ABSTRACT

The pricing of household work can be based on standardized times established for component parts of the job. Techniques for determining these standardized times and the component parts were developed in a study conducted at Purdue University and supported by a federal grant. After a preliminary survey of homemaker practices in cleaning living areas of 20 homes, a laboratory study was made which used eight household workers to perform dusting operations under controlled conditions. A work estimation formula was derived from these task situations. A multiple regression model was developed from the dusting and vacuuming of 20 family-living areas of 12 nonrandomly selected households by graduate research and laboratory assistants. Quota sampling was used to select 32 homes in which a regression equation was used to establish the factors most useful in predicting time use from a replication of the previous tasks by seven household workers. The following independent variables were important in estimating or predicting variation in cleaning time: (1) square foot area of the room, (2) moved-item density of the room, (3) total furniture density, (4) accessory rating, (5) type of . heating, (6) percentage of carpet in the room, (7) dexterity time score of the worker, and (8) other variables relating to the furniture and the homemaker. PREFACE.

The National Committee on Household Employment was established in 1965 by a group of volunteer organizations as a nonprofit organization. The Committee serves as a clearinghouse and coordinator for private organizations interested in the field of household employment. The NCHE concerns itself with these types of problems:

.upgrade the status of private household employment,

 develop job and training opportunities in household and related organizations,

.leadership in the establishment and promotion of standards for private households, and

.liaison activities between government agencies with a mutual interest in this field.

A national survey of private household employees and employers was completed in December 1965 by the NCHE. The most important finding, in the opinion of the Committee, was that a high percentage of workers indicated a willingness to take training that would not only improve their wages but would also show them how to perform their work more efficiently and expeditiously.

Assisting with the development of training programs, the NCHE found that the time needed to do household jobs based on efficient methods is not known. Time studies which have been done focus on the gross measurement of time use in household tasks: time spent in a week for daily and weekly care of the house. Such data are of limited use in estimating time requirements in houses of specific sizes or with specific cleaning problems.

The major conclusion of a study done by the Fry Consultants, Inc. for the Economic Development Administration of the U.S. Department of Commerce in 1966 was that the mechanism for bringing the demand and the supply for household workers together is faulty. Interposing reliable companies between the housewife and the worker was advocated to remedy such a fault. However, a major problem found in doing this is that the pricing or bidding of jobs is difficult.

Thus, the problem is: what is the standardized time for the performance of various household jobs by a household worker? Data are needed on task definitions and procedures as well as standards of time for performance of the task. Such information would be useful in pricing household service, and basic in the training of household workers to perform the various household jobs within definitions and standards set.

SUMMARY

The pricing of household work can be based on standardized times established for component parts of the job. The techniques for determining these standardized times and the component parts have been developed in a study conducted at Purdue University and supported by a grant from the Office of Education.

A survey of homemaker practices in cleaning living areas of their homes was first conducted to find out what furniture, accessories, floor coverings, and structural features were most common, what methods of cleaning were most used, with what frequency the cleaning was done, and what critoria determined when the work was satisfactorily done.

From these data, a laboratory study was made on the selected component of dusting the furniture and accessories, using identical rooms in which the density of the furniture, the density of the accessories on the furniture, and the ornateness of the furniture and accessories could be varied in a systematic manner. Eight household workers were selected and trained to perform the dusting operations using a specified procedure to yield satisfactory results. Under these controlled conditions it was possible to derive a work estimation formula as follows:

Estimated time = $C + X_1 + X_2 + X_3$

Where C = a constant, or 34 minutes average time

X1 = the ornamentation factor: -5 minutes if plain,
+5 minutes if ornate

 X_2 = the floor item density factor:

4 minutes if low,

#4 minutes if high

X₃ = the nonfloor item density factor:

-1 minute if low,

+1 minute if high

Twenty family-living areas of twelve nonrandomly selected households were used next to further develop the method in situations which could not be so rigidly controlled. The Project Graduate Research Assistants and Laboratory Assistants performed the task of dusting the furniture and accessories, and added the task of vacuuming the floor coverings. The variables used to predict the time used were expanded to include the floor area, the percentage of the floor area carpeted, the kind of heating system, the employment status of the homemaker, and a scale for rating the number of pieces of furniture which had to be moved in relation to the size of the room (the moved-item density). Again a regression equation was developed which gave an estimated time as follows:

Y (as estimated = S + DM + TD + AR - HE + C + EH, time)

With a constant of -16.95 minutes, and partial coefficients (in minutes) as follows:

S, room size: .12 x the square foot (area of the room;

DM, density moved: 49.76 x moved-item density of the room;

TD, total density: 43.37 x total furniture density;

AR, accessory rating: .46 x the accessory rating;

HE, heat: -3.61 if the home has non-forced air heat;

C, carpet: 8.41 x the percentage of carpet in the rooms and

EH, employed homemaker: 8.60 x the amount of time the wife works (0 if she does not work, 1 if she works half-time, and 3 if she works full-time).

