ABSTRACT

This health curriculum guide, intended for use with children in grades four through six, sees man's struggle to discover new knowledge for the prevention and control of disease in historical perspective. The contents of the guide are presented in outline form and cover the nature of disease, the history of disease, modern approaches to disease control, and the significance of disease to the individual and to society. For each content area and its sub-divisions fundamental concepts and understandings, teaching aids, and learning activities are suggested. The guide also supplies supplementary information--including infectious organisms, immunization, and antibiotics -- which a teacher could incorporate into the lessons at a simplified level. Appendices include a time line to chart key advances in man's understanding of disease, an outline of the development of medicine and public health from the Stone Age to the present, information on noncommunicable diseases and ailments, and guidelines for independent study and class discussion. Multimedia resources are also listed. Outcomes of this unit in physical health are given in terms of understanding the basic differences between communicable and noncommunicable diseases, perspective gained on man's historical efforts to understand and cope with disease, familiarity with the mechanisms of immunity, and comprehension of the significance of disease prevention and control. STRAND I

PHYSICAL HEALTH

Disease Prevention and Control

Grades 4, 5, and 6

OVERVIEW

Since ancient times, men have attempted to understand diseases and their relationship to human efficiency. Concern with specific diseases has changed dramatically through the years, but contemporary healthscientists continue their relentless efforts to discover new knowledge necessary for the prevention and control of diseases that influence man's well-being. Present efforts to understand the ecological implications and the epidemiological significance of diseases have added new dimensions to man's understanding of the disease process.

STRAND I

PHYSICAL HEALTH

Disease Prevention and Control

Grades 4, 5, and 6

OUTCOMES

PUPILS IN GRADES 4, 5, AND 6 SHOULD:

- understand the basic differences between communicable and noncommunicable disease syndromes and be familiar with representative diseases from each of these groups.
- gain perspective on man's historical efforts to understand and cope with disease, and appreciate how developments of the past are related to present efforts.
- be familiar with the mechanisms of immunity and take advantage of those immunizations recommended for the prevention of disease.
- comprehend the significance of disease prevention and control and work to protect themselves, their families, and society from all forms of disease.

The above can be made into a display. Invite other pupils to see it.

SUPPLEMENTARY INFORMATION FOR TEACHERS

Some causes of disease are specific, as in the case of infectious diseases, and some may be quite general, as in the case of some heart and circulatory diseases.

The most common kinds of intectious organisms are:

1. Bacteria

- 2. Fungi
- 3. Protozoa
- 4. Spirochetes
- 5. Viruses

(It is not necessary for pupils to learn or memorize all of these, but discussions of infectious diseases may be more meaningful if pupils are aware of the variety of organisms that may cause disease.)

Most microorganisms that cause disease are parasites, i.e., they live in or on other living things. Parasites make humans ill, and often interfere with human life processes.

SUPPLEMENTARY INFORMATION FOR TEACHERS

and the second se

Degenerative diseases are diseases due to the destruction of body tissues. They are usually associated with old age, but may occur in the very young. Some of these diseases are due partly to heredity or aging. Some are the indirect results of infectious diseases or of poor personal hygiene. Examples of degenerative diseases would include some kinds of heart and circulatory disturbances, diabetes, and nephritis.

Some diseases are more prevalent among members of one sex than another. Diabetes is more common in women, for example.

Rather than directly inheriting diseases, individuals may inherit a predisposition to some diseases (e.g., diabetes).

Appendix A represents a classroom chart which could be constructed of oaktag covered with acetate and events written in with water soluble markers.

۰.

Prehistoric men thought diseases were due to the invasion of the body by evil spirits. The treatment was to appease these spirits or drive them from the body. Religion has been closely associated with disease since the earliest times.

The Romans associated disease with unsanitary conditions as did the ancient Hebrew Culture. These conditions led to the development of elaborate drainage systems, water sysgems and general sanitary measures to deal with the problem on a public health level.

MAJOR UNDERSTNADINGS AND FUNDAMENTAL CONCEPTS

The discovery of microorganisms, and the formulation of the germ theory of disease led to the development of new approaches to disease control (e.g. immunology)

SUGGESTED TEACHING AIDS AND LEARNING ACTIVITIES

Organize a panel to discuss the application of disease theories of the past to the present.

Visit a modern health department or clinic. Compare the practices with those of 100 years ago; also just 25 years ago. How are they alike? How do they differ? .Make a comparison table and put on the bulletin board. Add to it as more knowledge is acquired. SUPPLEMENTARY INFORMATION FOR TEACHERS

Specific prevention measures and practices are noted with the advent of the modern age. The discovery of bacteria led to the development of the new sciences of bacteriology, virology, and immunology. Epidemiological practices improved and research became the key to the understanding and control of disease. The cornerstone of modern medicine was laid when Pasteur in 1864 demonstrated that specific microbes caused specific disease;.

Some disease control measures are very specific (immunization), while others may be very general (sanitation). See Strand IV - Public and Environmental Health for Details of Public Health Practices.

