployment contributed to lessening the time they had worked, it was not the primary factor A further indication is that, among all women who worked part year, only a small proportion (10 percent of the white and 16 percent of the Negro workers) said unemployment was the major reason for their part-year employment. Most women gave home and family responsibilities as the major reason for part-year work.

To repeat, unemployment is not the major factor here. It is, rather, a congruence of supply and demand factors which enables so large a proportion of married women to tailor their labor force participation to their needs and preserences.

In addition to the usual turnover in the labor force which arises from deaths and retirements, there are seasonal expansions and contractions in the demand for labor, such as those associated with agriculture, recreation activities, construction, and retail trade. The peak demands in retail trade, at Easter and Christmas, for example, create a requirement for temporary workers. During the year, many employers find it advantageous to increase their work force for peak hours, days, or seasons only. On the supply side, the need or desire of many married women to work only as

home and family responsibilities permit is made possible by these scasonal requirements. The intermittent work patterns of a significant proportion of women workers create vacancies for others to fill. The secretary who leaves her job because she is going to have a baby may be replaced by a woman who is reentering the labor force to help meet expenses of her college-age children.

#### Teenagers

The movement of teenagers into the labor force at the annual school-closing for the summer and their subsequent withdrawal upon school-opening in the fall result in the widest short-term swings in the labor force during the course of a year. Almost 10 million teenagers (16 to 19 years) were in the labor force at some time during 1968. This was about 3% million, or 50 percent, more than in an average month, but only 900,000 more than in July, the peak month for their labor force strength.

This annually recurring phenomenon places a tremendous demand upon the economy for a large number of very short term jobs within a 3-month period. In 1968, the number of teenagers in the labor force increased by 2½ million within the 30 days between May and June, and by another 190,000 within the next 30 days. By September, the number of teenagers in the labor force was back very close to its May level.

What is perhaps even more remarkable than the dimension of this mass movement into the labor force is that between May and June, teenage employment increased by more than half their labor force increase, and between June and July, by another 900,000. Thus, although unemployment increased, almost 2% million teenagers found employment within a 2-month period.

By September, the labor force, employment, and a temployment rate of teenagers were back to very nearly their May levels:

Number (in thousands)

		110 (4)	(14 ***	444,000	
_	Mag	June	Juli	August	Sep- tember
Civilian labor force	6,040	B, 295	8,891	8, 335	6, 179
Change from preceding month	+132	4 2, 255	+ 500	- 556	-1,156
Employed	5, 424	6, 097	7,589	7.512	5, 438
Change from preceding month	+143	+1.73	7 833	- 77	- 2, 074
Unemployment rate (percent)	10. 2	19. 8	14.6	9. 9	12.0

Because of the propensity of young people generally to move into and out of the labor force,

and because so large a proportion of the teenegers in the labor force are enrolled in school, movement in the teenage labor force is high throughout the year, though not as great in volume as during the summer months. In February 1969, 70 percent of the 16- to 19-year-olds in the population were enrolled in school. Among the 9.8 million teenagers who had worked or looked for work at some time during 1968, 2 out of 3 were students. As is to be expected, a larger proportion of the out-of-school youths (81 percent) had been in the labor force at some time during 1968, but even among the students, the proportion was quite high (66 percent).

However, the differences between students and nonstudents were marked with respect to number of weeks worked and whether they usually worked full or part time. Among those who worked, over two-thirds of the students compared with one-fourth of the nonstudents had worked part time, and nearly half of the students compared with a fifth of the nonstudents had worked only 1 to 13 weeks. Among both students and nonstudents, the proportions who worked the full year were low—about one-fifth and one-third respectively.

In this teenage segment of the labor force, as in the married-women segment, the length of time worked was more the result of the length of time they were available for work than of unemployment, though again, unemployment did play a considerable part in lessening the length of time worked.