To further test the premise that observable and objective factors could be used in any home situation to estimate the components of the task of cleaning a house, thirty two homes were selected by quota sampling to assure a distribution by income, age group, employment of

wives, employment of household worker, geographic area, size of the family living area, density of furnishings, and availability of both a living room and a family room in the same house. Seven household workers dusted and vacuumed in thirty two living rooms and sixteen family living areas, and replicated the tasks in eight of the living rooms. The factors a found most useful in predicting time use were established. The regression equation is as follows:

Y (as estimated = I + H + S + U + CU + W_2 + DT time)

With a constant of 13.66 minutes, and partial coefficients (in minutes) as follows:

- I, income: 6.35 x 1 if annual income exceeds \$25,000;
- H, hours away from home: $-.14 \times$ the number of hours the homemaker was away from home;
- S, room size: :05 x the square foot area of the room;
- U, number of upholstered items: $3.02 \times \text{che number of upholstered}$ items;
- CU, number of removable cushions: .32 x the number of removable cushions:
- W₂, word furniture ornateness: 3.21 if the wood furniture was ornate; and
- DT, dexterity time score: .99 x the dexterity time score of the worker who cleaned the room.

INTRODUCTION

Background for the Study

The homemaker of today spends as much total time on household tasks as did her counterpart fifty years ago (1, Hall and Schroeder, 1970): forty seven hours weekly. Changes in how the homemaker spends her working day were identified as:

increase in time spent at food preparation and dishwashing, increase in time spent at house care, and

decrease in time spent at clothing care, family care, and management and shopping.

When making comparisons between full-time homemakers in 1952 and 1968 studies, very little difference was ascertained in total hours spent at homemaking tasks.

However, employed homemakers spent more hours at household tasks in 1968 than in 1952 (forty two and twenty nine hours weekly, respective by). Employed homemakers spent considerably less time at household tasks than full-time homemakers.

On the average in 1968, homemakers hired only half an hour of house-hold help weekly.

Concepts of Household Help. At a 1967 consultation sponsored by the National Committee on Household Employment, the Women's Bureau, the YWCA of Metropolitan Chicago, and the Chicago Committee on Household Employment, Esther Peterson (2, Report of a Consultation, 1968) stated:

"We need to develop new concepts of household help for the housewife. In a way the present situation is our fault; we have not put much economic value, on what we do in our homes. Actually homemaking is one of the most skilled jobs. A very great part of the problem of women's employment has been that we put so low a value on the jobs we do. The homemaker needs to learn to organize her time. Then she can use the time of her household worker to better advantage. She will understand the relationship between wages and hours worked and other related problems."

There is an expressed need to think about the occupation of household care in new terms (3. Koontz, Nov 1970):

*isolate and study the core of skills involved,

*analyze the wide range of tasks actually performed, and

*determine the varying degrees of skill that these tasks require.

The Service Economy. By 1985 it has been estimated that the average U, S. family will be earning the equivalent of \$15,000 in today's purchasing power as compared with \$8,600 in 1969 (4, Miller 1970). Population growth will account for about thirty percent of the growth in terms of increased expenditures for housing, transportation, and recreation. The remaining seventy percent will result from affluence and will be manifested by a greater demand for more luxurious commodities and services.

Feldman believes that marketing is about to undergo a profound change by shifting its emphasis to nonmaterial consumption and societal considerations (5, Feldman, 1971). Emphasis would be shifted from the marketing of physical commodities which consume these resources to the marketing of services. Marketing of services includes both commercial services which benefit individual consumers, and firms, and social services which directly benefit society.

Also, Feldman indicates that a basic future marketing thrust would entail diverting consumers increasing affluence away from the purchase

of material commodities toward the consumption of services. A most relevant example cited is: household cleaning and maintenance services using highly efficient equipment as a substitute for present marketing of individual household equipment.

Status of Household Employment. Few deny the importance of house-hold employment. A greater need than ever before exists for different kinds of household assistance. But workers are leaving, not entering, this occupation. The number of household workers has declined by 351,000 but the number of working women has increased by over seven million during the last decade (6, Koontz, Nov 1970).

The data on the household employment situation issued in July 1969 by the Women's Bureau of the U.S. Department of Labor is included in order to make comparisons (7, Christensen, 1971).

Proposal for Household Occupation. To improve the conditions of household employment for those new in it, Mrs. Elizabeth Duncan Koontz, Director of the Women's Bureau of the U.S. Department of Labor, states (8, Koontz, Nov 1970):

"The only way to provide all the fringes and to be businesslike is, in fact, to make the servicing of households a business. A household employment business has some real advantages. It can act as an intermediary between the householder that a skilled worker will complete agreed-upon tasks, or put in a set number of hours on a set day and perform at an acceptable level. For the household worker, it can set wage and labor standards, provide fringe benefits that are common to other occupations, and build in a dignity which all too often was lacking before. In addition, businesses can have the flexibility to experiment with new approaches to household work, such as developing specialists or trying team cleaning."

