**ABSTRACT**

Using post-secondary vocational education students as the populations, these two sub-studies of the Project MINI-SCORE sought to determine the extent to which pre-enrollment standardized test data can be used to predict vocational success. For the purpose of the study, vocational success was defined either as successful graduation or successful graduation plus employment. The first sub-study investigated: (1) the ability of each of the separate scales of each instrument to differentiate occupational groups, and (2) the extent of difference between groups defined as successful graduates or as successful graduates employed in related occupations 1 year after training. The second sub-study investigated the ability of each total instrument to differentiate between occupational groups, and developed a method of presenting data pertaining to a multi-scale test instrument in the form of a counseling aid. Results of these sub-studies tend to indicate that there are significant differences between the types of people who enter and succeed in different occupations, and that it is possible to cluster occupations based on the characteristics of people who enter them. Related documents are available as VT 016 149-VT 016 152 in this issue.

## FOREWORD

This technical report is one of the technical reports of Project MINI-SCORE which summarize the findings of six years of intensive research into possible relationships between standardized test measures and a number of different criteria of vocational student success. The technical reports present a detailed discussion of Project findings. A general discussion of the goals and objectives of the total Project and the major findings can be found in the publication entitled PROJECT MINI-SCORE FINAL REPORT.

Through Project MINI-SCORE, test data consisting of measures derived from six separate instruments and test batteries were gathered on individual applicants to the area vocational-technical schools of Minnesota. The tests included in the battery were: (1) the General Aptitude Test Battery (Form B) written portions only, (2) the Minnesota Vocational Interest Inventory, (3) the Sixteen Personality Factor Questionnaire (Form C), (4) the Minnesota Importance Questionnaire (30-scale version), (5) the Vocational Development Inventory, and (6) the Minnesota Scholastic Aptitude Test. In addition, personal descriptive data were obtained from the students through the use of a questionnaire. The data from these instruments were analyzed to determine which of the information gathered would be useful in counseling individuals with reference to full-time, post-high school vocational-technical courses offered in the area vocational-technical schools of Minnesota. Measures of vocational student success included in the Project were: (1) reported graduation versus dropping out of programs, (2) employment status one year after graduation, (3) job satisfaction one year after graduation, and (4) job satisfactoriness one year after graduation.

The titles of all of the final technical reports of the Project can be found on the back cover of this report. Additional publications of Project MINI-SCORE which have dealt with some of the critical issues in vocational education research are listed on the last page. Limited numbers of copies of these reports are available.

**ABSTRACT  
(OVERALL SUMMARY)**

This report summarizes the results of two Project MINI-SCORE sub-studies aimed at determining the extent to which pre-enrollment standardized test instrument data are capable of providing meaningful information which can be used to differentiate persons who are later successful in different occupations.

The investigations were conducted using two different definitions of vocational student success. The first was successful graduation and the second was successful graduation plus employment in a related occupation one year after training. The first sub-study investigated (1) the ability of each of the separate scales of each of the instruments to differentiate occupational groups and (2) the extent to which groups defined as successful graduates and groups defined as successful graduates who were employed in related occupations one year after training differed. The second sub-study investigated the ability of each total instrument to differentiate occupational groups and developed a method of presenting data pertaining to a multi-scale test instrument in the form of a counseling aid.

The population of Minnesota post-high school area vocational-technical school students included in these studies was divided into three sub-parts. The first contained those people who had enrolled in curricula which included primarily males; the second contained those people who had enrolled in curricula which included primarily females; and the third contained those people who had enrolled in occupational curricula which included both males and females without a predominance of either sex. The analyses were conducted separately based upon the sex of the individuals included in the different curricula because past analyses had indicated that the scores of people on the standardized tests included varied systematically with the sex of an individual. The findings

presented in the second part of this report also bear out this fact.

The results obtained from both of the sub-studies which are reported herein tend to indicate that there are significant differences between the types of people who enter and succeed in different occupations on those factors measured by the standardized instruments included in the Project MINI-SCORE test battery. These differences were reflected in both the analyses of each of the separate scales of each of the instruments and the analyses of each of the instruments as a whole using each of the two definitions of success. Each of the scales of the GATB, MVII, VDI and MSAT revealed significant differences while some of the 16PF and MIQ scales revealed significant differences. The largest differences between the groups were found using the MVII. The analyses relative to the total instruments also indicated that it is possible to cluster occupations based on the characteristics of people who enter them. However, the occupational clusters derived through the use of standardized test data differ somewhat depending upon the constructs measured by an instrument. The investigation into differences between graduates and graduates who were employed in related occupations one year after training indicated that the groups were more similar than different.

The implications of these findings are great for persons interested in counseling individuals who wish to choose among a number of alternative vocational programs available to them. The results imply that it would be possible to present a person with valuable information, based upon the standardized tests used in the Project MINI-SCORE test battery, that he could use while exploring occupational alternatives. Also, the lack of differences between the graduates and those graduates who were employed in jobs related to training one year after graduation implies that little can be gained in the improvement of counseling aids by spending the energy necessary to identify graduates who

are successfully employed on the job. Apparently, counseling aids based on graduates would tend to be very similar to those based upon graduates successful on the job.

In light of the findings of these two studies, three different methods of presenting counseling information to students were developed. The first was a method using norm profiles which is presented in a series of norm booklets (see the back cover of this document for a list of these publications). The second was a graphic method based upon discriminant analysis which is described and presented in detail in part two of this report. (These first two methods can be used directly by counselors.) The third method requires a computer to implement. This methodology is termed the Centour methodology and its application as used in Project MINI-SCORE is described in an article entitled "The Centour Methodology Applied to Vocational Student Counseling and Admissions" (see Journal of Industrial Teacher Education, Fall, 1969). This latter methodology was adopted and implemented by the State of Minnesota in the Minnesota Statewide Vocational Testing Program. Complete details on the total system as it was implemented can be found in the School Counselors' Handbook of the Minnesota Statewide Vocational Testing Program.

Persons interested in findings concerning the ability of the standardized tests to predict success in an occupation once an occupation has been selected are referred to other Project MINI-SCORE reports. The Technical Report entitled The Ability of Standardized Test Instruments To Predict Training Success and Employment Success contains a detailed discussion of findings and the Project MINI-SCORE Final Report contains a general discussion of findings.

## INTRODUCTION

The Project MINI-SCORE studies reported herein utilized both the univariate and multivariate statistical techniques to investigate the ability of the instruments included in the Project MINI-SCORE test battery to differentiate group membership.<sup>1</sup> The instruments included in the battery were selected to represent the majority of those factors thought to be possible predictors of vocational student success as determined from the literature. The test instruments were administered to persons applying for admission to the post-high school area vocational-technical schools of Minnesota between September 1, 1966 and October 1, 1968. The battery included: (1) The General Aptitude Test Battery (Form B) (GATB), written portions only (GATB Manual, Section III, 1970); (2) the Minnesota Vocational Interest Inventory (MVII) (Clark and Campbell, 1965); (3) the Sixteen Personality Factor Questionnaire (Form C) (16PF) (16PF Handbook, 1962); (4) the Minnesota Importance Questionnaire (MIQ), 30-scale version (Weiss and others, 1964, 1969); (5) The Vocational Development Inventory (VDI) (Crites, 1969); and (6) the Minnesota Scholastic Aptitude Test (MSAT) (Berdie and others, 1962). A listing of the scales included in each instrument can be found in Appendix C, Table 1C.

The groups included in this report represented people who were tested and later became successful graduates of selected curricula offered by the schools. Success was defined in two ways, both as graduating from a program and as being employed one year after graduation in an occupation related to the curriculum from which the student graduated. These two definitions of success were adopted because they have been used most frequently in the past by vocational educators.

---

<sup>1</sup>A discussion of the ability of the instruments to differentiate successful from unsuccessful people within an occupational cluster can be found in the Project MINI-SCORE final technical report entitled The Ability of Standardized Tests to Predict Training Success and Employment Success.

Information concerning whether students graduated from the programs they originally enrolled in was provided by the schools. Information concerning whether graduates were employed in related occupations one year after graduation was obtained through the use of a mailed questionnaire which yielded 85 percent returns.

The desirability of counseling aids to assist individuals in learning about themselves in relation to occupations has been documented since Parsons wrote his book, Choosing a Vocation (Parsons, 1909). Since that time, persons attempting to develop predictive counseling aids have discovered that two problems are faced by the individual who wishes predictive information concerning his possibility of success in an occupation. The two problems are logically related. First, he needs information concerning what occupation he might wish to enter. Second, he needs information concerning his chances of success in that occupation. Counseling aids which are developed to solve the first problem generally concentrate on assisting an individual with determining group membership. In other words, how similar is the individual to those who have been successful in a variety of occupations? Counseling aids developed to solve the second problem concentrate on predicting success in the occupation. After obtaining knowledge of the similarity of an individual to successful people in an occupation, this additional knowledge is used to determine his probability of success in that occupation. The logic upon which this two-stage predictive model is based is discussed in detail in the book entitled Multivariate Statistics for Personnel Classification (Ruion and others, 1967) and is termed the joint probability model.

Part One of the study, entitled "The Ability of Each of the Instrument Scales to Differentiate Membership in Different Vocational-Technical Curricula," investigated the ability of each scale of each instrument to differentiate among

successful people from various occupational curricula utilizing univariate analysis of variance. This technique was successfully used in another Project MINI-SCORE study (Pucel, Nelson, Wheeler, 1970). Part Two, entitled "The Ability of Each of the Multi-Scale Instruments to Differentiate Membership in Different Vocational-Technical Curricula," investigated the ability of each of the total instruments to differentiate among successful people from the various curricula utilizing multiple discriminant analysis.

PART ONE

THE ABILITY OF EACH OF THE INSTRUMENT SCALES TO DIFFERENTIATE MEMBERSHIP  
IN DIFFERENT VOCATIONAL-TECHNICAL CURRICULA (UNIVARIATE ANALYSIS)

Objective

The objective of this part of the study was to determine the ability of each of the scales of each of the six instruments included in the Project MINI-SCORE pre-enrollment test battery to differentiate among graduates of various vocational-technical curricula, and among graduates of various vocational-technical curricula who were employed in a job related to training one year after graduation. Persons concerned with developing normative counseling aids have generally assumed that normative data produced relative to people who were successful on the job would be more effective than those produced relative to people who were successful in training. This assumption supposed that the norms developed from the two groups would be different. A secondary purpose of this part of the study was to determine whether the graduate population and the employed related population did, in fact, differ significantly in terms of the separate test scales.

Population

The analyses included in this study were carried out on two populations referred to as the "graduate" and "employed related" populations. The "graduate" population included all students in eighteen selected curricula who (1) had applied to one of the twenty-four cooperating Minnesota Area Vocational-Technical schools during the period from September 1, 1966, to October 1, 1968; (2) had taken the Project MINI-SCORE test battery; and (3) had later graduated from the curriculum in which they enrolled before July, 1970 (see Appendix F for a list of the schools). The second population, "employed related," included those

students in the "graduate" population who were employed on a job related to their training one year after graduation and who were followed up before July 15, 1970. Approximately 85% of the graduates followed up responded to the mailed follow-up questionnaires. (A more detailed description of the vocational student population included in Project MINI-SCORE can be found in the document entitled Project MINI-SCORE Final Report.)

The eighteen curricula selected for Part One of this study were twelve predominantly male groups and six predominantly female groups which had at least twenty individuals in the employed related category. The curricula were grouped according to sex because other Project MINI-SCORE studies detected differences between males and females on the variables being analyzed which were so large they tended to overshadow other potentially important findings (see Pucel and others, 1972). The effect of differences due to sex are also apparent in the second part of this report. Table 1 shows the sizes of these groups. Complete data were available on all instruments except MSAT for each individual. The number of individuals in each curriculum for whom MSAT scores were available are reported separately, in parentheses. Care must be taken when interpreting the analyses related to the MSAT since persons who had taken the MSAT were systematically different from those who had not. In order to have an MSAT score, most people would have had to have been high school juniors in Minnesota since 1955. This means that persons who attended high school before that time or who were high school drop-outs prior to their junior year would not have had MSAT scores. The same twelve male curricula and six female curricula were used for both the graduate analyses and the employed related analyses. The sizes of the groups of graduates employed in a related occupation are smaller than the sizes of the graduate groups since some graduates did not enter occupations related to training. Some of the graduates entered unrelated occupations, some remained

TABLE 1

unemployed, some were unavailable for employment because of military service, some became housewives, and some were unavailable for other reasons.

