#### ABSTRACT

This report, the second in a series which present the results of a systems analysis of the problem of providing science and engineering buildings at the university level, is a detailed analysis of California and Indiana buildings. It relates construction costs to performance and includes studies of alteration costs and different space types in these buildings. The document covers (1) cost/performance data -- summaries and comparisons; (2) cost/performance data -- bioscience buildings; (3) cost/performance data -- science and engineering buildings; (4) cost/performance data -- classroom office buildings; (5) alteration costs, and (6) functional area costs. Each section consists largely of cost charts and diagrams with analysis. Related documents are EA 003 886 and EA 003 887. (Author)

Where numbers a sequential procedures can be overtapped the time intersal, and consequently coats can be reduced. The use of a building system affords such appointunity. A building system provides "knowns" of subsystem design and cost performance cointrol allowing project development to be split into three phases in the first phase only that planning to establish the general area and mass configuration. If the building need be done. Then, following design of the basic framing and foundation plan construction of site work and foundations can start. As this construction issues proceeds the second phase of general planning of the interiors can be commenced. When the shell of the building is nearing completion, the strict phase involving final planning decisions on detailed departmental space arrangement, eighproved within the actual space they will occupy.

The combination of phased planning and construction and the use of an adaptable fluidding system can impult in academic facilities which are more responsive to user reads and also less costly.

The consperformance only was conducted to provide the statiscal data base for ABS subsystems describe purpose of this report is to document the effort and summarise the findings of the ABS computant hopefully, the study will provide new mainst to significant analyses and compose to a statedomic facilities.

All documents have been prepared by the ABS staff of the Office of the President, University of California. Except for a limited printing by the University of California Printing Department, the documents have been printed by Indiana University fundaments at the expense of Educational Facilities Laboratories, Inc. Copies are available from either of the two Universities.

Performance data becomes extremely useful to the subsystems designer when it is presented along with costs—an essential ingredient in the systems approach. For this reason, and also to establish the actual cost targets for ABS, an extensive cost study was undertaken.

This section presents summaries and comparisons of the cost and performance data (detailed in the sections following) for six science and engineering buildings, selected as typical examples in Indiana and at the University of California. These buildings are as follows:

Bioscience Buildings: Californiaa

U.C. Davis — Biological Sciences Unit 3

U.C. Irvine - Natural Sciences Unit 1

U.C. Santa Barbara — Biological Sciences Unit 2

Science, Engineering Buildings: Indiana

Jordan Hall — Indiana University, Bloomington

Krannert Hall — Indiana University and Purdue University, Indianapolis

Civil Engineering Building - Purdue University, Lafayette

The source materials were the working drawings, specifications and bid documents of the six buildings, estimated for purposes of comparison as if they had been bid in January 1970, in the San Francisco Bay Area, with an Engineering News-Record (ENR) Construction Cost Index of 1300.

The buildings are presented in terms of their individual subsystems. This organization of cost and performance data readily permits comparisons between buildings or subsystems. Each building can be considered as a separate package of subsystems which, working together, exemplify the ranges of performance of that building. Once the buildings are seen as packages, or related groups of subsystems, it is possible to consider and evaluate other hypothetical combinations or packages of subsystems. Thus the subsystems were considered in terms of performance and cost separately, and new groupings formed of the highest and lowest performance packages of subsystems, and of the highest and lowest cost packages. The hypothetical packages provide a base of the extremes of existing costs and performance against which proposed packages may be evaluated.

8/

The following charts are included in this Summaries and Comparisons Section:

| Chart | Description                                    |
|-------|--|
| Α     | Subsystem Equivalent Costs, \$/OGSF            |
| В     | Component Unit Costs, \$/Component Quantity    |
| С     | Subsystems Cost/Performance                    |
|       | Structure Subsystem                            |
|       | HVAC Subsystem                                 |
|       | Partitions Subsystem                           |
|       | Lighting/Ceiling Subsystem                     |
|       | Exterior Skin Subsystem                        |
|       | Laboratory Casework Subsystem                  |
| Đ     | Highest Cost Package of Subsystems             |
| E.    | Lowest Cost Package of Subsystems              |
| F     | Highest Cost Performance Package of Subsystems |
| G     | Lowest Performance Package of Subsystems       |

Summary charts of alteration costs and functional area costs appear in other sections of this document.

Cost/Performance data on other than science and engineering buildings is presented in the section dealing with a classroom-office building beginning on page 149.

#### COMPARISONS

General Building Characteristics and Costs: Of the six buildings studied, Bloomington is by far the largest with 222,065 OGSF; the middle-sized group includes Indianapolis with 134,276 OGSF, Santa Barbara with 132,000 OGSF, and Irvine with 121,000 OGSF; the smallest buildings are Purdue with 113,000 OGSF and Davis with 92,167 OGSF. Purdue has the most efficient ratio of assignable to gross square feet: ASF/OGSF = .61. Bloomington has the least efficient ratio: ASF/ OGSF = .54. Of the Indiana buildings, Indianapolis has the most efficient ratio of exterior wall area to gross square feet: .26, because in plan it is a simple rectangle with a length to width ratio of 2 to 1, and a good deal of interior space. Of the California buildings, Irvine has the most efficient ratio of exterior wall area to gross square feet: .37, due to combined factors such as a relatively low floor-to-floor height and a very large area per floor; like Indianapolis, it also has a simple rectangular shape without projections, which tend to dramatically increase the perimeter area. The other two California buildings are rectangular in plan, but Bloomington is U-shaped and Purdue is L-shaped. All of the Indiana buildings have five stories, with one floor below grade in both Bloomington and Indianapolis, and two in Purdue. In California, Irvine has five stories, Santa Barbara and Davis have six, and all have one story below grade.

All the buildings analyzed as part of this project were estimated to the same cost base. The average cost was \$38.73/OGSF for the Indiana buildings and \$40.56 for the California buildings. The range of the six buildings is from \$33.44/OGSF for Indianapolis to \$44.88/OGSF for Santa Barbara. Although all the California examples are similarly complex, rather heavily serviced buildings, of the Indiana buildings only Bloomington is strictly a science building. Its cost is \$44.13/OGSF. In spite of these similarities in total cost per OGSF, there are significant differences in the areas of expenditure in the two groups of buildings. In Indiana, the buildings tend to have more costly exterior walls and HVAC systems, whereas the California buildings are costly in plumbing and electrical installations.

The three Indiana buildings range from \$33.44 to \$44.13/OGSF. The highest cost at Bloomington results from such factors as the cut stone and ashlar exterior wall, a complex configuration, heavy utility services and an extensive greenhouse installation. The least costly building is Indianapolis, a simple rectangular block with a brick cavity exterior wall and a very high percentage of general classrooms requiring minimum services.

Of the California buildings, ranging from \$37.60 to \$44.88/OGSF, the facility at Santa Barbara is conspicuously more costly than the other two. The reason for this is principally the higher performance characteristics of the building. Santa Barbara has more plumbing systems (sea water, etc.), more electrical power capacity, air conditioning with 100% fresh air (no recirculation), humidifiers which none of the other buildings have, considerably more instrumentation and controls on all systems, a completely separate air conditioning system for the animal study areas in the upper floors, and similar refinements. Irvine is the least costly of the California buildings for a combination of reasons; it has a very large area per typical floor (reducing the relative amount and therefore price of the exterior wall), a lower floor-to-floor height, and lower service capacity, particularly electrical, than the other buildings.

The Indiana buildings vary in construction over a fairly long period of time. Bloomington was contracted for in 1952, Indianapolis in 1960, and Purdue in 1962; whereas Irvine was bid in 1963, and Davis and Santa Barbara in 1966. Naturally there have been changes in construction materials during that time, and some of the materials and mechanical equipment would be exorbitantly expensive to duplicate. Yet, in spite of the cut stone walls and terazzo corridors in Indiana, even at today's prices the buildings are slightly less costly than their more recent California equivalents.

Structure: All six buildings have reinforced concrete structures, but each of the subsystems has a set of performance characteristics particular to it. The three Indiana buildings have a poured concrete joist, beam and column structural system using a moment resisting frame to take the lateral forces. In California, Davis has a poured concrete frame and slab, and both Irvine and Santa Barbara have poured concrete columns and waffle slabs; in all three the lateral forces are taken by shear walls. The California buildings are all in UBC Earthquake Zone 3. In the six buildings the range of bay sizes is fairly consistent, with primary spans from 14' to 30', and secondary spans from 30' to 40'. The waffle slabs at Santa Barbara and Irvine are 30' square. The structural depths range from 3'-0" at Indianapolis to 1'-7" at Irvine. One advantage of the waffle slab is this relatively shallow structural depth. A disadvantage is the lack of horizontal permeability that the waffle slab implies. The structure-services depth is greatest at Davis, where it is 5'-10", the second deepest at Santa Barbara, where it is 5'-5"; and least at Bloomington, where it is 2'-6". In this latter case the users complained that when air conditioning had been added, there was inadequate space for ductwork and terminals. Laboratories at

Davis, Irvine and Bloomington are designed for floor live loads of 50 psf at Indianapolis for 75 psf and at Santa Barbara and Purdue for the highest loading of 100 psf.

Although all the buildings are essentially of concrete frame construction, the California buildings are generally more expensive than their findums counterparts as a result of the high seismic design loads. The one Indiana building that is exceptionally high in cost is Purdue, with some areas designed for 300 psf live load. In terms of cost of structure per OGSF, not including costs of foundations of slabs on grade, the Indiana subsystems average \$5.10/OGSF, the California structural subsystems average \$7.48/OGSF.

