ABSTRACT

The ability of various Aerospace Materials Information Center (AMIC) information specialists to prepare search strategies for document retrieval was studied by providing ten typical search request statements to seven information specialists. Each specialist prepared search strategies independently. Significant variations occurred among the strategies, although even with these variations reasonably consistent document returns resulted. The experiment indicated that the proper interpretation of a search request and the conversion of the request to an appropriate search strategy even with a well-established thesaurus is a considerably more difficult task than indexing. In another experiment, the consistency of relevance judgments among information specialists was examined. Relevance judgment is more difficult than indexing and search strategy preparation. Agreement on nonrelevance is better than agreement on relevance. The system of relevance judgment, according to nonrelevant, partially relevant and relevant, appears optimum for AMIC. Communication between the requester, the information specialist and the retrieval system itself are of prime importance. Because of certain human interactions which must occur, some variability is unavoidable. However, current AMIC procedures of searching to achieve high recall and screening the results for relevance provide good results to the ultimate requester. (Author)

FOREWORD

This report was prepared by the University of Dayton Research Institute, Dayton, Ohio, under Air Force Contract F33615-71-C-1069. The work described herein was accomplished under Project 7381 "Materials Application" and Task 738103 "Materials Information Development, Collection and Processing." The effort was administered under the direction of the Materials Information Branch, Materials Support Division, Air Force Materials Laboratory with Mr. Harold B. Thompson (AFML/LAM) as Project Monitor.

This is a final summary report and covers the work accomplished from 1 December 1970 through 30 November 1971.

The authors acknowledge the efforts and contributions of Mrs. C. Marie Shanley, Mr. Howard H. Schumacher, Mr. Eugene R. Egan, Mr. David Z. Winters as well as a number of students who participated in the program.

This technical report has been reviewed and is approved.

SECTION I

INTRODUCTION

1. DESCRIPTION OF AMIC SYSTEM

The Information Systems Section of the University of Dayton Research Institute (UDRI) has established and presently maintains and operates a document retrieval system in support of the Aerospace Materials Information Center (AMIC). The document retrieval system operated by the University of Dayton contains approximately 60,000 documents concerning materials research and development with new accessions being made continually. The establishment, modification and operation of the document retrieval system are described in the following reports: RTD-TDR-63-4263 (AD 428 423), AFML-TR-65-20 (AD 613 301)², AFML-TR-66-36 (AD 633 614)³, AFML-TR-66-391 (AD 651 039)⁴, AFML-TR-67-379 (AD 666 462)⁵, AFML-TR-68-367 (AD 686 804)⁶, AFML-TR-70-27 (AD 670 597)⁷ and AFML-TR-71-11 (AD 725 036)⁸. The present report describes the work performed from December 1970 to December 1971.

The AMIC document retrieval system has been in operation with retrospective search capabilities since 1963. The purpose of the system is to provide scientific and technical information to qualified requesters in a timely and efficient manner. The information is supplied in the form of abstracts of documents pertinent to the search request; these abstract forms also contain complete bibliographic information including AMIC access number, DDC AD number or NASA N number, generating agency, report number, title, author, contract number (if applicable), and date of issue of the document. The documents themselves are available from the Materials Documentation Center (MDC) maintained at the Air Force Materials Laboratory (AFML). These documents are available on loan to the local requester, or may be referred to in the center. Abstracts of the documents are provided to the requesters.

The AMIC document retrieval system is primarily concerned with the materials aspect of technical documents. Because of the concentration on materials, retrieval capabilities from a materials standpoint are very comprehensive. Retrieval can be very specific, as, for example, all information on the alloy Aluminum 2024-T6, or retrieval could be as general as high temperature fatigue of all metals and alloys. Similarly, one may request information on boron reinforced Epon epoxy composites, or one may ask for aircraft structural applications of any composite material.

Searches encompassing the entire range of materials information are regularly run by the UDRI in response to requests from technical personnel in the AFML. To ensure that the requester receives abstracts which are relevant to the request, all abstracts and index cards retrieved are screened for content by a UDRI information specialist to assess their relative pertinence to the originally-stated request.

2. SUMMARY OF AMIC PROCEDURES

The Aerospace Materials Information Center prepares documents by human indexing from the full text using a controlled vocabulary of index terms. The index terms serve as the storage and retrieval records for the computer system. The AMIC thesaurus is used to aid the indexer in the selection of appropriate terms. The indexers are familiar with the discipline represented by the document content, and they are carefully trained in indexing procedures. Automatic hierarchical posting of terms is provided to ensure that retrievals can be accomplished at the highest generic level desired.

