ABSTRACT

The purposes of the study reported in this document were to investigate the relationship between children's manifest anxiety and their perceptions of negative environmental stimuli, and to determine the effects of socioeconomic status (SES) and race on both of these variables. The hypotheses tested concerned: (a) the degree of anxiety manifested by children from different SES, race, and sex groups; (b) the frequency of negative environmental stimuli perceived by children from different SES, race, and sex groups; and (c) the relationship between degree of anxiety manifested and frequency of negative environmental stimuli. Additional data were collected concerning the quality of negative environmental stimuli perceived by children from each group. The instrument used to measure anxiety was the General Anxiety Questionnaire, which incorporates items from the Children's Manifest Anxiety Scale and the General Anxiety Scale for Children. All subjects were sixth-grade pupils from four Philadelphia schools. Each school represented one of four SES-racial combinations: lower SES black, lower SES white, middle SES black, and middle SES white. Three hundred and fifty-one pupils -- three classes from each school -- participated in the study. The instruments were administered to an entire class at one sitting. Paper presented at the annual meeting of the American Educational Research Association, New Orleans, Louisiana February, 1973.

Introduction

Two recent studies (Hawkes and Koff, 1970; Hawkes and Furst, 1971a), have found that lower-socioeconomic (SES) black children manifest higher anxiety, than do their middle-SES white counterparts.

In addition, Hawkes and Furst (1971b) have reported that the attitudes toward children's anxiety held by pre- and inservice teachers tend to be in conflict with this finding. Many felt that since lower-SES children live in environments which are more stressful than are those of their middle-SES peers, they are better able to adapt to environmental stress.

At least three important questions have been raised in relation to these investigations. First, what is the nature of anxiety in children? Does it incorporate genuine fear (Erikson, 1963)? Does its meaning change as children from different backgrounds are observed? Second, if lower-SES and black children do manifest higher anxiety than do middle-SES and white children, have urban teacher-training institutions failed to equip teachers with the knowledge and orientations needed to deal adequately with their students? Third, are public schools providing programs which are sensitive to the social-emotional needs of their diverse clientele?

<u>Objectives</u>

One objective of this presentation is to explore the existence, the nature, and some of the causes of anxiety in elementary school children from different SES and racial backgrounds.

A second purpose is to explore means of providing teachers and others concerned about the education process with orientations

toward their charges which are more consistent with empirical findings. It is hoped that this may enable them to better serve the social-emotional needs of these pupils.

It is hoped to stimulate the thinking of the participants, so that this discussion will be carried back to their own communities. We hope that additional steps may be taken to both establish a firmer empirical foundation for our orientations toward children, and to use this empirical knowledge to provide programs which are more sensitive than at present to the socialemotional needs of school children from divergent backgrounds.

Background and Purposes

Children's anxiety has been widely studied during the past twenty-five years. It has been repeatedly observed that the degree and quality of anxiety vary as children from different SES and racial backgrounds are sampled. Differences, similar to those regarding anxiety, have also been reported in the fears of children from different SES, race, and sex groups. In addition, theorists have noted the tenuousness of any proposed distinction between nonobjective anxiety and objective fear in children. Caution has been urged in applying these terms to childhood manifestations as they are understood in the context of adult psychology.

In an expansion of the Hawkes Et Al studies (1970,1971a), Yasgur (1973) undertook to investigate the consturct of anxiety in children, in terms of its relation to realistic fear, as well as to obtain normative data for SES, race, and sex on the degree of anxiety manifested by children, as measured by a self-report scale.

The hypotheses tested concerned: (\underline{a}) the degree of anxiety manifested by children from different SES, race, and sex groups, (\underline{b}) , the frequency of negative environmental stimuli perceived by children from different SES, race, and sex groups, and (\underline{c}) the relationship between degree of anxiety manifested and frequency of negative environmental stimuli perceived. Additional data were collected concerning the quality of negative environmental stimuli perceived by children from each group.

Procedure

The instrument used to measure anxiety was the General Anxiety Questionaire, or GAQ (Hawkes and Koff,1970), which incorporates items from the Children's Manifest Anxiety Scale and the General Anxiety Scale for Children. Two assessment devices were developed for the study. The first was a self-report check-list, to obtain children's perceptions of the frequency with which negative environmental experiences are encountered. The second was an individual interview, to obtain children's perceptions of the quality of negative experiences in their environments. (Copies of these instruments may be found in Appendixes I-III.)