HVAC: Davis, Irvine and Purdue have heating and cooling supplied from central campus sources. Santa Barbara and Indianapolis have their own heating and cooling plants. Bloomington has its own cooling plant, but heating comes from a central plant. Air handling units are central to the buildings at Santa Barbara, Irvine, Bloomington and Indianapolis. Davis has air handling unit on each flour of the building. Purdue has a combination of multi-zone units on each floor with local unit ventilation and reheat coils. Indianapolis has unit ventilators under the windows to minimize window drafts, but at the expense of possible casework locations. The multiple air-handling units at Davis appear to take up a slightly higher percentage of floor area than a single unit, but with various advantages for zoning and adaptability

The six buildings use fume hoods for exhaust, but intake locations vary from basement, grade, each floor (Purdue and Davis), or the roof. The distribution system at Santa Barbara and Irvine takes air from two separate air handling units in the basement, via two separate vertical cores, each serving half the building, to main horizontal ducts in the corridor ceilings. In Bloomington, the perimeter is heated by radiation, air handling units feed air in four separate shafts. Air conditioning was an after-thour t, and the chiller was placed under the main auditorium with high disruption to the use of this space. Further, cold air ducts run down the non-air-conditioned corridors causing extensive condensation through the metal ceiling. The dual duct system at Indianapolis feeds up the middle of the building in a vertical service shaft.

The California buildings have 100% heating and oir conditioning. The Indiana buildings all have 100% heating and 80%, 90% and 75% air conditioning in Bloomington, Indianapolis and Purdue respectively. The capacities of the buildings

ward as the angles of the continue of the country cappaint of the indicate buildings and a generally higher continue cappaint to the California buildings. Drawn and trains have 1865 tome and 1860 tome respectively and Carris Barbara 75.2 tome 9 toorningson is the omity exception of this with a continue cappaint of 5000 tome. These relationships reflect the apparental designated of the companion of the terms.

A means remed my figure absolut the performance of the expension is the relation of CHENS & North out rather agree and come. Search a Marchant a sea than beightered poor floors come by altern march. 175 CHCASA non-specialist teres is Dennis, theird is trushe and the three Indiana buildings follows with the townest purformance that of indistriguishs, with \$20 OKGS for Ackloridang to the Julius, senitalistican is madequate in all all buildings. The highest positionnessies in an Dissue with 1.8 ctm OGSF assessed Santa Barbara with 76 often OCISE shard frome Pundue and Indianapoles fourth and fifth and Bloominesco. toward with 66 chin OGSF Agent in territor of percumbages of or returned and recordinated in the eyetim the California buildings have a higher level of performance. Santa Barbara enhances of its oil. Dovin Jum 16.5% return oil, and Irvine upo 40%. Purdue, Indianapolis and Bloomington up 40%, 72% and 75% respectively. The highest quality filter is in Bloomington, which has an electrostatic filter with 90% efficiency. Second highest is the replaceable filter at Santa Bathera which is 50% efficient. All the others are around 36%, the California examples being replacement and the Indiana creat roll type. Of the exa buildings, only Santa Bartana has any humidity control. 15% of the building

The HVAC costs for Indiana average \$4.53.0GSF and for California \$4.55.0GSF. The Catifornia average is considerably higher than its mean of \$4.20.0GSF because of the influence of the elaborate system at Santa Barbara, conting \$5.83.0GSF.

Although the California buildings have a considerably larger percentage of all conditioned floor successions the Indiana are generally higher. Only Santa Barbara and indianapolis contain their own heating and childing plant. In the charts, the cost of this plant has been omitted to that overall costs are comparable. The Indianabuildings have a sendency to mis several different types of heating and cooling systems in one building. This and the much greater heating demands in their climate have created generally more expensive HVAC subsystems. Only the very elaborate Santa Barbara system, using no return air, is more costly than the Indiana systems.

The black partitions of the indians buildings have the highest perform ance I the most of the replacement partitions shaded they provide good furniture authorist but for redocation or charging utilities they present difficulties and high engagement & toccorrectly on, on fact, thus conduct which can be supplied by the provisions and and a surround attachment devices. The coats of the Indiana partitions are all greater than those in the California buildings.

The cost part aguare foot of partition everages \$5.46 in the Indiana buildings and \$4.76 in the Carriornia buildings. The highest cost at \$400mington, results from extensive use of steel demountable partitions and structural facing life. The highest cost quart most are equal by the users California partitions are the treated wood study and gypnum board at Davis, which among other things, provide excellent support for experiments, commons and others.

Laphang-Carling. Of the Indiana buildings, Bloc nington and Puriture have hung contings throughout and Indianapolis has a hung ceiling in clearocoms, offices and corridors. Of the California buildings, laboratorius are ceilinghes, but Devis and Invine have hung ceilings in the offices and corridors, and Santa Barbara has them in the corridors only. Some accountic treatment has been applied to the coffers of the structural stab at Invine. All six buildings have fluorescent lighting. In Purdue, the tight fixtures are received throughout, and received in the offices, classrooms, and corridors in Indianapolis. Bloomington has suspended fixtures. At Devis, lights are suspended in taboratories and offices, received in classrooms and corridors, in Invine

This are subspecified in catice at ories and classer domis and receives and received in offices and commit and received in Caterias Baritians they are subspecified in laborastic estimation or classer occurs and offices and surface missing in contradions

in studying the lighting subsystem it was impossible to misasure foot cardins of light in all of the various functional areas of each building. For this reason, the design performance of the system, taken from the original documents is expressed in watts per aguare foot to measure the comparative performance of the various lighting subsystems. Of the lindians buildings lindianspoles has the highest light levels in offices and classrooms (5.2 and 4.5 watts 5F) but low levels in corridors (98 wetts 5F) which the users found too low, although this level is about the same as at Bloomington and Purdue, which the users considered excellent Probably this is because of the extreme contrast in illumination levels between corridor and the other spaces. The lowest light levels in Indians are in Bloomington (2.2.1.1 wetts SF) but there were no adverse remarks by users. Davis had the highest light level of the California buildings, where laboratories and classrooms were 4 wetts/SF, and Santa Barbara is second with 3.4 wetts/SF. Invine has a higher light level in offices than laboratories (3.5 wetts/SF) versus 3.0 wetts/SF.

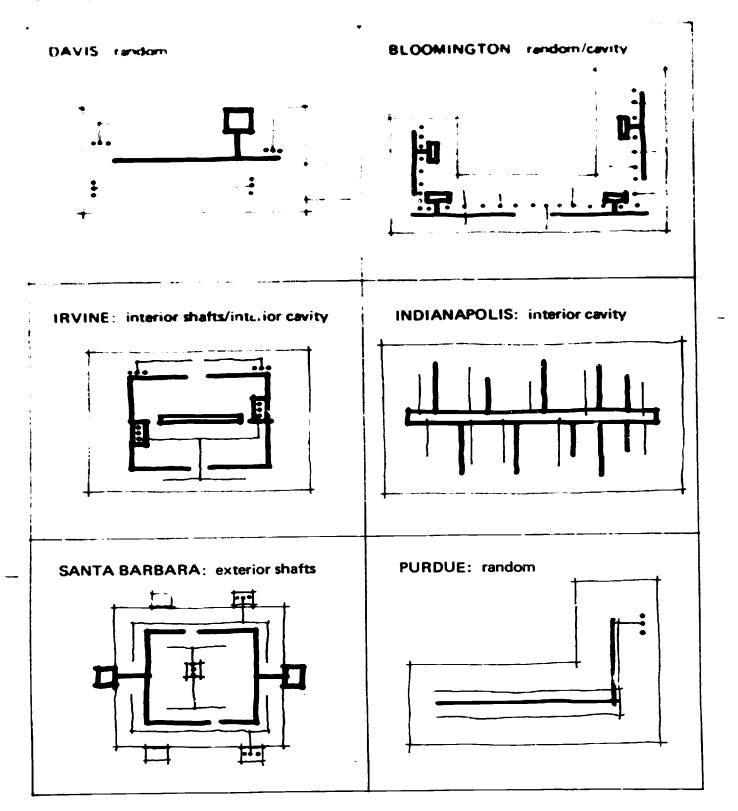

Variation in the lighting costs reflects the quality of fixtures selected rather than the quality of illumination. The average lighting cost in the lighting ceiling subsystem in the Indiana buildings is \$87/OGSF and in California \$1.16/OGSF.

Certing costs per OGSF reflect both quality and quantity of ceiling. Many taboratories do not have ceiling treatment other than paint. Offices and classrooms generally have acoustical ceilings. Corridors must usually have a one-hour, fire-rated ceiling. In spite of the pussible variations, the combined lighting-ceiling subsystem averages of \$1.49 in Indiana and \$1.61 in California appear representative of academic buildings of this type.

Services Organization. The six buildings illustrate a variety of ways of handling services organization. The term "services" is inclusive of electrical, plumbing, utility services, and HVAC. Three of the buildings—Indianapolis, Irvine, and Santa Barbara—demonstrate very strong patterns of vertical organization, and three—Bloomington, Purdue and Davis—are less formal and demonstrate an ad hoc placement of vertical service risers. The strong vertical patterns are of three different types. Indianapolis has a simple, continuous interior cavity or vertical service space; Irvine has a combination of two major interior, structural shafts housing service

#### SERVICES ORGANIZATION

risers with a less significant carity; Santa Barbara has six structural shafts housing service risers on the perimeter of the building. In the other three buildings the risers are randomly placed but usually related to another building element such as a staircase, elevator shaft or corridor. Horizontal services movements are all related to the corridor patterns of the buildings with the exception of Indianapolis, where horizontal movements are direct between the vertical mains and the spaces they supply. In all six buildings, floor drains are randomly positioned.