#### Nonworkers who looked for work

The group of persons who look for work at some time during the year but do not find jobs is relatively small during periods of economic prosperity. Nonetheless, these individuals account for a significant portion of the volume of movement in the labor force over the year. During 1968, the 1% million nonworkers who looked for work represented about 10 percent of the persons who had unemployment at some time during the year, and a little more than 1 percent of all persons in the labor force. Seventy percent of the nonworkers were women, of whom half were married. In terms of age, a third of all the group were teenagers. These proportions give yet another buttressing to the labor force truism that teenagers and married women are more highly represented in the

floating contingent of the labor force than are other groups in the working-age population. More than other groups, these two are given to sporadic labor force participation, as school and home responsibilities permit, and many of them stop looking for work if jobs do not materialize quickly. Often, as in the case of students, the period during which they can fit work into their schedules is itself relatively short, so their search for work is necessarily limited by the period for which they are available. Similarly, married women may try to find work that will fit in with their home responsibilities, or during seasonal periods such as the Christmas and Easter rush in stores, or the school vacation period when older children are at home to look after the younger ones. Because they are not the primary workers in their families, persons in these groups tend to leave the labor force if the search for work becomes too extended, and to reenter when it is convenient or the likelihood of a job seems good.

Of the nonworkers, about two-thirds of the married women had looked for work 4 weeks or less, and more than half the teenagers. In contrast, among the small number of men 25 years old and over, only 20 percent looked for 4 weeks or less, and about 40 percent for 40 weeks or more.

There are no data to indicate whether any appreciable proportion of these nonworkers had several periods of unemployment during the year. Even the minimal one-time entry and subsequent withdrawal from the labor force, however, would account for 2% million gross changes in terms of entries and exits from the labor force, and an equal number of gross changes in unemployment entries and exits. In the Negro labor force, the nonworkers who looked for work were 15 percent of the total unemployed during the year; in the white labor force, the nonworker was 19 percent of the total who looked. In this group, married women were a smaller proportion of the Negro women than of the white women. Among both whites and Negroes, nonworkers were predominantly secondary workers.

THE VOLUME OF MOVEMENT in the labor force over the course of a year is indicative of a high degree of flexibility in labor supply and demand, which results from the interplay of economic and social factors, as well as geographic and occupational mobility. A preponderant portion of the

movement is the result of part-year and part-time work by persons who are not available for fullyear full-time work.

The high degree of movement and flexibility notwithstanding, there is a broad base of stability in the labor force. Close to 2 out of every 3 persons who worked during 1968 did so year round. To the extent that it constitutes a medium for the fulfillment of both worker and employer needs,

the combination of flexibility and stability is a force for a dynamic and viable economy.

The degrees of st bility and mobility differ considerably among verious groups in the labor force. The group whose labor force experience is most stable is married men, particularly those who are white and in the central ages. Mobility is relatively high among teenagers, married women, and older workers.

----FOOTNOTES--

<sup>1</sup> Since the annual survey of the work experience of the population during a given year is made in February of the following year, the information obtained relates to the civilian work experience of those persons 16 years old and over in the civilian noninstitutional population as of the February date. Thus, the work experience of persons who were in the civilian labor force during 1968 but not in the civilian noninstitutional population as of February 1969 is not included; similarly, persons who died during the course of 1968 or in the 1969 period preceding the survey date are also not reflected in the figures. On the other hand, those persons who reached age 16 in January and February 1969 are included.

The data are from supplementary questions to the February 1969 monthly survey of the labor force, conducted for the Bureau of the Scattistics by the Bureau of the Census through its Carrent Population Survey.

This is the tenth in a series of reports on this subject. The ninth in the series was published in the Monthly Labor Review, June 1969, and reprinted with addition a tabular data and explanatory notes as Special Labor Force Report No. 107.

<sup>2</sup> Data for all persons other than white persons are used in this report to represent data for Negroes, since the latter constitute about 92 percent of all persons other than white in the United States

# **Explanatory** note

Estimates in this report are based on supplementary questions in the February 1969 Current Population Survey conducted and tabulated for the Bureau of Labor Statistics by the Bureau of the Census. Basic labor force concepts, sample design, estimating methods, and reliability of the data are described briefly in the following sections.