All subjects were sixth-grade pupils from four Philadelphia Schools. Each school represented one of four SES-racial combinations: (a) lower SES black, (b) lower SES white, (c) middle SES black, and (d) middle SES white. Three-hundred fifty-one pupils (three classes from each school) participated in the study.

The GAQ and checklist were admisistered to an entire class at one sitting. Interviews were conducted three to four weeks later, with a stratified random sample (an equal number of boys and girls) from each school. Seventy-six pupils were interviewed. Statistical Analyses

For purposes of the statistical analysis, the GAQ was divided into two parts: an anxiety scale and a lie scale. Mean scores for each subsample, on the anxiety scale, lie scale, and checklist, are displayed in Table 1. The scores for each scale were analyzed using a three-way (SES, race, sex) univariate analysis of variance, to determine the relative standing of each subsample on degree of anxiety, lying, and perception of frequency of negative environmental stimuli. In addition, Pearson product-moment coefficients were computed for correlatioons between anxiety and lie scores,

lie Scale and	Checklist /			078	

^{*} p < .01, with 350 degrees of freedom

anxiety and checklist scores, and lie and checklist scores. These correlations are displayed in Table 2. An alpha level of .05 was established for testing significance in all analyses.

For the interviews, descriptive, rather than inferential, statistics were employed. Categorized data for all questions are displayed in Appendix IV, Tables I through 35. The data are presented in an effort to help ascertain whether qualitative differences were found in children's perceptions of negative stimuli. Tests for statistical significance (e.g. chi square) were considered,

but were not used for two reasons:

- 1. Responses were classified into arbitrary categories after the data were collected.
 - 2. Individual categories were not independent of one another.

Summary of Results and Discussion

Null hypothesis 1, that there will be no significant difference in anxiety scores between lower SES and middle SES, was rejected at the .005 level of significance. Although the absolute difference in the mean scores of the two subsamples was only 1.88 points, lower SES pupils attained significantly higher scores than did middle SES pupils.

Null hypothesis 2, that there will be no ignificant difference in anxiety scores between black and white, was rejected at the .001 level of significance. The absolute difference in the mean scores of the two subsamples was 3.14 points, almost twice that of the difference between SES subsamples. It was concluded that black pupils scored significantly higher than white pupils, in both statistical and absolute terms.

for SES and race. The absolute difference in the mean anxiety scores of lower SES black pupils and middle SES white pupils was 5.04 points, indicating considerably higher anxiety in the former subsample than in the latter.

Null hypothesis 3, that there will be no significant difference in anxiety scores between boys and girls, was rejected at the .05 level of significance. The absolute difference in the mean scores of girls and boys was only 1.37 points. Although the girls scored significantly higher than the boys in statistical terms, the absolute difference in scores was small.

A three-way interaction approaching statistical significance (pc.054) was observed for SES, race, and sex. The absolute difference in the mean anxiety scores of lower SES black girls and middle SES white boys was 7.41 points, which indicated a difference in anxiety between these two subsamples, with the lower SES black girls scoring higher.

Null hypothesis 4, that there will be no significant difference in lie scores between lower SES and middle SES, was rejected at the .01 level of significance. Despite the fact that statistical significance was observed, the absolute difference in lie scores was only .52 points, with the lower SES subsample attaining the higher score, and consequently "lying" slightly more, than the middle SES subsample.

Null hypothesis 5, that there will be no significant difference in lie scores between black and white, was rejected at the .005 level of significance. Again, the absolute difference in mean score; was low. Black pupils scored .55 points lower, and consequently "lied" slightly less, than white pupils.

Null hypothesis 6 that there will be no significant difference

in lie scores between boys and girls was not rejected. An almost negligible difference of .27 points was observed, with boys tending to lie slightly more than girls.

No significant interactions were observed for lie scores.

Null hypothesis 7, that there will be no significant differnece in checklist scores between lower and middle SES, was not rejected. Middle SES pupils tended to score slightly higher (.23 points) than did lower SES pupils.