The greatest problem of services distribution in most existing buildings is in the area of accessibility; most services are hard to get at and modify or repair. Users at Indianapolis were enthusiastic about their generous vertical service cavity which made possible the repair of services distribution elements without disruption to usable space and without physical difficulty. A problem brought up recurrently by building users concerns the fact that drainage is always below the structural floor of the space it serves. When it has to be remained or rerouted because of a desired change in that space, the space directly below must also be disturbed. Generally any major alteration to services distribution has been difficult, costly, and formidable to the point of constraining users from making desirable changes.

Exterior Walls: In terms of exterior materials, the six buildings fall into three groups: (1) the three California buildings are concrete, Davis poured and Santa Barbara and Irvine precast; (2) Indianapolis and Purdue are concrete block and brick, with limestone trim at the windows; and (3) Bloomington is sheathed in split-face ashlar limestone, with smooth-face and carved limestone at the doors and windows. Davis is the only building with structural exterior walls. With the exception of the collegiate Gothic detailing at Bloomington and the highly sculptured walls at Irvine, the buildings have quite simple, straightforward exterior treatments.

In Indiana, the exterior wall itself make. no provision for sun control, and of the three buildings, only Indianapolis has any exterior sun control, with metal sunscreens attached to individual windows on the south side. In California buildings, however, where sunlight is a greater problem, elaborate provision is made for sun control: applied sculptured window surrounds at Irvine, cantilevered shades over each window at Davis, and cantilevered extension of the complete floor slab at Santa Barbara. The percentages of glazed area to total exterior wall area are surprisingly close in the six buildings, with a range from 5% at Santa Barbara to 32% at Indianapolis.

The cost/OGSF of exterior skin ranges from \$2.44 to \$7.03. The cost per square foot of exterior ranges from \$7.69 to \$17.58. Bloomington is highest in cost because of the block cavity wall with limestone facing and elaborately carved bay windows, entrances and trim; the other Indiana buildings were \$10.76 and \$11.40/SF wall. The exterior skin of the California projects is generally less costly than the Indiana projects because of the lesser insulating requirements. They do, however, have extensive structural shear walls. It is clear that the lower buildings, with large areas per floor, have relatively low exterior wall costs if stated in dollars per OGSF. Thus the expensive Irvine enclosure is only \$3.91/OGSF, compared to \$2.67/OGSF at Santa Barbara and \$4.03/OGSF at Davis.

Casework: All six buildings have a complete range of laboratory furniture. Hardwood and plywood casements are used in all the buildings with a variety of bench tops, including materials such as plastic laminates, stainless steel, epoxy resin compound, cement asbestos and soapstone. Sinks are generally made of similar materials.

#### SUBSYSTEMS PACKAGES

The comparative cost and performance data are of use in evaluating the effectiveness of subsystems in existing facilities. These data may be further developed in order to demonstrate the extremes of cost and performance which are represented. This will be of great value to the subsystems designer and building user in outlining the range of choices available to them. From the complete range of subsystems cost and performance hypothetical combinations or packages of subsystems have been composed in order to demonstrate:

- 1. The highest cost package of subsystems (Summary Chart D)
- The lowest cost package of subsystems (Summary Chart E)
- 3. The highest performance package of subsystems (Summary Chart F)
- 4. The lowest performance package of subsystems (Summary Chart G)

The extraction of highest and lowest costs is a simple mechanical process whereas the extraction of highest and lowest performance is judgmental. Summary Charts D.G represent the four packages drawn from the existing facilities subsystems, and consist of a statement of subsystem cost and its related performance, and a total cost for all the subsystems in the package. The names of buildings from which the subsystems are extracted are interesting, retrospectively, but incidental to formulating the projections which are the object of this exercise.

Significant comparisons may be made between these subsystem packages. The highest cost package is not the highest performance package. HVAC and partitions in these packages are identical. However, there is a noticeable difference of \$.37/OGSF in the lighting-ceiling subsystem cost, and a substantial difference of \$1.46/SF in the cost of the structural floor component.

The lowest performance package is not the lowest cost package. Although partitions are the same in both cases, there is a much higher level of performance in the lower cost (\$.21/OGSF) lighting-ceiling subsystem. The cost difference of \$.90/OGSF in the HVAC subsystem is not substantiated by the performance difference. The less expensive subsystem of the two has a higher level of performance, providing .48 cfm/OGSF more than the other and 35% more fresh air. Of particular significance is the fact that the lowest cost structural floor component has also the highest performance in the six buildings.

### COST/PERFORMANCE DATA SUMMARIES AND COMPARISONS

It would be a mistake to oversimplify the conclusions from this kind of comparison, but they are indicative of the kinds of savings possible without loss of performance, or where performance may be increased and paid for by a more economical toal package. It must also be borne in mind that reshuffling of different packages may not result in the same unit costs and could increase the total package cost. However, this same consideration is vital to the subsystems design process of formulating packages of proposed subsystems performance and cost. Therefore this method is valid for making comparisons between the cost and performance range of theoretical packages and the content of any proposed package.

The ABS consultant analyzed and compared three University of California biological sciences buildings recently completed at the Davis, Irvine, and Santa Barbara campuses. These buildings are:

Biological Sciences Unit No. 3, <u>Davis</u> (Storer Hall) Natural Sciences Unit No. 1, <u>Irvine</u> Biological Sciences Unit No. 2, <u>Santa Barbara</u>

Cost and performance data in the preceding "Summaries and Comparisons" section are extracted from the detailed information herein.

#### **COST DATA**

The costs of existing facilities establish the bases for those cost parameters applicable to ABS subsystems. Working drawings, specifications, and bidding documents for the three buildings were submitted to the Koch Company, Construction Cost Consultants, of San Francisco, assisted by J. Rumsey for mechanical and electrical work. They prepared an estimate for each project as if it were bid January 1970 in the San Francisco Bay Area with an Engineering News-Record (ENR) Construction Cost Index of 1300.

The base bid, without alternates or change orders, was the amount estimated. For comparison, the actual base bids were projected to ENR 1300 and adjusted from the campus location to the San Francisco Bay Area by application of the American Appraisal Company's Boeckh Time-Location Modifiers for institutional reinforced concrete frame buildings. The estimates exceeded the adjusted actual low bids by 2% in two cases and 3% for Irvine. The three study projects are compared by component costs. Within the component cost divisions the cost of elements equivalent to the ABS subsystems were isolated and tabulated separately, for use in establishing target prices for the subsystems. Upon completion of the subsystems design, these tabulations were reassessed and revised to correspond as precisely as possible with the ABS final design. No change was made in cost division estimates except for redistribution of cost elements between systems and non-systems categories.

Table 1 indicates, in dollars per outside gross square foot (\$/OGSF), the costs of components equivalent to ABS subsystems and components outside of the ABS system. Table 2 indicates, for certain cost divisions, the component unit cost in terms of dollars per square foot of component surface area as tabulated in the last column of cost division breakdowns.

All costs represent subcontract prices, including subcontractor's overhead and profit, but general contractor's mark-up is itemized separately.

The three buildings studied at the Davis, Irvine, and Santa Barbara campuses are quite similar in character, although the costs of some of their elements vary considerably. Observed reasons for variation are discussed with relationship to the individual cost divisions.

In general, the higher cost of the Santa Barbara building may be attributed to meachanical, plumbing and electrical systems which are more elaborate than the others, even though the cost of steam boilers, chillers, and their electrical switchgear was omitted for comparison with the other two buildings served by central plants.

A number of the more costly items at Santa Barbara such as the ocean water supply system and the lecture hall, were postponed or eliminated by alternate bids or change orders during construction.

The relatively low unit cost of the Irvine building results from mechanical efficiencies, and from most of the site work and utility installations being completed under a previous contract.

The relatively high cost laboratory utility distribution at Santa Barbara is mostly "non-subsystem" in the tabulations. It should be noted that these systems are designed for a high degree of adaptability.

For the purposes of this study, laboratory casework estimates for all three buildings were based on the same unit pricing structure, without cost adjustment for individual differences in laboratory tops, types of fume hoods and quantity of fixtures, since it was believed that the installations were comparable in quality and the differences were not significant.

#### PERFORMANCE DATA

The performance characteristics of subsystems in the three sample buildings were studied concurrently with costs for analysis of the relationships and for projection of proposed performance requirements for ABS subsystems. The intent was to indicate in simple descriptive terms the subsystems capabilities and how well they perform. Data, in the form of gross measurable quantities expressed as percentages of gross floor area, are supplemented with descriptive and quantitative statements of the performance characteristics.

### U.C. Davis - Biological Sciences Unit No. 3 (Storer Hall)

Architect: Anderson, Simonds, Dusel & Campini

Structural Engineer: McClure & Messenger
Mechanical Engineer: Ralston & Dwyer
Electrical Engineer: C. P. Martineau, Jr.

Bid Date: April 12, 1966 Completion Date: June 1968

### U.C. Irvine - Natural Sciences Unit No. 1

Architect: W. L. Pereira & Associates

Structural Engineer: Brandow & Johnson & J. A. Martin & Associates

Mechanical Engineer: Ralph E. Philips, Inc. Electrical Engineer: Ralph E. Philips, Inc.