Bureau of the U.S. Department of Labor "Household Employment: The latest data on the household employment situation issued in July 1969 by the Women's

Ethlyn Christensen 1971: Vol. 2, No. 1, 48/ISSUES IN INDUSTRIAL SOCIETY,

CHRISTENSEN/49 Restructuring the | Occupation"

The median age of all employed private homechold worken was 45 years.

were 45 years and over;

cittling lathysitters. Women constituted 98 percent of all workers in private household (The data quoted here refer to women 16 years of age and over unless the seaty 1.7 million women were employed as private household workers-inotherwise indicated.) Ξ

Annual wages in this occupation are very low:

In 1967 the median wage of even those women 14 years of age and over who were year Must full time private household workers, including babysitters, was \$1,298.

as all forms of social insurance and public assistance payments—of almost all women in this field of employment in 1967 was still very iow: The total cash income-which included wage and self-employment income as well

Aculian total eash income of the women who were year-round full-time workers 83 percent had total cash incomes under \$2,000, and 58 percent, under \$1,000. -about one fifth the total-was \$1,466.

estimated that nearly half of the women private household worker family , fr. is estimated that nearly half of the women private hears reported intomes below the poverty level in 1967.

The low aurusal wages of all women-private household workers reflect the Internittent character of their employment as well as their fow rates of pay when employed: Part time/full time

In 1968, 62 percent of the women private household workers worked part time (less than 35 hours a week).

Of the full-time workers, 61 percent worked between 35 and 40 hours a week The remaining 36 percent worked longer hours.

Part year/full year

out of 10 worked between 27 and 49 weeks; and fore than 4 out of 10 worked 26 weeks or less; women private household workers in 1967; inst under 2

A high proportion of women private household workers are heads of families: Only about 4 out of 10 worked 50 to 52 weeks.

An estimated 15 percent of the women in this occupation were heads of families in 1967.

hold workers included children under 18 years of age. About one-fourth of the families with children under 18 had at least 4 children in the family, 1900, inoclifeds of the families headed by either men or women private hnuse-Ξ

More than a quarter of a million families were headed by women private household

Of the 1.5 million women 14 years of age and over who reported their occupations as dayworkers, housekeepers, msiderand laundreses; but excluding babystuers, in 1960:

More lived in the South than elsewhere:

Over 19 percent were in the Northeastern States; About 54 percent were in the South;

About 18 percent were in the North Central States; and

More than 9 percent were in the West.

Negroes predominated:

Relatively few were "live-lit" workers: Some 64 percent were Negro;

About 11 percent "lived in." Almost I percent were other nonwhites, Abdut 35 percent were white; and

This was an urban occupation:

About 74 percent were in urban areas;

percent were in rural nonfarm areas; and About 5 percent were in rural farm areas, The agerage private household worker was about 6 years older than the typical woman in the labor force:

The median age for white employed private household workers was \$1 years. 1967 less than 3 out of 10 private household workers were single: company with 13 years for nonwhites. over 55; and Abspecent were 65 and over

percent were married and living with their husbands; and 28 percent were single;

35 percent were either widowed, divorced, or separated

Legislatively, the private household worker is disadvantaged:

By and large, they are not afforded the protection of the major forms of labor legislation and social finanzance from which most other workers screen: survivors, or disability pension only if they earn a mininum of \$50 from any one employer in a calendar quarter. While piivate householdsworkers are eligible, for coverage undersale Social Security Act, they are not covered by the Federal minimum wage and hour law. Workers in this occupation receive credits toward an old-age.

employed more than 15 hours a week by the same employer. Private household workers are covered by the statutory rate in three States: Arkansas, where the law applies only to those private household employees who work for an employer of five or more persons in a regular employment relationship; Michigan, where the minimum wage law applies only to those private household workers who work for an employer of four or more persons at any one time in a calemar year; and Wess Virginia, where the law applies only to those who work for an employer of at least Wager: Wixcoustu has a minimum wage order that covers all donessic service worker. six persons during a calendar week,

Tours: Washington's miximum hours law exablishes a 60-hour week for household workers; Montana's constitution establishes an 8-hour day for all employees, except those in agriculture.

tork, coverage has been extended to all persons in personal domestic service in a private household where the note the nave \$500 or more in a calendar our to all such employees. And in Hawaii, private household workers are covered only Inemployment Compensation: New York and Hawaii have limited coverage menployment compensation laws. In if they earn at least \$225 from an employer in a calendar quarter. domestic workers under their State

thold workers employed more than 26 hours a week by one employer; California, for those working more than 52 hours a week for one employer; Ohio, for those regularly employed private household workers in Puerto Rico and for all but pare. time workers in Alaska. Connecticut has compulsory coverage for all privase Mouse. for those employed a minimum of 48 hours a week by one employer in cities or more. Massachuscus has compulsory coverage for private housebold workers other than those who are scasonal or casual, or who work less than 16 hours n week. For the latter group, coverage is elective. In Michigan, while enverage is three or more workers, the employer is not liable for any such employee unless the person worked 35 hours or more a week jurisdictions that do no: be brought under voluntary coverage, except in Alabana, the specifically cover private household workers under workmen's compensation laws in households where the employer has three or more such employees; and Workmen's Compensation (as of January 1, 1969): Coverage is compulsory least 13 weeks thiring the preceding 52 weeks. Coverage is elective but the employer is not required to insure. In jurisdictions that District of Columbia, Iowa, West Virginia, and Wyoming. romputsory in households employing such workers may

NOTE: The statistical data in this report are from the U.S. Department of Westare, Social Scentity Administration; and U.S. Department of Labor, Bureau Department of Haalth, Commerce, Bureau of the Census; U.S.