Searching is performed using Boolean logic linking of allowable index terms. A unique search cut-off feature provides a means of searching at various levels of specificity within a given search. This feature permits the search to be so constructed that the information specialist can be certain of achieving high recall. The cut-off feature also permits sorting of the search results by groups so that the most pertinent documents appear in the first groups. Retrospective search results are screened before they are submitted to the requester so that the requester receives only those abstracts judged relevant to his request.

A Selective Dissemination of Information (SDI) program is in operation to provide abstracts on a recurring basis to the technical personnel in the AFML participating in the SDI program. The SDI results are run and distributed for each update of the search file; each update represents the most recent input of indexed technical documents.

The effectiveness of the AMIC system is dependent on three basic operations which represent interactions of the information specialists with the system. These are: indexing, search strategy formulation and the screening of retrospective search results. The consistency of indexing was investigated in a previous UDRI study. ⁵

3. INDEXER CONSISTENCY ANALYSIS

An evaluation procedure was developed to measure the indexing consistency of indexers in the AMIC program. The evaluation was based upon the choice of index terms of an experienced information specialist, as a standard of indexing performance. The selection of index terms chosen by trained indexers was compared.

2

Distinction was made between index terms which are essential for indexing a particular document and those which were helpful for retrieval but not essential to the information content. This distinction accommodates the indexing philosophy employed at UDRI governing the selection of index terms by which it is considered better to "overindex" (risking a false retrieval) than to "underindex" (risking nonretrieval of pertinent documents).

Studies of intra- and interindexer consistency were undertaken to determine the validity of using an experienced indexer's indexing as a reference standard and to assess the quality of indexing among various indexers. In 1966, 35 documents were selected which dealt primarily with chemistry as the primary subject. These documents were indexed independently by indexers and the information specialist. Several months later the experiment was repeated with another series of documents. Comparisons were made of essential terms, total terms, and time required for indexing. In 1967, the first set of 35 documents was recalled and indexing was performed by the two new indexer trainees and by two experienced indexers. Both experienced indexers were instructed to designate the essential terms for each indexed document.

By comparing the indexing performed by the same indexer of the same document, a statistical correlation coefficient was obtained for essential terms which served as a measure of intraindexer reliability or consistency. The common essential terms were obtained between the two experienced indexers as a measure of interindexer consistency. The statistical correlation techniques used were the phi coefficient (\emptyset) and chi square (X^2).

The essential and total terms were compared by groups and the degree of correlation was determined between groups. For intraindexer consistency, the first group of terms was taken from one year's indexing and compared with the second group of terms from other year's indexing, all taken from the same set of documents. The results show statistically significant correlation for essential terms regarding intraindexer and interindexer consistency.

Intraindexer consistency for the experienced information specialists was determined to be 78% overall and 92% for essential terms. When trained indexers were compared to experienced information specialists, the interindexer consistency was 62% overall and 83% for essential terms.

The UDRI results compare reasonably well with the human indexing consistency studies reviewed by Mary Elizabeth Stevens in Automatic Indexing: A State-of-the-Art Report. Table I contains a list of results. This is especially true when the consistency values are derived from the statistics on essential terms. However, it is important to recognize the difficulties of comparison across differences in systems operation and subject areas.

TABLE I

SUMMARY OF VARIOUS STUDIES OF INTER- AND INTRA-INDEXER

CONSISTENCY 9

	Inter- Indexer Consistency	Intra- Indexer Consistency
Macmillian and Welt	18%	
Kyle	70%	
AEC	65%, 5 4 %	86%
Jacoby and Slamecka	20%	50%
Rodgers	59%	
Painter	62%	
Korotkin and Oliver	53%, 5 4 %	
UDRI	62% (overall) 83% (essential terms)	78% (overall) 92% (essential terms)

Several aspects of the UDRI AMIC operation enhanced the quality of indexing consistency. These include the extensive training program with which all indexers are introduced to the system, the well-developed AMIC thesaurus, and the comparatively specialized subject area of materials information.

4. PURPOSE OF THE MOST RECENT EXPERIMENTS

Students have been trained to index with reasonable consistency for the AMIC system. The most recent study sought to determine the ability of trained students to prepare search strategies independently with similar recall and relevance results and to examine their relevance judgments. Student performance was compared with professionals in a typical request and search situation.

Various factors were recognized in studying relevance judgments. The amount of background in indexing and involvement with search requests could affect relevance judgments. Indexers from various disciplines were represented in the experiment. Since the same group of documents was used for eliciting relevance judgments, the formal academic training of the indexers might significantly affect their viewpoints in relevance judgments. Biology, chemistry, physics and engineering were disciplines represented among the indexers participating in the experiment. A fatigue factor is introduced by the quantity of abstracts for which relevance judgments must be made. Larger numbers of abstracts for a particular search for which judgments must be made may tend to reduce the discriminatory ability of persons applying relevance assessments.

