ABSTRACT

This document describes how American education may be organized and operated three decades hence and investigates the effects of population growth on the cost of providing this future schooling and on the number of instructional personnel it will require. Projections resulting from this research suggest that relatively more resources will probably go to the prekindergarten and elementary levels in the year 2000; many students will earn high school and college diplomas through instructional television and computer-assisted instruction; and college degrees will be earned with an average of 2 years' work after high school. This report also investigates the effects of population growth -- 2-child versus 3-child families -- on the cost of future schooling. The investigation also led to the conclusion that more rapid growth rate will lead to about 45 percent higher educational spending in the year 2000 and to relatively more spending at the prekindergarten and elementary levels. However, educational expenditures are deemed unlikely to rise as rapidly in relation to the gross national product (GNP) as they did between 1960 and 1970. (Author)

PREFACE

This report was prepared for the President's Commission on Population Growth and the American Future, which was established with the passage of Public Lav 91-23. The Commission—as charged, among other duties, with estimating the "resources in the public sector of the economy that will be required to deal with anticipated growth in population." Rand, under contract to the Commission, has prepared studies which examine the relationship between population change and the requirements for services in the education, passenger transportation, welfare and health sectors. The present report analyzes the effects of alternative rates of population growth on educational spending over the next three decades. En initial version was submitted to the President's Commission in October 1971.

This study may be of interest to persons concerned with the economic and political prospects for alternative teaching methods, a structional technologies, and administrative organization in American schools. It may also interest those who are investigating methods of projecting costs and public resource requirements. Finally, this report will be useful to readers concerned with broader questions of the impact of population growth on our national life.

SUMMARY

This study of the financial requirements of american education during the next representation of the property of the study of the first is to construct on the basis of trends and prospects in educational methods and technology and school and classroom organization, a descriptive outline of the way schools may be organized and operated where decades hence. The second purpher is to investigate the effects of population growth on the cost of providing the study are schooling and the number of instructional personnel it will require.

Four underlying demand are supply factors will introduce ourse of future educational expenditure as the line of the past identifying their separate roles rocuses be forecasting effort on the most important underlying trends. On the demand side are (1) the size of the school-age population, and (2) the types and amounts of skills people will want to acquire, to use in their increasing leisure time and to meet the economy's demand for manpower with the abilities that schooling at various levels produces. The supply factors are (3) the development of more productive inputs into the educational process, and (4) changes in the prices of schooling inputs due to demand and supply changes outside the education sector.

For the first objective of this study, these underlying factors are anticipated to result in a variety of changes in American schooling. A review of the recent literature of educational criticism along with evaluations of the costs and effectiveness of various organizational and technological innovations suggests several principal differences between today's schools and those of the year 2000.

- A larger proportion of educational resources will be allocated to the prekindergarten and elementary levels in 2000.
- Schools at all levels will use their physical plant and equipment for more of the calendar year.
- Specially trained paraprofessional instructional personnel will be heavily used at the prekindergarten, elementary, and secondary levels.
- Relatively low-cost instructional television and computer-assisted instruction will be widely used in classrooms and elsewhere in the community.
- To insure that each graduate is prepared to continue in school or to support himself in the economy, secondary schooling will include a variety of work-study programs in which students can have many work experiences and learn several

trades. Most material formerly taught in college survey courses will be taught in high school.

- Many students will earn high school and college diplomas through instructional television and computer-assisted instruction, while away from a campus.
- College degrees will be earned with an average of two years' work following high school graduation, though many persons will attend college intermittently throughout their werking careers.

The second main purpose of this apport is to instigate the effects of population growth on the cost of providing the seducational changes and on the number of instructional personnel they will require. Costing the resource requirements implied by these changes and assuming these different rates at which society will adopt hem yield alternative annual projections of expenditure per student at four schooling levels—prekindergarten, elementary, secondary, and higher clucation—and for four categories of expenditure—personnel, plant, equipment, and of termosciety similar procedures produce projections of personnel requirements for instructional ersonnel. These expenditure and personnel digness are their multiple by versous analyment projections that reflect the differences between application population implying an average three-chir family in 2000 (Census Series B) and a slowly growing population implying an average two-child family (Census Series E).

