ABSTRACT

The author attempts to determine the value of psychometric measures of impulsiveness and anxiety for predicting potential disciplinary problems among high school males. A secondary purpose is to relate these personality factors to academic achievement. Approximately 320 sophomores were administered a psychometric battery which included: (1) an impulsiveness scale; (2) the Rotter Incomplete Sentences Blank; (3) a culture-fair intelligence test; (4) a temperament survey; (5) a capacity test; (6) a survey of study habits; (7) an adjective check list; and (8) an anxiety scale. Criterion measures utilized were grades in selected courses, conduct scores, number of behavioral infractions, and drop-out information. Comprehensive and varied data analyses were undertaken both for answers to specific questions and for exploration of other possible relationships. The most significant findings indicate: (1) a low but significant correlation of anxiety with impulsiveness; (2) a relationship of both to study habits; (3) a positive relationship between high impulsiveness and behavioral infractions and dropping out; and (4) no significant relationship between the ratio of impulsiveness to anxiety and academic achievement when other factors are partialled out. (TL)

Project title:	The Teaching of Gymnastics in the Second Year of the Secondary School and the Eighth Year of the Comprehensive School
Carried out at:	The Institutes of Education at Stockholm and Umeå Schools of Education
Scientific leader:	Professor Sten Henrysson
Investigation leader:	Lars-Magnus Engström, Phil.Cand.
	Gudrun Hedberg, Phil.Cand.

Background

In February, 1967, the National Board of Education arranged a symposium on the teaching of gymnastics. It became evident during the symposium that very few psychological and educational studies directly bearing on physical culture have been undertaken. This is especially true of research that can be applied to Swedish conditions.

It was stated at the symposium that more information is required on the way gymnastics is taught in schools and also on the attitude of the pupils to this subject. This information is of importance in order to give every individual the possibility of recreation and optimum development of his physical aptitude in accordance with prevailing conditions and his interests. From those who placed emphasis on the importance of gymnastic instruction for physical activities in spare time after leaving school similar requests for research were put forward. A survey of the pupils' spare time athletic activities was also considered desirable.

Against the background of this discussion investigations have now been completed of gymnastic teaching in the eighth school year of the comprehensive school and the second school year of the secondary school at the Schools of Education in Stockholm and Umeå. The investigation was financed by a grant from Department L4 of the National Board of Education.

Aim

The aim of the investigation is to throw light on three spheres which are of essential importance to the presentation of the subject of gymnastics:

a. The organization of gymnastic instruction in the second year of the secondary school as well as the attitude of the teachers to various problems concering the content of the subject, its objectives and marking.

b. The attitude of the pupils to gymnastic instruction.

c. The pupils' interest and participation in spare time athletic activities.

The underlying purpose of the investigation is thus to obtain more information on the situation of gymnastic teaching to-day, as well as on the attitude of pupils to this instruction and spare time physical training, and thereby to extend the basis for reviewing the objectives and organization of the subject of gymnastics.

The Organization and Execution of the Investigation

The investigation has included random sample tests from the counties of Malmöhus, Stockholm, Örebro and Västerbotten. These counties were chosen in order to obatin the most representative results with regard to climate, premises and equipment. From each county 20 classes of the eighth school year and 10 classes from the second school year of the secondary school were chosen at random. The teachers of gymnastics who instructed these classes have thereby been included in the investigation. In all the investigation included 225 teachers of gymnastics, 920 secondary school pupils and 2,144 pupils of the eighth school year.

The collection of data was carried out with the aid of questionnaires addressed to both teachers and pupils. The investigation of the eighth school year was carried out during May, 1968, and the questions in the questionnaire referred to instruction given in the school year 1967-68. The investigation of the second year of the secondary school was carried out during the period April 21st-25th, 1969, and the questions in the questionnaire were concerned with the instruction given during the school year 1968-69 in those classes chosen for inclusion in the investigation.

The questionnaire addressed to the teachers was issued to all teachers who instructed classes included in the investigation. The questionnaire dealt with the following points.