A review of the literature suggested that certain situations could be expected. Specifically, Saracevic ¹⁰ suggests that persons with a particular subject expertise and professional involvement tend to display greater disagreement in judging a set of documents than persons with a more general background. Furthermore, the persons with less subject knowledge of the documents tend to be more lenient in their judgments of relevance. Another influential factor in relevance judgments is the judges' understanding of the intended use of the relevant documents.

In a more philosophical vein, Saracevic questions whether relevance judgment is a very subjective human process, or whether it has "associated with it regularity patterns that may be eventually utilized in the design of more effective IR systems." Saracevic says "agreement as to what is not relevant may be expected to be greater than agreement as to what is relevant; judging relevance is not the same as judging non-relevance."

Lancaster claims "a relevant document is a document that is useful to the requester in relation to the information need that prompted his request." Doyle warns that "there may be a great difference between relevance to a given request statement and relevance to a person's real information need." The ideal would be "to retrieve all and only those documents the searcher would regard as relevant to his need if he could personally inspect every document in the library." In his exploratory study, Cuadra considered the effect of academic and professional training on relevance judgments and concluded: "It appears likely that the disagreement at low experience levels stems from lack of knowledge, while that at higher levels reflects academic and interest specialization."

The AMIC experiments on the formulation of search strategies and on relevance judgments by various individuals were designed primarily to show the degree of consistency which could be expected by having different trained individuals perform these functions. It should be recognized that the experiments were specifically intended for the AMIC system which deals specifically with aerospace materials information. Furthermore, the individuals involved consisted of both trained students and prc'essionals. Although a number of factors were recognized as contributing to results which might be obtained, the primary purpose was to determine if adequate reliability in AMIC searching and screening operations could be obtained with the personnel assigned to these functions.

SECTION II

DOCUMENT RETRIEVALS AS A FUNCTION OF SEARCH STRATEGY

The ability of information specialists to formulate effective search strategies in response to information requests is of great importance in the AMIC operations. As indicated earlier, the AMIC system depends on authorized keywords for indexing and retrieval. Retrieval is accomplished by Boolean logical linking of keywords with a cut-off feature, and access numbers corresponding to the various groupings of retrieval terms within the search are printed out.

The students employed by AMIC receive training in the formulation of search strategies after they have mastered the indexing function. Experienced student personnel as well as professionals have been used to process technical search requests. In order to determine the consistency with which trained students and professionals can formulate searches, it was desired to investigate search strategies derived independently for a group of searches on various subjects. Differences in search strategies between individuals would be expected, but the degree to which various strategies are able to retrieve the same documents and, specifically, the ability to retrieve relevant documents (see Section III on consistency of relevance judgments) is important. Ideally, the requester should be provided with those abstracts from the entire file of documents which are relevant for his needs. In order to provide relevant documents to the requester, it is first necessary to retrieve approximately the same groups of documents regardless of the information specialist formulating the search strategy. The experiment on document retrievals as a function of search strategy was to determine the degree to which similar retrieval results would be attained by various information specialists.

1. EXPERIMENTAL DESIGN

Ten retrospective search requests were selected from our files of previous actual search requests. Care was exercised to include a variety of subject areas. A list of the requests used in this experiment appears in Table II. The requests were processed by six trained student indexers with varying backgrounds and one professional information specialist. The students' backgrounds were as follows:

Student	Field of Study	Experience with AMIC
Sl	Mathematics, Physics	18 mo.
S2	Biology, Chemistry	3 mo.
S3	Chemistry	15 mo.
S 4	Chemistry	9 mo.
S5	Chemical Engineering	3 mo.
S 6	Chemistry	3 mo.
		3 11.01