Procedure

Each of the scales of each instrument in the Project MINI-SCORE test battery was analyzed to determine the ability of each scale to distinguish the different curricula for each of the two populations. One-way analyses of variance were used with significant F-test results reported at the .05 and .01 level. Four analyses of variance were run on each scale; one for male graduates, one for female graduates, one for male employed related, and one for female employed related (see Figure 1). In addition, an ANOVA was run on each scale to determine

FIGURE 1  
SCHEMATIC  
OF THE TWENTY-FOUR UNIVARIATE ANALYSES

if the group that became employed in a related occupation was systematically different than the graduate group. This ANOVA is not parallel to the other analyses and is not included in Figure 1.

Results Related to Graduates

Results related to the graduate groups regarding all six instruments are reported below. They are reported separately in relation to each instrument. (See Appendix A for complete tables including individual group mean scores and standard deviations.)

The General Aptitude Test Battery (GATB)

The written portion of the GATB consists of eight part scores which have been re-interpreted as seven factorially derived aptitude scores (GATB Manual,

Section III, 1970). The aptitude scores were used in this study. The F-values for the analyses of variance between groups for the GATB are reported in Table 2. Significant differences were found among the male graduate groups and among female graduate groups on all scales of the GATB at the .01 level. For both male and female groups, the highest F-values were associated with the following three scales: G-Intelligence, V-Verbal Aptitude, and N-Numerical Aptitude. Between-group differences were more evident for the female groups than for the male groups. Examination of the male group means (see Appendix 1A) shows that electronics, mechanical drafting and design, and optical technology groups have high means while welding means are low on the three scales G, V, and N. In the case of the female groups, high means for the medical laboratory assistant group and low means for cosmetology and clerical groups seem to account for the large F-values on those three GATB scales (see Appendix 2A). The GATB scales appear to be very effective in separating the graduates of the different curricula under study.

TABLE 2

K-Motor Coordination	** 5.448	**14.668

\*\*Significant at .01

The Minnesota Vocational Interest Inventory (MVII)

The nine homogeneous keys of the MVII were used in this study.<sup>1</sup> The results related to the MVII are reported in Table 3. The MVII was also effective in significantly differentiating among the male graduate groups and among the female graduate groups at the .01 level. Two very large F-values occurred for the female groups. The F-value for H-2, Health Service, was 447.616. An examination of group means on that scale (see Appendix 4A) shows that practical nursing and medical laboratory assistant groups scored quite high, while clerical and secretarial training groups scored low. The high F-value,  $F = 379.899$ , for H-3, Office Work, seems to be caused by the high scores of clerical and secretarial training groups, and the low scores for practical nursing and medical

TABLE 3  
ANOVA OF DIFFERENCES BETWEEN CURRICULUM GROUPS (GRADUATES)  
(MVII HOMOGENEOUS KEYS)

SCALES	F - VALUES	
	MALE GROUPS	FEMALE GROUPS
H-1 Mechanical	**27.793	** 17.203
H-2 Health Service	**13.795	**447.616
H-3 Office Work	**17.667	**379.899
H-4 Electronics	**85.308	** 31.257
H-5 Food Service	** 3.244	** 43.409
H-6 Carpentry	**74.302	** 8.098
H-7 Sales-Office	**20.888	** 56.015
H-8 Clean Hands	** 9.406	** 94.922
H-9 Outdoors	**11.255	** 8.254

\*\*Significant at .01

<sup>1</sup>It must be noted that the populations used in this study exhibit distributions on the MVII homogeneous keys which are considerably non-normal. Investigation of this problem in another Project MINI-SCORE study (Pucel, Nelson, Wheeler, 1970A) indicated that results of nonparametric analyses using chi-square agreed very well with results of parametric analyses using ANOVA.

lab assistant groups. This probably indicates that scales H-2 and H-3 do a good job of differentiating between the health-oriented curricula and clerical-secretarial type curricula. The largest F-values for the male groups were H-4, Electronics,  $F = 85.308$ , and H-6, Carpentry,  $F = 74.302$ . High means for electronics and for power and home electricity probably caused the high F-value on H-4. The high F-value for H-6 seems to be due to a high mean for the carpentry group. It is interesting that group means rank in approximately reverse order on these two scales. Electronics has the highest mean on H-4, lowest on H-6. Power and home electricity is second highest on H-4, second lowest on H-6. The carpentry mean is lowest on H-4, highest on H-6 (see Appendix 3A).

#### The Sixteen Personality Factor Questionnaire (16PF)

Table 4 reports the results of the 16PF analyses of variance. The scales of the 16PF were not as effective as the GATB or MVII scales in distinguishing between graduates of the different curricula. The male graduate groups were significantly different on nine of the sixteen scales. The differentiation among the female graduate groups was better with fourteen of the sixteen scales significant. On the three scales with the largest F-values for the female groups, A-Aloof vs Outgoing, Q1-Conservative vs Experimenting, and Q3-Uncontrolled vs Self-Controlled, the practical nursing and medical lab assistant groups had high mean scores, while the clerical and secretarial training groups had low mean scores (see Appendix 6A). The male groups showed no clear patterns. Groups which scored high on one scale scored low on others. However, it is interesting that the high scoring groups on Scale G-Casual vs Conscientious were farm equipment mechanics and agri-technology while the electronics group scored high on M-Conventional vs Eccentric and Q1-Conservative vs Experimenting (see Appendix 5A).

TABLE 4

\*Significant at .05

\*\*Significant at .01

The Minnesota Importance Questionnaire (MIQ)

The results using the MIQ are reported in Table 5. Twenty-seven of the thirty scales were effective in differentiating between the female graduate groups. Seventeen scales significantly differentiated the male graduate groups. The MIQ was considerably more effective in differentiating female groups than male groups. The number and size of the significant F-values were much larger for the female groups. Looking at the means of the female groups on the three scales with the largest F-values shows the practical nursing group is most unlike the other groups. On scale 4, Advancement, and scale 9, Creativity, practical nursing scored lower than the other female groups. On scale 15, Social Service, the practical nursing scores were higher than the other female

groups (see Appendix 8A). Scales 4 and 15 were also two of the better differentiators of male groups. Male groups scoring high on scale 4, Advancement, tended to score low on scale 10, Independence, and scale 15, Social Service (see Appendix 7A).

The Vocational Development Inventory (VDI)

The VDI is designed to measure attitudes related to vocational development. It consists of only one scale. Table 6 presents the results of the VDI analyses of variance. Both male graduate groups and female graduate groups were significantly differentiated by the VDI. The F-value for female groups was much larger than for the male groups. From the means of the female groups, it appears that this large F-value is caused by high means for practical nursing, dental assistant, and medical lab assistant groups; and low means for cosmetology, clerical training, and secretarial training groups (see Appendix 10A). Among the male groups, the diesel mechanics, optical technology, and aircraft mechanic curricula showed high means, while the welding curriculum had a low mean (see Appendix 9A).

\*\*Significant at .01

The Minnesota Scholastic Aptitude Test (MSAT)

The MSAT was used to measure scholastic aptitude. These test scores were obtained from the Minnesota Statewide Testing Program. As a result, MSAT scores were only available for part of the population stated, as indicated in Table 1. Table 7 shows the ANOVA results for MSAT. Curricula within both male and female graduate groups were significantly different. The medical

\*\*Significant at .01

laboratory assistant group was high and the clerical training group low among the female group means (see Appendix 10A). The highest means for the male groups were for the electronics curriculum, the mechanical drafting curriculum, the aircraft mechanic curriculum, and the optical technology curriculum. The welding group had a low mean (see Appendix 9A).

Results Related to Individuals Employed in Related Occupations

Results related to the employed related groups regarding all six instruments are reported below in relation to each instrument separately. (See Appendix B for complete tables including individual group mean scores and standard deviations.)

The General Aptitude Test Battery (GATB)

The analyses of variance F-values for the GATB are reported in Table 8. Both male and female employed related groups were significantly differentiated by all seven of the GATB scales. G-Intelligence and V-Verbal Aptitude were the two scales which were most effective in separating curricula for both male groups and for female groups. The high F-values for male groups on scales G and V appear to be caused by high scores of persons in electronics, aircraft mechanics, mechanical drafting and design, and optical technology, and by low scores for people in welding (see Appendix 1B). In the case of female groups,

\*Significant at .05

\*\*Significant at .01

the high F-values for scales G and V were probably caused by high scores of people in cosmetology and clerical training (see Appendix 2B). Overall, the GATB seems effective in distinguishing between both male employed related groups and female employed related groups.

The Minnesota Vocational Interest Inventory (MVII)

Table 9 displays the F-values of the MVII analyses of variance. All nine scales were effective in significantly differentiating among the female employed related and among the male employed related groups. Two of the F-values for the male groups were several times larger than the other F-values. These were for scale H-4, Electronics, and scale H-6, Carpentry. High group means for two curricula, electronics and power and home electricity, and low group mean for carpentry caused the high F-value on scale H-4, Electronics. The high F-value on H-6, Carpentry, was caused primarily by very low group means for the electronics group and the power and home electricity group together with a high mean for the carpentry group (see Appendix 3B). There were also two very large F-values for the female groups on scales H-2, Health

Service, and H-3, Office Work. Looking at group means, scale H-2, Health Service, seems to separate the six female groups into two clusters. Practical nursing, dental assistant, and medical lab assistant have high means while cosmetology, clerical training, and secretarial training have low means. Scale H-3, Office Work, shows high means for clerical and secretarial and low means for practical nursing and medical lab assistant. Two more F-values for female groups were rather high (see Appendix 4B). These scales, H-7, Sales-Office, and H-8, Clean Hands, have group means which tend to support the idea of two female clusters suggested above (see Figure 2). The MVII, like the GATB, does a good job of differentiating between the employed related groups.

The Sixteen Personality Factor Questionnaire (16PF)

The analyses of variance F-values for 16PF analyses are reported in Table 10. Five of the sixteen scales seemed effective in significantly differentiating the employed related male groups (see Appendix 5B). For the employed related female groups, thirteen of the scales had significant F-values. The highest F-value for female groups was scale Q3, Uncontrolled vs Self-Controlled.

Practical nursing and medical lab assistant group means were high on scale Q3, while the dental lab assistant mean was low (see Appendix 6B). Overall, it can only be stated that some of the 16PF scales effectively separate the groups, with more scales able to separate female groups than male groups.

The Minnesota Importance Questionnaire (MIQ)

Table 11 shows the F-values for employed related groups on the MIQ. Eight of the thirty scales significantly differentiated male employed related groups. The largest F-value for male groups was on scale 10, Independence. The group means for welding and for agri-technology were high on this scale, and the diesel mechanics group mean was low (see Appendix 7B). Twenty-five of the thirty scales had significant F-values for the female employed related groups.

\*Significant at .05

\*\*Significant at .01

Examination of group means for the female groups shows a clustering of occupations which is fairly consistent for the scales with the highest F-values. Practical nursing, medical lab assistant, and dental assistant seem to cluster together on scale 4 - Advancement, scale 7 - Compensation I, scale 10 -

Independence, scale 16 - Social Status, and scale 23 - Organization Control. Two additional scales with high F-values show practical nursing and medical lab assistant clustering together. These two are scale 15 - Social Service, and scale 27 - Company Prestige (see Appendix 8B). Overall, the MIQ does a good job of separating the female groups, but is relatively ineffective in separating the male groups.

The Vocational Development Inventory (VDI)

Table 12 indicates that the VDI was effective at distinguishing between both the male and the female employed related groups. The F-value for the female groups was much larger than for the male groups, but both were significant at the .01 level. A high group mean for the automotive group and low means for farm equipment mechanics and aircraft mechanics seem to account for the differences between the male groups (see Appendix 9B). For the female groups, practical nursing and medical laboratory assistant groups had high means, and clerical training and cosmetology groups had low means (see Appendix 10B).

\*\*Significant at .01

mechanical drafting and design, and agri-technology; while the welding and aircraft mechanics groups had low group means (see Appendix 9B). A high group mean for medical laboratory assistants helped produce the significant F-value for female groups (see Appendix 10B).

Results Related to the Analyses of Variance of Differences Between the Graduate Group and the Employed Related Group for Each Curriculum

The results presented in this section are relative to the question of whether or not norms developed on a population of vocational school graduates would be different than norms developed on a population of graduates who are employed in training related occupations one year after graduation. The extent to which the two groups within each of the curriculum areas were different was investigated by comparing the test scale scores of the two groups using analysis of variance. Table 14 indicates how many scales of each instrument significantly differentiated the graduate group from the employed related group at  $\alpha = .10$  for each of the eighteen curricula. The actual F-values associated with each instrument scale for each curriculum can be found in Appendix C. Examination of Table 14 reveals that only three of the eighteen curricula showed significant differences between the graduate group and the employed related group on one or more GATB scales. These curricula were agri-technology, welding and clerical training. Only one of the curricula, electronics, showed

any differences based on MVII scales. One or more scales of 16PF separated the graduate group from the employed related group for four of the eighteen curricula - agri-technology, aircraft mechanics, automotive, and diesel mechanics. Five curricula showed differences based on one or more MIQ scales. These were agri-technology, aircraft mechanics, electronics, welding, and dental assistant. There were no differences on the VDI scale. MSAT separated the graduate group from the employed related group for one curriculum, secretarial training. These data seem to indicate the employed related group for each curricula is not very different from the corresponding graduate group. The F-values were also examined at a significance level of .25. At that level there were more scales which significantly differentiated the graduate group from the employed related group, but even at such a relaxed significance level only a small proportion of the scales showed significant F-values.