1. The background data of the teachers (sex, age, education, seniority, stage of instruction, etc.).

2. Conditions with regard to premises and equipment.

3. The actual content of gymnastic and open-air activities during the school year, the actual amount of time devoted to different parts of the instruction and the attitude of the teachers to these parts.

4. The views of the teachers on marking and the evaluation of merit in the subject, its objectives and the teachers' wishes with regard to the number of hours to be devoted to gymnastics and their distribution throughout the week.

5. The occurrence of individualized instruction, marked tests, etc.

The questionnaire addressed to pupils was completed under the supervision of visiting investigators and included questions on the following main subjects:

1. Background data.

2. Interest in gymnastics compared with other subjects.

3. The attitude of the pupils to various parts and exercises included in gymnastic instruction and open-air activities.

4. Wishes as to the distribution of various principal parts.

5. The pupils' views on the premises, athletic equipment, marked tests, marking, competitions, showers and changing facilities, number of hours of gymnastics competitions, showers and changing facilities, number of hours of gymnastics per week, etc.

6. Athletic spare time activities.

Acknowledgements

I want to thank the administrative officers, counselors, and teachers of Ball H. S. and Kirwin H. S. who were most cooperative in making this study possible. I am also grateful to the students of both schools who assisted us in all of our requests for taking make-up tests and being on time for the testing sessions.

Mrs. Eva Levy was very conscientious in collecting the data and Dr. Will Kouw was most helpful in suggesting certain data analyses.

I. Purpose and Background

The basic goal of this research was to determine the value of psychometric measures of impulsiveness and anxiety for predicting potential disciplinary problems among high school males. A secondary purpose was to relate impulsiveness and anxiety measures to academic achievement.

The specific questions answered in this research were: (1) Does the ratio of impulsiveness and anxiety relate to social adjustment among high school males when socio-economic status, intelligence, need-for-achievement, and study habits are held constant (i.e., statistically partialled out)? (2) Does the ratio of impulsiveness to anxiety relate to academic achievement among high school males when socio-economic status, intelligence, need-for-achievement, and study habits are held constant (i.e., statistically partialled out)? (3) Are there any differences in the above relationships in a public vs. a private high school?

In past studies, anxiety and impulsiveness were stable second-order orthogonal personality factors that interacted to influence behavior on a wide variety of laboratory tasks and in everyday life situations (1, 2, 3, 4). If a subject's impulsiveness was high and his anxiety was low, the influence of impulsiveness on both cognitive and skill behavior was more obvious than when the ratio between the two traits was higher. The basic question asked in this research is "to what extent

do these two well-documented personality traits correlate with social adjustment among high school males?"

In addition to the work of Barratt (1, 2, 3, 4), there are a number of studies that relate to the rationale of this study. Matsushima (8) has devised a scale (Impulse Control Categorizations Instrument) for measuring impulse control among boys. In a study involving the performance of a "frustrating" task, Matsushima reported that no subjects who made a high score on the scale left the room while a high percentage of subjects making a low score did leave. Battle and Rotter (5) studied children's feelings of personal control with regard to whether there are separate internal vs. external control variables; they concluded that there is one internal-external control variable as a personality dimension.

Megargee (9) in a study of impulse control among assaultive and homicidal adolescents demonstrated a relationship between amount of control and hostility; they used psychometric techniques. At a theoretical level, Eysenck's (6) concept of extroversion is similar to impulsiveness as measured in this study except that impulsiveness as measured here involves more risk taking and "super-ego" measures.

Kogan and Wallach (7) found impulsiveness to be related to risk taking when anxiety was partialled out. Both impulsiveness and anxiety as measured in this study are second-order orthogonal factors that remained stable over time in adults in past studies (1, 3).

II. Procedure

A. Subjects. Subjects for this study were sophomore male high school students at Ball High School (N = 269) and Kirwin High School (N = 51) in Galveston, Texas. Ball is a public high school and Kirwin is a Catholic high school run by the Christian Brothers. (Note: the N will vary with analyses because complete data were not always available for all subjects).