TABLE II

RETROSPECTIVE SEARCH STATEMENTS

- 1) Diffusion bonding, diffusion welding, solid state bonding, or solid state welding of aluminum and aluminum alloys
- 2) The use of nematic liquid crystals in electro-optical display devices. There are three types of liquid crystals: nematic, cholesteric, and smectic. The first two are of special interest in that they are sometimes mixed for use in particular devices. The phenomenon of light-scattering by these materials is called dynamic scattering and the phase they are in is sometimes called mesomorphic. Temperature range -- 20°C to 80°C.
- 3) The effect of reentry environments on the thermochemical erosion characteristics of ablative plastic composites. Rain/dust erosion effects to be excluded.
- 4) Effect of heat treatment on microstructure and mechanical properties of titanium-6A1-4V.
- 5) Laser cutting
- 6) Flammability of organic and inorganic textile materials in all environments (air, oxygen, mixed gas system).
- 7) Production, forming or joining metal matrix composites. Ni, Al, Ti, Co, or Nb reinforced by metal wires; B, SiC, Al₂O₃, graphite etc. filaments; rods, thin films, or indigenous phase particles (in-situ reinforced composites).
- 8) Gallium phosphide for light emitting diodes, especially crystal growth and characterization.
- 9) The use of photochromic and thermochromic compounds for nondestructive inspection systems.
- 10) Adhesion of electroplated coatings to nonmetallic substrates (except ABS plastics or substrates).

8

Each indexer was instructed to formulate his own strategy independently for each request, following normal AMIC procedures. Index terms were selected using the AMIC Thesaurus as a guide. Boolean AND. OR, NOT logic was applied to the grouping of terms used for retrieval in the search strategy. The students also utilized the cutoff feature, which enables the returns to be sorted into groups in order of anticipated relevance and allows the separation of different sub-topics. All of the returns were screened for relevance by an information specialist who was not involved in the strategy formulation aspect of the experiment.

Certain assumptions were made in the conduct of the experiment. First, it was assumed that among all the strategies prepared all of the relevant documents would be represented. This assumption is of course an approximation, since practical considerations obviate the possibility of manually screening the entire file of 60,000 documents. A second assumption was that the relevance judgments applied to the search returns by an independent information specialist were sufficiently consistent to serve as a basis for recall and precision. Third, because of the cutoff feature, certain search strategy results included groups representing large numbers of documents known to have low relevance. This situation is consistent with the AMIC philosophy of effecting high recall, but in those cases where the screening process would have been prohibitive and it was known that very low relevance would have resulted, these groups were omitted from screening.

2. CRITERIA FOR ANALYSIS

The primary consideration for analyzing the results was the ability of retrieval strategies prepared by different individuals to elicit from the entire document file similar document subsets. In particular, it would be most desirable for a high degree of consistency to occur among the various individuals for those documents actually considered relevant.

Another consideration for assessing the performance of various search strategies is the precision and recall performance. Precision is defined as the proportion of relevant documents retrieved to the total documents retrieved and recall is defined as the proportion of relevant documents retrieved to the total available relevant documents; the approximation of total available relevant documents should be kept in mind.

A third criterion is the degree to which the same retrieval terms were used among the various individuals for retrieval in response to a given request. A related factor is the number of distinct individual retrieval terms used by each person. It should be noted that with the AMIC search program a given term can be used more than once to achieve sorting of the documents retrieved.

3. RESULTS

The number of documents retrieved by each person's strategy for all ten searches is given in Tables III - XII. These tables also indicate the precision and recall results. The commonality of the relevant retrievals is shown by a frequency distribution. The commonality refers to the number of searchers out of seven retrieving the same relevant documents. Table XIII gives the combined results for all ten searches. Precision, also called relevance, is defined as the ratio of the relevant documents retrieved to the total number of documents retrieved. Recall is defined as the ratio of the relevant documents actually retrieved to the number of relevant documents available; in this study the number of relevant documents available is assumed to be the summation of the relevant documents retrieved by all searchers. The search results indicate a considerable variation between individual searches. For certain searches there is surprising uniformity, whereas for others much variation occurs both with search strategy and with results obtained. In analyzing the search strategies it was found that in some cases the inclusion or exclusion of a particular term can make a great difference in retrieval results. This was particularly true in the case of RS 9, in which Searcher S5 included the term LIQUID CRYSTALS. This term retrieved many relevant documents which were not retrieved by the others. In Search RS 1, one individual used more general terminology for retrieval resulting in a large number of retrieved documents.

Referring to Table XIII, one can see that there is relatively little difference between precision and recall ratios among various individuals across the ten searches. As would be expected, the recall tends to vary inversely with the precision. This trend is shown in Figure 1.

To evaluate the effect of the number of individual terms in the search strategy on precision and recall, terms used by each searcher for each request was examined as shown in Table XIV. From each searcher's average number of individual terms in relation to average recall as shown in Figure 2, recall increases with more terms in the strategies, but this effect becomes less pronounced as the overall number of individual terms increases. The recall achieved by searcher S3 using 10.2 terms per search strategy does not significantly exceed that of another searcher P1 using 8.0 terms per search strategy. It should also be noted that the number of retrieval terms is only an indication of the retrievals to be anticipated. The posting density of documents under the terms also has an effect.