Visit the public health department or county laboratory. Learn how this department functions. Discuss:

 Why are there special clinics for the control of disease? Many diseases can be prevented by modern measures for disease control. These measures would include:

 Individual responsibility

Public prevention measures

ppropriate Antibodies are chemical sub-), from McGraw- stances that may be injected

stances that may be injected into or developed by the body. These protect the individual from contracting a specific disease for which the antibody is intended.

Immunity may be classified as specific, that is, the ability of an individual to resist a <u>specific</u> disease. Specific immunity is relative, not absolute.

î

SUPPLEMENTARY INFORMATION FOR TEACHERS

- Special cooperative measures, campaigns and activities
 Application of research
- Application of research data.

The first successful artificial immunization occurred in 1796 when Edward Jenner vaccinated a young boy against smallpox. This was the first specific preventive measure against disease developed by man. The process, basically, involves the introduction of an antigen into the body which, in turn, stimulates the body to produce antibodies.

product advertising is one form of health education that has a tremendous influence on health practices as well as consumer buying. It might be well to indicate to pupils that everyone's efforts are important in that they tend to reinforce each other.

Some of our newest drugs are antibiotics which are "germ-killing" substances produced by living plants. Dr. Alexander Fleming is given credit for discovering the first of the antibiotic drugs, penicillin, in 1928. Since then many antibiotics have been developed--Streptomycin is the second most important antibiotic drug in this category. RE

Scientists continue to search the "world of molds" for substances that may be beneficial in the treatment

SUPPLEMENTARY INFORMATION FOR TEACHERS

of disease. During the past 20 years numerous antibiotics have been identified and used for a variety of diseases. They are not, however, "cure-alls" since they have been ineffective against many diseases caused by virus agents. There is evidence, for example, that antibiotics may actually delay the recovery in the case of such diseases as the common cold, measles, mumps, and influenza. Many individuals have developed allergic reactions to some of the antibiotics. There is little doubt, because of a lack of information to the general public, as well as to the medical practitioner, that antibiotics have been too widely and indiscriminately used.

Examples of drugs would include: insulin for the control of diabetes, antibiotics for the treatment of many infectious diseases, and tranquilizers for the control of certain emotional conditions.

SUGGESTED TEACHING AIDS AND LEARNING ACTIVITIES

A rehabilitation counselor may be available to discuss the many ways that individuals may be rehabilitated.

Make a wall-size chart of the major causes of death 50 years ago and superimpose those of today. What kinds of changes have occurred? Why?

SUPPLEMENTARY INFORMATION FOR TEACHERS

An individual may not be cured of a disease, for example, diabetes, but he should be taught to "live with his disability" and function to the best of his ability.

The major killers 50 years ago, pneumonia, tuberculosis, influenza, diphtheria, all of which are communicable diseases, have decreased significantly. They have been replaced by such conditions as accidents, heart and circulatory diseases, cancer, and kidney diseases. Man's average life expectancy has increased so that the degenerative diseases are a greater problem than are the communicable diseases.

APPENDIX D

Noncommunicable Diseases and Ailments

With the phenomenal reduction in deaths from communicable diseases since 1900, people are living longer and into the age range where they are more likely to be afflicted with the noncommunicable diseases. Included in this category are chronic, degenerative, or constitutional diseases. Of the 10 leading causes of death in the United States today, six are in this category, namely, diseases of the heart, cancer, stroke, arteriosclerosis, diabetes, and cirrhosis of the liver. Others that take their toll in sickness and possibly death are rheumatism, nephritis and other kidney diseases, asthma, and hay fever.

In a sense, the chronic diseases are a result of the destruction of the human body and of the gradual slowing down of its function. So it would be impossible with our present knowledge to prevent all the deaths and disabilities that they cause. However, many deaths and a great deal of incapacitation could be prevented if more people were better informed about these diseases and were willing to take precautions. These measures, in many instances, need emphasis in early childhood.

In spite of the fact that these are essentially diseases of middle and old age, children need instruction in this area. For the following reasons, this inclusion in the elementary grades is amply justified:

- 1. They are often the result of improper health practices that are formulated during childhood and adolescence.
- 2. Though they are essentially diseases of older people, chronic and degenerative diseases do afflict some children and young adults.
- 3. It is quite likely that school children will have indirect experience with one or more of these diseases as older relatives and/or friends become ill from them.
- 4. Periodic medical examinations can detect these illnesses and may prevent illness and premature loss of life.

APPENDIX E

Guidelines for independent study and class discussion:

- 1. Distinguish between communicable and noncommunicable disease.
- 2. What is an infection? How does it occur?
- 3. What are some common symptoms of infections?
- 4. What are the names of the organisms that cause infectious diseases? Name one disease resulting from the invasion of each organism named.
- 5. What general defenses against disease does the body have? Are these defenses against communicable disease only? Explain.
- 6. How do disease-producing agents enter the body?
- 7. How are germs transmitted from person to person?
- 8. What is the difference between body resistance to disease and immunity?
- 9. Distinguish between each of the following kinds of immunity:

inherent

temporary

acquired active

acquired passive

natural

artificial

- 10. What is a carrier?
- 11. How does disease control today differ from disease control 75 years ago?