The resulting projections indicate that population and encollment growth rate will be significant determinants of total expenditures on schooling and of the proportions spent at the various school levels. Rapid population growth implying an average three-child family in 2000 will lead to about 45 percent higher educational spending in 2000 than will slow population growth implying an average two-child family. Rapid population growth will also lead to relatively more spending at the prekindergarten and elementary levels.

Requirements for teachers and parateachers will be similarly affected, but the distribution of noncollege educational spending among broad categories—instructional personnel, physical plant, and equipment—does not appear sensitive to population growth or enrollment rate variations.

Educational expenditures are unlikely to rise as fast, relative to GNP, as they did in the decade of the 1960s, even with substantial infusions of new technology and even at the highest projected enrollment growth rate. If the educational improvements identified in this report are adopted relatively quickly, rapid growth in school enrollment (based on Series B) will require about 13 percent of GNP to be spent on education in the year 2000. Slow enrollment growth (based on Series E) will require about 8 percent, an increase of only one-half percent over the 1970 figure. Slower adoption of improved methods and technologies will slow the growth of educational spending accordingly.

There will be a large financial tradeoff in the coming decades between the quality of education and the number of people to be educated. This tradeoff can be illustrated by assuming that enrollment rates will increase relatively rapidly and that we will spend 10 percent of our GNP on education in the year 2000. With the "three-child" population this expenditure would provide 7 percent of the students with all of the educational improvements identified in this report, while 93 percent

would receive education characterized by the same kind of school inputs used 1970. With the same proportion of GNP spent on education of the "two-child population, all students could receive high quality schooling.

ACKNOWLEDGMEN'SS

The authors are indebted to Rand colleague Stephen J. Carroll for methodological advice at this study's inception and to colleagues Stephen M. Barro, David S. Chu, David H. Greenberg, Sue A. Haggart, Emmett B. Keeler, Herbert J. Kiesling, Anthony H. Pascal, and T. Paul Schultz for useful criticisms and suggestions at intermediate stages. Mary Rudolph's library assistance and John Enns' computational work are gratefully acknowledged.

I. INTRODUCTION

This study of the financial requirements of American education during the next 30 years has two main purposes. The first is to construct, on the basis of trends and prospects in educational methods and technology, several alternative pictures of how American education may change in the next three decades. The second is to investigate the effects of population growth on the cost of providing this changing educational system and on the number of instructional personnel it will require.

For the first objective, we have examined current trends in teaching methods, educational technology, and school and classroom organization. We also reviewed the growing literature of research and opinion that is critical of American schooling and evaluated the costs and effectiveness of various technological innovations that now exist but have not yet been widely adopted in schools. These considerations suggest features of school organization, teaching methods, and technology that seem likely to characterize American schools of the year 2000. Combining these features, we construct a broad descriptive outline of the way schools may be organized and operated three decades hence. Although this outline can be only an informed guess, we intend it to be internally consistent, technologically and politically possible, and useful in evaluating the aggregate financial effects of population growth.

For the second objective, the per-pupil requirements for instructional personnel, physical plant, and equipment of various kinds are estimated for 1970 and 2000 and costed at 1970 prices. Then, by adjusting these prices for demand and supply changes and assuming three alternative rates at which society will adopt the future types of schools, we construct three paths of per-pupil expenditure over the next 30 years. These expenditure figures are multiplied by various enrollment projections that reflect the differences between a rapidly growing population, implying an average three-child family in 2000 (the Census "B" projection), and a slowly growing population, implying an average two-child family (the Census "E" projection). The result is alternative forecasts of educational expenditures that illuminate the tradeoffs between population growth and improvement in school quality.