B. Psychometric Scales. The following psychometric scales were group administered at both schools:

a. Barratt Impulsiveness Scale (1, 3);

b. The Rotter Incomplete Sentences Blank (Psychological Corp.);

c. The IPAT Culture Fair Intelligence Test, Scale 3 (Institute for Personality and Ability Testing, Champaign, Ill.);

d. The Guilford-Zimmerman Temperament Survey (Sheridan Supply Co.; Beverly Hills, Calif.);

e. The Channel Capacity Test; an experimental perceptual speed test designed by Dr. Winton Manning (College Boards, Inc.) and being developed in cooperation with Dr. Ernest Barratt; the test consists of a six separate two minute tests; in each test, the S is required to locate a discrepancy among the cells of two different figures (see Appendix A); the items on each successive test involve more cells to peruse; hence, a higher level of information processing is reflected in each of the successive tests;

f. Brown-Holtzman Survey of Study Habits and Attitudes (Psychological Corporation);

g. Gough-Heilbrum Adjective Check List (Consulting Psychologists Press, Palo Alto, Calif.).

a. Teacher rating scale; an experimental scale developed for this study; two teachers rated each student on nine scales (seven pt. scales); (see Appendix A). The teachers were paid $.50/student for rating the students.

h. IPAT Anxiety Scale (Institute for Personality and Ability Testing, Champign, Ill.).

Table I contains a list of the total measures available on the above scales.

C. Personal Data.[1] The following personal data was obtained for each subject:

a. Age

b. Father's occupation (rated on six pt. scale)

c. Home address (dwelling area in town - rated on six pt. scale).

d. Parent's marital status

e. Student's ninth grade academic status and any available test data.

D. Criterion Data.

The following criterion data were collected for each student:

a. Conduct scores in at least two classes

---

[1] In the results section below various personal data and criterion measures will be described in more detail. For example, father's occupation and dwelling area were combined to get a socio-economic class rating.

b. English grades

c. Math grades (for those students taking math)

d. Infractions listed in central office

e. Drop outs by mid term of the junior year

E. Data Analyses.

Statistical techniques appropriate for answering the different questions were used; techniques included factor analysis, analysis of variance, non-parametric ranking techniques (e.g., Wilcoxon's test for non-paired replicates, and chi square), and conventional parametric techniques. It will be obvious in the results section below what statistical techniques were used for answering specific questions and for exploring for relationships which were not part of the formal purpose of the study.

It became clear early in the data analyses that the criterion data were heavily influenced by the attitudes and personalities of the teachers. Thus, a number of analyses were performed relating predictor variables to criterion data for the students of individual teachers.

III. Results

A. Correlational and factor analyses of psychometric data.

Separate correlation and factor analyses were computed for the Ball H. S. and Kirwan H. S. data (Tables II through VII). The Ball High data were factor analyzed three dif-

ferent ways; because of the relatively small N, the Kirwin data were only submitted to power vector analysis and not promax or normalized principle axis analyses.

A surprising result in the correlation analysis was the significant correlation between the BIS and the IPAT Covert and Overt anxiety scales (Tables I & II). The BIS had never correlated significantly with any anxiety scales in any previous studies of this age group. No explanation for this finding is obvious from reviewing the overall test results. Since this result was obtained for both high schools, it cannot be interpreted as an artifact.

The power vector analyses for Ball High and Kirwin High did not produce consistent factors for the two populations. In the Ball High analysis the BIS had a high loading along with the SSHA on factor seven; the GZTS restraint scale had a moderate negative loading on this factor and masculinity had a moderate positive loading. Anxiety measures did not have a significant loading on this factor but did help define a separate factor along with several other scales from the GZTS.

In the power vector analyses of the Kirwin High data, the BIS and GZTS restraint scale defined an impulsiveness-restraint factor, (Factor 2) on which the anxiety measures had low loadings. Factor five was a clear anxiety-objectivity factor and the BIS and GZTS restraint loadings were low on this factor. These results are more in line with

past factor analyses in which impulsiveness and anxiety measures defined separate orthogonal factors.