Bid Date: October 31, 1966 Completion Date: July 1966

### U.C. Santa Barbara - Biological Sciences Unit No. 2

Architect: A. Quincy Jones & Frederick Emmons

Structural Engineer: Greve & O'Rourke
Mechanical Engineer: Ayres & Hayakawa
Electrical Engineer: Frumhoff & Cohen

Bid Date: July 7, 1966 Completion Date: June 1968

| Elevators                         |       | 72,000  |       | .60 | 2  |
| General Contractor                | 2     | 211,000 | 1.    | .74 | 5  |
|                                   | \$4,5 | 50,254  | \$37. | .60 |    |

The cost estimate exceeds the projected and adjusted base bid by less than 3%.

NOTE: This cost estimate is based on the contract documents as bid, and it includes an attached lecture hall (not illustrated) of 13,200 OGSF.

<sup>\*</sup>Boeckh Modifier Los Angeles - San Diego to San Francisco Bay Area = 1.09

### Cost Divisions

### U.C. SANTA BARBARA BIOLOGICAL SCIENCES UNIT 2

Bid July 7, 1966; ENR Construction Cost Index 1047

132,000 Outside Gross Square Feet (OGSF)

Base Bid:

\$4,936,000 @ ENR 1047 (\$37.39/OGSF)

Projected:

\$6,128,540 @ ENR 1300 (\$46.43/OGSF)\*

Geographical Adjustment:

None. Santa Barbara and San Francisco Bay Area costs are approximately equal.

#### Cost Estimate (Jan. 1970 – ENR 1300)

|                                   | -           | \$/OGSF_ | _%_ |
|-----------------------------------|-------------|----------|-----|
| Site Work, Below Grade & Basement | \$ 440,580  | 3.34     | . 7 |
| Floors                            | 666,210     | 5.05     | 11  |
| Roof                              | 170,550     | 1.29     | 3   |
| Interior Partitions               | 706,410     | 5.35     | 12  |
| Interior General                  | 663,670     | 5.02     | 11  |
| Exterior Skin, above ground       | 537,870     | 4.08     | 9   |
| HVAC*                             | 769,768     | 5.83     | 13  |
| Plumbing                          | 800,537     | 6.07     | 14  |
| Electrical                        | 703,618     | 5.33     | 12  |
| Elevators                         | 165,000     | 1.25     | 3   |
| General Contractor                | 300,000     | 2.27     | 5   |
|                                   | \$5,924,213 | \$44.88  |     |
| Boiler and Chiller Plant*         | 356,877     | 2.70     |     |
|                                   | \$6,281,090 | \$47.58  |     |

<sup>\*</sup>The total cost estimate of \$6,281,090 (\$47.58/OGSF) exceeds the projected base bid by 2%. Unlike the Davis and Irvine buildings, served by central plants, this building supplies its own steam for heating and its own chilled water. For comparison, therefore, the costs of boilers and chillers and their electrical switchgear are excluded in this cost analysis.

# Site Work, Below Grade and Basement Cost Division.

This cost division includes basement walls and slab, foundations and sitework. None of these are within the scope of an ABS subsystem.

The Davis building has a full basement containing laboratories as well as mechanical rooms.

The Irvine building has a partial basement containing storage, mechanical and electrical rooms.

The Santa Barbara building has a full basement with boiler and chiller rooms, fan rooms and electric switchgear.

The lower cost of this division for the Davis project results from simple foundation and wall conditions and a minimum of site improvement work.

### Floors Cost Division.

The Irvine and Santa Barbara buildings have similar floor construction systems, concrete waffle slabs with 30'-0" x 30'-0" bays. The variance in cost per OGSF of the complete floor components results mainly from the degree of finish, with Irvine having a paved cantilevered deck and considerably more ceiling, which is included as an element of the Floors Cost Division.

The Davis building is principally of long-span joist construction in concrete, with more suspended ceiling than Santa Barbara.

Roof Cost Division Area = 24,580 S.F. = .19 OGSF

### Roof Cust Division.

The \$/OGSF cost of the roof components, including ceilings, insulation and surfacing, naturally varies with the size of the roofed area compared with the OGSF of the building. Therefore, Irvine is the most costly and Davis the least.

Further, however, Irvine has a considerable amount of relatively expensive clay tile.

In unit cost per square foot of roof, the Santa Barbara project is the most costly, principally because of provisions for equipment and penthouses requiring special steel structures.

Interior Partitions Cost Division Area = 193,750 S.F. = 1.47 OGSF

### Interior Partitions Cost Division.

The costs of interior partitions per OGSF reflect both planning characteristics and the quality of the products used. The floor-to-floor height at Irvine is considerably less than that of the other projects, so results in a saving in quantity and the lowest cost per OGSF.

The highest partition cost, at Davis, is due to fire-retardent wood studs with gypsum board faces. This design has been very satisfactory according to interviews and inspection. It permits easy attachment of equipment to the walls. This relatively expensive wall (treated studs at this date are about three times the cost of untreated Douglas fir studs) is approximately the same cost per OGSF as the lower cost partitions at Santa Barbara because the Davis plan is essentially a double-loaded corridor, whereas the Santa Barbara plan is an interior "race track" corridor requiring more lineal feet of partition. ("Race track" is a double-loaded corridor encircling the entire floor, generally with offices on the outside and laboratories inside.)

The Santa Barbara partitions are laminated gypsum board with relatively simple demountability.

### Interior General Cost Division.

The principal interest in subsystems in this division concerns the educational and scientific aids such as laboratory casework and chalk and tack boards.

The cost differences in these elements mainly reflect the degree to which sinks and utility connections were specified under "laboratory equipment" or "plumbing." The quality and nature of all installations are similar.

Exterior Skin--Above Ground Cost Division Area = 70,000 S.F. = .53 OGSF

56

, **55** 

## Exterior Skin Above Ground Cost Division.

The exterior skin costs relate to building configuration. Although the Irvine building has by far the most elaborate exterior treatment, with sculptured precast concrete sunshades at each opening, its low floor-to-floor heights and a large floor area to peripheral area ratio result in a cost per OGSF which is median in the group.

The Santa Barbara building has the lowest unit cost, either per OGSF or per square foot of wall, yet it includes large areas of exterior utility shafts.

The Davis exterior wall costs are increased by the use of an elaborate five-story precast concrete grille in the wing connecting to Hutchison Hall, and a trellis-like screen concrete parapet around the roof.

NOTE: Items 4 and 5 are central plant costs amounting to \$2.63/OGSF and are peculiar to Santa Barbara only, and are, therefore, excluded in cost comparisons.

### Heating, Ventilating, Air Conditioning Cost Division.

A conspicuous reason for the highest cost HVAC system at Santa Barbara is that it supplies its own steam for heating and its own chilled water, the one of the three projects to do so. Also, it is more elaborate in controls, supplies and BTU per area unit, has the lowest OGSF per ton of refrigeration, and is the only project with 100% fresh air, no return. The location of the shafts at the outside corners of the building contributes to large runs of ductwork.

By contrast, the Irvine building uses high temperature water and chilled water from a campus central plant. The building is served from a central core of essentially two basic zones from a basement air-handling room. This has resulted in the lowest cost installation.

The Privis system has an air handling unit at each floor, utilizing campusplant steam and chilled water. The lower cost of controls is because there is one thermostat per 1,000 square feet at Davis as against 2½ per 1,000 square feet at irvine and Santa Barbara.

### Plumbing Cost Division.

The Santa Barbara project is again conspicuous in the cost of its plumbing because it has more systems than the others and more elaborate details. The acid waste, for instance, extends throughout the entire building; whereas in the other buildings it extends only to the point where it is mixed with other effluent. The water and gas supply lines provide valves periodically for new tap-ins so that extension may be made without shutting down the system. Although costly initially, these provisions enable additions or relocation of facilities at a minimum cost.

The plumbing costs at Davis and Irvine reflect good current practice but not as much flexibility as at Santa Barbara.

# Electrical Cost Division.

The difference in the \$/OGSF costs of the three projects varies with the capacities provided, except that Santa Barbara provides a continuous bus-duct system around each corridor. This makes additions and changes very easy to accommodate.

The relative lighting costs again reflect capacity. In none of the buildings was there complaint about the quantity of light. Location of fixtures, however, because of shadows, was criticized in some cases.

#### DAVIS STRUCTURE

Poured concrete floor and mot slabs are supported by poured concrete columns and beams. Shear resistance is by internal poured concrete shear walls.

#### **IRVINE - STRUCTURE**

A poured concrete waffle slab is supported on poured concrete columns. The precast concrete panels on the north and south walls are structural. The roof framing to the fifth floor penthouse is structural steel. Shear resistance is by internal poured concrete shear walls to vertical shafts and by poured concrete spandrels.

### SANTA BARBARA – STRUCTURE

A poured concrete waffle slab is supported on poured concrete columns. Shear resistance is by internal poured concrete shear walls and by poured concrete walls to vertical shafts.

### DAVIS - HVAC

High pressure steam and chilled water supply are from a central campus plant. Each floor has a machinery room consisting of air handling unit and fresh air intake with cooling and preheat coils. Air is recirculated from classrooms and offices. Each floor is a separate HVAC zone in which distribution is by a single duct with reheat coils in each room. Temperature control is by a thermostat in each room. Air is exhausted by exhaust ducts (to which fume hoods are also connected) via periodic vertical mains with fans at roof level.

### **IRVINE - HVAC**

High temperature water and chilled water supply are from a central campus plant. Two air handling units and preheat coils, each serving one half of the building, are located in the basement with air intakes. Air is recirculated from classrooms, offices and miscellaneous spaces via corridor ceiling plenum and main wartical shafts. Vertical distribution is via two main shafts within the building, and from these, double ducts over the corridors serve each floor. Control is by zones of one or two rooms. Air is exhausted by fume hoods and exhaust plenum both contained in a central services cavity. Air supply, return and exhaust is at low pressure.