Null hypothesis 8, that there will be no significant difference in checklist scores between black and white, was not rejected. The mean scores of these two subsamples were almost identical.

Null hypothesis 9, that there will be no significant difference in checklist scores between boys and girls, was rejected at the .01 level of probability. Although girls scored .50 points higher than boys, the absolute difference was so small as to make it almost impossible to generalize that girls perceive greater frequencies of stressful stimuli than do boys.

No significant interactions were observed for checklist scores.

One plausible explanation for these findings of no difference amond subsamples in perceived frequency of stressful environmental stimuli, is to be found in the response format for the instrument. The alternateve responses provided were in terms of relative frequencies: Never; Hardly ever; Sometimes; A lot of the time; All the time. The findings may indicate that children from all subsamples tended to perceive stressful stimuli in their environments with similar frequency, although these stimuli may have varied in the qualities of their adverse dimensions.

Another possible explanation is that different language norms may exist for different subcultural groups, with regard to des-

relation to his own milieu, where "sometimes" might mean daily or monthly, depending on the norm.

Null hypothesis 10, that there will be no relationship between anxiety and checklist scores, was rejected at the .01 level of significance. A correlation of -.31 was obtained between anxiety and checklist performances, indicating a tendency for those pupils who revealed higher anxiety to report perceiving fewer negative stimuli in their environments. This correlation was not in the expected direction.

Although a non-relationship might be accounted for by the nature of the checklist response categories, a different explanation must be sought for the negative correlation between anxiety and checklist scores. Perhaps the GAQ measures different constructs in different groups, i.e. more fear in children from more dangerous environments and more anxiety in children from less dangerous environments. Added to this is the possiblity that children from high stress backgrounds tend to ignore situations which are perceived as very stressful by children from more secure back-grounds.

An inspection of Table 1 reveals that the actual differences in the mean checklist scores of each group were almost negligible. Low standard deviations indicate that very little variation was observed within groups. Since a correlation of -.31 means that less than 10 percent shared variance existed between the anxiety scale and the checklist, it may be concluded that the checklist was inadequate for revealing differences in the perceptions of different groups, as well as individual differences within groups.

Probably the most interesting single finding of this study

was that lower SES and black children were "anxious" about stimuli in their environments which were realistically more fear-provoking than were the negative stimuli reported by their middle SES and white peers.

Several trends were evident in the interview data:

- 1. Inner-city, particularly black, children were far more concerned about their physical well-being than were their outer-city, particularly white, counterparts. This finding supports the notion that anxiety and fear are cleosly related in children, particularly in those whose environments are realistically cangerous.
- 2. Middle SES children interviewed expressed more concerns about academic success than did their lower SES counterparts. Since middle SES pupils are relatively more successful in school than are lower SES pupils, this finding indicates that the GAQ may be more of an assessment of anxiety, as opposed to fear, in middle SES children in lower SES children. Even though, in earlier studies, lower SES children were observed to manifest higher anxiety over schoolrelated, in addition to most other items in the GAQ, their interview responses indicated that their concern with personal safety was more salient than was their concern with school acheivement. This does not indicate that lower SES children are less concerned about school acheivement than are middle SES children, however.
- 3. Boys evidenced greater concern with their physical wellbeing than did girls. This finding stands in apparent contrast with the higher anxiety and checklist scores of

the girls. One plausicle explanation for this seeming disparity is that girls have more general anxiety than do boys, who have more realistic fear of their environments. Perhaps parents treat girls in restrictive ways that make them more generally anxious than boys. Boys may have more freedom to explore their environments and, consequently, learn for themselves which elements impinge on their safely.

Inferences

The purposes of the study were to investigate the relationship between children's manifest anxiety and their perceptions of negative environmental stimuli, and to determine the effects of SES and race on both of these variables. Based on the findings, the following inferences were drawn;

- 1. Neither race nor SES seems to be the greater determinant of manifest anxiety, when each is observed independently of the other in this study.
- 2. Manifest anxiety in sixth grade children appears to incorporate realistic fear as well as anxiety. This is
 particularly so for children from environments which are
 objectively least safe (i.e., inner city).
- 3. Inner-city children seem able to realistically appraise the dangers in their environment, though not to adapt to those dangers without concern.
- 4. Although none of the groups tested was without manifest anxiety, those living amid the greatest danger manifested the greatest anxiety. It is inferred, therefore, that manifest anxiety in children is affected by environmental, in addition to psychological, press.