In the promax factor analysis (Table VI) of the Ball H. S. data, factor seven clearly reflected the variables which are of interest in this study; this factor was defined by high loadings of the GZTS restraint scale, the BIS, the SSHA, and moderate loadings of the IPAT covert anxiety scale and the GZTS thoughtfulness scale. This same factor (factor seven) was obtained in the normalized principle axis solution (also, factor seven) of the Ball H. S. data (Table VII). Both of these analyses suggest that anxiety and impulsiveness are negatively related to good study habits. Since a number of validity studies (see manual for SSHA) have shown that SSHA relates positively to academic achievement, this is considered to indirect (factorial validity) evidence supporting the basic hypothesis of this study.

B. Anxiety and Impulsiveness related to Social Adjustment and Academic Achievement.

The suitability of the criterion measures for social adjustment was difficult to assess. The infractions listed in the central office files were available but the majority of students had no infractions; hence, it was not meaningful to do a correlational analysis with infractions as a criterion. Students did have conduct grades and these were used as a social criterion measure in a correlational analysis. Since

all students in both schools were taking English, English grades were primarily used as a criterion measures for academic achievement.

For both Ball H. S. and Kirwin H. S. the ratio of impulsiveness to anxiety was not significantly correlated with English grades when intelligence (CFIT), study habits, the need for achievement (ACL), and socio-economic status were partialled out. ($r_{123456} = .05$ for both schools). The following relationships were obtained as part of this analysis:

(1) Intelligence (CFIT) was significantly related to English grades for Ball H. S. ($r = .25$, $p < .05$) but not for Kirwin H. S. ($r = .02$);

(2) Study Habits (SSHA) were significantly related to English grades for both schools (Ball H. S., $r = .37$, $p < .01$; Kirwin H. S., $r = .43$, $p < .01$);

(3) Socioeconomic status was significantly related to English grades for Ball H. S. ($r = .27$; $p < .05$) but was not related to English grades for Kirwin H. S. ($r = -.08$).

(4) Intelligence (CFIT total score) was significantly correlated with socioeconomic status for Ball H. S. ($r = .22$; $p < .05$) but not for Kirwin H. S. ($r = -.18$).

(5) Study habits were significantly correlated with need for achievement (ACL) for both Ball H. S. ($r = .19$, $p < .05$) and Kirwin H. S. ($r = .28$, $p < .05$);

(6) Study habits were not significantly correlated with socio-economic status for either school.

Using infractions reported to the central office at Ball H. S. as a criterion of social adjustment, three groups of students were selected to relate to impulsiveness: (1) serious offenders (N = 22); these were students who were either truant or were involved in fights (or both) and who had been reported to the central office at least three times (at least one offense was for truancy or fighting); (2) less serious offenders (N = 77); these students were those reported to the central office who did not meet the above definition of a serious offender; although some of them had been reported to the office many times it was for offenses that were not flagrant violations of the mores (e.g., smoking in the halls or talking in class); (3) non-offenders (N = 179); these were students who were not reported to the central office.

Dividing the three groups at the median (14) on the BIS, the chances are 18 out of 22 that a serious offender will be above the median on impulsiveness; the other two groups divided about evenly about the median (Table IX).

There were only four boys at Kirwin H. S. who fit the above definition of a serious offender: Three of these boys had very high impulsiveness scores (19, 20, and 21); the fourth boy answered only half of the BIS items and put a note on the answer sheet that the "questions were silly." Thus, approximately the same percentage of boys were serious offenders at both schools and the probability of a serious

offender at both schools being above the median on impulsiveness was significant.

Data were available on eighteen boys at Ball H. S. who dropped out of school after starting their sophomore year and having taken the tests for this study. These eighteen boys did not include those who moved from Galveston or who dropped out because of illness. Twelve of the eighteen boys had impulsiveness scores above the median (i.e., 14 on the BIS).