### SANTA BARBARA — HVAC

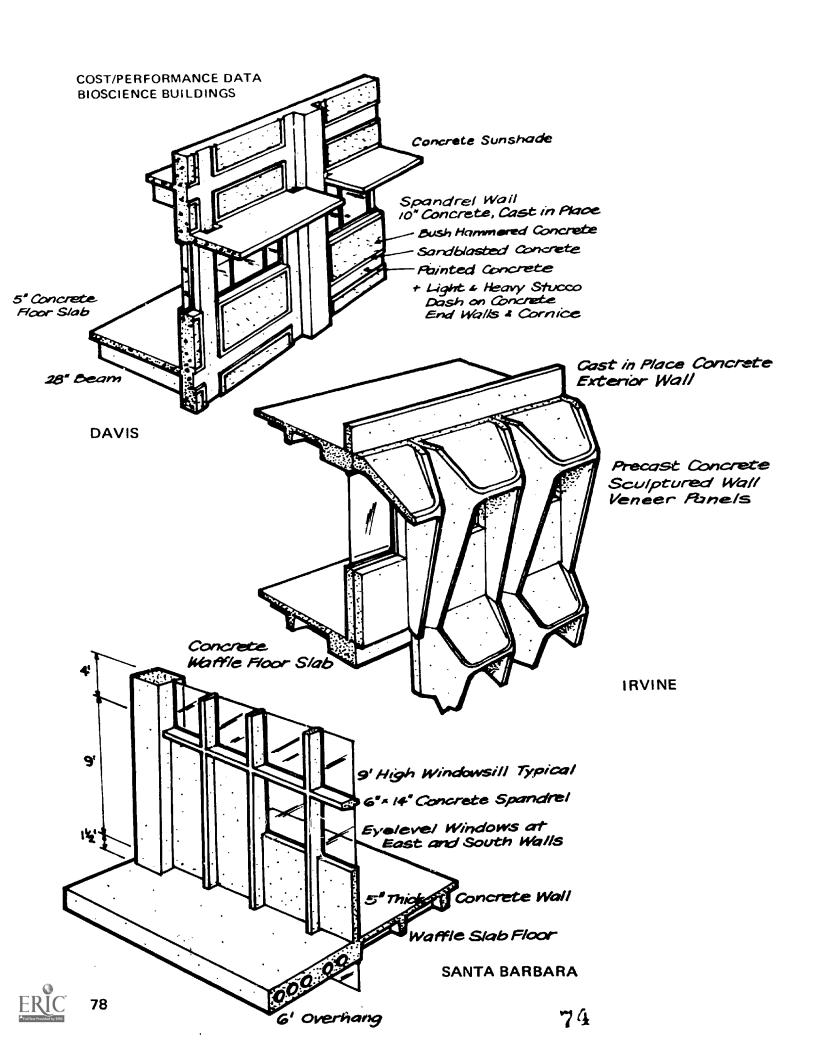

High pressure steam and chilled water are from gas fired boilers and absorption chiller in the basement machinery room. Air handling and preheat coils for the first to fifth floors are in the basement with 100% fresh air intake. The sixth floor and penthouse are served by a separate air handling unit on the roof. This is the only zoning of HVAC in the building. Vertical distribution is via two main shafts on the perimeter of the building, and from these, double ducts over the corridors serve each floor. There are a number of special temperature rooms on reheat coils or refrigeration coils with humidity control. HVAC control in the building is central. Air is exhausted at roof level via fume hoods and corridor ceiling plenum carried vertically in perimeter shafts.

### **DAVIS - EXTERIOR WALLS**

The spandrel walls are poured concrete with poured concrete cantilever sunshades over windows. The exterior finish of the spandrel panels is bush hammered and delineated by a sand blasted edge or trim. The interior finish is plaster and paint.

# **IRVINE - EXTERIOR WALLS**

The panels on the north and south walls are structural precast concrete welded in place. They have an exposed aggregate finish. Spandrel panels are poured concrete with an exposed aggregate, precast concrete facing. Interior finishes are exposed concrete. Windows are surrounded by a precast concrete sculptured form for sun protection with exposed concrete finish. The poured concrete casing to the penthouse framing is also sculptured and has an exposed concrete finish.

# SANTA BARBARA - EXTERIOR WALLS

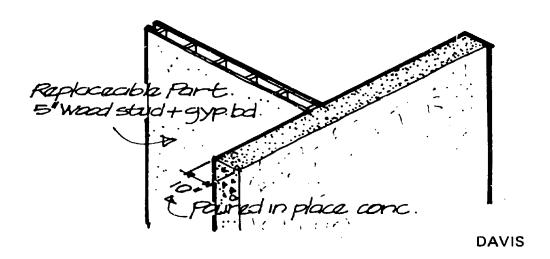

Mul!ions and spandrels with varying window sill heights are formed in precast concrete with a plain, painted concrete finish. The interior finish is exposed concrete. Sun shades are formed by cantilever floor slabs.

SANTA BARBARA

# DAVIS - LIGHTING/CEILING

There are no suspended ceilings provided in labs; fluorescent light fixtures are suspended from the structural ceiling. In classrooms suspended ceilings are painted gypsum board; fluorescent light fixtures are recessed in wooden trims. In offices, suspended mineral fiber tile ceilings are provided; fluorescent light fixtures are suspended below the ceilings. In corridors suspended mineral fiber tile ceilings are provided; fluorescent light fixtures are recessed into the ceilings.

### IRVINE - LIGHTING/CEILING

There are no suspended ceilings provided in labs; fluorescent light fixtures are suspended from the structural ceilings. There are no suspended ceilings provided in classrooms; some acoustic tiling is applied to the coffers of the waffle slabs; fluorescent lighting fixtures are suspended from the structural ceilings. In offices, suspended mineral fiber ceilings are provided; fluorescent light fixtures are recessed into the ceilings. In corridors suspended mineral fiber ceilings are provided; fluorescent light fixtures are recessed into the ceilings.

# SANTA BARBARA - LIGHTING/CEILING

There are no suspended ceilings provided in labs; fluorescent light fixtures are suspended from the structural ceiling. There are no suspended ceilings provided in classrooms; fluorescent light fixtures are suspended from the structural ceiling. There are no suspended ceilings provided in offices; fluorescent light fixtures are suspended from the structural ceiling. In corridors suspended acoustic tile ceilings are provided; fluorescent light fixtures are mounted on the surface of the ceilings.

- 3

### **DAVIS - SERVICES**

This building has four main vertical risers for plumbing, and one for electricity and communications. The corridor and HVAC ducts separate the horizontal plumbing distribution zones. Benches are supplied down from ceiling mains. Floor penetrations for drain lines are random. Bus ducts for horizontal electrical distribution are a feature of this building.

### **IRVINE — SERVICES**

This building has four main vertical risers for plumbing and two for electricity. The corridors, HVAC ducts and main vertical chases separate the horizontal plumbing distribution zones. Benches are supplied down from ceiling mains or up through the floor with main runs on alternate floors. Floor penetrations for drain lines are random.

# SANTA BARBARA - SERVICES

This building has three main vertical risers for plumbing and one for electricity. The corridor and HVAC ducts separate the horizontal plumbing distribution zones. There are five main vertical risers for plumbing waste lines. Benches are supplied down from ceiling mains or up through the floor with main runs on alternate floors. Floor penetration for drain lines are random.

The ABS consultant analyzed and compared three existing science and engineering buildings in Indiana. These buildings are:

Jordan Hall, Indiana University, <u>Bloomington</u>, Indiana
Krannert Hall, Indiana University and Purdue University,
<u>Indianapolis</u>, Indiana
Civil Engineering Building, <u>Purdue</u> University, Lafayette, Indiana

Cost and performance data in the preceding "Summaries and Comparisons" section are extracted from the detailed information herein.

### **COST DATA**

The costs of existing facilities establish the bases for those cost parameters applicable to ABS subsystems. Working drawings, specifications, and bidding documents for the three buildings were submitted to the Koch Company, Construction Cost Consultants, of San Francisco, assisted by J. Rumsey for mechanical and electrical work. They prepared an estimate for each project as if it were bid January 1970 in the San Francisco Bay Area, with an Engineering News-Record (ENR) Construction Cost Index of 1300.

Estimates were based on contract documents without change orders. In the case of the Krannert Building, the estimate includes work under contracts bid in April 1960 for the original building, but not contracts bid February 1966 for an addition. For comparison, except for Jordan Hall, the actual bids were projected to ENR 1300 and adjusted to San Francisco Bay Area prices by the application of the American Appraisal Company's Boeckh Time-Location Modifiers for institutional reinforced concrete frame buildings. For Jordan Hall, because of the lengthy interval from the bid date of March 1952 to January 1970, Marshall Valuation Indexes were used instead. The estimates varied from the projected and adjusted bids by minus 4% for Jordan Hall, minus 2% for Krannert Hall, and plus 7% for the Civil Engineering Building at Purdue.

The three study projects are compared by component costs. Within the component cost divisions the cost of elements equivalent to the proposed ABS subsystems were

isolated and tabulated separately, for use in establishing target prices for the subsystems. Upon completion of the subsystems design, these tabulations were reassessed and revised to correspond as precisely as possible with the ABS final design. No change was made in cost division estimates except for redistribution of cost elements between systems and non-systems categories.

Table 1 indicates, in dollars per outside gross square foot (\$/OGSF), the costs of components equivalent to ABS subsystems and components outside of the ABS system. Table 2 indicates, for certain cost divisions, the component unit costs in terms of dollars per square foot of component surface area as tabulated in the last column of cost division breakdowns.