Except as otherwise indicated, legislative data are as of June 1, 1969.

Performance Standards. Maintaining superior performance is a vital concern of major importance or high priority (9, Fry Consultants, Inc., 1966). Worker performance determines customer satisfaction, his willingness to renew the service and recommend it to others.

A reason given in support of establishing household work as a business is (10, Fry Consultants, Inc., 1966):

"A home service business is, by necessity, a highly personalized operation. The person doing the work for the housewife must adhere to rigid performance standards because the housewife is demanding in her desires for a clean house. She could even be described as unreasonable at times so that the person performing the service must not only be well- qualified but willing to go to extra lengths to satisfy the customer."

Systematic analysis of performance requirements and results is suggested (11, Fry Consultants, Inc., 1966) in order to derive specification of training needs, specific objectives, desired content, and methods of implementation. Such an analysis is a process of working backward from an output to identify the necessary input which must be provided.

Specific objectives may be identified through task analysis of the various operations and performance elements that are involved in cleaning services. For each operation, determine:

*what are the specialized skills?

*what equipment and materials are used?'

*what.amount and level of knowledge are required to meet the specified standard of performance?

*what requirements are identifiable in the way of safety considerations, hazards, and special physical factors influencing safe and successful performance?

Rationale for the Study

There is still a large market for employed household workers even in these days of "labor saving" devices. Until recently it has not been necessary for a person or agoncy to negotiate between a homemaker (employer) and her household workers (employees). She either hired workers or did her own work, and generally she did not work outside the home. The recent trends are toward women working outside and home and/or participating in many more outside activities. The frequent geographical separation from relatives, who previously contributed to household production, also brings about a greater reliance on "employable" assistance.

Private arrangements for household help have proven to be less than satisfactory for all concerned. From the perspective of the worker, the lack of a reasonable level of pay, job security, and fringe benefits does not make this type of work attractive. The job is also viewed as demeaning because of its racial and social history. From the perspective of the homemaker, the problem of finding, training, and being able to rely on the household worker has proven very difficult. However, a large market for household care exists among the upper- and upper-middle income level households.

There are companies and firms entering the home service field.

Several problems have been encountered in the various attempts. Among those is the inability to adequately cost (or, estimate the cost of) the job in terms of the standards and time required.

With the support of the U.S. Department of Health, Education, and Welfare, the Department of Home Management and Family Economics at Pur-

due University began a project in May 1969 to cost (or, estimate the cost of) the job in terms of the standards and time required. Or, the problem is: what is the standardized time for the performance of various jobs by household workers? Data are needed on task, definitions and procedures as well as standards of time for performance of the task.

Objectives of the Study

The priority objectives are to:

1. Standardize elements in the selected household task of regular cleaning of the house by delimiting the variations accepted in the definition of each element as to physical properties and work (motions) performed, or, the abbreviated form of the objective

*Standardize the elements in the household task of regular (weekly) cleaning;

2. Standardize times for the performance of the elements and sum into composite standardized times for cleaning specific areas in the house, or the abbreviated form of the objective

*Standardize performance times; and

- 3. Validate standardized times for elements in actual situations in homes, or the abbreviated form of the objective
 - *Validate standardized times in actual home situations.

PROCEDURE

- Objective 1. Standardize the elements in the household task of regular (weekly) cleaning.
 - 1.0 Develop definitions for elements associated with the household task.
 - 1.1 Within a conceptual framework, delimit items which are dusted weekly and the cleaning processes used.
 - 1.11 Interview twenty middle- to upper-income homemakers, selected by a disproportionate stratified sampling design.
 - 1.12 Formulate operational definitions from the home-makers questionnaires.
- Objective 2. Standardize performance times.
 - 2.0 Have workers in a laboratory set-up perform the elements.

Time the elements of the household tasks in a laboratory situation.

Replicate each element a specified number of times by a designated number of workers performing each element.

- 2.1. Three environmental factors, which may cause variation and which can be used as predictors of time, were selected for the laboratory study: plain and ornate ornamentation of a room; low and high density of furniture in a room; and low and high density of accessories on furniture.
 - 2.11 The eight task situations were simulated in the living rooms, which are identical in area and structural features, of the two Purdue University Home Management Houses.
 - 2.12 In each task situation, the household workers dusted furniture and accessories only.
 - 2.13 Replication 1 was conducted during 29 January 1970 through 14 February 1970, with eight household workers completing all eight task situations which were randomly assigned.
 - 2.14 Replication 2 was conducted during 18 February 1970 through 17 March 1970, with eight household workers completing all eight task situations which were -15-

ERÍC

- 2.14 randomly assigned.
- 2.15 A work estimation formula was derived for dusting a living room.
- Objective 3. Validate standardized times in actual home situations.
 - 3.0 Have nonlaboratory workers perform the tasks in selected homes. 4.0
 - 3.0 Nonrandom Home Phase
 - 3.1 Dusting of furniture and accessories and vacuuming floor surfaces were combined as a single operation for cleaning.
 - 3.11 Data were obtained from twelve select households regarding cleaning of furniture, accessories, and floor surfaces.
 - 3.12 Methods for cleaning different typical groupings of furniture, accessories, and floor coverings were formulated.
 - 3.13 Twenty rooms were cleaned by the Project Assistants using the standardized procedures in the fall of 1970.
 - 3.14 A work estimation formula was derived for cleaning family-living areas of the home.