C. Psychometric Scales related to Academic Achievement and Social Adjustment.

On the basis of the factor analyses, fourteen psychometric scales which had high loadings on various factors were selected as predictor variables and related to academic achievement and social adjustment criterion measures. The fourteen psychometric scales were: (1) CFIT - Test 3; (2) Study Habits, (SSHA); (3) Covert Anxiety, (IPAT); (4) Overt Anxiety, (IPAT); (5) Sociability (GZTS); (6) Ascendance (GZTS); (7) Intelligence (CFIT-Tot. Sc.); (8) Impulsiveness (BIS); (9) Favorable Adj. Chk'd. (ACL); (10) Unfavorable Adj. Chk'd (ACL); (11) Dominance (ACL); (12) Nurturance (ACL); (13) Succorance (ACL); (14) Self Control (ACL).

The SSHA was the best predictor of math and English grades at both high schools (Tables, X, XI, XII, XIII). Impulsiveness and anxiety contributed little to the multiple prediction of math and English grades at both schools. The

other psychometric variables also selected for these analyses added very little significant variance to the prediction of math and English grades at both schools.

Three additional psychometric scales in addition to the above fourteen scales were used in a step down regression analysis using conduct grades in English classes as a criterion of social-adjustment at Ball H. S.: (1) self confidence (ACL); (2) lability (ACL); (3) masculinity (GZTS).

The best predictors of conduct grades in English classes were a perceptual speed test (CCT-3), sociability (GZTS), and masculinity (GZTS) (Table XIV). It is interesting to note that overt and covert anxiety were related to conduct scores in opposite directions in this analysis (Table XIV). Neither impulsiveness nor anxiety, however, were highly related to conduct scores for the entire class. (Because of the small N and the number of different teachers involved, this analysis was not computed for Kirwin H. S.).

A three way analysis of variance, (Table XV) combining data from Ball H. S. and Kirwin H. S. and including grade point average, impulsiveness, and anxiety related to conduct scores indicated: (1) impulsiveness interacted with anxiety to related to conduct scores (Fig. 2 and Fig. 3); the significant F was due primarily to the interaction of low impulsiveness with medium anxiety scores, a finding which is difficult to interpret; (2) conduct scores were highly related to grade point average (Fig. 1); students with high grade point averages made "good" conduct scores and vice versa.

D. Multivariate Analyses involving individual teachers.

On an a priori basis it was concluded that the conduct scores as a measure of social adjustment should not be combined for different teachers because of the probable subjective attitude of the teachers in assigning the conduct scores. The individual teacher's personalities would certainly be a variable in assigning conduct scores. Also, as noted above, the performance of students would be related to the teacher's assessment of a student's conduct. To try to evaluate the extent to which the various teachers assigned conduct grades differently, a rating scale (see Appendix A) was devised to assess some of the teacher's attitudes toward students. The teachers were paid $.50 per student to complete the rating scale. These teacher's ratings and psychometric scales were then related as predictor variables to conduct scores and class grades as criterion variables. These analyses were concentrated primarily on Ball H. S. data because of the small N at Kirwin H. S. Summaries of these analyses will be presented below. These analyses must be interpreted cautiously because of the small N involved in the analyses of some classes. Many analyses were performed which will not be presented here in detail. Only those analyses are presented in detail which give some insight into the extent to which teachers differ in their assessement of students. The remaining analyses will be briefly summarized.

Teacher's ratings vs. fourteen psychometric variables (Ball H. S. English Teachers).

The r's between teacher's ratings and the fourteen psychometric variables (listed above) were computed for the seven English teachers at Ball H. S. These R matrices are contained in appendix B.

Fourteen psychometric variables vs. English grades for teachers.

As can be seen in Table XVI, no single psychometric scale was consistently related to the grades of the different English teachers. Covert anxiety (IPAT) had the most consistent relationship of any of the fourteen psychometric scales with English grades.

Teacher's ratings vs. English Grades (Ball H. S.).

The reliability of the teachers rating scale was obtained by correlating the English teachers ratings with those of other teachers. Since English was the only subject which all students were taking, the "other teachers" included math, P.E., band, and military science teachers (Table XVIII). Considering the heterogeneity of the "other teachers", the inter-rater reliabilities of the various scales are surprisingly high and compare favorably with the reliabilities of a number of scales used in psychiatric and other clinical settings.