THE DETERMINANTS OF AGGREGATE EDUCATIONAL EXPENDITURES

Understanding the probable determinants of future educational spending requires prior identification of the causes of recent spending trends. Between 1960 and 1970 educational expenditure per pupil in constant dollars increased 170 percent in the United States. This 5 percent annual increase resulted from rising teacher wages and prices of other inputs, as well as from increasing teacher-pupil ratios and amounts per pupil of other broad categories of inputs. Accompanying this trend was a 2.4 percent average annual increase in enrollment at all levels from kindergarten to graduate school. As a result, total educational expenditures as a percent of GNP rose from 5.4 percent in 1960 to 7.5 percent in 1970.

Four basic demand and supply factors underlie these trends. By identifying their separate roles and determining which of the many possible interactions among them could have produced the recent history of spending and resource use in education, we improve our ability to forecast future trends.

- 1. The first underlying factor is the size of the school-age population, which itself depends on fertility, mortality, and international migration during the previous two or three decades. The generally rising birth rate in this country between 1945 and 1955, for example, was the primary cause of the increasing enrollments of the 1960s, though the proportion of the population enrolled, particularly in colleges, also rose.
- 2. A second basic factor which influences both enrollment and expenditure per student is the types of skills people want to acquire to meet the economy's demand for people with the abilities and skills provided by schooling and to use in their in asing leisure time. This influence is reflected in the amount of resources that people, individually and collectively, are willing to spend on schooling for themselves and others. Their expenditures may take various forms: direct payments for tuition, supplies, and living expenses; tax obligations at federal, state, and local levels; purchases of bonds for school construction and improvement; and use of their time and abilities in classrooms and laboratories instead of in leisure or income-producing activities.

This factor along with the first—the population of school age—determines the aggregate demand for schooling, which may be thought of as the amounts of schooling of a given quality which the community is willing to pay for (in both money and students' time) at various prices. This demand will be larger if (1) the school-age population is larger, and (2) the economy's demand for skilled workers and peoples' personal desire for skills and knowledge are higher.

3. There are similarly two basic factors affecting the supply of schooling. One is the development of more productive inputs to the educational process, allowing the same quality and amount of schooling to be produced at lower cost (of money or of teachers' or pupils' time), or enabling pupils to learn more at the same cost than they could before. These more productive inputs may take the form of more highly trained teachers, better designed school buildings, or improved teaching methods and instructional technologies.

4. The other factor affecting the supply of schooling consists of demand and supply changes outside the education sector. For example, a general increase in the demand for people with a college education and the resulting rise in their salaries can be expected to result in higher teacher salaries, even though neither the demand for schooling nor the productivity of teachers has increased. Such effects may occur whenever an input—in this case, educated labor—can be employed in several industries, and its price initially increases in one of them. The same effect may result if resources used in the education of teachers, the production of textbooks and equipment, or the construction of school buildings experience price rises in excess of their productivity increases.

How did these demand and supply forces interact during the last decade? In the first place, enrollment increases resulting from the first two factors clearly contributed to rising total educational spending. Since our subsequent analysis is based in part on alternative enrollment projections, we are able to identify the effects on future educational spending of differences in the growth of this component of the demand for schooling.

It is also necessary to forecast expenditures per student over the next three decades in order to calculate projected total educational spending. We must therefore seek an explanation for recent trends in per-student educational spending. During the last decade the real wages of instructional personnel and real prices of broad categories of school equipment and facilities increased steadily. In the same period, pupil-teacher ratios in elementary and secondary schools declined and the average per-pupil amounts of other broad categories of inputs rose. These trends could have resulted from several combinations of demand and supply changes. Under certain demand conditions, increasingly effective educational inputs (the third factor) would have led to rising prices and larger expenditures and amounts of schooling per pupil, even with no aggregate change in the demand for education expressed on behalf of each student (from the second factor).7 Alternatively, if demand has increased, the supply of schooling inputs may not have changed, or they may have become more productive (the third factor) or simply more expensive (from the fourth factor); in either case, the amount of educational resources and expenditure per pupil would have risen.8