#### Part One Conclusions

The analysis of the ability of each of the scales of each of the instruments included in the test battery to differentiate successful persons in different occupations indicated that differences do exist between persons who are successful in the different occupations. These differences exist both between graduates of different occupational training programs and between graduates who later go out on the job and who are successful in an occupation related to the program from which they graduated.

All the scales of four of the instruments were effective in differentiating both among the male groups and among the female groups when success was defined as successful graduation as well as when success was defined as employment in a related occupation. These four instruments were the MVII, MSAT, VDI, and GATB. In all cases differences were significant at at least the .05 level and in most cases differences were significant at the .01 level of significance.

Many of the scales of the 16PF and MIQ also significantly differentiated among the male groups and among the female groups using both criteria of success. In all cases more scales of the 16PF and MIQ were capable of significantly differentiating the female groups than were capable of differentiating the male groups. The F-values, which are related to the magnitude of the differences between groups, were consistently larger for female analyses than they were for the male analyses, suggesting that the ability of these instruments to separate the female groups is greater than their ability to separate the male groups. This finding is logical, however, when one reviews the actual occupations included in the female and male groups. The female groups represent a wider range of occupations than do the male groups. The male groups appear to be representative of a more homogeneous group of occupations.

An attempt to review the results to determine if any clusters of occupations could be determined within the male group and within the female group revealed no readily apparent clusters within the male group. Groups within the male group did not consistently separate themselves as indicated by the analyses of the various instruments. Some clustering was evident among the female groups, however. On the basis of group means, the practical nursing and the medical lab assistant groups clustered together quite consistently at the opposite end of the continuum from the clerical training and the secretarial training groups. In some analyses the dental assistant group joined with the practical nursing and medical lab assistant groups and the cosmetology group joined with the secretarial and clerical training groups.

Using the scales included in the battery, few differences were found between those people who were successful graduates and those people who later went on to become successful in a job related to training. This finding would appear to indicate that in further studies attempting to develop normative data

for counseling purposes, using graduate groups as criterion groups for the development of normative data would produce approximately the same level of precision of normative data as using data on people who were employed in occupations related to training one year after graduation.

PART TWO

THE ABILITY OF EACH OF THE MULTI-SCALE INSTRUMENTS TO DIFFERENTIATE  
MEMBERSHIP IN DIFFERENT VOCATIONAL-TECHNICAL CURRICULA  
(MULTIVARIATE ANALYSIS)

Objective

The major objective of Part Two of this Project MINI-SCORE study was to investigate the ability of the multi-scale instruments included in the Project (GATB, MVII, 16PF, and MIQ) to individually discriminate among groups that attended vocational schools and graduated, as well as groups that graduated and were later successfully employed in occupations related to the program from which they graduated. A second objective was to develop a method of reporting the findings that would be useful to people who are trying to assist individuals to select among alternative occupational education programs. As indicated, success was defined in two ways, the first being successful graduation from the program the student was enrolled in, and the second successful graduation from the program the student was enrolled in plus successful employment in an occupation related to the program one year after training. Analyses related to each of the two methods of defining success were conducted separately. The analyses reported in this study were conducted using discriminant analysis. A similar multivariate analysis was also conducted using the Centour methodology; a description of this system can be found in two previously published references (Pucel, 1969; Minnesota Statewide Vocational Testing Program handbook, no date).

Population

The population used in Part Two of the study included all students and groups included in Part One, plus a group of three curricula which included approximately an equal number of males and females. The curricula were grouped according to sex because other Project MINI-SCORE studies detected differences between males and females on the variables being analyzed which were so large

they tended to overshadow other potentially important findings (Pucel and others, 1972). These findings were also supported by this sub-study.

Each curriculum selected had at least twenty individuals in the employed-related category. The same curricula were used in both the "graduate" and "employed related" analyses. Tables 15, 16, and 17 show the curricula selected and the group sizes in both the "graduate" and "employed related" populations.

The size of the "employed related" population is less for each of the curricula than its "graduate" counterpart because some of the graduates from each curriculum were not employed in occupations related to the curriculums they graduated from one year after graduation. Some graduates entered unrelated occupations, were unemployed, entered military service, became housewives, or were unavailable for other reasons.

\*Curricula containing both male and female

Procedure

The analyses were conducted for each of the four instruments separately on each of the graduate and employed related classifications for each of the three curriculum groupings (male, female, combined). Figure 3 illustrates the instrument by occupational status by sex classification system, which underlies the twenty-four analyses reported in this part of the study.

FIGURE 3  
SCHEMATIC  
OF THE TWENTY-FOUR MULTIVARIATE ANALYSES

Discriminant analysis was the method used in this part of the study to investigate the differences between groups of individuals who were successful in different occupations utilizing the Project MINI-SCORE pre-enrollment test data. Discriminant analysis is a technique which attempts to maximally separate groups of individuals on the basis of whatever the independent variables are that are being used to describe the groups (Nunnaly, 1967). In other words, if the independent variables gathered on electricians, welders, and auto mechanics were the nine Minnesota Vocational Interest Inventory homogeneous scales, the technique would attempt to derive a set of equations that would maximize the differences between the three groups on the basis of the MVII data. The equations calculated during the process are called discriminant functions, and the scores that are obtained by inserting a given individual's scores on the original variables into the equations are called discriminant scores. One can think of the process as one of deriving equations that will result in being able to calculate discriminant scores for individuals that would result in the greatest differences between the scores of those people who are members of the different populations.

If the differences obtained from the above process are significant and meaningful, such information can be useful in the counseling process. Counselors could calculate the discriminant scores for individuals and, based upon the scores obtained, they could compare the individuals' scores with the scores of individuals that are known to be successful in the various occupations. The assumption is that the more similar a particular individual's scores are to those of members of a successful group, the more likely he is to be successful. (For a discussion of the contrast between this approach and that of predicting the group in which an individual might maximally perform, see Nunnaly, 1959; Rulon, 1967; Tiedeman, 1951.)

Usually there is more than one discriminant function that is meaningfully interpretable from any analysis. Throughout this study, only the two most significant functions derived from the analyses were reported. Two were selected because in most instances the first two functions account collectively for a large proportion of the variance attributable to the data and operationally it is possible to plot two scores on a graph on a flat surface. An example of such a plot can be found in Figure 4.

The plots, such as the one shown in Figure 4, were derived as follows: A discriminant analysis was conducted using a particular instrument to differentiate among groups of individuals that were defined as successful in different occupations. The analysis resulted in two or more significant discriminant equations or functions. The two functions accounting for the greatest amount of variance were then used to calculate the discriminant scores for all of the people in each group. The mean or average discriminant score of all of the people in a given group on a given function was defined as the centroid on that function. Centroids were then plotted on a graph similar to that shown in Figure 4.<sup>2</sup>

Function 1 was the function accounting for the greatest amount of variance, and was represented by the X-axis, or the horizontal axis; function 2 was the function accounting for the second greatest amount of variance and was represented by the Y-axis, or vertical axis. The centroids for a given group on function 1

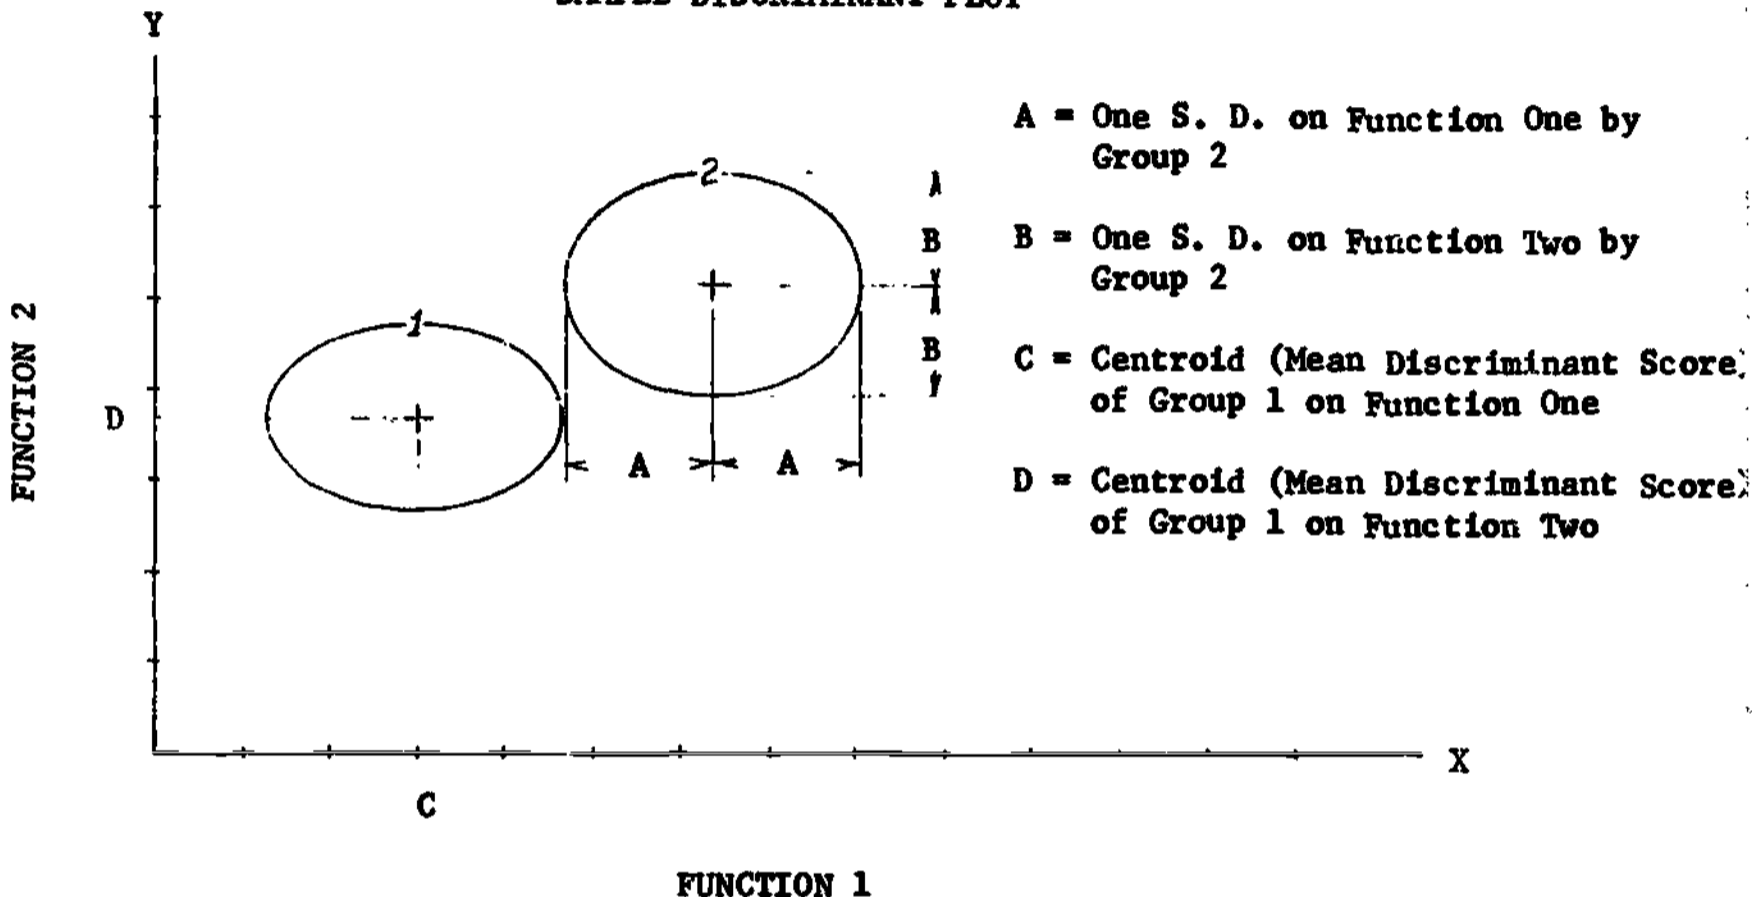

---

<sup>2</sup>Although the discriminant functions derived through discriminant analysis are orthogonal for the entire group on which the analysis was conducted, it is possible that the discriminant functions are not orthogonal for each of the sub-groups within the analysis. The figures presented in this publication were drawn making the assumption that the discriminant functions plotted were in fact orthogonal for each of the sub-groups within the analysis. In other words, it is assumed that the correlation between the scores derived from the two functions is zero within each of the sub-groups in the analysis as well as within the total analysis.