4.0 Random Home Phase

- 4.1 Dusting of furniture and accessories and vacuuming floor surfaces were combined as a single operation for cleaning.
 - 4.11 Quota sampling was used to determine eligibility of respondent's homes to be used.
 - 4.111 Demographic information was obtained from the cooperating respondents: composition of the household, use of the living and/or family rooms, and characteristics of the living and/or family rooms.
 - 4.12 Methods for cleaning different typical groupings of furniture, accessories, and floor coverings were used as formulated in 3.12 above.
 - 4.13 During the period from December 1970 through January 1971, the seven household workers performed the cleaning tasks in the living and/or family rooms:

- 4.13 thirty two living rooms of which eight were replicated once; sixteen family living areas (in sixteen of the homes that had both a living and a family room); or, a total of fifty six rooms.
- 4.14 A work estimation formula was derived for cleaning living rooms and family rooms in the aggregate.

RESULTS

Objective 1. Standardize the elements in the household task of regular (weekly) cleaning (12, Schaurer, 1971).

From the findings of the twenty middle- to upper-income homemakers surveyed, the variation in household cleaning tasks was delimited within a conceptual framework of items dusted weekly, and cleaning processes used (Figure 1. and Figure 2.).

The basis for developing operational definitions was the number of homemakers reporting weekly dusting for types of surfaces and basic work processes. The higher frequency of the reported observations was an important criterion.

Objective 2. Standardize performance times (13, Schaurer, 1971).

Three environmental factors, which may cause variation and which can be used as predictors of time, were selected for the laboratory study: plain and ornate ornamentation of a room; low and high density of furniture in a room; and low and high density of accessories on furniture.

Using these three environmental factors, eight combinations or task situations result (Figure 3.).

The eight task situations were simulated in the two Purdue University Home Management Houses. The two living rooms are identical in area and structural features. One living room is "plain" and the other living room is "ornate." The number and arrangement of the furniture and accessories are identical for each paired task situation (Figure 3. A and E, B and F, C and G, D and H; and Figure 4.).

In each task situation (Figure 3. A through H), the household work--18-

Laboratory No. 2 (B, D)

Figure 4. Floor item arrangement for low floor item density task situations (E, G) and for high floor item density task situations (B, D).

ers dusted only the furniture and accessories, and used the shoulder type of vacuum cleaner with attachments (dust brush, upholstery tool, and crevice tool), and untreated cloths.

During January and February 1970, the eight workers completed all eight task situations which were randomly assigned. Replication of the task situations was done during February and March 1970.

Cleaning Processes Used (Figure 2.)

Sixty seven percent of the household worker's cleaning time was spent on the basic work processes.

Twenty one percent of the time was spent on the facilitating processes.

Eleven percent of the time was spent on the pretasks and posttasks.

Work Estimation Formula Derivation

A factorial analysis of variance was used for the laboratory study.

The hypothesis testing conclusion is that there were statistically significant differences between the levels for these factors in the variation of time: two replications, eight workers, plain and ornate ornamentation, low and high floor item density, low and high nonfloor item density, and cleaning processes.

Statistically significant interactions were not found for the three environmental factors. Thus these factors were statistically independent and additive: plain and ornate ornamentation of a room, low and high density of furniture in a room, and low and high density of accessories on furniture.

The additive property of these environmental factors was the basis for the derivation of a work estimation formula for dusting a living

room:

Estimated time = $C + X_1 + X_2 + X_3$.

Where C = a/constant, or 34 minutes average time

X1 = the ornamentation factor: -5 minutes if plain,
+5 minutes if ornate

 X_2 = the floor item density factor:

-4 minutes if low, +4 minutes if high

X₃ = the nonfloor item density factor:
 -1 minute

-1 minute if low, +1 minute if high Objective 3. Validate standardized times in actual home situations.

Nonrandom Home Phase. Dusting or vacuuming was selected as the weekly floor care standard for family-living areas, based on data obtained from the twenty middle- to upper-income homemakers (14, Schaurer, 1971)

Dusting of furniture and accessories and vacuuming floor surfaces were combined as a single operation in the family-living areas.

Methods for cleaning different typical groupings of furniture, accessories, and floor coverings were formulated.

In the fall of 1970 data were obtained from twelve select (nonrandomly selected) households regarding cleaning of furniture, accessories, and floor surfaces. Also, twenty rooms in these twelve households were cleaned by the Project Graduate Research Assistants and Laboratory Assistants using the standardized procedures previously developed.

A multiple regression model was developed to serve as a time estimator or predictor in cleaning the family-living area. The model for predicting time is:

Y (as estimated = S + DM + TD + AR - HE + C + \int EH time)

With a constant of -16.95 minutes, and partial coefficients (in minutes) as follows:

S, room size: .12 x the square foot area of the room;

DM, density moved: 49.76 x moved-item density of the room;

TD, total density: 43.37 x total furniture density;

AR, accessory rating: .46 x the accessory rating:

HE, heat: -3.61 if the home has non-forced air heat;

C, carpet: 8.41 x the percentage of carpet in the room; and

EH, employed homemaker: 8.60 x the amount of time the wife works, (0 if she does not work, 1 if she works half-time, and 3 if she works full-time).