The "dependable scale" of the teacher's rating scale had a consistently high relationship with English grades for all teachers (Table XVII). Although the various teachers undoubtedly had their own concept of dependability, this scale was significantly related to English grades in all classes.

Except for teacher Y, the bright-dull scale was also significantly related to English grades. Although one can't determine from these data which is most basic, the teacher's perception of a student as bright or dull correlates highly with the grades the student makes. However, teacher's perception of the student as bright or dull does not correlate significantly with his intelligence (see Appendix B).

Fourteen psychometric scales related to English grades (Ball H. S.) with teacher's ratings partialled out.

After partialling out the variance related to each teacher's ratings, no psychometric variable was consistently related to English grades for all teachers (Table XVIII). For three teachers (A, B, and Y), the relationship of several of the psychometric scales to grades was almost a perfect relationship. For the remaining four teachers, the relationship between the psychometric scales and grades was not much enhanced by partialling out the variance related to the teacher's ratings.

Fourteen psychometric variables related to English conduct grades (Ball H. S.) for each teacher.

The best overall psychometric predictor of conduct grades given by individual English teachers at Ball H. S. was the SSHA; except for teacher P, SSHA was one of the four best predictors for each teacher (Table XIX).

Although different predictors were involved for each teacher, the four best psychometric predictors for each teacher were significantly related to conduct grades for each teacher.

Thirteen psychometric scales related to conduct grades (English classes, Ball H. S.) with teacher's ratings partialled out.

Again, no psychometric scale was significantly related to conduct grades for all teachers when the teacher's ratings were partialled out (Table XX). Dominance (ACL) had the most consistent relationship with conduct grades in this analysis; it was significantly related to conduct grades for four teachers and was almost significant for a fifth teacher.

Impulsiveness and anxiety related to conduct grades by teachers (English, Ball H. S.) with intelligence, study habits, and need for achievement partialled out.

No significant relationships were obtained between impulsiveness and anxiety as predictors and conduct scores for individual English teacher (Ball H. S.) as criterion measures when intelligence, need for achievement, and study habits were partialled out (Table XXI).

Distribution of conduct grades by English teachers (Ball H. S.).

As noted earlier no consistent relationships between psychometric scales and conduct grades were obtained. This is not surprising considering the differences in the teacher's ratings of students and also the differences in the distribution of conduct scores for the various teachers (Table XXII). It is interesting to note that for the two English teachers (G & Y) whose classes had the lowest average study habits scores, the teachers conduct scores were also distributed toward the low end of the range for conduct scores.

E. Item Analyses of BIS.

Since the SSHA scale has been well standardized and since the appropriateness of the social adjustment and academic achievement criteria measures were questionable in this study, an item analysis of the BIS was done against the SSHA scale. This analysis is still in progress and will be expanded into on M.A. thesis for Mrs. Eva Levy. The students at Ball H. S. were divided into high, medium, and low groups according to their study habits; it was then noted whether they answered an item as T or F on the BIS. A 2 x 3 chi square analysis was done for each item. Some of the items on the BIS which were significantly related to the SSHA scale:

(1) I like to take a chance just for the excitement; students with poor study habits answer this question true more often than they answer it false;

(2) I usually think before I act; very few students with good study habits answer this false while a large number of students with poor study habits answer it false;

(3) I like to solve complex problems; good study habit students answer this true significantly more often than students with poor study habits;

(4) I consider myself always careful; students with good study habits answer true more often while students with poor study habits answer false;

(5) I like work requiring patience and carefulness; students with good study habits answer this true more often than students with poor study habits;

(6) I like work involving competition; students with good study habits answer true more often than students with poor study habits;

(7) I easily become impatient with people; students with poor study habits answer ture more often than students with good study habits;

(8) It is easy for me to concentrate on my work; students with good study habits answer this true more often than students with poor study habits;

(9) My interests tend to change quickly; students with good study habits answer this false significantly more often than they answer it true; the reverse is true for students with poor study habits.

Although other items discriminate between students with good and poor study habits, these items had the highest chi square values.