FIGURE 4

SAMPLE DISCRIMINANT PLOT

and 2 were plotted and the intersection of these two centroids determined the center of that group on the bivariate plot. Standard deviations of the discriminant scores around the centroid for each group were calculated on function 1 and function 2. The ellipse which encircles the centroid of a given group was plotted such that the distances from the centroid to the top of the ellipse and to the bottom of the ellipse were each equivalent to one standard deviation on the second function discriminant scores. The width of the ellipse was determined by plotting one standard deviation to the left and one standard deviation to the right of the centroid for the given group using the first discriminant function standard deviation for members of that group. It is hypothesized that this ellipse includes approximately forty percent of the individuals who were defined as successful in the occupation. In other words, if one took the scores of each individual included in the group on the instrument in question and calculated both his discriminant function scores on function 1 and function 2 and

plotted them on the plot as shown in Figure 4, the discriminant function scores of forty percent of the members of the group would intersect within the ellipse.

#### Use of the Discriminant Function Data

The discriminant function profile plots are a useful tool to counselors who wish to assist students in selecting among alternative vocational training programs. The method weighs each of the variables used to try to predict the differences between the groups in terms of their ability to differentiate between the groups, and takes into account the relationships among the variables. In other words, the discriminant functions are derived in such a way that if one were to calculate individual student discriminant scores using the discriminant function equations, the most important elements of the student's test scores will be utilized.

The following is an example of how female students who wish to select among alternative vocational programs might be assisted in making a choice through the use of the discriminant analysis data. In this example, we will assume that the instrument being used by the school is the Minnesota Vocational Interest Inventory and that the vocational programs which are of interest to the students are (1) practical nursing, (2) cosmetology, (3) dental assistant training, (4) medical lab assistant training, (5) clerical training, and (6) secretarial training. Figure 5 is a graph derived from actual scores of graduates of Minnesota Area Vocational-Technical schools who were successful employees in the six occupations listed. Upon inquiring about any of these programs, students would be asked to take the Minnesota Vocational Interest Inventory (MVII). The scores on the nine homogeneous scales of the MVII would be obtained for each of the students that took the inventory. The nine homogeneous scales obtained for the MVII for each student would be used to calculate discriminant score 1 and discriminant score 2 for each student.

FIGURE 5

PLOT OF THE FEMALE OCCUPATIONS ON THE FIRST TWO DISCRIMINANT  
FUNCTIONS DERIVED FROM THE ANALYSIS OF MVII  
SCORES IN THE EMPLOYED RELATED POPULATION

-37-

$$X = \text{FUNCTION 1: } (-.2734)(H-1) + .5663(H-2) + (-.6973)(H-3) + (-.1874)(H-4) + .0009(H-5) \\ + (-.0975)(H-6) + (-.0054)(H-7) + (-.2296)(H-8) + (-.1449)(H-9)$$

$$Y = \text{FUNCTION 2: } (-.5370)(H-1) + .5221(H-2) + .4961(H-3) + .0037(H-4) + (-.3414)(H-5) \\ + (-.1529)(H-6) + .1425(H-7) + .0788(H-8) + .1625(H-9)$$

Let us assume that three girls come to the counselor for counseling in terms of vocational programs available to them. The counselor asks them to take the MVII and obtains their homogeneous key scores. He then takes each of the girls' scores and proceeds to calculate their function 1 and function 2 scores according to the function equations indicated in Figure 5. He would accomplish this as follows. He would take each of Jane's scores on the homogeneous keys of the MVII and multiply it by the appropriate multiplier as indicated in the equation for function 1. In other words, he would take Jane's scale H-1 score and multiply it by  $-.2734$  and add that to Jane's H-2 scale score multiplied by  $.5663$  and add that to Jane's H-3 scale score multiplied by  $-.6973$ , etc., until he had multiplied each of Jane's nine scores by the appropriate weight for function 1. The sum of the products obtained when each score is multiplied by its proper weight is Jane's score on discriminant function 1. (Table 18 illustrates the calculation for the three girls in this example.)

The counselor would then take Jane's scores and do the same thing for function 2 by multiplying each of her scores by the appropriate weight and deriving a discriminant score for function 2. Jane's function 1 score would then be plotted along the horizontal X-axis and her function 2 score would then be plotted along the vertical Y-axis. The intersection of these two plots would locate Jane on the graph. In this case Jane is located within the ellipses that include 40% of the graduates who were successful on the job in clerical training and 40% of the graduates who were successful on the job in secretarial training (see Figure 5). Her discriminant score intersect does not fall within any of the other ellipses. Therefore, one might conclude that based on information from the Minnesota Vocational Interest Inventory, Jane's interests are more like those of people who have been successful on the job in secretarial training and clerical training than in the other female occupations represented on the graph.

	H-9	3	(-.1449)	-0.4347	(.1625)	0.4875
				Sum(Score X Weight) 3.3496	Sum(Score X Weight) 7.9443	

Rose's discriminant function 1 and discriminant function 2 scores would be calculated similarly and plotted on the profile. Rose's intersect falls within secretarial, clerical, and cosmetology ellipses. Relatively, her score intersect is closer to the centers of the secretarial-clerical groups than it is to the center of the cosmetology group, but the differences are not great. It might be well to advise Rose that her interests are more like those of the secretarial, clerical and cosmetology groups who went through vocational programs and were successful on the job. Sally's discriminant function 1 and 2 scores would be calculated similarly and plotted on the graph. Sally's intersect falls within the ellipses of the practical nursing and the medical lab assistant groups. It might be well to advise Sally that her interests are more like those of practical nurses and medical lab assistants who have gone through vocational programs and have become successful on the job than they are to the interests of the other groups. Also, her interests are more like those of medical lab assistants than practical nurses because her intersect falls closer to the center of the medical lab assistant group than to the center of the practical nursing group.

The example given here was relative to interest inventory information obtained from the Minnesota Vocational Interest Inventory. The scores for these girls could also be similarly plotted on the graphs that have been prepared for the other instruments if scores were available on the other instruments. Therefore, the students or potential students could view how similar their scores are to the scores of people in fields of interest who have graduated and have become successfully employed. This information provides the student with additional information in making occupational choices.

### Interpretation of Functions

The information gained through the construction of two-dimensional plots of occupational groups or curricula and the placement of individual counselees on the graph thus produced may be supplemented by the interpretation of the constructs underlying the discriminant functions utilized in the graphs.

Although it is not always possible to attach a simple label to the psychological construct underlying a function, it is generally informative to examine both the weights applied to the original variables to form the function and the correlations of the function with the original variables. An interpretation of a discriminant function will give the counselor and counselee a feeling for "how" the occupations or curricula being considered differ (see Tatsuoka, 1970).

The following example is an interpretation of the first two functions from the analysis of MVII scores for females in the employed related population. (This is the same analysis used previously for the placement of three hypothetical students.) The data reported in Table 19 was taken from Table 29 and lists only those MVII scales with the highest weights and correlations for the first two functions. The interpretation of any function should include the consideration of all of the original variables, but in the case where some variables clearly have higher weights, consideration of only those variables usually provides a reasonable definition of the construct underlying the function.

The first function in this analysis accounted for 93.87% of the variance accounted for by the analysis and may be interpreted as reflecting interests in health service in the positive direction and office work in the negative direction. Examination of Figure 5 tends to corroborate this interpretation with clerical training (5) and secretarial training (6) falling at the low (highest negative) end of the function and practical nursing (1) and medical lab assistant (4) at the opposite or positive end of the function.

TABLE 19

SELECTED ENTRIES FROM TABLE 29 USED IN THE INTERPRETATION OF THE FIRST TWO DISCRIMINANT FUNCTIONS IN THE ANALYSIS OF MVII SCORES FOR THE FEMALE OCCUPATIONS IN THE EMPLOYED RELATED POPULATION

MVII SCALE	DISCRIMINANT FUNCTION 1		DISCRIMINANT FUNCTION 2	
	FUNCTION WEIGHTS	CORRELATION OF FUNCTION WITH ORIGINAL SCALES	FUNCTION WEIGHTS	CORRELATION OF FUNCTION WITH ORIGINAL SCALES
H-1 MECHANICAL			-.5370	-.5952
H-2 HEALTH SCIENCES	.5663	-.9286	.5221	.3072
H-3 OFFICE WORK	-.6973	-.9021	.4961	.3779
H-5 FOOD SERVICE			-.3414	-.4145

The second function accounted for an additional 4.10% of the variance accounted for by this analysis and can be interpreted as representing interest in both health services and office work in the positive direction and mechanical and food service interests in the negative direction. Since the first function had already accounted for most of the variance accounted for in the analysis, discrimination along this function is not as clear-cut as along the first function. Cosmetology (2) was discriminated from the other five occupations by its lower placement on function two.

One will not always find a one-to-one correspondence in the rank order of variables on both weights and correlations. In the event that two or more scales of a test instrument tend to measure the same trait or characteristic (are intercorrelated) it may be found that one or more of the variables will have a high correlation and a low weight. This can be accounted for by the fact that once that particular variance that differentiates between groups has been accounted for by the relatively heavy weighting of the first scale, later scales that measure some of the same variance will not logically also be highly

weighted. If all the scales of a test instrument were independent (measured a single and separate trait or characteristic), one would find a correspondence in the rank-order of scales on both weights and correlations.

### Results

The results are organized in four major sections, each section presenting the findings for one of the four instruments used in this part of the study. Each of these four sections contains six analyses: (1) Graduates, Male Grouping, (2) Employed Related, Male Grouping, (3) Graduates, Female Grouping, (4) Employed Related, Female Grouping, (5) Graduates, Combined Grouping, and (6) Employed Related, Combined Grouping.

#### Results Related to the General Aptitude Test Battery (GATB)

Male Occupational Grouping, Graduate Population.

The analysis of GATB scores for the male occupational grouping in the graduate population yielded four discriminant functions with  $P < .05$ . The first two functions are plotted as Figure 6.

A rather tight cluster was formed along function one by power and home electricity (2), carpentry (3), automotive mechanics (4), diesel mechanics (6), machine shop (7), farm equipment mechanics (9), and agri-technology (11). Electronics (1), mechanical drafting and design (5), and optical technology (12) were differentiated by somewhat higher placement on function one and welding (8) was differentiated by its lower placement along function one.

Clearest differentiation along function two was the separation of carpentry (3) and mechanical drafting and design (5) by their higher placement, and agri-technology (11) by its lower placement along function two.

Combination of the first two functions graphically in Figure 6 resulted in one cluster of five curricula with almost total overlap [power and home electricity (2), automotive mechanics (4), diesel mechanics (6), machine shop (7),

and farm equipment mechanics (9)]. The remaining seven curricula were at least partially discriminated from this central cluster.

Table 20 gives the weights applied to the original GATB variables to yield the first two discriminant functions plotted in Figure 6 and the correlations of the functions with each of the original GATB variables. Additional information concerning this analysis may be found in Tables 1D and 1E in the Appendices. Male Occupational Grouping, Employed Related Population.

The analysis of GATB scores for the male occupational grouping in the employed related population yielded three discriminant functions with  $P < .05$ . The first two functions are plotted as Figure 7.

Curricula were fairly evenly distributed along the first function with the lowest placement by welding (8), and the highest by optical technology (12) and electronics (1). Agri-technology (11) and optical technology (12) were discriminated from the other curricula by their lower placement along function two.

K - Motor Coordination	.1085	.3609	-.0957	-.1885

Combination of the first two functions graphically in Figure 7 resulted in three clusters of curricula. The first cluster was composed of power and home electricity (2), carpentry (3), automotive mechanics (4), machine shop (7), welding (8), and farm equipment mechanics (9). The second cluster was composed of electronics (1), mechanical drafting and design (5), and aircraft mechanics (10). The third cluster was composed of agri-technology (11) and optical technology (12).

Table 21 gives the weights applied to the original GATB variables to yield the first two discriminant functions plotted in Figure 7 and the correlations of these functions with each of the original GATB variables. Additional information concerning this analysis may be found in Tables 2D and 2E in the Appendices.

Female Occupational Grouping, Graduate Population.

The analysis of GATB scores for the female occupational grouping in the graduate population yielded four discriminant functions with  $P < .05$ . The

TABLE 22

N - Numerical Aptitude	.3359	.6661	-.5846	-.3019
S - Spatial Aptitude	.0518	.2997	.2404	.5342
P - Form Perception	-.2256	.1263	.4308	.4885
Q - Clerical Perception	.0832	.3540	-.0478	.0379
K - Motor Coordination	.2377	.4143	-.3312	-.3670

first two functions are plotted as Figure 8.