In other words, cleaning time

- *increased .12 minutes x the square foot area of the room,
- *increased 49.76 minutes x moved-item density of the room.
- *increased 43.37 minutes x total furniture density,
- *increased .46 minutes x the accessory rating, /
- *decreased 3.61 minutes if the home has non-forced air heat,
- *increased 8.41 minutes x the percentage of carpet in the room.
- *increased 8.60 minutes x the amount of time the wife works, (0 if she does not work, 1 if she works half-time, and 3 if she works full-time).

In the multiple regression analysis of the eighteen living and family areas between the dependent variable Y, total elapsed time spent in cleaning the room, and the independent variables (Table 2.), seven independent variables were associated with ninety percent of the variation in cleaning time $(R^2 = .90)$.

R, which measures the combined effect of the independent variables on the dependent variable Y, total elapsed time spent in cleaning the room, was .95.

Using this multiple regression equation with seven variables, computations of the estimated times were made with the actual times required to clean the rooms (Table 4.).

- Table 1. Independent Variables Used in Multiple Regression Analysis 1/
 for Nonrandom Home Phase
 - S room size; area in square feet
 - DM density moved; total floor area occupied by furniture that was moved divided by the room size
 - TD total density of floor items; total floor area occupied by furniture divided by the room size
 - CU number of removable cushions; number of cushions independent of frame of sofa or chair .
 - AR accessory rating; based on fragileness or carefulness required in handling, such as
 - 1 x item if nonbreakable accessory
 - $1\frac{1}{2}$ x item if accessory requires careful handling
 - 2 x item if fragile accessory needs, cautious, gentle handling
 - 2 x item if lamps under 18 inches
 - $2\frac{1}{2}$ x item if lamps between 18 and 36 inches
 - 3 x item if lamps over 36 inches
 - 3 x item if very large, ornate accessory not previously listed above
 - LS linear surfaces; total number of linear structural surfaces in feet that were cleaned
 - P number of people in the home
- E₁ & E₂ homemaker employed (used as a dummy variable in categories of not working, working half-time, working full-time)
 - H hours away from home; total number of hours homemaker at gainful employment and/or volunteer work
 - F fireplace; yes or no
 - HE heat; forced air or non-forced air
 - RU room use; number of hours room is used daily, such as less than 3 hours or more than 3 hours
- U1 & U2 users; who used room (used as a dummy variable in categories of adults only; adults and children; adults, children, and pets)
 - OA open area; that part of the floor space not covered with furniture
 - C carpet; percentage of the floor covered with carpet
- W₁ & W₂ ornateness of wood furniture (used as a dummy variable in categories of plain, mixed, and ornate)
 - EH employed homemaker; yes or no
 - WU, who uses; number of persons allowed to use the room

A standardized computer program BIMD2R, developed at the University of California and modified at Purdue University, was used. In the build up of the equation, one variable is added at each step. The variable added is the one which makes the greatest reduction in time variation.

Random Home Phase. Quota sampling was used to determine eligibility of respondent's homes to be used. Criteria for eligibility involved these factors:

- *minimum annual income level of \$15,000;
- *age groups, such as age of head under 40 or over 40;
- tworking wives (gainful employment) or nonworking wives;
- *employed household worker in the home or without any employed household worker in the home;
- *geographic location, such as Lafayette or West Lafayette;
- *size of family living area or living room, such as less than 250 square feet or more than 250 square feet;
- *density of furnishings, such as two major classifications on a continuum of fullness to emptiness (accessories and furnishings);
- *availability of both a living room and a family living area in the same home.

Demographic information was obtained from the thirty two cooperating respondents: composition of the household; use of the living and/or family rooms; and characteristics of the living and/or family rooms.

Methods for cleaning different typical groupings of furniture, accessories, and floor coverings had previously been formulated.

During the period from Necember 1970 through January 1971, the seven household workers performed the cleaning tasks in the living and/or family rooms (Figure 5):

- *thirty two living rooms of which eight were replicated once, and
- *sixteen family living areas (sixteen of the homes that had both a living and family room):
- *or, a total of fifty six rooms.

• *			56

The worker was timed to the nearest whole minute during the actual cleaning of the room. A supervisor evaluated the work being done (Appendix B) on a pass/fail basis. If the quality standards were not met, the room was either done over by the same or another worker, or was not used in the data analysis. The supervisor took measurements and recorded information about the room (Appendix C). The process by which the room was cleaned is described in the Training Manual with Evaluation Devices (REFERENCES, 15, page 55).

- A 26 factorial analysis of variance was performed on total elapsed time. The experimental design factors of two levels for each of the six factors are:
 - *age of head of household: under 40 or over 40 years:
 - *wife gainfully employed: yes if employed outside of the home fifty percent or the time or more) or no;
 - *employed household worker: yes or no;
 - *geographic location: Lafayette or West Lafayette;
 - *size of living room: under 250 square feet or over 250 square feet;
 - *living room content: full or empty (density of accessories and furniture).