All costs represent subcontract prices, including subcontractor's overhead and profit, but general contractor's mark-up is itemized separately.

The three buildings studied at Bloomington, Indianapolis, and Purdue are generally similar in character, although the costs of some of their elements vary considerably. Observed reasons for variation are discussed with relationship to the individual cost divisions.

Laboratory casework estimates were not included initially, but were added for cost comparison with the three California buildings, wherein the general contract work included laboratory casework.

### PERFORMANCE DATA

The performance characteristics of subsystems in the three sample buildings were studied concurrently with costs for analysis of the relationships and for projection of proposed performance requirements for ABS subsystems. The intent was to indicate in simple descriptive terms the subsystems capabilities and how well they perform. Data, in the form of gross measurable quantities expressed as percentages of gross floor area, are supplemented with descriptive and quantitative statements of the performance characteristics.

# Jordan Hall, Indiana University, Bloomington, Indiana

|                                   | \$9,166,717      | \$41.28      |            |
| Laboratory Casework               | 750,580          | 3.38         |            |
|                                   |                  |              |            |

For comparison with other buildings served by central plants, the cost of the building chilled water plant is excluded from the HVAC cost division. The cost of laboratory casework was estimated separately and is not included in the Interior General cost division.

<sup>\*</sup>Because of the long time period from bidding to date, the bid total was projected and adjusted on the basis of Marshall Valuation Indexes, rather than ENR. The cost estimate of \$9,166,717 is 4% less than the projected and adjusted bid total.

For comparison with other buildings served by central plants, the cost of the building boiler and chilled water plant is excluded from the HVAC cost division. The cost estimate of \$4,301,451 exceeds the projected and adjusted bid total of 2%. The cost of laboratory casework was estimated separately and is not included in the Interior General cost division. This cost estimate does not include a 35,454 OGSF addition bid February 1966.

PURDUE

#### **BLOOMINGTON - HVAC**

High pressure steam is from a central plant. Chilled water is from an electric chiller in the basement. Air handling equipment is installed in four fan rooms located on the roof. Perimeter of building is heated by radiation. Each floor has four cooling and ventilating zones with radiation control in each room. Air is exhausted by fume hoods and exhaust ducts via periodic vertical mains with fans at roof level.

#### INDIANAPOLIS - HVAC

Hot water and chilled water are from gas fired boilers, and electric chiller is located in the basement. Air handling units are in the basement with provision for 30% outside air. Dual duct system feeds vertically in the center of the building. Provisions have been made for an additional floor. Classroom type unit ventilators are installed around the perimeter of the building. Control is by room with individual thermostats. Air is exhausted by fume hoods. Air supply and return are low pressure.

#### **PURDUE - HVAC**

High pressure steam and chilled water supply are from a central campus system. The building system consists of a combination of multi-zone units on each floor plus heating-cooling type unit ventilators. Control is by individual room. Air is exhausted by fume hoods and exhaust ducts at the roof level. Fresh air is taken in at each floor. Air supply, return and exhaust is at low pressure.

+++4" Block With Facing Tite :: 46 DB

INTERIOR PARTITIONS SUBSYSTEM

PURDUE

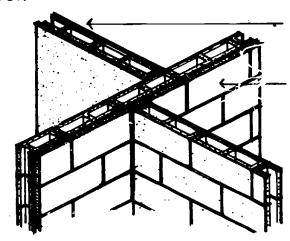

Demountable metal (classrooms, offices) partition w/insulation core,

2" structural facing tile (corridor) on 4" block wall.

4" concrete block.

#### **BLOOMINGTON**

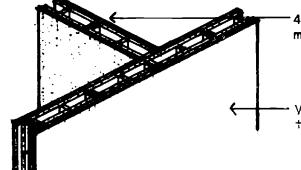

4" concrete block with (classrooms, offices) plaster on metal lath, both sides.

2" structural facing tile (corridor) on 4" concrete block.

4" concrete block, painted.

#### **INDIANAPOLIS**

4" concrete block with plaster metal lath, both sides.

- Vinyl fabric surface over plaster, this side (corridor).

SCALE

**PURDUE** 

#### **BLOOMINGTON - INTERIOR PARTITIONS**

None of the interior walls are structural; 80% of the walls are replaceable and 20% are demountable. Replaceable walls are constructed of concrete block with and without structural facing tile. Demountable walls are  $mad \varepsilon$  of manufactured metal panels with baked-on enamel finish and an insulation core.

#### INDIANAPOLIS - INTERIOR PARTITIONS

None of the interior walls are structural; 100% are replaceable. Replaceable walls are constructed of concrete block, painted concrete block and structural facing tile and concrete block plastered and painted.

#### **PURDUE - INTERIOR PARTITIONS**

6.2% of the interior walls are structural; 93.8% are replaceable. Structural walls are reinforced concrete and occur below grade. Replaceable walls are concrete block plastered and painted or covered with vinyl wall fabric.

#### **PLUMBING SUBSYSTEM**

# **BLOOMINGTON**

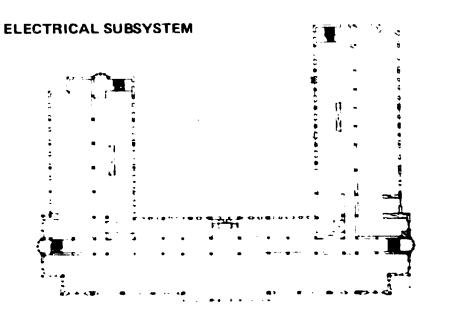

INDIANAPOLIS

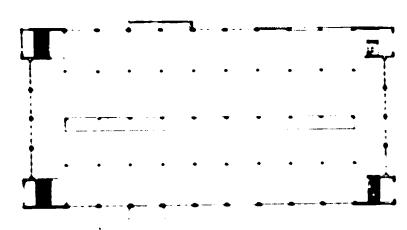

PURDUE

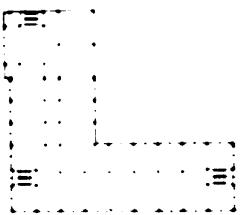

# **BLOOMINGTON**

## INDIANAPOLIS

## PURDUE

#### **BLOOMINGTON - SERVICES**

Plumbing vertical risers are dispersed throughout the building going down in the corridor walls. Benches are supplied up through the floor. There are four main electrical vertical risers.

#### IND: ANAPOLIS -- SERVICES

The huilding has one main vertical riser for plumbing with each electrical distribution having an individual feed. There are two vertical risers for plumbing waste lines. Horizontal mains at each floor are located in the central utility core. Floor penetration for drain lines are at random.

#### **PURDUE - SERVICES**

. 31

The building has one main vertical riser for plumbing with one vertical electrical feed. Floor penetration for drain lines are at random. Horizontal mains rur above the corridor ceilings.

The Cost/Performance Study was centered on six science and engineering buildings in California and Indiana. However, for comparison with a different type of building, the ABS consultant analyzed a classroom-office building at the University of California Berkeley campus—Barrows Hall.

Cost data was developed in exactly the same way. The cost estimate was based on contract documents, without change orders, and was prepared as though the project was bid January 1970 in the San Francisco Bay Area with an Engineering News-Record (ENR) Construction Cost Index of 1300.

The Barrows Hall HVAC cost (\$4.44/OGSF) was about the same as the average for the six science and engineering buildings (\$4.54/OGSF). While this, at first, did not appear realistic (Barrows is a non-laboratory building without air conditioning), investigation showed higher control, duct and insulation costs and a lower fan cost than the other buildings. Apparently the higher percentage of smaller zones in Barrows balanced the higher airflow and air conditioning costs in the science and engineering buildings.

As far the other ABS subsystems equivalents, the cost of the structure at \$7.14/OGSF was comparable to the average cost of \$7.48/OGSF for the three California bioscience buildings; the cost of partitions at \$3.72/OGSF was higher than the \$3.06/OGSF California average; and the lighting/ceiling cost of \$1.93/OGSF was higher than for any of the six science and engineering buildings.

ABS subsystems equivalents in Barrows Hall accounted for 56% of the total construction cost. This, of course, is considerably greater than for any of the other six buildings, and indicates that an economical ABS system would have application to classroom-office buildings and similar non-science buildings.

# **ALTERATION COSTS**

# GENERAL

One of the main objectives of the ABS project is to attack the problems inherent in methods of design and construction that result in buildings not easily adaptable to changing educational, technological, and administrative conditions. The ABS' goals are to increase building adaptability and to reduce building life costs by permitting faster and more economical changes.

In studies of the cost of adaptability, the ABS consultant investigated the following

- 1 Cost histories of several science buildings.
- 2 Comparative alteration costs—six existing buildings.
- 3. Comparative disruption costs—six existing buildings.
- 4. Cost of change of occupancy.

These investigations provided the bases for evaluating relative costs of adaptability in existing facilities and for establishing target costs for ABS.

## COST HISTORIES

The need for adaptability in university laboratory buildings may be dramatically expressed by graphs relating costs of construction, additions, and alterations to the life and evolution of a few existing laboratory buildings. These graphs were derived from records of construction costs incurred during the life of the buildings, to date. The extent of change in some buildings is surprisingly high, as illustrated by the Life Sciences Building at Berkeley. It now represents a 330% increase in investment over the initial construction cost of 40 years ago.