Function one most clearly discriminates medical lab assistant (4) from the other five curricula by its higher placement along the function. Function two did not clearly discriminate among the six curricula although maximum separation was between a cluster composed of clerical training (5), and secretarial training (6), and the single curriculum medical lab assistant (4). Combination of the first two functions graphically in Figure 8 showed the greatest separation to be between medical lab assistant (4) and clerical training (5).

Table 22 presents the weights applied to the original GATB variables to yield the first two discriminant functions and the correlations of these functions with each of the original GATB variables. Additional information concerning this analysis may be found in Tables 3D and 3E in the Appendices.

Female Occupational Grouping, Employed Related Population.

Analysis of GATB scores for the female occupational grouping in the employed related population yielded four discriminant functions with  $P < .05$ . The first

FIGURE 8  
 PLOT OF THE FEMALE OCCUPATIONS ON THE FIRST TWO DISCRIMINANT  
 FUNCTIONS DERIVED FROM THE ANALYSIS OF GATB  
 SCORES IN THE GRADUATE POPULATION

$$X = \text{FUNCTION 1: } .1957(G) + .8555(V) + .3359(N) + .0518(S) + (-.2256)(P) + .0832(Q) + .2377(K)$$

$$Y = \text{FUNCTION 2: } .0084(G) + .5503(V) + (-.5846)(N) + .2404(S) + .4308(P) + (-.0478)(Q) + (-.3312)(K)$$

two functions are plotted in Figure 9.

Function one most clearly separates medical lab assistant (4) with its high placement on the function from the other five curricula. Discrimination on function two was between two clusters of three curricula each. The first cluster, characterized by its lower placement on function two was composed of practical nursing (1), clerical training (5), and secretarial training (6). The second cluster, with higher placement on the function, was composed of cosmetology (2), dental assistant (3), and medical lab assistant (4).

Combination of the first two functions graphically in Figure 9 resulted in a cluster of three curricula with considerable overlap: practical nursing (1), clerical training (5), and secretarial training (6). The medical lab assistant curriculum group (4) was relatively differentiated from the other curricula with cosmetology (2) also being somewhat differentiated.

Table 23 presents the weights applied to the original GATB variables to yield the first two discriminant functions plotted in Figure 9 and the correlations of the functions with each of the original variables. Additional information on this analysis may be found in Tables 4D and 4E in the Appendices.

**Combined Occupational Grouping, Graduate Population.**

The analysis of GATB scores for the combined occupational grouping in the graduate population yielded six discriminant functions with  $P < .05$ . The first two functions are plotted as Figure 10.

Plotting the two functions graphically resulted in five clusters of occupations. The first cluster included seven occupations which had a high degree of overlap: power and home electricity (2), carpentry (4), automotive mechanics (5), diesel mechanics (7), machine shop (8), farm equipment mechanics (10), and agri-technology (14). The second cluster was composed of optical technology (15), accounting (18), and data processing (21). The third cluster was practical nursing (3), and secretarial training (20). The fourth cluster showed considerable overlap between cosmetology (11), dental assistant (13), and clerical training (19). The fifth cluster was composed of electronics (1), and mechanical drafting and design (6). One occupation, medical lab assistant (16) was separated from the other occupations by its high placement on both functions.

Table 24 presents the weights applied to the original GATB variable to yield the first two functions plotted in Figure 10. Additional information on this analysis may be found in Tables 5D and 5E in the Appendices.

Combined Occupational Grouping, Employed Related Population.

The analysis of GATB scores for the combined grouping in the employed related population yielded four discriminant functions with  $P < .05$ . The first two functions are plotted as Figure 11.

Combination of the first two functions graphically in Figure 11 resulted in five clusters of occupations with considerable overlap. The first cluster consisted of power and home electricity (2), carpentry (4), automotive mechanics (5), machine shop (8), and farm equipment mechanics (10). The second cluster was composed of electronics (1) and mechanical drafting and design (6). The third cluster was made up of practical nursing (3), dental assistant (13), and secretarial training (20). The fourth cluster was cosmetology (11) and clerical training (19), and the fifth cluster was composed of accounting (18) and data processing (21). One occupation, medical lab assistant (16), had little overlap with the other occupations and had higher placement on both functions.

Table 25 presents the weights applied to the original GATB scales to yield the first two discriminant functions and the correlations of these functions with the original GATB variables. Additional information on this analysis may be found in Tables 6D and 6E in the Appendices.

Results Related to the Minnesota Vocational Interest Inventory (MVII)  
Male Occupational Grouping, Graduate Population.

The analysis of MVII scores for the male occupational grouping in the graduate population yielded six discriminant functions with  $P < .05$ . The first two functions are plotted as Figure 12.

Function one discriminated electronics (1) and power and home electricity (2) from the rest of the male occupations by their high placement. Carpentry (3) was discriminated by its low placement on this function.

On function two, carpentry (3), agri-technology (11), optical technology (12), electronics (1), mechanical drafting and design (5), and power and home electricity (2) were discriminated from the other six occupations by their

relatively higher placement.

Combination of the first two functions graphically in Figure 12 revealed one large cluster composed of automotive mechanics (4), diesel mechanics (6), machine shop (7), welding (8) and farm equipment mechanics (9). Carpentry (3) was relatively independent of the other groups. Agri-technology (11) and optical technology (12) formed a relatively independent cluster as did electronics (1) and power and home electricity (2).

Table 26 presents the weights applied to the original MVII scales to yield the first two discriminant functions and the correlations of these functions with the nine original MVII scales. Additional information on this analysis may be found in Tables 7D and 7E in the Appendices.

Male Occupational Grouping, Employed Related Population.

The analysis of MVII scores for the male grouping in the employed related population yielded four discriminant functions with  $P < .05$ . The first two

functions are plotted in Figure 13.