None of these six factors contributed significantly to cleaning time. Significant interactions were not found. This analysis provided evidence that the sample had effectively included households who do hire household workers or who would potentially hire workers.

The multiple regression model, developed in the Nonrandom Home.

Phase, was reformulated or revised. Several variables previously used

were removed. Some variables not previously considered were added to the

model for the Random Home Phase. The model for predicting time is:

A standardized computer program, developed at the University of California and modified at Purdue University, was used for analysis of variance. The program is identified as BIMD2v (Biomedical Computer Programs Manual, 1 January 1964 edition).

Y (as estimated = I + H + S + U + CU + W_2 + DT, time)

With a constant of 13.66 minutes, and partial coefficients (in minutes) as follows:

I, income: 6.85×1 if annual income exceeds \$25,000;

H, hours away from home: -.14 x the number of hours the home-maker was away from home;

S, room size: $.05 \times$ the square foot area of the room;

U, the number of upholstered items: 3.02 x the number of upholstered items;

CU, number of removable cushions: $.32 \times$ the number of removable cushions;

 W_{2}^{\prime} , wood furniture ornateness: 3.21 if the wood furniture was ornate; and

DT, dexterity time score: .99 x the dexterity time score of the worker who cleaned the room.

In other words, cleaning time

- *increased 6.85 minutes when family income was over \$25,000,
- *decreased .14 minutes x the number of hours the homemaker was away from home.
- *increased .05 minutes x the square foot area of the room,
- *increased 3.02 minutes x the number of upholstered items, *
- *increased .32 minutes x the number of removable cushions,
- *increased 3.21 minutes if the wood furniture was ornate, and
- *increased .99 minutes x the dexterity time score of the worker who cleaned the room.

In the multiple regression analysis of the fifty six living and family areas between the dependent variable Y, total elapsed time spent in cleaning the room, and the independent variables (Table 9.), seven independent variables were associated with sixty three percent of the variation in cleaning time $(R^2 = .63)$.

R, which measures the combined effect of the independent variables on the dependent variable Y, total elapsed time spent in cleaning the room, was .79 for both step seven and step eight of the analysis.

Using the multiple regression equation with seven variables, computations of the estimated times were made with the actual times required to clean the rooms (Table 11.).

- Table 8. Independent Variables Used in Multiple Regression Analysis 1/for Random Home Phase
 - A age of head of household; actual age in years
 - I income; 0 if \$15,000 to \$24,999, 1 if over \$25,000
 - P number of people in home; actual number.
 - E homemaker employed; 0 if no, 1 if half-time, or more
 - H hours away from home; total number of hours homemaker at gainful employment and/or volunteer work
 - S room size; area in square feet
 - T room type; 0 if living room, 1 if family room
 - FI number of floor items; total number of pieces of furniture
 - TD total density of floor items; total floor area occupied by furniture divided by room size
 - U number of upholstered items; total number in room
 - CU number of removable cushions; number of cushions independent of the frame of sofa or chair
 - AR accessory rating; based on fragileness or carefulness required in handling, as
 - 1 x item if nonbreakable accessory
 - $1\frac{1}{2}$ x item if accessory requires careful handling
 - 2 x item if fragile accessory needs cautious, gentle handling
 - 2 x item if lamps under 18 inches
 - $2\frac{1}{2}$ x item if lamps between 18 and 36 inches
 - 3 x item if lamps over 36 inches
 - 3 x item if very large, ornate accessory not previously listed above
 - CA percentage of floor covered with carpet; carpet area divided by room size
- W1 & W2 ornateness of wood furniture; use a dummy variable with categories of plain, mixed, and ornate
- U₁ & U₂ ornateness of upholstered furniture; use a dummy variable with categories of plain, mixed, and ornate
 - AC number of activities; based on Walker's list, or the total number of different activities ordinarily carried out in the room cleaned
 - DT dexterity time score; combined time in minutes and seconds that it takes each worker to do the three tasks during the training tests

A standardized computer program BIMD2R, developed at the University of California and modified at Purdue University, was used. In the build up of the equation, one variable is added at each step. The variable added is the one which makes the greatest reduction in time variation.

Household Workers (15, HMFE Department, 1972)

The eight household workers employed for the Laboratory Phase of the Project were also employed as housekeepers in the Women's Residence Halls of Purdue University, except one who is a housewife.

The seven household workers employed for the Random Home Phase of the Project were initially contacted through an employment advertisement in the local newspapers, recommendations from previously employed persons (the Laboratory Phase), and the University and State employment offices. Household workers employed for the Laboratory Phase of the Project were ineligible to participate in either the Nonrandom or Random Home Phase.

Interviews were conducted to determine the employability of applicants, based on criteria such as:

- *high school graduate or less,
- *availability,
- *pay rate,
- *physical examination, and
- *interest in terms of being involved in a research project.

Pretraining of the household workers included assessment activities such as:

- *reading competency (ability to read and understand manufacturers instructions for use and care of equipment),
- *scales which measure attitudes toward homemaking activities and vocations, and
- *devices to ascertain levels of physical dexterity (requisite in the performance of the actual household cleaning process).