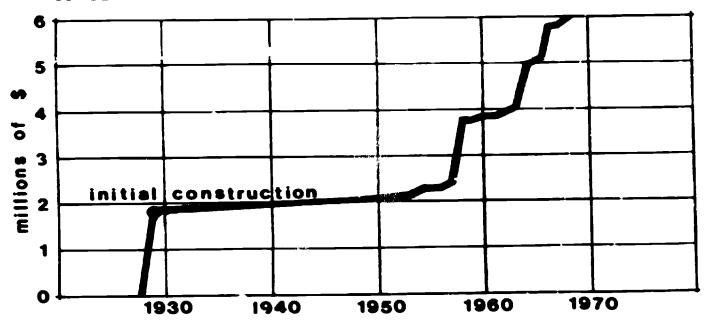

Costs for altarations have increased substantially in recent years, due to rising construction costs, more rapid evolution of the sciences, and more sophisticated service and equipment requirements. This trend toward more expensive changes in laboratory buildings clearly indicates the need for improved adaptability.

The graph representing an old building, the Life Sciences Building at Berkeley, shows very little dollar increase for the first 25 years of the building's life. Thereaf(er, however, the alteration costs rise sharply. This example may be contrasted with the other graphs pertaining to more recent laboratory buildings, where costs for changes are felt much sooner after their initial construction.

Whether this pattern is due more to obsolescence of the building, or to the evolution of research and teaching techniques, is not known. The fact that the newer buildings need alterations so early in their lives, however, tends to indicate that physical obsolescence is not a major cause of change, since components do not becomminated in a very short period of time. Thus, the growing rate of evolution in science and related teaching methods is strong evidence in favor of providing maximum adaptability within an academic building system.

## ALTERATION COSTS -SIX EXISTING BUILDINGS

The basic measure for adaptability is the cost of making changes relative to first the cost of change itself depends on such factors as the ease or difficulty of accept to components, the skill required of the labor involved, the time it takes, depution to other users, mechanical system "down-time" and the size of the molation zone, and the equipment used.

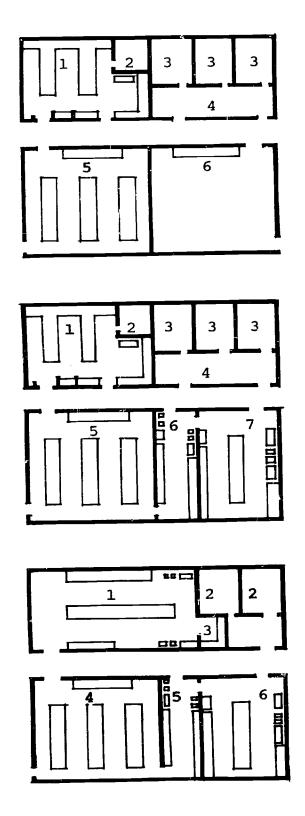

traditionally built facilities are so expensive to change. In considering how to provide buildings that easily and relatively inexpensively respond to changing needs, it was necessary to study the particulars of alterations and modifications in existing buildings. Since comparing costs of actual changes made in the six existing buildings was not practicable, a hypothetical model was developed to illustrate an opening condition and two successive changes.

A laboratory plan segment your 30' x 30' bays) applicable to any of the six existing buildings was chosen. A logical service configuration was selected from the original drawings of the three Indiana and the three California buildings as a potential location for change, and so applied to the model. This Initial Plan A was analyzed for cost. Two subsequent alterations were then made to each model, and the services modified accordingly. These changes penerated cost estimates and provided a cost breakdown by subsystem to show the areas most expensive and least costly to modify. Thus, by demonstrating the common cost hierarchies involved in most alterations, the models provide guidelines for designing more adaptable components.

Certain assumptions were made upon which the cost estimates were based. These assumptions were reassessed at the completion of system design. Cost estimates were modified as required to compare with systems composition and to eliminate inconsistencies of assumption application among the California and Indiana facilities. Following are some of the general assumptions in the final analysis:

- 1. Resilient base is used on both sides of all partitions and walls (except outside surface of exterior walls).
- 2. Where new resilient tile is added, new resilient base is also added.

- 1. chemistry lab
- 2. office
- 3. faculty offices
- 4. typists
- 5. teaching lab
- 6. storage
- A. INITIAL PLAN

- 1. chemistry lab
- 2. office
- 3. faculty offices
- 4. typists
- 5. teaching lab
- 6. prep room
- 7. graduate research
- **B. ALTERATION**

- 1. biology lab
- 2. TA offices
- 3. dark room
- 4. teaching lab
- 5. prep room
- 6. graduate research
- C. ALTERATION

ERIC

- 3. Existing resilient tile and base is patched as necessary in modification areas, not replaced entirely.
- 4. Storage room floors and concrete ceilings are unfinished.
- 5. In modification areas, existing partitions, concrete walls, and exposed concrete ceilings are painted. However, the cost of repainting existing walls untouched by modification is not included in this cost estimate.
- 6. Casework and fume hoods, including sinks and trim, are not included in this cost estimate.
- 7. Removal of deleted casework is included in this cost estimate. Space is emptied of all deleted items, ready to receive new casework and equipment.
- 8. All plumbing, electrical and mechanical hook-up for casework is included in this cost estimate.
- 9. All deleted waste lines are capped-off at floor. No pipes are removed.
- 10. All deleted utility supply lines are capped-off at ceilings with only vertical drops removed.
- 11. All deleted mechanical ductwork is removed.
- 12. Acid vents are not included in this cost estimate.
- 13. New electrical distribution is surface mounted, rather than concealed.
- 14. Lighting fixtures are salvaged, relocated.
- 15. For HVAC changes, zone addition costs are identical for reheat systems or double duct systems; diffusers are salvaged, relocated.
- 16. The general contractor's cost is estimated at a fixed percentage, the same in all cases.
- 17. Five percent of suspended ceilings is replaced in modification areas.
- 18. Alterations from A to B and from B to C are made five years apart.

### **ALTERATION COSTS**

Following are tables showing estimated costs in each of the six buildings studied for the Initial Plan A, Alteration B (changing a store room to a preparation room and graduate research laboratory), and Alteration C (converting a chemistry laboratory and two offices into a biology laboratory and darkroom). The same cost base applicable to all other studies is used herein (ENR 1300, January 1970, San Francisco Bay Area prices).

Cost estimate tabulations and drawings for U.C. Irvine are included as illustrative samples only.

(m) . 160

The cost breakdown of the hypothetical alterations on the six buildings discloses a number of interesting conclusions about the comparative costs of adaptability in existing buildings and in future ABS buildings. The task here is not to analyze precise cost breakdowns in the six existing building, but to identify and analyze areas where costs are significantly different.

Alteration B involved changing a storeroom to a prep-room and graduate research laboratory.

In the California examples, by far the most expensive item to change was the plumbing, ranging from 38% to 44% of the total cost. The second most costly item was General Contractor's Fee, in all cases amounting to around 17% of the total cost. Third most costly item was partitions at 15% of the cost, and fourth was flooring.

In the Indiana buildings, several items amounted to large expenditures. Because their plaster suspended ceilings must be ripped out and replaced in the space being remodeled as well as the one below, the ceiling costs represented from 20% to 22% of the total. Plumbing costs were high for essentially the same reasons as the California buildings and accounted for 22% to 25% of the total. Third was the General Contractor's Fee. Partitions accounted for 10% to 13% of the total. HVAC ranged from 9% to 14%.

In Alteration C, a chemistry laboratory and two offices were converted into a biology laboratory and darkroom. Total remodeling costs were highest in the Indiana buildings, where the average is \$9,664; the California average is \$6,137.

In the California buildings, partitions and plumbing were the most expensive items to change. The partitions costs were especially high because of adding new partitions and removing old ones, accounting for 18% to 23% of the remodeling costs. The plumbing costs were due to the addition of pipe and outlets, accounting for 14% to 24%. Aside from the 17% General Contractor Fee, the next most expensive items to change are HVAC and lighting, which range from 8% to 15% of the costs. Although material costs here are significant, so are labor factors for such tasks as removing existing ductwork and light fixtures.

In the Indiana buildings, the ceiling again was the most costly item to change, accounting for 28% to 30% of the total remodeling expenses. Second was the partitions at 15% to 18%, principally because the block partitions are difficult and slow to remove. Third was plumbing at 12% to 18% of the total.

# **DISRUPTION COSTS — SIX EXISTING BUILDINGS**

Although alteration cost is usually used to measure adaptability in a general sense, the evaluation of a building's adaptability must tak, into account other, less quantifiable considerations. The most important of these concerns disruption of spaces other than those being remodeled.

In the Alterations and Modifications study of the sample buildings, a brief study was made of disruption to users during alteration. The results of this study are tabulated below.

| 1 | A   | 4 | 0 days      |
|---|-----|---|-------------|
|   |     | _ | 1 - 6 days  |
| 2 | 6/3 | 5 | over 6 days |

# NOTE:

- Disruption in corridor ignored.
- Casework assumed ready for installation. 2.
- Ten days down-time attributed to necessity of removing and replacing hung 3. ceiling in Indiana buildings.

In the existing buildings, conventional plumbing is the major expense, especially when plumbing services must be brought from another area in use, involving new plumbing connections or rerouting. Because waste lines are under the floor, in the ceiling of the space below, that space is also disrupted.

Disruption time for university personnel costs, conservatively, is \$70 per room disrupted per day of disruption. In most alterations to academic facilities today, disruption to personnel costs an additional 15 to 30 percent of the total remodeling work. The elimination or reduction of these costs would represent a sizeable cost saving.

Changes are continually occurring in university academic programs, and the physical facilities that house them are subject to correspondingly changing requirements.