To obtain an indication of the degree of consistency among searchers, a frequency distribution of search terms was determined as shown in Table XV. According to this table, the frequency with which nearly all searchers used the same term for retrieval was fairly high. On the other hand, for many searches a number of retrieval terms was used by only one or two of the searchers. It is interesting to note that even with a fairly high degree of variability in the terms used for retrieval, the precision and recall results

for most individuals was nearly the same. This situation can be attributed in large measure to the fact that many of the same documents are retrieved even with different strategies. This, in turn, reflects the AMIC philosophy of indexing documents in some depth (about 20 terms per document before automatic hierarchical posting), to index with specificity and to use as many portions of the document as necessary (up to the complete text of the document) as a source of index terms.

Since search strategies and the corresponding results varied among individuals, it was considered whether experience might influence average precision and recall. However, the two most experienced student searchers (S3 and S1) tended respectively toward the highest and lowest recall rates. The same situation is true for two of the less experience searchers. S2 had the highest and S6 the lowest recall of the entire group. The professional information specialist P1 was among the searchers achieving high recall.

The consistency of results of different searchers on the same request varied considerably for different requests, indicating that perhaps the nature and wording of the statement are important. Some requests are concise and fairly straightforward, and the principal terms in the request used are also AMIC thesaurus terms. Other requests, however, leave considerable latitude for variation in term selection. This is due in some cases to ambiguous statement of the request.

Search RS 4 is one of the more direct and clearly-worded requests. All of its key terms (HEAT TREATMENT, MECHANICAL PROPERTIES, MICROSTRUCTURE, and TITANIUM-A1-V) are AMIC terms, so that little imaginative effort is necessary for expression of these concepts. As a result, for an average of 5.3 individual terms used for this search, these 4 AMIC terms were used by at least 6 searchers, (3 of these terms were used by all 7). Four searchers had identical returns as a result of using a variation of this strategy:

AND	TITANIUM-Al-V
AND	HEAT TREATMENT
AND	MECHANICAL PROPERTIES
OR	MICROSTRUCTURE

The other three searchers used a few other related terms in addition to those in the above strategy. One such strategy was:

TITANIUM-AL-V
HEAT TREATMENT
CHARR ING
QUENCHING
HEATING
MICROSTRUCTURE
MECHANICAL PROPERTIES

As a result of this consistency in strategy formulation, 39 (60%) of the 65 relevant documents returned were found by at least 6 searchers. Twelve of these documents were retrieved by everyone. This consistency is reflected in the recall statistics. Five of seven searchers had recall higher than 0.70, and all seven achieved recall greater than 0.50.

When the results from Search RS 3 is examined, a different trend is observed. Since the phrase "thermochemical erosion" is not directly represented in the AMIC Thesaurus, many different terms (EROSION, SPALLING, ABRASION, DECOMPOSITION, SUBLIMATION, VAPORIZATION, CHEMICAL REACTIONS, etc.) were used by various individuals to express this concept. The average strategy used 9.7 individual terms for this request; only three of these terms were common to six or more searchers. Some strategies were short and restrictive, like the following:

NOT	RAIN
NOT	SAND
NOT	WEATHERING
AND	RE-ENTRY
OR	RE-ENTRY VEHICLES
AND	ABLATION
AND	POLYMER COMPOSITES
AND	EROSION

Other strategies, however, were quite long and allowed for much broader coverage of the subject:

NOT	RAIN
NOT	SUSPENSIONS
AND	POLYMER COMPOSITES
AND	RE-ENTRY
OR	RE-ENTRY VEHICLES
AND	ABLATION
OR	DECOMPOSITION
OR	CHEMICAL REACTIONS
OR	VOLATILIZATION
OR	SUBLIMATION
OR	VAPORIZATION
AND	EROSION
OR	SPALLING
OR	SURFACES
OR	RE-ENTRY
AND	EROSION
OR	SPALLING
OR	SURFACES
AND	RE-ENTRY
AND	EROSION

Because the strategy formulations differed so widely for this request, there was little consistency in results. Of a total of 35 relevant documents retrieved, only 2 (6%) were common to more than two different searchers. 20 relevant documents were retrieved only once. As a result of this inconsistency, recall figures were low: 4 searchers had a recall of less than 0.25 while only one searcher attained a recall of more than 0.5.

The variation of consistency in search strategies and results with the nature of the search request seems to indicate that, in some cases, clarification of the request statement would have improved search results. Normally, the searcher is able to contact the original requester if the request statement is not clear. However, due to the design of this experiment, the searchers were required to work only from the written request.