Training involved instructor (supervisor) demonstrations and house-

hold worker rehearsals (dry runs) of mock-ups (simulations) of the task situations:

*dusting furniture and accessories in the Laboratory Phase, and *dusting furniture and accessories, and floor surfaces in both the Nonrandom and Random Home Phases.

Workers were trained to perform the standardized cleaning activities. Also, they were acclimated to timing of their performances during the training period. The household workers demonstrated the standardized cleaning procedures and were evaluated by the Project supervisors before any data collection in either the Laboratory or Home Phases.

Post training encompassed an assessment of workers' attitudes, particularly regarding the occupation of household cleaning. Also, a critique of the training program was conducted to obtain recommendations, suggestions, and criticisms. This critique was fundamental to the development of the training manual for the supervisor's use: especially in instructing household workers in procedures and skills in dusting and vacuuming.

CONCLUSIONS

The basic purpose of his project was to determine the standardized time for the performance of various household jobs by a household worker. Data on task definitions, procedures, and standards of time for the performance of the task could be used in pricing household services. Thus, the thrust of the research effort has been in terms of developing techniques for determining standardized times and the component parts. Or, the development of methodology is viewed as a bench mark accomplishment.

While the scope of household jobs performed by the household worker is of some magnitude, delimitation has been a priority concern at each stage of the investigation. While only a few of the many household jobs have been incorporated into this project, the foundation has been established for expanding such basic methodology to other types of household jobs.

Objective 1. Standardize the elements in the household task of regular (weekly) cleaning.

From the findings of a survey of twenty middle- to upper-income homemakers, the variation in household cleaning tasks was delimited within a conceptual framework of items dusted weekly, and the cleaning processes used.

Three environmental factors, which cause variation and can be used as predictors of time, were identified.

Objective 2. Standardize performance times.

Eight household workers completed the task situations which were derived from the environmental factors. In each task situation, the worker dusted furniture and accessories only. A work estimation formula was derived from the data obtained.

Objective 3. Validate standardized times in actual home situations.

Nonrandom Homo Phase. Progressing from the initial Laboratory

Whase, the task situation was extended to dusting furniture and accessories, and vacuuming floor surfaces. Actual homes were used in the data collection: family-living areas of staff members' homes. The Project Research Assistants, working as teams, performed the household cleaning tasks and collected the data.

This phase was a mini-prototype, or an intermediary link between the Laboratory Phase and the Random Home Phase. Methods for cleaning different groupings of furniture, accessories, and floor coverings were formulated and standardized.

A multiple regression model was developed to serve as a time estimator or predictor in cleaning the family-living areas. While restrictions are inherent in the utility of such a regression model (selected homes with family-living areas within a narrow range of variation, small number of family-living areas cleaned, and Research Project Assistants as the household workers), it was demonstrated that cleaning time could be successfully estimated.

Also, from the regression model leads were obtained as to the independent variables which are important in estimating or predicting variation in cleaning time:

- *the square foot area of the room,
- *the moved-item density of the room,
- *the total furniture density,
- *the accessory rating,
- *the type of heating in the home,
- *the percentage of carpet in the room, and
- *the employment status of the homemaker.

Random Home Phase. This phase was the sophistication of methodology established in conjunction with statistical analyses:

- *quota sampling design to obtain eligible respondent homes in which to perform the cleaning task.
- *seven household workers, not previously associated with the Project, to clean the living and/or family rooms,
- *standardized method for cleaning different groupings of furniture, accessories, and floor surfaces: to dust furniture and accessories, and to vacuum floor surfaces.

A multiple regression model was developed to serve as a time estimator or predictor. Independent variables identified in the Nonrandom Home Phase multiple regression model were carefully reviewed, revised, or eliminated.

As ascertained from the Random Home Phase multiple regression model, these variables are important in estimating or predicting variation in cleaning time:

- *the amount of annual income,
- *the number of hours the homemaker was away from home,
- *the square foot area of the room,
- *the number of upholstered items.
- *the number of removable cushions,
- *the wood furniture ornateness, and
- *the dexterity time score of the worker who cleaned the room.

RECOMMENDATIONS

Results of this project could be utilized in terms of:

- *developing a technique for standardization of definitions and times associated with other household jobs,
- *occupational training of household workers, and
- *expanding employment opportunities, and facilitating the provision of desired household cleaning services to those willing to pay for such services.

A priority recommendation for further basic research is to:

- *delimit items which are wet cleaned weekly in the family or living room and in other areas of the home; and the cleaning processes used.
- *use methodology to standardize wet cleaning process performance times.
- *derive work estimation formulas, and
- *validate standardized times.
- A priority recommendation as an educational innovation is to:
- *develop career ladders and lattices based on the core of skills in household employment.

While occupational training of household workers was not initially incorporated into the research proposal, in reality such training became of paramount importance in the standardization of cleaning procedures. Thus, occupation training of household workers could be given equivalent priority with basic research to standardize other household jobs.

- A priority recommendation as an employment development is to:
- *establish procedures for team cleaning in the occupation of house-hold employment.

A household employment business is advanced as a means of facilitating employers (households desiring services) and employees (household workers). Employment opportunities may be expanded with combinations of

teams in this occupation, either as self-employed or affiliated with a household employment business.