F. Rotter Incomplete Sentences Blank. (ISB)

The ISB was scored by two raters, one a college sophomore, the other a graduate psychology student. The correlation between the total adjustment scores for both raters was .869 ($p < .001$). The total adjustment score was significantly negatively related to impulsiveness (BIS) for both Kirwin H. S. and Ball H. S. students. The analysis of the ISB is still in progress and will also be included as part of Mrs. Levy's M.A. thesis.

IV. Discussion and Summary of Results

The most significant findings of this study are:

(1) Impulsiveness and anxiety were not obtained as separate factors in either the normalized principle axis or the promax factor analyses; also, anxiety had a low but significant correlation with impulsiveness. In previous studies with college students and medical students, this result had not been obtained in comparably large samples. Also, in smaller samples of high school age students, impulsiveness and anxiety were never correlated. Thus, it was surprising to obtain this result in this study. It is possible that the selection of high school students in previous studies had led to biased samples in which impulsiveness and anxiety are not correlated. Since the lack of relationship between impulsiveness and anxiety is well established in large samples of college age students, it is possible that the clear separation of impulsiveness and anxiety is a personality characteristic that becomes more evident sometime between the beginning of high school and the beginning of college. It is also possible that it is not characteristic of the general population but in only ~~fairly~~ highly selected college students or medical students. This is an interesting result that needs further study.

(2) Impulsiveness (BIS) and anxiety (IPAT anx.) were related to study habits (SSHA) in both the normalized principle axis factor analysis and in the promax factor analysis; since the SSHA has been demonstrated to be related to achievement in a number of other studies, this finding is in-

direct evidence for the role of anxiety and impulsiveness in academic achievement.

(3) Both serious offenders and school drop-outs are characterized by high impulsiveness. These two categories of social adjustment are considered more objective measures of social adjustment than are the less serious infractions and conduct scores. It is quite obvious that teachers are very subjective in assigning conduct scores; their evaluations are colored by a student's achievement plus the reflection of their own per onality. Although high impulsiveness scores do not mean that a student will necessarily be a serious offender, if a student is a serious offender, the chances are 9 out of 11 that he will have a high impulsiveness score.

(4) For both Ball H. S. and Kirwin H. S., the ratio of impulsiveness to anxiety was not significantly correlated with English grades (as criterion of academic achievement) when intelligence (CFIT), study habits (SSHA), the need for achievement (ACL), and socio-economic status were partialled out.

(5) No psychometric scale consistantly related to achievement or social adjustment for all teachers, even when teachers ratings, socio-economic status, need for achievement and certain other variables were partialled out. However, for each teacher there were at least four psychometric variables that correlated with conduct grades and academic acnievement when the teacher's ratings of the students were partialled out. This suggests that knowing something about

the teacher's personalities is a prerequisite for predicting academic achievement and social adjustment for students with different personality patterns. In some instances, partialling out the teacher's ratings resulted in very high relationships of the psychometric scales to the students achievement and social adjustment scores for that teacher. Since the teacher's rating scale used in this study was not well standardized (although it had a respectable inter-rater reliability) this phase of the study should be followed up in further research. An effort should be made to provide a way of evaluating teacher's personalities and to weight their personality scores as part of the total equation for predicting a student's social adjustment or academic achievement.

N = 250

1. R is the multiple correlation with English grades using the psychometric predictors which have entries in each column; the predictor which accounts for the least variance drops out first; the predictor accounting for the most variance is in the last column; cell entries are the standard weights for each predictor: decimal points are omitted in table.

52

1. R is the multiple correlation with English grades using the psychometric predictors which have entries in each column; the predictor which accounts for the least variance drops out first; the predictor accounting for the most variance is in the last column; cell entries are the standard weights for each predictor: decimal points are omitted in table.

1. Channel Capacity Test

2. Teacher's Rating Scale

DO NOT OPEN THIS BOOKLET UNTIL YOU ARE TOLD TO DO SO

Directions

This test involves pairs of figures which are made up of a number of blocks. Each pair of figures will be exactly alike for all the blocks except one. Your task will be to find the single block or square which is different. Then place a mark (X) in the corresponding square of the blank figure which is located between the two test figures. Look at the examples below.