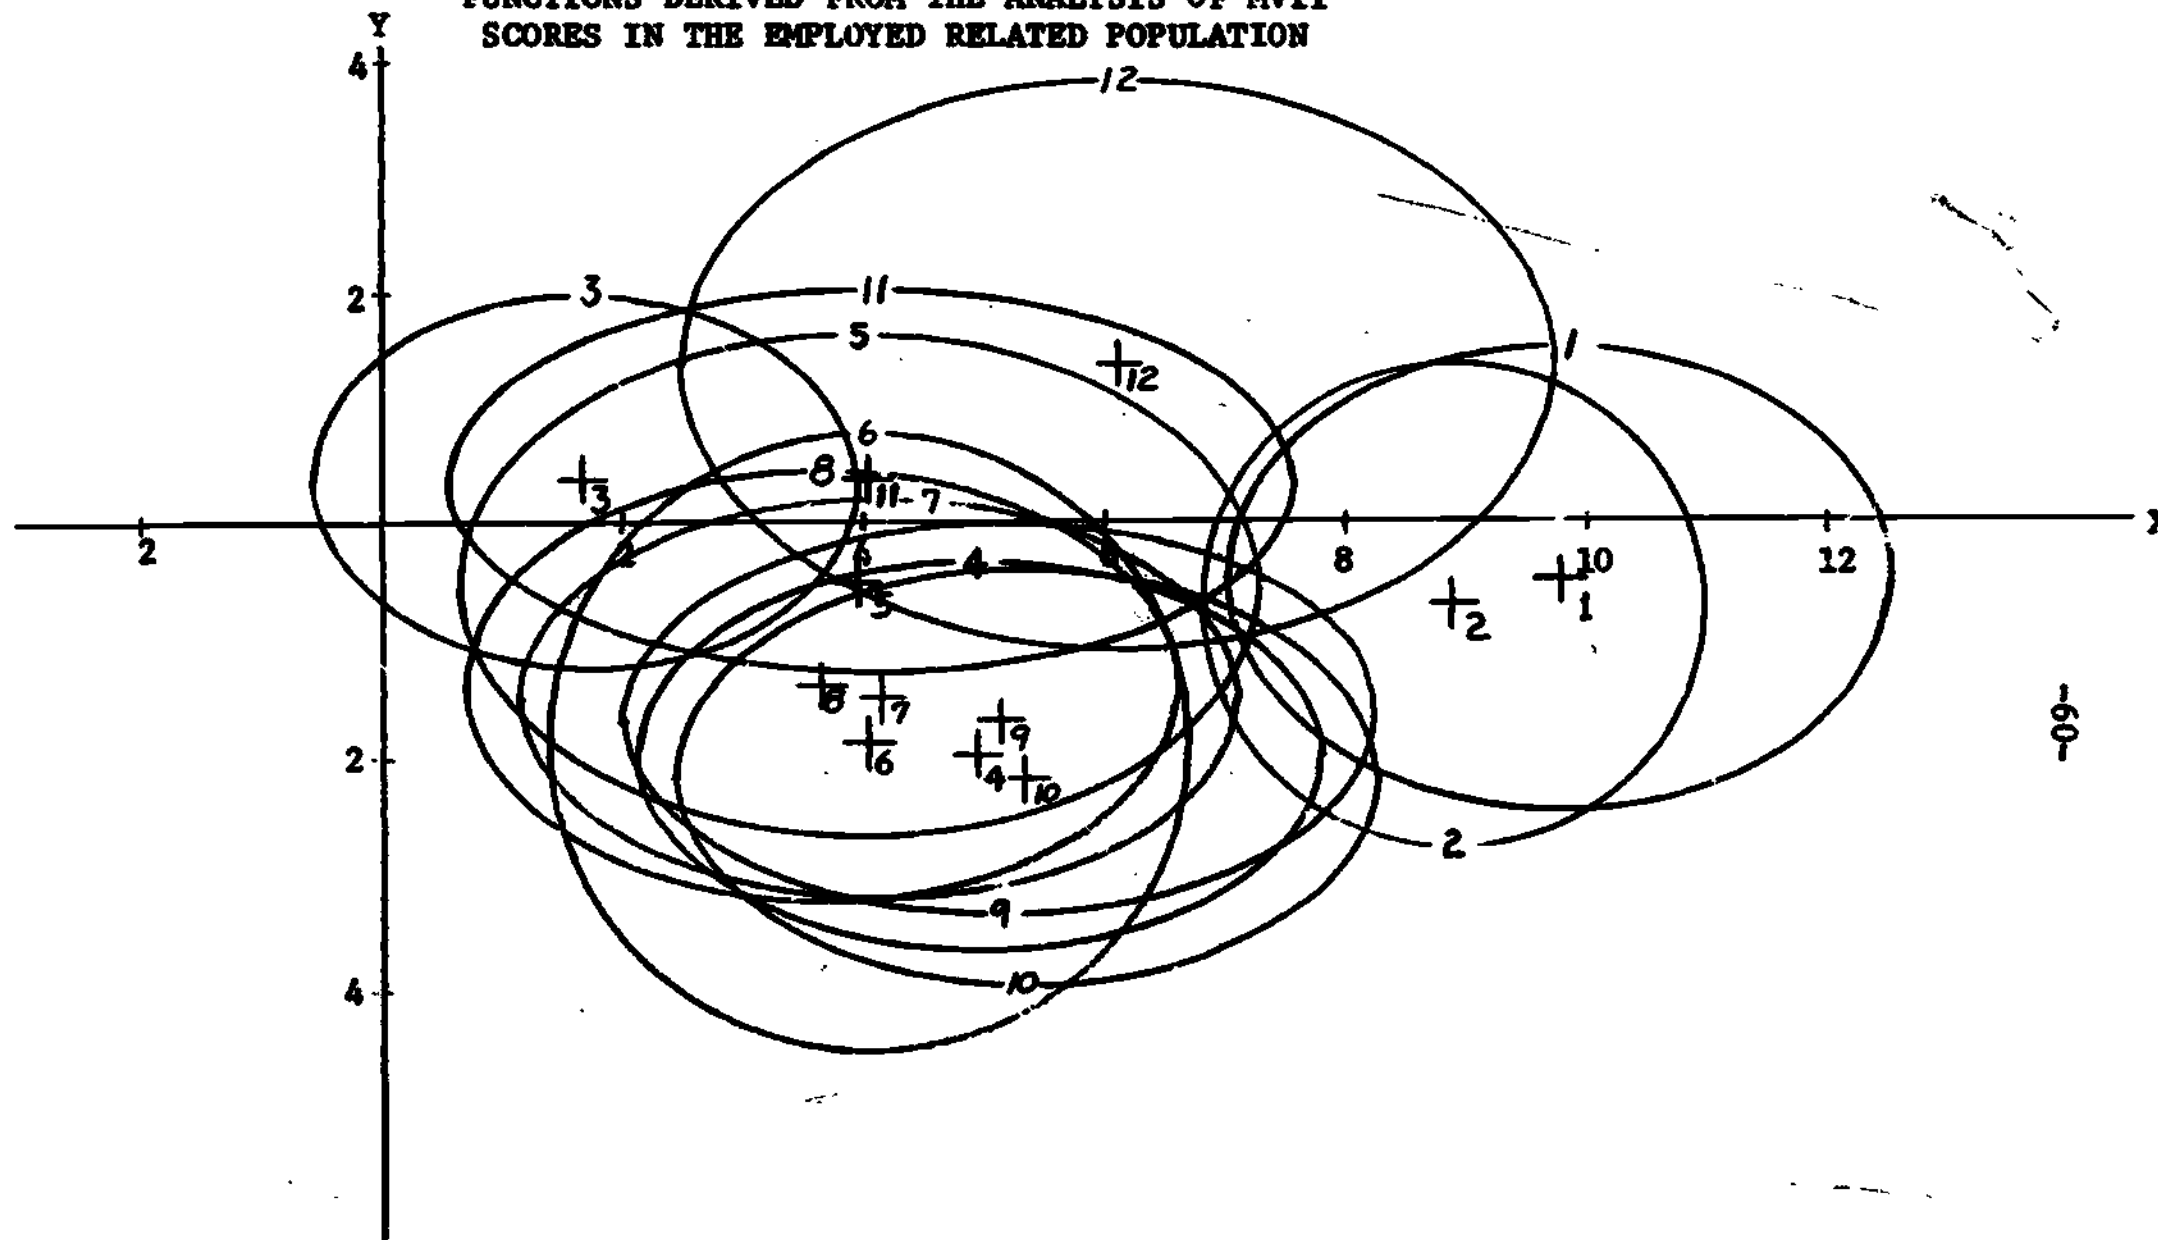

On function one, the greatest discrimination was between a cluster composed of electronics (1) and power and home electricity (2) on the high end of the function, and carpentry (3) on the low end. The other nine occupations are fairly tightly clustered on this function, falling between the two extremes of electronics and carpentry.

On function two, optical technology (12) was discriminated in the positive direction and the remainder of the occupations were grouped into two clusters. Cluster one contained electronics (1), power and home electricity (2), carpentry (3), mechanical drafting and design (5), and agri-technology (11). The second cluster was composed of automotive mechanics (4), diesel mechanics (6), machine shop (7), welding (8), farm equipment mechanics (9), and aircraft mechanics (10).

Combination of the first two functions graphically in Figure 13 resulted in essentially the same clusters as on function two with the exception that electronics (1) and power and home electricity (2) formed a third cluster, and carpentry (3) as well as optical technology (12) were discriminated from the three basic clusters.

Table 27 presents the weights applied to the original MVII scales to yield the first two discriminant functions and the correlations of these functions with the nine original MVII scales. Additional information on this analysis may be found in Tables 8D and 8E in the Appendices.

Female Occupational Grouping, Graduate Population.

The analysis of MVII scores for the female occupational grouping in the graduate population yielded four discriminant functions with  $P < .05$ . The first two functions are plotted as Figure 14.

Three clusters were formed along function one. The first cluster, at the higher end of function one, consisted of practical nursing (1), dental assistant (3), and medical lab assistant (4). The second cluster, at the lower end of the function, consisted of clerical training (5) and secretarial training (6). The third cluster containing cosmetology (2) fell between the two clusters on this functions.

Discrimination along function two was not evident with the exception of cosmetology (2) which placed somewhat lower on the function than the other five occupations. Combination of the first two functions graphically in Figure 14 yielded the same clusters as described on function one.

Female Occupational Grouping, Employed Related Population.

The analysis of the MVII scores for the female occupational grouping in the employed related population yielded three discriminant functions with  $P < .05$ . The first two functions are plotted as Figure 15.

Four clusters were discriminated along function one. Practical nursing (1) and medical lab assistant (4) formed a cluster at the high positive end of function one; clerical training (5) and secretarial training (6) formed a cluster at the negative end. Dental assistant (3) and cosmetology (2) were individually discriminated and located between the two extremes. Function two discriminated cosmetology (2) from the other five occupations.

Combined Occupational Grouping, Graduate Population.

The analysis of MVII scores for the combined occupational grouping in the graduate population yielded eight discriminant functions with  $P < .05$ . The first two functions are plotted as Figure 16.

Discrimination along function one resulted in the separation of the male occupations, as a group, from the female occupations with the occupations containing both males and females located between these two clusters. Function

FIGURE 16

 SCORES IN THE GRADUATE POPULATION

X = FUNCTION 1:  $.8145(H-1) + (-.3036)(H-2) + (-.3835)(H-3) + .1453(H-4) + (-.1052)(H-5) + (-.0087)(H-6) + .0770(H-7) + .1616(H-8) + .1817(H-9)$

Y = FUNCTION 2:  $(-.1421)(H-1) + .6544(H-2) + (-.7115)(H-3) + (-.1302)(H-4) + .0106(H-5) + (-.0330)(H-6) + .0020(H-7) + (-.1608)(H-8) + (-.0357)(H-9)$

two did not discriminate among male occupations but did effectively separate the occupational groups having primarily female membership. Practical nursing (3) and medical lab assistant (16) formed a cluster with high placement on function two. A second cluster with low placement on function two was composed of accounting (18), clerical training (19), secretarial training (20), and data processing (21).

Combination of the first two functions graphically in Figure 16 yielded a tight cluster of male occupations [excepting agri-technology (14) and optical technology (15)] clearly separated from the remaining occupations. Clerical training (19) and secretarial training (20) formed a cluster within the female occupations, and practical nursing (3) fell completely within the space occupied by medical lab assistant.

Table 30 presents the weights applied to the original MVII scales to yield the first two discriminant functions and the correlations of these functions with the nine MVII homogeneous scales. Additional information on this analysis may be found in Tables 11D and 11E in the Appendices.

**Combined Occupational Grouping, Employed Related Population.**

The analysis of MVII scores for the combined grouping in the employed related population yielded seven discriminant functions with  $P < .05$ . The first two functions are plotted as Figure 17.

Function one clearly discriminated three clusters. Practical nursing (3) and medical lab assistant (16) formed a cluster at the high end of the function and accounting (18), clerical training (19), secretarial training (20), and data processing (21) formed a cluster at the lower end of the function. The remaining occupations were clustered between these two extremes on the second function.

Combination of the first two functions graphically in Figure 17 yielded a cluster composed of most of the male occupations [optical technology (12) and agri-technology (11) were somewhat discriminated from this cluster]. A second cluster was composed of clerical training (19) and secretarial training (20). A third cluster was composed of practical nursing (3) and medical lab assistant (16).

Table 31 presents the weights applied to the original MVII scales to yield the first two discriminant functions and the correlations of these functions with the nine MVII homogeneous scales. Additional information on this analysis may be found in Tables 12D and 12E in the Appendices.

**Results Related to the Sixteen Personality Factor Questionnaire (16PF)**

**Male Occupational Grouping, Graduate Population.**

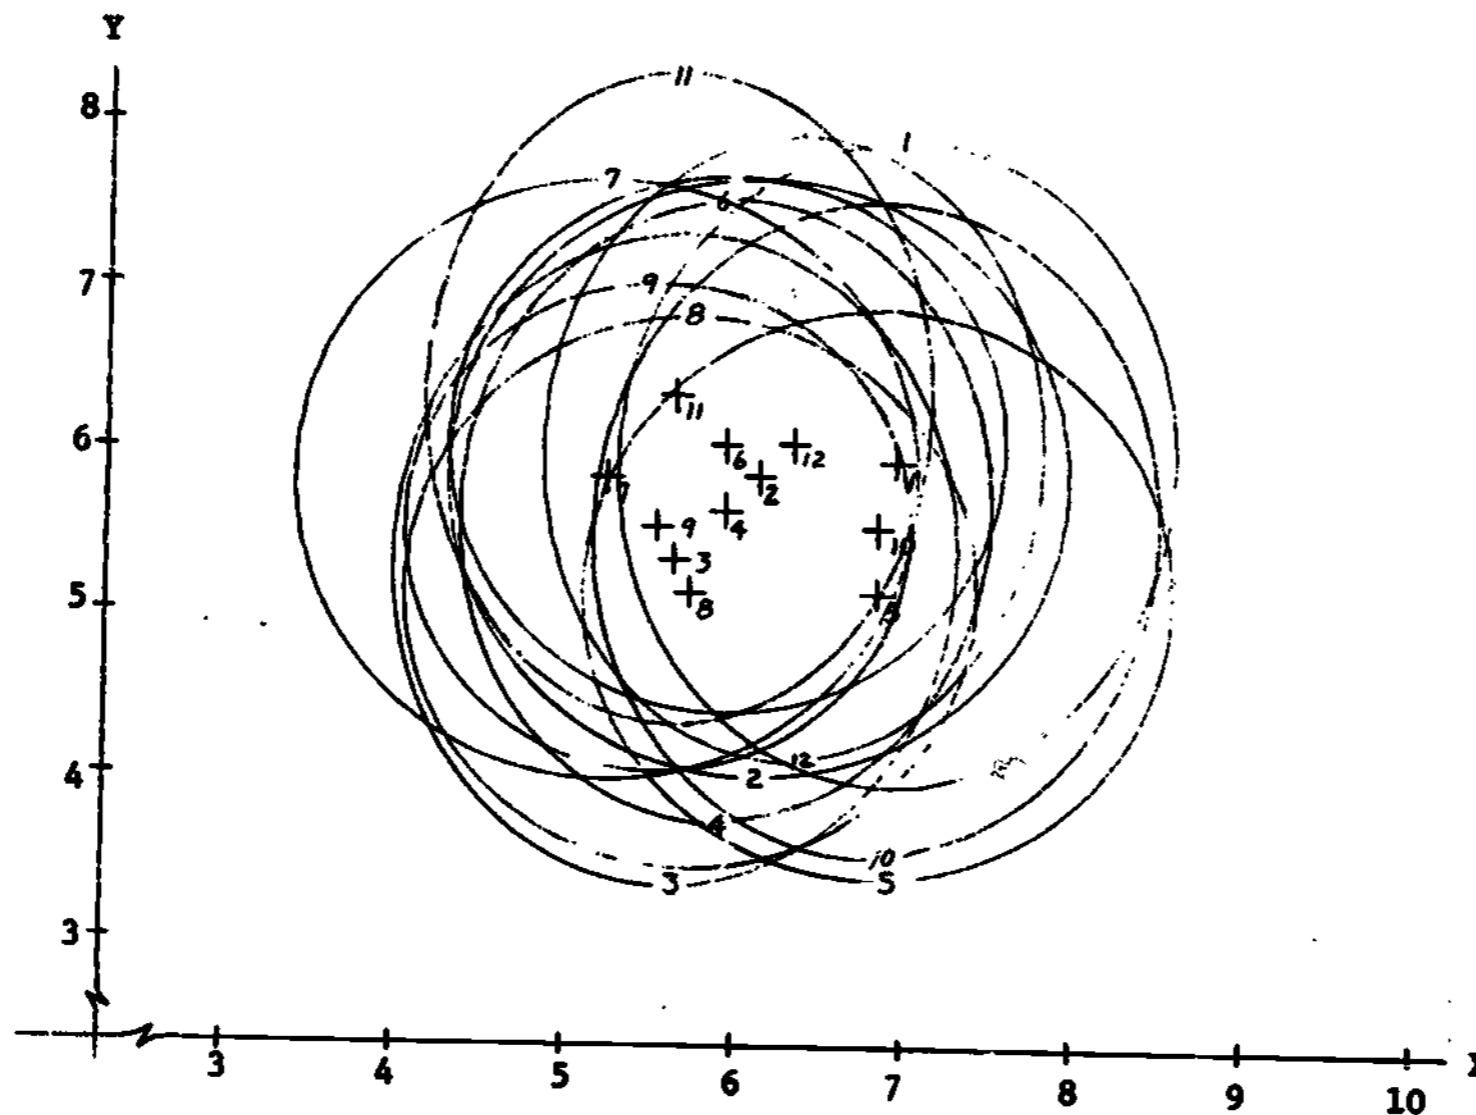

The analysis of 16PF scores for the male occupational grouping in the graduate population yielded six discriminant functions with  $P < .05$ . The first two functions are plotted as Figure 18.

Function one discriminated two clusters of curricula, although there was considerable overlap of the clusters. One cluster was composed of electronics (1), mechanical drafting and design (5), and aircraft mechanics (10). The second cluster was composed of the remaining nine occupations.

Function two did not discriminate any clearly defined clusters. Combination of the first two functions graphically in Figure 18 revealed considerable overlap among the twelve male occupations.