SECTION III

CONSISTENCY OF RELEVANCE JUDGMENTS OF INFORMATION SPECIALISTS

The consistency of relevance judgments of various individuals associated with the screening of AMIC searches is an important factor, because the material received by the requester is dependent on the relevance judgments assigned by the information specialist. The AMIC system philosophy of searching is to strive for high recall to ensure that failure to retrieve relevant documents does not occur. With high recall, there is also a tendency toward low relevance. To provide the requester with useful documents, all search results are screened, and a judgment of relevance is applied by the information specialist. The judgments are indicated as probably relevant, possibly relevant and not relevant. The abstracts and index cards corresponding to the retrieved documents serve as the basis for judgment. Only those abstracts deemed either probably relevant or possibly relevant are actually forwarded to the requester, thus obviating the need for him to look through nonrelevant material. A prime consideration in this process is the consistency with which relevance judgments are applied by various information specialists.

1. EXPERIMENTAL DESIGN

The basic philosophy of the experimental design was to simulate actual AMIC operations as closely as possible. Four search results were selected. These were composed of four groups of retrieved access numbers designated as Group A, Group B, Group C and Group D. For each group, a statement of the search request was provided. The retrieved abstracts were compared one at a time with the search request statement and a relevance judgment of probably relevant, possibly relevant, and nonrelevant was indicated for each abstract by each individual participant in the experiment. Six trained students in technical disciplines took part in the experiment. Group C was also screened by two professional information specialists. The search request statements were as follows:

Group A

205 documents

Interest is in vibration damping, especially of aircraft, aerospace vehicles and components thereof. Keywords: vibration damping, vibration theory, infrasonic vibration, mechanical vibration, flexural vibration, vibration damping, vibration measurement, vibration analysis, vibration synthesis vibration simulation, vibration stress, acoustic damping, acoustic shielding, noise, structural vibration.

Group B

196 documents

The entire area of hypervelocity impact is of interest including materials, testing methods and theoretical studies. Hypervelocity is being explored in connection with research on the meteoroid hazard to spacecraft, impact craters on planetary surfaces, material properties under conditions of shock loading. Meteoroid protection, debris clouds, impact craters, shock waves, shock hydrodynamics, shock physics, gas guns, powder guns, sensors for impact measurement, computer programs and simulation of impact, rain erosion, high pressure and velocity behavior of materials, explosions and effects on materials. Nuclear physics is not of interest.

Group C

213 documents

Interest is in protective coatings to prevent corrosion. Electrochemical and stress corrosion are of particular concern. Inorganic polymers, semi-organic polymers, silicones, phosphonitrile materials as nonrigid coatings are of interest. High temperature environments are of interest, it is desired to develop a semiflexible high temperature resistant coating. The area of interest is research and development oriented.

Group D

Interest is in erosion resistant coatings both metallic and nonmetallic; the application is for turbine blade coatings in gas turbine engines.

112 documents

2. CRITERIA AND METHOD FOR ANALYSIS RESULTS

The basic criterion for analyzing the results was the degree of agreement among the participants in the experiment. The three-value relevance judgment conditions represented by probably relevant (\checkmark or C), possibly relevant (X), and nonrelevant (O) were used. For any two given individuals, the following combinations of values could occur, namely, C-C, X-X, O-O, C-O, X-O, X-C. To analyze the consistency of the relevance judgment results of the six students, the frequencies of the six possible combinations were derived by considering two students at a time until all possible combinations of students had been exhausted. In this way, a composite frequency distribution for all students was calculated and presented in terms of percentages. This procedure was repeated for all four searches. In the case of the two professional indexers, only a single calculation was needed, since only two individuals and one search group was involved.

Another aspect of interest was the degree of variation between the various groups of documents screened. This degree of variation was expressed in terms of the standard deviation among the four searches for each relevance judgment combination. The standard deviation represents the tendency of data to cluster about the mean value. Eighty-four percent of the data will fall within two standard deviations of the mean value. Therefore the smaller the standard deviation, the less variability of data occurs.

3. RESULTS

The results are presented in Tables XVI-XX. These tables show the frequencies with which indexers taken two at a time agree and disagree on their relevance judgments. The columns are ordered from left to right such that the left hand column represents the best situation (agreement that the document is nonrelevant) and the right hand column represents the worst situation (one person judges that the document is probably relevant, the other judges that the document is nonrelevant).

For Group C shown in Table XVIII two professionals also screened the document group for relevance. A comparison of the performance of professionals for Group C with the performance of the composite group of students tends to indicate that the professionals tended to agree better on judgments of nonrelevance. However, it is surprising to see that the frequency of disagreement as indicated by the frequency of O-C is actually higher than for the student composite.