A Study of Teachers Attitudes

Simultaneously, Carner (1973) was exploring means of conveying these findings to undergraduate, pre-service teachers in order to bring their attitudes more in line with empirical reality. A pre-test of some 250 undergraduate students corroborated the results of Hawkes and Furst (1971b). These studies found that undergraduate, pre-service teachers consistently predicted that white, suburban youngsters would manifest greater "concerns", "worries", "anxieties", "fears", than would their black, inner-city counterparts.

Five treatment models were compared on their effectiveness in changing the attitudes of pre-service teachers toward the relative anxiety levels of black, inner-city children and white suburban children. Although no treatment was demonstrated to be more effective than any other, the attitudes of subjects in all five treatment groups changed significantly (.001) in the direction of greater consonance with the observations of Hawkes and Koff (1970), Hawkes and Furst (1971a), and Yasgur (1973).

The results indicate that the presentation of information alone was sufficient to change the subjects' attitudes. It is interesting to note that Hawkes and Furst (1971b) reported that those undergraduate and graduate students who had the greater number of hours in Psychology and Education and who had the higher grade point average were less able to accurately predict which group of youngsters manifested the greater anxiety. Whether or not the material is learned well, therefore, has no bearing on the subjects ability to accurately predict the anxiety levels of black, inner-city and white, subjects about the subjects.

By implication, the findings support the position that universities are failing to provide urban teachers with information that will enable them to deal effectively with the socialemotional problems of their pupils.

APPENDIX I

GENERAL ANXIETY QUESTIONNAIRE

Please Mark Your Answer Sheets as Follows for Each Item: $Yes = A \quad No = B$

- 1. It is hard for me to keep my mind on anything.
- 2. I get nervous when someone watches me work.
- 3. I feel I have to be best in everything.
- *4. Do you ever worry about knowing your lessons?
- 5. When you are in bed at night trying to go to sleep, do you often find that you are worrying about something?
- 6. Are you sometimes frightened when looking down from a high place?
- 7. Do some of the stories on radio or television scare you?
- *8. Do you ever worry about what other people think of you?
- 9. Do you think you worry more than other boys and girls?
- 10. Do you worry that you might hurt in some accident?
- *11. Do you ever worry that you won't be able to do something you want to do?
- 12. Without knowing why, do you sometimes get a funny feeling in your stomach?
- 13. Do you get scared when you have to go into a dark room?
- 14. Do you sometimes get the feeling that something bad is going to happen to you?
- *15. Have you ever had a scary gream?
- *16. When you were younger, were you ever scared of anything?

- 17. At times I feel like shouting.
- 18. I wish I could be very far from here.
- 19. Others seem to do things easier than I can.
- 20. I am secretly afraid of a lot of things.
- 21. I feel that others do not like the way I do things.
- *22. Have you ever been afraid of getting hurt?
 - 23. I feel alone even when there are people around me.
 - 24. I have trouble making up my mind.
 - 25. I get nervous when things do not go the right way for me.
 - 26. I worry most of the time.
- *27. Has anyone ever been able to scare you?
- 28. I worry about what my parents will say to me.
- 29. I get angry easily.
- 30. Other children are happier than I.
- 31. I worry about what other people think about me.
- *32. Do you ever worry about something bad happening to someone you know?
- 33. I have worried about things that did not really make any difference later.
- 34. My feelings get hurt easily.
- 35. I worry about doing the right things.
- 36. I worry about what is going to happen.
- *37. Are you ever unhappy?
- 38. I worry about how well I am doing in school.
- 39. My feelings get hurt easily when I am scolded.
- 40. I feel someone will tell me I do things the wrong way.
- 41. I am afraid of the dark.

- *42. Do you ever worry about what is going to happen?
 - 43. It is hard for me to keep my mind on my schoolwork.
- 44. I worry when I go to bed at night.
- 45. I often do things I wish I have never done.
- *46. Do you ever worry?
- 47. I often worry about what could happen to my parents.
- 48. I get tired easily.
- 49. I have bad dreams.
- 50. I often worry about something bad happening to me.