Table 32 presents the weights applied to the original 16PF scales to yield the first two discriminant functions and the correlations of these functions

with the original 16PF variables. Additional information on this analysis may be found in Tables 13D and 13E in the Appendices.

**Male Occupational Grouping, Employed Related Population.**

The analysis of 16PF scores for the male occupational grouping in the employed related population yielded three discriminant functions with  $P < .05$ . The first two functions are plotted in Figure 19.

Discrimination along function one resulted in three clusters. The first was composed of electronics (1) which was discriminated by its high placement along the first function. The second was composed of power and home electricity (2), mechanical drafting and design (5), diesel mechanics (6), aircraft mechanics (10), agri-technology (11), and optical technology (12). The third cluster was composed of machine shop (7), welding (8), farm equipment mechanics (9),

and carpentry (3).

Discrimination along function two resulted in three groupings. Mechanical drafting and design (5) was discriminated by its low placement and agri-technology (11) by its high placement on this function. The remaining occupations formed the third cluster.

Combination of the first two functions graphically in Figure 19 yielded four clusters. The first was composed of carpentry (3), machine shop (7), welding (8), and farm equipment mechanics (9). The second cluster was composed of diesel mechanics (6) and optical technology (12). The third and fourth clusters were composed of mechanical drafting and design (5) and agri-technology (11), respectively.

Table 33 presents the weights applied to the original 16PF scales to yield the first two discriminant functions and the correlations of these functions with the original 16PF variables. Additional information on this analysis may be found

in Tables 14D and 14E in the Appendices.

**Female Occupational Grouping, Graduate Population.**

The analysis of 16PF scores for the female occupational grouping in the graduate population yielded four discriminant functions with  $P < .05$ . The first two functions are plotted as Figure 20.

Placement of the six female occupations along function one clearly resulted in two clusters. One cluster was composed of practical nursing (1) and medical lab assistant (4). The second cluster was made up of the remaining four occupations. Discrimination along function two did not result in clearly defined clusters.

Combination of the first two clusters graphically in Figure 20 yielded two clusters. The first cluster was composed of practical nursing (1) and medical lab assistant (4), and the second was made up of cosmetology (2), dental assistant (3), clerical training (5), and secretarial training (6). The second cluster was composed of two sub-clusters, the first including clerical training (5) and secretarial training (6), and the second composed of cosmetology (2) and dental assistant (3).

Table 34 presents the weights applied to the original 16PF scales to yield the first two discriminant functions and the correlations of these functions with the original 16PF variables. Additional information on this analysis may be found in Tables 15D and 15E in the Appendices.

**Female Occupational Grouping, Employed Related Population.**

The analysis of 16PF scores for the female occupational grouping in the employed related population yielded two discriminant functions with  $P < .05$ . These two functions are plotted as Figure 21.

Discrimination along function one resulted in two clusters. The first cluster was composed of practical nursing (1) and medical lab assistant (4).

Combined Occupational Grouping, Graduate Population.

The analysis of 16PF scores for the combined occupational grouping in the graduate population yielded seven discriminant functions with  $P < .05$ . The first two functions are plotted as Figure 22.

Discrimination along function one grouped the occupations according to the original sex classifications with the female occupations having the higher placement, the male occupations the lower placement, and occupations containing both males and females placed between the first two clusters. Discrimination along function two did not produce clearly defined clusters nor occupational groups clearly differentiated by their placement along this function.

Combination of the first two functions graphically in Figure 22 yielded essentially the same clusters as described for function one above with the cluster composed of occupations containing both males and females falling between and overlapping both the male cluster and the female cluster.

Table 36 presents the weights applied to the original 16PF scales to yield the first two discriminant functions and the correlations of these functions with the original 16PF variables. Additional information on this analysis may be found in Tables 17D and 17E in the Appendices.

Combined Occupational Grouping, Employed Related Population.

The analysis of 16PF scores for the combined occupational grouping in the employed related population yielded six discriminant functions with  $P < .05$ .

The first two functions are plotted as Figure 23.

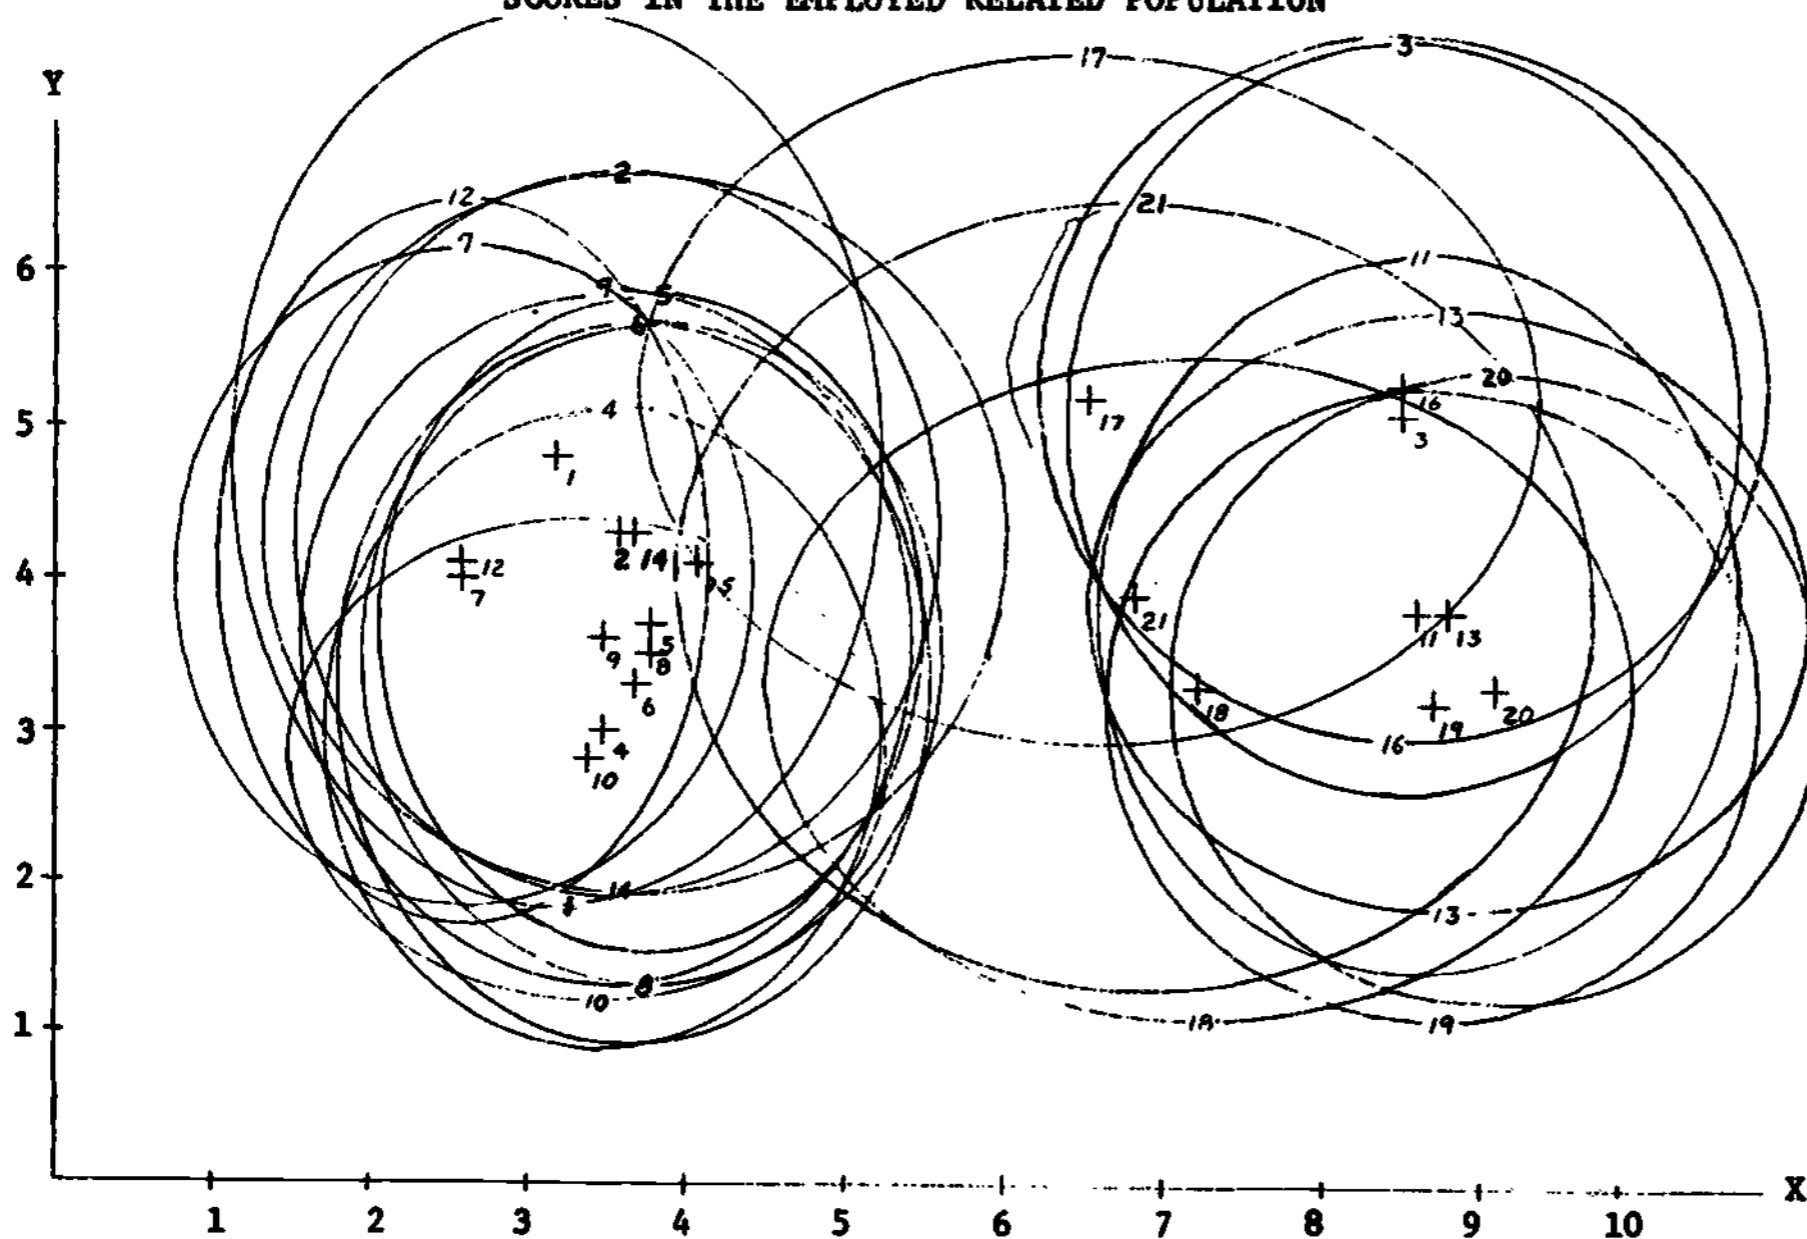

Discrimination along function one clearly separated the three basic occupational groupings with the female occupations placed at the high end of the function, the male occupations at the lower end, and the occupations containing both males and females placed between these two extremes.

Function two discriminated two clusters. The first, toward the higher end of the function, was composed of electronics (1), practical nursing (3), medical lab assistant (16), and sales (17). The second cluster consisted of the remaining seventeen occupations.

Combination of the first two functions graphically in Figure 23 resulted in the same gross clusters as described along function one with seven identifiable sub-clusters. Within the overall male cluster, four sub-clusters were formed. The first was composed of automotive mechanics (5), mechanical drafting and design (6), machine shop (8), and welding (9). The second sub-cluster within the larger male grouping was composed of power and home electricity (2), agri-technology (14), and optical technology (15). A third sub-cluster was composed of diesel mechanics (7) and aircraft mechanics (12). The fourth sub-cluster within the overall male cluster was made up of carpentry (4) and farm equipment mechanics (10). Within the cluster of primarily female occupations, three sub-clusters were discriminated. The first was composed of practical nursing (3) and medical lab assistant (16). The second was made up of cosmetology (11) and dental assistant (13), and the third sub-cluster was composed of clerical training (19) and secretarial training (20).

Table 37 presents the weights applied to the original 16PF scales to yield the first two discriminant functions and the correlations of these functions with the original 16PF variables. Additional information on this analysis may be found in Tables 18D and 18E in the Appendices.

Results Related to the Minnesota Importance Questionnaire (MIQ)

Male Occupational Grouping, Graduate Population.

The analysis of MIQ scores for the male occupational grouping in the graduate population resulted in six discriminant functions with  $P < .05$ . The first two functions are plotted as Figure 24.