Table XX shows that there may be some difference between searches as indicated by the standard deviations for the six possible combinations of agreement on relevance. The standard deviation for the O-O condition is very small. This finding suggests that differences in subject matter and search statements probably have little effect on the composite relevance judgments.

The normal procedure in the AMIC operation is for the information specialist performing the search to screen the search results for relevance and to forward probably relevant and possibly relevant abstracts to the requester. The differentiation is made primarily as an aid to the requester so that he can decide if he wishes to review all the abstracts or just those indicated as having close relevance to his request. Thus, both C and X abstracts are forwarded. Nonrelevant abstracts are not sent in order to preclude the need for the requester to have to sort through them. Therefore, from the standpoint of reviewing the results of the experiment, the situation in which disagreement of relevance value occurs between a C and an X is not as significant as disagreements resulting in O-C or Q-X, since the latter situation would cause the document either to be sent or not to be sent.

The experiment shows that there is fairly good agreement on non-relevant abstracts but there is significantly less agreement regarding the attributes which cause an abstract to be judged probably relevant or possibly relevant. An additional factor which is not accounted for in this experiment is the judgment of relevance which would have been assigned by the requester himself. However, previous UDRI studies 7,8 indicated that generally requesters were satisfied with the relevance of material received. The findings of this experiment show that although the judgment of nonrelevance

is fairly good, the judgment of relevance is much more difficult. The practical result of the findings is that the group of abstracts actually forwarded to the requester for any given search request will vary depending on the information specialist handling the request.

An informal study was made of the possibility of using a two-value relevance judgment system for the screening of abstracts; that is, the abstract must be judged either as relevant or nonrelevant. The results of this brief study indicated that judging with a two-value situation required more time in decision making and usually resulted in fewer abstracts which would have been sent to the requester.

With reference to other studies on relevance, 9, 10, 11, 12, 13, 14, 15, 16, 17 our results tend to confirm findings of some others that relevance judgments are somewhat elusive. Many factors can contribute to variations in relevance judgments including the experience and background of the individual judge, the understanding and interpretation of the request statement, the content of the abstracts being screened, and others. There seems to be a difference in judging nonrelevance in contrast to judging relevance, as indicated by Saracevic 11.

SECTION IV

CONCLUSIONS

The results of the experiments on determining document retrievals as a function of search strategy and the consistency of relevance judgments of information specialists tended to show that overall consistency among various individuals is extremely difficult to achieve. Our earlier study on indexer consistency showed that the indexing function is probably the easiest factor to control. Good indexing consistency is not entirely unexpected, since the indexer has available to him the entire text of a document for reference in conjunction with the AMIC thesaurus and other reference materials. Consequently the meaning and intent of the document usually can be recognized and AMIC index terms can be selected with relative ease.

In the case of retrieving documents from the AMIC system, one is provided with a fairly short statement of a request, although at times the request statement can be so detailed that improper retrieval terms may be suggested. Thus the problem of properly interpreting a search request and properly correlating it with the available retrieval terms even with the aid of a carefully constructed thesaurus is much more difficult than the indexing problem. Perhaps an encouraging result was that even with fairly wide variations in strategy, reasonably consistent document returns were obtained. The number of relevant documents recalled seems to increase with an increasing number of individual retrieval terms. This result is not surprising, since the possibilities for retrieval increase with an increased number of retrieval terms. However, there is the risk of poorer precision.

The consistency of relevance judgments among information specialists is also based on the interpretation of the search request. Furthermore, the information specialist also must correlate his relevance judgment based on an abstract of the document with his interpretation of the search request. Thus the judgment of relevance is probably the most difficult of the three tasks of indexing, search strategy formulation and screening for relevance. There did seem to be better agreement on judging abstracts to be nonrelevant than on judging the relevance of abstracts.

The experiments pointed out that document retrieval even from the well-established AMIC system is a difficult and highly interactive process involving the search requester, the information specialist and the information storage and retrieval system itself. Because of the many possibilities for differences in human expressions, interpretations and judgments, variability seems inherent in the overall process of information storage and retrieval.

In general it is important that the best possible communication take place between the information requester, the information specialist and the retrieval system itself. Since the possibilities for variability are recognized, the best policy for the information specialist is not to be too restrictive either in search strategy formulation or in screening for relevance. The current AMIC procedures of using the cutoff feature in searching to achieve maximum recall and in providing both relevant and partially relevant abstracts to the requester appear to represent an appropriate means of providing the best results to the ultimate requester.