Unfortunately, no clear evidence points to a particular combination as the cause of the increases in expenditure per pupil that have characterized American education in recent years. Because of great conceptual and statistical difficulties in measuring the "output" or "product" of educational processes, and in defining inputs and changes in their effectiveness, the data required to answer the question have been neither defined nor collected.⁹

Despite this uncertainty, past experience suggests a continuing rise in real educational wages and the prices of conventional schooling inputs, whether due to increasing demand for schooling inputs or changes in their supply. In our consideration of the emerging needs for compatibility between the American school system and the social, economic, and political changes that are taking place in this country, we anticipate that several innovations in teaching methods, educational technology, and school and classroom organization are likely to gain increasing acceptance and

adoption in the coming decades. The costs of these innovations and changes in the prices of conventional school inputs will determine anticipated per-pupil expenditures in our future schools.

FACTORS OMITTED FROM THE ANALYSIS

In order to concentrate attention on the effects of population growth and changing educational organization, methods, and technology, the following simplifying assumptions have been made. The effects of relaxing several of these assumptions are explored later.

- 1. Elementary and secondary enrollment projections were made by the Bureau of the Census. Although we have altered the Census projections of enrollment in institutions of higher education and constructed our own projections of prekindergarten enrollment, there has been no attempt to account for changes in the demand for elementary and secondary schooling as reflected in enrollments.
- 2. We assume that the prices of all resources used in schooling will increase as fast as productivity growth in the whole economy. A rough measure of productivity increase is the change in per capita real disposable income. Since the Department of Commerce projections yield an average annual growth in per capita real disposable income of 2¾ percent, 10 the costs of all resources in both "current-input" schools and future schools are projected to increase at this annual rate. 11 No attempt has been made to foresee changes in relative prices of educational inputs or the future course of inflation.
- 3. Foregone earnings of students are omitted as a cost of education at all levels. Although they form the largest component of the cost of higher education and a sizable part of the cost of high school education, 12 they are not included in public expenditures for schools, which is the concern of this study. Since the future school system described later implies substantial savings of students' time at the higher levels, we comment at that point on the significance of this saving.
- 4. We do not consider the separate prospects for public and private schooling or changes in school financing (for example, a voucher system) that might affect the demand for or supply of schooling.
- 5. Possible changes in administrative costs, as might arise from planning, programming, and budgeting systems and electronic data processing, seem relatively insignificant and are neglected.¹³
- 6. The effects on educational expenditures of the spatial distribution of the population seem to be dominated by the impact of total enrollment growth and the adoption of educational innovations. We have therefore abstracted from issues of spatial distribution.
- 7. Alternative tax and expenditure programs to pay the projected costs of education are not considered.

II. PROJECTIONS OF ENROLLMENT AND PER-PUPIL EXPENDITURE

Having described the conceptual relationships between enrollment growth and changes in expenditure per pupil on the one hand, and aggregate educational expenditures on the other, we now turn to a discussion of our enrollment and per-pupil expenditure projections. These shape the aggregate expenditure and teacher requirement projections discussed in the last section of this report.

THE ENROLLMENT PROJECTIONS 15

The 1970 prekindergarten enrollment of children aged three to six, adjusted to its full-day equivalent, constituted 6.5 percent of the children in that age group. Our low enrollment rate projection assumes that this percentage will increase by the same amount each year until it reaches 30 percent of the relevant age group in the year 2000. The high projection grows to 83 percent in 2000. The high projection grows to 83 percent in 2000.