Two clusters were formed along function one with carpentry (3), automotive mechanics (4), diesel mechanics (6), farm equipment mechanics (9), and agri-technology (11) forming the cluster with the higher placement. The second cluster was composed of power and home electricity (2), mechanical drafting and design (5), and machine shop (7).

- FUNCTION 1:  $.3090(1) + (-.1339)(2) + (-.0099)(3) + (-.3265)(4) + (-.1715)(5) + (-.2392)(6) + .3201(7) + (-.0298)(8) + .0187(9) + .1637(10) + (-.0888)(11) + .0860(12) + .0154(13) + (-.1047)(14) + .3608(15) + .1018(16) + (-.0650)(17) + (-.0384)(18) + (-.2468)(19) + .0884(20) + (-.1865)(21) + .3044(22) + .2060(23) + (-.1654)(24) + .0300(25) + (-.1475)(26) + (-.2566)(27) + .0948(28) + .1607(29) + (-.0291)(30)$
- FUNCTION 2:  $.0169(1) + (-.3527)(2) + (-.0919)(3) + .2006(4) + (-.0357)(5) + .0323(6) + .0726(7) + .3256(8) + (-.2607)(9) + .0293(10) + .2415(11) + .1876(12) + .1852(13) + .0249(14) + .1065(15) + (-.0152)(16) + (-.3434)(17) + (-.0977)(18) + .1854(19) + (-.1528)(20) + (-.2192)(21) + .2110(22) + .2570(23) + (-.2201)(24) + (-.0846)(25) + (-.0310)(26) + .0971(27) + .1460(28) + (-.1320)(29) + (-.2363)(30)$

Discrimination along function two resulted in discrimination of agri-technology (11) from the rest of the male occupations by its high placement.

Combination of the first two functions graphically in Figure 24 resulted in the very tight clustering of power and home electricity (2), mechanical drafting and design (5), and machine shop (7).

Table 38 presents the weights applied to the original MIQ scales to form the first two discriminant functions and the correlations of these functions with the original MIQ variables. Additional information on this analysis may be found in Tables 19D and 19E in the Appendices.

#### Male Occupational Grouping, Employed Related Population.

The analysis of MIQ scores for the male occupational grouping in the employed related population yielded four discriminant functions with  $P < .05$ . The first two functions are plotted as Figure 25.

Discrimination along function one resulted in four clusters. The first cluster was composed of carpentry (3), automotive mechanics (4), and farm equipment mechanics (9). The second was composed of machine shop (7) and optical technology (12), the third was composed of power and home electricity (2) and mechanical drafting and design (5), and the fourth of electronics (1) and diesel mechanics (6).

Function two discriminated diesel mechanics (6), welding (8), and optical technology (12) from the other occupations.

Combination of the first two functions graphically in Figure 25 resulted in two clusters although no occupations were totally discriminated from any other occupations. The first cluster was composed of carpentry (3), automotive mechanics (4), and farm equipment mechanics (9). The second cluster was composed of power and home electricity (2), mechanical drafting and design (5), machine shop (7), and agri-technology (11).

Female Occupational Grouping, Graduate Population.

The analysis of MIQ scores for the female occupational grouping in the graduate population yielded four discriminant functions with  $P < .05$ . The first two functions are plotted as Figure 26.

FIGURE 26  
 PLOT OF THE FEMALE OCCUPATIONS ON THE FIRST TWO DISCRIMINANT  
 FUNCTIONS DERIVED FROM THE ANALYSIS OF MIQ  
 SCORES IN THE GRADUATE POPULATION

-06-

FUNCTION 1:  $.1579(1) + (-.1969)(2) + (-.1270)(3) + .4050(4) + (-.1319)(5) + .0616(6) + .1834(7) + .1233(8) + .2837(9) + .0723(10) + (-.0536)(11) + .1584(12) + (-.0077)(13) + (-.0619)(14) + (-.5894)(15) + .0856(16) + .0638(17) + (-.2703)(18) + (-.0645)(19) + .0623(20) + (-.0095)(21) + .0711(22) + .0802(23) + (-.0733)(24) + (-.0813)(25) + .0630(26) + (-.1267)(27) + .1149(28) + .1128(29) + (-.2434)(30)$

FUNCTION 2:  $.1193(1) + (-.0577)(2) + .0946(3) + (-.2461)(4) + (-.2270)(5) + (-.2285)(6) + .0985(7) + (-.2530)(8) + .6618(9) + .0924(10) + (-.0965)(11) + .0720(12) + .0194(13) + .0633(14) + .1429(15) + .0036(16) + (-.0607)(17) + .0570(18) + (.3548)(19) + .1106(20) + .1096(21) + .0013(22) + (-.1389)(23) + .1051(24) + .1084(25) + (-.1373)(26) + (-.0815)(27) + .0406(28) + .1477(29) + .0393(30)$

Discrimination along function one resulted in three clusters. The first cluster was composed of cosmetology (2), clerical training (5), and secretarial training (6). The second cluster was composed of medical lab assistant (4), and the third of practical nursing (1). Function two discriminated cosmetology (2) from the other five curricula.

Combination of the first two functions graphically in Figure 26 resulted in three clusters. The first was composed of dental assistant (3) and medical lab assistant (4); the second cluster included clerical training (5) and secretarial training (6), and the third included cosmetology (2).

Table 40 presents the weights applied to the original MIQ variables to yield the first two discriminant functions and the correlations of these functions with the original MIQ variables. Additional information on this analysis may be found in Tables 21D and 21E in the Appendices.

**Female Occupational Grouping, Employed Related Population.**

The analysis of MIQ scores for the female occupational grouping in the employed related population yielded four discriminant functions with  $P < .05$ . The first two functions are plotted as Figure 27.

Discrimination along function one resulted in two clusters. The first was composed of cosmetology (2), dental assistant (3), clerical training (5), and secretarial training (6). The second cluster was composed of practical nursing (1) and medical lab assistant (4). Discrimination along function two resulted in one cluster made up of practical nursing (1) and medical lab assistant (4).

Combination of the first two functions graphically in Figure 27 resulted in two clusters. The first was made up of practical nursing (1) and medical lab assistant (4), and the second contained the other four occupations.

Combined Occupational Grouping, Graduate Population.

The analysis of MIQ scores for the combined occupational grouping in the graduate population yielded ten discriminant functions with  $P < .05$ . The first two functions are plotted as Figure 28.

FIGURE 28  
 PLOT OF THE COMBINED OCCUPATIONS ON THE FIRST TWO DISCRIMINANT  
 FUNCTIONS DERIVED FROM THE ANALYSIS OF MIQ  
 SCORES IN THE GRADUATE POPULATION

-95-

FUNCTION 1:  $(-.0784)(1) + (-.2611)(2) + .0478(3) + .2680(4) + .0888(5) + (.0639)(6) + .1793(7) + (-.1310)(8) + .3250(9) +$   
 $(-.0382)(10) + (-.1214)(11) + .0252(12) + .0544(13) + .0741(14) + (-.6513)(15) + .0466(16) + .3556(17) +$   
 $(-.1242)(18) + (-.1527)(19) + (-.0338)(20) + .0882(21) + (-.0702)(22) + .0492(23) + .0109(24) + .0781(25) +$   
 $.1243(26) + (-.0051)(27) + (-.1328)(28) + .0836(29) + (-.0719)(30)$

FUNCTION 2:  $.1628(1) + (-.1643)(2) + (-.1886)(3) + .4398(4) + (-.2030)(5) + .1735(6) + .0416(7) + .3020(8) + (-.0495)(9)$   
 $+ .1434(10) + .1155(11) + .2144(12) + (-.0073)(13) + (-.2032)(14) + (-.1272)(15) + .1144(16) + (-.2102)(17)$   
 $+ (-.2582)(18) + .0376(19) + .0794(20) + (-.1087)(21) + .1703(22) + .0377(23) + (-.1216)(24) + (-.2374)(25) +$   
 $.0467(26) + (-.1508)(27) + .2822(28) + .0460(29) + (-.2484)(30)$

Function one essentially discriminated two clusters on the basis of sex. The first cluster was composed of the six curricula containing primarily females. The second cluster contained the male curricula plus the three curricula containing both males and females. Function two failed to discriminate among curricula to the extent that clusters could be defined.

Combination of the first two functions graphically in Figure 28 resulted in three clusters. The first was composed of practical nursing (3) and medical lab assistant (16). The second cluster was made up of cosmetology (11), dental assistant (13), clerical training (19), and secretarial training (20). The third cluster included the twelve male curricula with sales (17), accounting (18), and data processing (21) overlapping both the female and the male clusters but falling more nearly within the overall male cluster.

Table 42 presents the weights applied to the original MIQ scales to yield the first two discriminant functions and the correlations of these functions with the original MIQ variables. Additional information on this analysis may be found in Tables 23D and 23E in the Appendices.

#### Combined Occupational Grouping, Employed Related Population.

The analysis of MIQ scores for the combined occupational grouping in the employed related population yielded nine discriminant functions with  $P < .05$ . The first two functions are plotted as Figure 29.

Discrimination along function one tended to separate occupations according to sex. Practical nursing (3) and medical lab assistant (16) were clustered at the lower end of the function, and the twelve male occupations were clustered at the higher end. Cosmetology (11), dental assistant (13), clerical training (19), accounting (18), and secretarial training (20) were clustered between the extremes defined by the previous groups. Function two did not result in any clearly defined clusters of occupations.

The combination of the first two functions graphically in Figure 29 resulted in three clusters which were fairly well defined. One cluster, which included the male occupations plus sales (17) and data processing (21), was separated from a second cluster composed of practical nursing (3) and medical lab assistant (16).

A third cluster composed of the remaining female occupations plus accounting (18) fell between and overlapped to some extent the first two clusters.

Table 43 presents the weights applied to the original MIQ scales to yield the first two discriminant functions and the correlations of these functions with the original MIQ variables. Additional information on this analysis may be found in Tables 24D and 24E in the Appendices.

### Part Two Conclusions

Discriminant function analysis appears to be a powerful technique for uncovering potential differences between groups of people who are successful in different occupations through the use of standardized test instruments. The multivariate approach used in discriminant analysis maximizes the differences between groups of people using a weighted combination of the instrument scales included in the analysis. In all of the analyses conducted, the results indicated highly significant differences between groups of individuals who were successful in different occupations based on the pre-enrollment test data; both among female groups and among male groups. The largest differences were found using the MVII.

As was true in Part One, differences among the female groups were more apparent than differences among the male groups. These relative differences are readily seen by observing the figures which plot the locations and distributions of discriminant functions scores for the male occupations and those for the female occupations.

When all of the occupational groups were combined, without reference to the sex of the individuals who took part in the training, it became apparent that the sex composition of the groups is related to the scores that they receive on each of the standardized tests used in the project. In most cases those occupational groups which enrolled primarily males clustered together, and those occupational groups which enrolled primarily females clustered together, while those groups which enrolled both males and females without either sex clearly predominant fell somewhere in between.

An examination of the figures on which the discriminant function scores were plotted for the various occupations indicates that the use of such figures as vocational counseling aids may represent a useful tool in the hands of a counselor. With these figures and the accompanying equations which were used to generate the

figures, counselors could take an individual's scores obtained from a given instrument and calculate his discriminant function scores. These discriminant function scores could then be used to locate the individual on the plot represented on the appropriate figure. An individual then could visually see which groups he is most like based upon how close his plotted score is located to the center of each of the occupational groups. This knowledge of how similar he is to people who have been successful in the past would provide a meaningful piece of information which could be used by him in occupational decision making.

Due to the voluminous findings presented in this report concerning each of many different standardized test instruments, the reader should review the specific findings pertaining to the instrument or instruments of interest to him. The findings pertaining to the separate instruments tend to differ somewhat for each of the populations studied.

VOLUMES OF PROJECT-MINI SCORE\* FINAL REPORT

PROJECT MINI-SCORE FINAL REPORT

PROJECT MINI-SCORE FINAL TECHNICAL REPORTS:

- Report One - The Ability of Standardized Test Instruments to Predict Training Success and Employment Success
- Report Two - The Ability of Standardized Test Instruments to Differentiate Membership in Different Vocational-Technical Curricula
- Report Three - General Aptitude Test Battery Training Success Norms and Employment Success Norms
- Report Four - Minnesota Vocational Interest Inventory Training Success Norms and Employment Success Norms
- Report Five - Minnesota Scholastic Aptitude Test and Vocational Development Inventory Training Success Norms and Employment Success Norms

\*The project was commonly known as Project MINI-SCORE (Minnesota Student Characteristics and Occupational Related Education) but was originally proposed with the formal title: Characteristics of Full-Time Students in Post-Secondary Trade Courses; U.S.O.E. project number HRD 5-0148.