SECTION V

DOCUMENT RETRIEVAL SYSTEM OPERATION

1. INPUT

During the period covered by this report, 1 Dec 70 through 30 Nov 71, 8913 documents were indexed and processed into the system. Of this number, 88 were handbooks, 109 were state of the art, 76 were bibliographies and 175 were symposia proceedings. The documents were indexed with an average of 20.9 terms per document (exclusive of automatic generic postings) with an average indexing time of 31.5 minutes. There are now approximately 60,000 documents in the AMIC document retrieval system.

2. SEARCHING

A total of 322 technical requests were processed by the Information Systems Section during the report period. An average of 9 abstracts was printed per search for forwarding to the search requesters. Figure 3 presents the number of searches processed in each contract year since 1966.

3. THESAURUS DEVELOPMENT

A thesaurus updating was made during the reporting period. New terms were added as shown to be necessary from indexing and searching, and certain infrequently used terms were deleted from the system after a search to determine recent use. Custom thesauri were provided according to the preference of individual indexer: 1. separated into three sections - general terminology, metallic materials terminology and organic chemical fragments; 2. two sections with general terminology and chemical fragments combined, and the metallic materials terminology printed separately; 3. only the chemical fragments printed separately; 4. an alphabetical listing of the complete thesaurus. A Master Word List was also provided.

Non-technical special type document retrieval terms are now indicated, such as: = = Bibliography 70 = = =

Dates are designated as follows: DECADE 1920 - 1929; YEAR 1960

Thirty foreign country terms representing the foreign technology source are listed in the introduction to the thesaurus, for example AFRICA, AUSTRALIA etc. General non-technical terms such as LITERATURE REVIEW are included. Generating or sponsoring agencies that can be recalled specifically include AEC (Atomic Energy Commission), AFML IN-HOUSE, etc. More explanatory notes as well as reference terms are included. The thesaurus

40

provides a high degree of specificity as demonstrated by the following:

1. Twenty-two military types of aircraft can be searched for: B-52, C5A, F-111, etc. 2. Seventeen coefficient terms including COEF. OF FRICTION, DRAG COEF., HALL COEF. There are 44 listings of collection terms ranging from Additives through Waves. Conversion tables are available for Energy terms, Mach number, Pressure, Temperature, Frequency and Wavelength. One hundred forty-one items under Polymers list a specific type or individual trade name as listed in Appendix VI.

APPENDIX I

DEFINITION OF TASK NUMBERS

01 General Includes:

Supervision

Meeting & trips

Holidays & sick leave

Writing of reports

Training of students

Time spent with visitors

02 Input Includes:

Assignment of accession numbers

Document accounting records

Preparation of index and abstract cards

Indexing

Keypunching

03 Output Includes:

Preparation of search strategy

Search

Screening of searches

Search accounting records

Library loan functions

Keypunching

04 Updating Includes:

Review of vocabulary and thesaurus

Changes or additions to previous records

Keypunching

Acquisition of missing documents

05 (UD) Research Includes:

Evaluation studies

Studies of new techniques

Investigation of new systems

05 (AFML/MDC) Includes:

Preparation of Materials Information Bulletin

06 Special Projects Includes:

Work performed in support of the AFML

not directly related to AMIC retrieval system

07 Microfilming Includes:

Time spent on the microfilming of index/

abstract records

08 SDI Includes:

Preparation of SDI profiles

SDI records

Keypunching

Photocopying of abstracts

Distribution of abstracts

16 1498s Includes:

Keypunching of MASIS Data

APPENDIX II

IS. ABSTRACT TILL Shillian of the ANATOLIC		
ine ability of various AMIC info	rmation specialists to	o prepare search
strategies for document retrieval was st	adied by providing ten	typical search re-
quest statements to seven information sp	ecialists. Each spec	ialist prepared search
strategies independently. Significant var	lations occurred amo	ong the strategies,
although even with these variations, reas	ionably consistent doc	ument returns result-
ed. The experiment indicated that the pr	oper interpretation o	f a search request and
the conversion of the request to an appro	priate search strateg	y even with a well-
established thesaurus is a considerably n	nore difficult task tha	in indexing. In another
experiment, the consistency of relevance	judgments among inf	formation specialists
was examined. Relevance judgment is m	nore difficult than inde	exing and search
strategy preparation. Agreement on non	relevance is better th	an agreement on
relevance. The system of relevance judg	ging according to non	relevant, partially
relevant and relevant appears optimum fo	or AMIC. Communic	ation between the
requester, the information specialist and	the retrieval system	itself are of prime
importance. Because of certain human i	nteractions which mu	st occur. some
variability is unavoidable. However, cur	rrent AMIC procedure	es of searching to
achieve high recall and screening the res	sults for relevance pro	vide good results to
the ultimate requester.		The Book I could be