#### Definitions and Explanations

Population coverage. Each month trained interviewers collect information from a sample of about 50,000 households in 449 areas in 863 counties and independent cities with coverage in each of the 50 States and the District of Columbia. Estimates in this report are for persons 16 years or age and over in the civilian nonistitutional population during the calendar week ending February 15, 1969. The civilian noninstitutional population excludes all members of the Armed Forces and inmates of institutions, such as homes for the aged and correctional institutions. All persons were asked how many weeks they worked and whether they locked for work during 1968. Persons who worked less than 50 weeks were asked detailed questions on reasons for part-year work and whether they had more than one period of unemployment.

nork experience. Persons with work experience are those who worked as civilians at any time during the year at full-time or part-time jobs.

Part-time and full-time jobs. Persons are classified as having worked at full-time jobs if

they worked 35 hours or more per week in a majority of the weeks worked during the year. They are classified as having worked at part-time jobs if they worked 1 to 34 hours per week in a majority of the weeks worked during the year. In tables E-1 and E-2, persons are classified as full-time or part-time workers in accordance with the number of hours they usually work each week at the job held iring the survey week in February 1969.

Weeks worked. Persons with work experience are classified according to the number of weeks in which they did any work during the year as civilians for pay or profit (including paid vacations and sick leave) or worked without pay on a family-operated farm or business.

Year-round full-time workers. Year-round full-time workers are persons who worked primarily at full-time jobs for 50 weeks or more. These persons are also referred to as regular full-time workers.

<u>Part-year workers</u>. Part-year workers are persons who worked either full time or part time for 1 to 49 weeks.

Major reason for part-year work. Part-year workers are classified by major reason for part-year work on the basis of what they were doing most of the weeks in which they did not work. Their reasons are reported as unemployment or layoff from a job, illness or disability (not including paid sick leave), taking care of home, going to school, retirement, in the Armed Forces, and other reasons. The "going to school" category was restricted to persons under 30 years of age, and "taking care of home" was restricted to women.

Nonworkers. Nonworkers are persons who did not work during the year. They are asked whether they looked for work during the year and,

For a more complete description of the methodology, see "Concepts and Methods Used in Manjower Statistics" from the <u>Current Population Survey</u> (BLS Report 313).

if they looked, for how many weeks. Nonworkers are classified according to the main reason for not working. Their reasons are reported as illness or disability, taking care of home, going to school, inability to find work, retired, in the Armed Forces, and other reasons.

Longest job. A person's longest job during the year is the one at which he worked the greatest number of weeks. For most wage and salary workers, a job is defined as all the time worked for the same employer. The only exception is work for private families (domegive, babysitting, odd jobs and the l') which is counted as a single job regardless of number of employers. Self-employment and unpaid work in family-operated enterprises are also designated as jobs for purposes of this survey.

Occupation, industry, and class of worker. The data on occupation, industry, and class of worker refer to the job held longest during the year. Persons who held two jobs or more are reported in the job at which they worked the greatest number of weeks.

The occupation and industry categories used here are those used in the 1960 Census of Population. The class-of-worker breakdown specifles "wage and salary workers," "self-employed workers," and "unpaid family workers." Wage and salary workers are persons working for a wage, salary, commission, tips, payment in kind, or at piece rates for a private employer or any government unit. Self-employed workers are persons working in their own unincorporated business, profession, or trade, or operating a farm for profit or fees. Unpaid family workers are persons working without hay on a farm or in a business operated by a member of the household to whom they are related by blood or marriage.

Spell of unemployment. A spell of unemployment is a continuous period of unemployment of at least 1 week's duration. A spell is terminated by employment or withdrawal from the labor force.

Duration of unemployment. The number of weeks accumulated in all spells of unemployment.

represents the total number of weeks of unemployment during the year.

Employed in February 1969. Employed persons are all those who during the survey week (a) did any work at all as paid employees or in their own business or profession, or on their own farm, or worked 15 hours or more as unpaid workers in an enterprise operated by a member of the family or (b) did not work but had jobs or business from which they were temporarily absent because of illness, bad weather, vacation, labor-management dispute, or personal reasons, whether or not they were paid by their employers for the time off, and whether or not they were seeking other jobs.