Example 1: 

Compare the right-hand and left-hand test figures. Each is made up of three blocks. Find the block which is different. Then place a check mark in the corresponding square of the blank figure in the middle. The correct answer is indicated below:

Answer to Example 1: 
Now look at these additional examples, and mark the correct answer:

Example 2: 
Example 3: 
For Example 2 the answer is 
For Example 3 it is 
Each page of the test booklet contains a number of problems like those illustrated in the examples. On each page do as many of the problems as possible during the time allowed. When the examiner says "STOP," put down your pencil and await further instructions. Your score will

Example 1: 

Compare the right-hand and left-hand test figures. Each is made up of three blocks. Find the block which is different. Then place a check mark in the corresponding square of the blank figure in the middle. The correct answer is indicated below:

Answer to Example 1: 

Now look at these additional examples, and mark the correct answer:

Example 2: 
Example 3: 
For Example 2 the answer is  For Example 3 it is 
Each page of the test booklet contains a number of problems like those illustrated in the examples. On each page do as many of the problems as possible during the time allowed. When the examiner says "STOP," put down your pencil and await further instructions. Your score will be the number correct. Work as rapidly as possible without making careless mistakes. If you have any questions raise your hand and the examiner will answer them. Remember, there is only one incorrect block per problem.

DO NOT OPEN THE BOOKLET UNTIL THE EXAMINER GIVES THE SIGNAL

Student Rating Scale

Please rate the student whose name appears at the top of the next page on the ten scales on the page. Circle the number between the words for each scale as follows:

(1) If you feel that a student is extreme, on any scale, mark either 1 or 7; for example,

THIS

sad 1 2 3 4 5 6 7 happy

OR THIS

sad 1 2 3 4 5 6 7 happy

(2) Circle 2 or 6 if a student is not extreme but approaches being extreme;

(3) Circle 3 or 5 if a student has a tendency in a certain direction but is not strong or extreme on that scale;

(4) Circle 4 if he is neutral with regard to any scale;

(5) Circle only one number on each scale for each

(1) If you feel that a student is extreme, on any scale, mark either 1 or 7; for example,

THIS

sad 1 2 3 4 5 6 7 happy

OR THIS

sad 1 2 3 4 5 6 7 happy

(2) Circle 2 or 6 if a student is not extreme but approaches being extreme;

(3) Circle 3 or 5 if a student has a tendency in certain direction but is not strong or extreme on that scale;

(4) Circle 4 if he is neutral with regard to any scale;

(5) Circle only one number on each scale for each student.

Base your ratings on other students whom you have known. These ratings will be kept strickly confidential so please rate the students as you feel they really are.

If you are not certain about a rating for a particular student, give your best estimate (even if you have to guess).

Student's Name:_____

Sad	1	2	3	4	5	6	7	happy
Social	1	2	3	4	5	6	7	asocial
Leader	1	2	3	4	5	6	7	follower
Bright	1	2	3	4	5	6	7	dull
Introvert	1	2	3	4	5	6	7	extrovert
Dependable	1	2	3	4	5	6	7	undependable
Coordinated (Physical)	1	2	3	4	5	6	7	uncoordinated (Physical)
Troublemaker	1	2	3	4	5	6	7	sets good example
Rapid changes in mood	1	2	3	4	5	6	7	mood remains constant

								happy
Social	1	2	3	4	5	6	7	asocial
Leader	1	2	3	4	5	6	7	follower
Bright	1	2	3	4	5	6	7	dull
Introvert	1	2	3	4	5	6	7	extrovert
Dependable	1	2	3	4	5	6	7	undependable
Coordinated (Physical)	1	2	3	4	5	6	7	uncoordinated (Physical)
Troublemaker	1	2	3	4	5	6	7	sets good example
Rapid changes in mood	1	2	3	4	5	6	7	mood remains constant
Low Frustration tolerance (acts impulsively on slight provocation)	1	2	3	4	5	6	7	high frustration tolerance (very stable-doesn't act impulsively)