In general, academic buildings have not been able economically to meet new demands, thus placing major physical constraints on the changing activities of the building users. Traditional design and construction methods are in large measure responsible for the lack of adaptability of these buildings, principally because the need for change has only recently been recognized. Partitions are built as virtually immovable walls, plumbing and services are fixed. When physical changes are needed, major remodeling work is necessary. This in itself is costly, and inevitably involves disruption to the normal activities of the users. Not only is the space being remodeled disrupted, but also the adjacent spaces. The rooms below, providing access to drains and plumbing for the remodeled space, cannot be used while the workmen are active. Those rooms directly above may be affected by the noise of hammering or of making connections in the floor slab. Because of this, even when administrators acknowledge the need of one man or a department for physical changes, they are constrained by the costs and the disruption to others that the changes would entail.

# **COST OF CHANGE OF OCCUPANCY**

A major objective for ABS is to meet the continuing need for change by providing buildings that can better accommodate both foreseeable and unanticipated trends during their lifetimes, and within a realistic cost context. The goal is to lower the

cost of change, while, at the same time, maintaining or improving the performance of the building. In designing for adaptability, it must be recognized that, on account of costs, compromise will be necessary. Immediate changes of services and total interchangeability of different space types (laboratories, offices, specialty rooms, etc.) is not economically feasible. The task is to determine the degree of spatial and service capability to provide, in order to give the best dollar return for future alterations. In doing so, all the subsystems of the building must be considered as a unit; the cost of providing a higher degree of adaptability in one subsystem will be wasted if the remaining subsystems cannot adapt to the same degree. The first step in the process is to examine the potential range of adaptability and its implications, and then to set realistic design goals.

# ADAPTABILITY OF SPACE AND SERVICES

The two related aspects of a building most susceptible to change are the area requirements of various space types, such as research labs, teaching labs and offices, and the required services which vary in intensity according to the activity housed. Because the utility and mechanical services are the most expensive subsystems to alter, they typically account for up to 50% of remodeling costs. In science buildings, especially, it is important to understand how services relate to particular space types, and how those space types are likely to be affected by demands for change.

A simplified set of adaptability characteristics related to spaces makes the following distinctions:

- 1. High intensity of service requirements.
- 2. Low intensity of service requirements.
- 3. High likelihood of service and/or spatial change.
- 4. Low likelihood of service and/or spatial change.
- 5. Minimal likelihood of service and/or spatial change.

The following chart relates these characteristics to typical space types in present laboratory buildings.

### **ALTERATION COSTS**

|  | HIGH SERVICE<br>HIGH CHANGE | HIGH SERVICE<br>LOW CHANGE | LOW SERVICE<br>HIGH CHANGE | LOW SERVICE<br>LOW CHANGE | MINIMAL<br>CHANGE |

# ADAPTABILITY SCALE

NOTE: This scale refers to existing conditions; a more adaptable building might change the scale; e.g., offices and classrooms might become high change spaces.

As far as the space/services relationship affects adaptability, it is easy to "downgrade" a space, that is, to move from a high degree of services to a low one. Although it is not usually economical to utilize a space at a lower standard than it was designed for, laboratories, for example, can fairly easily become classrooms. On the other hand, a move from low to high on the scale greatly affects the costs of structures and services. For example, if the capacity for "upgrading" is to be built into an office, it must be built initially with a high degree of service capability but without certain equipment.

The Adaptability Scale groups space types on the basis of likely changes and degree of services. Clearly, those spaces on the same scale should be economical to interchange, though often today they are not.

The following chart compares the relative costs of changing space uses under conventional conditions today, and clearly illustrates the principle of "downgrading" as it operates in traditional laboratory buildings. Presented in dollars per square foot, the figures are taken from the cost data generated in the studies of the six existing buildings, and are estimated to the same bases (ENR Construction Cost Index 1300).

This study is based on the hypothetical model of a typical 30' x 30' bay of a conventionally constructed laboratory building to which various uses and their accustomed services are applied, and upon which subsequent changes of occupancy are imposed.

For example, in determining the cost of change from a research laboratory to a teaching laboratory, first the scope of the alteration is delineated by tasks, such as "remove and replace laboratory equipment and casework," and "add acoustical ceiling"; each of the necessary operations is then estimated for cost; and finally these figures are added up to show total cost of change of each occupancy type. In cases when a space is to be "upgraded," or changed to an occupancy type with a higher degree of service provision, utilities mains are assumed to be in the adjacent corridor and submains may be connected to them. It is the objective of ABS to lower these costs, and to provide a higher standard of adaptability performance.

# **FUNCTIONAL AREA COSTS**

The cost data provided for each subsystem in the existing facilities has a direct application in establishing cost targets for the proposed ABS system. When these data are presented as price per OGSF, they include statements about both the quality and the quantity of the subsystem as used in the context of each building wherein its own particular configuration and size affect the cost figures. In order to establish an equitable basis of comparison of subsystems, both quality and quantity must be well defined. Some subsystems, such as partitions, provide a rapid quantity analysis by the simple computation of area as of partition. This type of enumeration of quantity characteristics has been done for structure and partitions, but HVAC and Lighting/Ceiling have been omitted. Quantity is more elusive, particularly as regards the HVAC subsystem. The number of quantity variables in HVAC (such as cfm, BTU, number and size of zones, number of controls, quantity and size of ducts, number and size of fans), and those of the Lighting/Ceiling to a lesser degree, become overwhelming when subjected to quick review.

An alternative method of assessing the quantity characteristics of subsystems, in a general way, is to determine the cost impact of various occupancy types. It is assumed that certain occupancy types consume more of some subsystems than others. It has been verified that a spectrum of costs exists, where occupancy types such as laboratories are highest and storage is lowest, and that the contribution of specific subsystems is significant. With these relationships established, the comparison of occupancy type percentages with subsystem costs tends to substantiate a general quantity level for a specific subsystem. For example, it is known from analysis that HVAC costs are higher for laboratories than any other space. If laboratories for a particular building occupy a small percentage of the building, it can be deduced that the quantity level should be lower for that building, with a resultant lower HVAC unit cost.

Costs of functional areas in the six buildings studied have been compiled in the tables of Functional Area Costs, on pages 183 and 184. The quantities are expressed as percentages of gross square feet. Average costs on page 184 for occupancy types derived from the studies of existing facilities provide an accurate and useful tool for the facilities planner in establishing a building budget.

180

The traditional means of establishing building budgets begins with a program of assignable areas for departments to be housed. An acceptable ratio of assignable to gross area is applied. The resulting gross area is multiplied by a cost per gross square foot factor to determine building cost. The cost per gross square foot is a figure generally acceptable for that particular type of building, such as classroom-office building, engineering building, bio-science laboratory building. The accuracy of this method is dependent on assumed ratios of space use or occupancy types.

The first table indicates the variation in occupancy types of six similar facilities; all could be classified under the same building type. The disproportion of the more expensive laboratory space in one building could cause a serious budget constraint on quality within a fixed building area cost. A more accurate method is the direct application of area costs for the specific functional use within the indicated percentage of total space.

These costs will vary for building types other than the six studied. For example the cost of offices will differ among science, humanities, or administration. Although offices do not need the services or the sophisticated HVAC systems of laboratories, they must share part of the basic costs of such systems when grouped together in the same building. Office buildings do not have this degree of basic services sophistication and therefore will have lower unit costs. Breakdown of unit costs within a proposed science and engineering facility provides a more meaningful basis of budget projections than the customary single unit figure for the total building, since the latter does not take the proportion of various occupancy types into account.

In the following tabulations, specific costs were assigned to the precise functional area types within each building to discover how the types of uses directly affect cost. The procedure was as follows: costs of finishes unique to a specific functional area (such as an office, a classroom, a teaching laboratory, a research laboratory) were tabulated for each building. To these are added a general figure called the "common component costs," which signifies the costs of shared elements: site work, floors excluding finishes, roof, interior partitions, general interior features, exterior wall, plumbing for fire protection and outside lines, general electrical costs for clocks, fire alarms, telephones, elevators and general contractor. Although these costs do not pertain to a specific space but to the building as a whole, the costs are shared by every square foot of the building, and are therefore incorporated equally into all functional and non-assignable areas.

TABLE 2

AVERAGE FUNCTIONAL AREA COSTS

| FUNCTIONAL AREAS | AVERAGE \$/S.F. |
|------------------|-----------------|
| CLASSROOM        | 34.99           |
| OFFICE           | 35.06           |
| TEACHING LAB     | 54.87           |
| RESEARCH LAB     | 54.83           |
| LIBRARY          | 40.90           |
| GENERAL SERVICE  | 31.20           |
| NON-ASSIGNABLE   | 29.18           |

Where significantly higher costs occur they appear to result from one or more of the following reasons:

- 1. A program requirement for the higher performance.
- 2. Redundancy in materials or equipment.
- 3. Relatively inefficient configuration or arrangement of spaces.

The most conspicuous difference between the unit costs is the much greater cost of laboratory spaces in the Santa Barbara project than in the others. This project resulted in the highest cost per OGSF also. The apparent principal reason for this is the higher performance characteristics of the building.

The higher performance capabilities of the Santa Barbara laboratories result from more plumbing systems, more electrical power capacity, air conditioning with 100% fresh air (no recirculation), humidifiers (lacking in the other projects), considerably more instrumentation and controls on all systems, a completely separate air conditioning system for the animal study areas in the upper floors and similar refinements. The result is the capability of alterting offices to laboratory use and of revising space arrangements with a minimum of disruption.

The high cost of Bloomington's Non-Assigned Area reflects its exterior wall construction, corridor treatment and collegiate Gothic stone detailing. The low costs of the other Indiana examples reflect their relative simplicity and inexpensive treatments of non-assigned space.