Unemployed in February 1969. Unemployed persons are all those who did not work during the survey week, made specific efforts to find a job within the preceding 4 weeks, and were available for work during the survey week or would have been available except for temporary illness. Also included as unemployed are those who did not work at all, were available for work, and (a) were waiting to be called back to a job from which they had been laid off, or (b) were waiting to report to a new wage or salary job within 30 days.

Civilian labor force in February 1969. The civilian labor force comprises all civilian persons classified as employed or unemployed according to the above definitions.

Not in civilian labor force in February 1969. Persons not classified as employed or unemployed are defined as not in the labor force. Persons doing only incidental unpaid family work (less than 15 hours) are also classified as not in the labor force.

Age. The age classification is based on the age of the person at his last birthday.

Color. The term "color" refers to the division of the population into two groups—white and "Negro and other races." Other races include Indians, Japanese, Chinese and any other race except Negro and whites.

Marital status. Persons are classified into the following categories according to their marital status at the time of interview: Single, married, spouse present, and other marital status. The classification "married, spouse present" applies to husband and wife if both are reported as members of the same household even though one may be temporarily absent on business, vacation, on a visit, in a hospital, and the like at the time of interview. The term "other marital status" applies to persons who are married with spouse absent, widowed, or divorced.

Sums of distributions. Sums of individual items, whether absolute numbers or percentages, may not equal totals because of independent rounding of totals and components. Percentage totals, however, are always shown as 100 percent.

#### Reliability of the Estimates

Estimating procedure. The estimating procedure used in this survey inflates weighted sample results to independent estimates of the civilian noninstitutional population by age, sex, and color. These independent estimates were based on statistics from the 1960 Census of Population and other data on births, deaths, immigration, emigration, and strength of the Armed Forces.

Variability. Since the estimates are based on a sample, they may differ somewhat from the figures that would have been obtained if a complete census had been taken using the same schedules and procedures. As in any survey, the results are also subject to errors of responses and reporting. These may be relatively large in the case of persons with irregular attachment to the labor force.

The standard error is primarily a measure of sampling variability, that is, of the variations that might occur by chance because a sample rather than the entire population is surveyed. As and for this report, the standard error

partially measures the effect of response

and enumeration errors but does not measure any systematic biases in the data. The chances are about 2 out of 3 that an estimate from the sample would differ from a complete census by less than the standard error. The chances are about 19 out of 20 that the difference would be less than twice the standard error.

Tables 1 and 2 show approximations of the standard errors of various characteristics and should be interpreted as providing an indication of the order of magnitude of the standard error rather than a precise standard error for any specific item.

Table 1. Standard errors of estimated numbers 1

Size of estimate	Standard error	Size of cstimate	Standard error
50		2,500	73
100	15	5,000	104
250	23	10,000	139
500	33	25,000	205
1,000	46	50,000	246

<sup>1 68</sup> chances out of 100.

The following examples illustrate their use. An estimated 14,255,000 persons 16 to 21 years old vorked in 1968. Table 1 shows the standard error on this estimate to be approximately 157,000. The chances are about 2 out of 3 that the difference between the sample estimate and a complete census count is less than 157,000. The chances are 19 out of 20 that the difference would have been less than 314,060.

The 14,255,000 persons represented 71.3 percent of the 19,984,000 pepulation 16 to 21 years old. Table 2 shows the standard error of 71.3 percent with a base of 19,984,000 to be about 0.5 percent. Consequently, the chances are 2 out of 3 that a complete census count would have disclosed the figures to be between 70.8 and 71.8 percent, and 19 out of 20 that the figure would have been between 70.3 and 72.3 percent.

The reliability of an estimated percentage that is based on sample data for both numerator and denominator depends on both the size of the percentage and the size of the total upon which this percentage is based. Estimated percentages

are relatively more reliable than the corresponding absolute estimates of the numerator of the percentage, particularly if the percentage is large (50 percent or greater).