For elementary schools, the 1970 enrollment rate was 95.6 percent. This rate is projected to be 96.4 percent and 97 percent in 2000, under the low and high assumptions concerning enrollment rate growth, respectively. Similarly, whereas 85 percent of the relevant population were enrolled in secondary school programs in 1970, the low and high projections for 2000 are 87 percent and 89 percent, respectively. For higher education, the 1970 figure was 27 percent and the two projections for 2000 are 35 percent and 44 percent. 19

The age-specific enrollment rates implied by these proportions were multiplied for each year of the forecast period by the population size projected in both Series B and Series E of the Census population projections. At each of the four levels of schooling, therefore, there are four enrollment projections, the highest assuming large enrollment rate increases and Series B population, and the lowest assuming small enrollment rate increases and Series E population.

The compound growth rates of enrollment which these four projections imply appear in Table 1. The eargest increases are projected for prekindergarten and

Table 1
COMPOUND GROWTH RATE OF PROJECTED ENROLLMENT

Prekindergarten Elementary Secondary Higher	10.3 1.4 1.7 3.3	7.0 1.3 1.5 2.6	8.7 -0.0 0.1 2.3	5.3 -0.1 0.0 1.6	

SOURCE: Appendix Tables C-1 through C-4.

higher education; it is at these levels also that the difference between rapidly and slowly growing enrollment rates would make the most difference. Both results are caused by the lower rates at these two levels in 1970 which leave more room for increase over the forecast period.

Figure 1 suggests the magnitude of difference between rapidly and slowly growing populations, anticipating some of the results reported below. The number of children reaching school-entering age, which foreshadows future school enrollments, is plotted in actual and projected values. It reached a peak of 4.3 million children in 1967 when it was 11 percent higher than in 1960 (and 60 percent more than in 1951).

With high fertility, the number of children reaching age six will continue to fall until 1974, and only in 1979 will it recover its 1967 peak. Series E population growth, however, yields a declining number until 1977 and never again reaches the 1967 peak. In either case, the recent fall in numbers reaching school age vill work its way through the education system and is even now affecting the lower grades.

GENERAL FEATURES OF CURRENT-INPUT SCHOOLS AND FUTURE SCHOOLS

To project education expenditures per pupil, it has first been necessary to estimate the amount per pupil spent on several categories of educational resources in the United States in 1970. We have then made similar estimates for schools in the year 2000, based upon a conception of the ways in which these schools will differ from the present ones. After describing some general features of schools which use current 1970 inputs and of schools considered most likely to be common in 2000, we

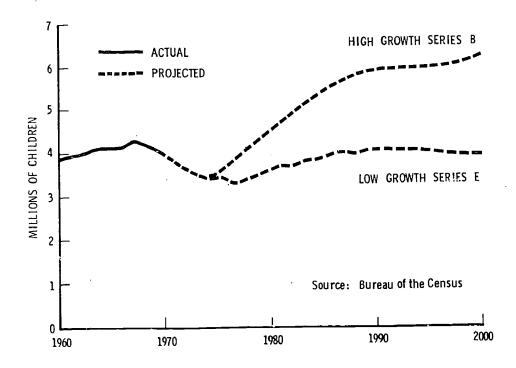

Fig. 1—Children reaching age six

turn to specific features and expenditures of the future schools, taking each school level separately.

Although schools at different levels and in different geographic areas can vary immensely in their organization, size, and teaching methods, most of American education in 1970 can be fairly characterized in a brief description. The teaching strategy at all school levels has proved durable over many decades: for each class, a single teacher who relies on textbooks as the most important medium of instruction. The teacher uses some films and records and perhaps a small amount of instructional television, and he alone carries most of the burden of course organization without outside help in planning. Nor does he receive assistance in instruction from paraprofessional people. For the school system as a whole, what pupils are to learn is laid out in advance by years, months, perhaps days, and regular progression through the grades is expected of most pupils. Employing physical facilities which are in reasonably full use for only about 180 days of the year, the process of instruction is at all levels largely a matter of teachers telling and questioning, and pupils answering.

The opinions of leading educators and public decisionmakers, as well as current trends in American education and prospects for different but effective teaching methods and technologies²¹—all considered together—point to several pervasive differences between these current schools and the educational system that will evolve during the next 30 years. To begin, it seems evident that a primary function

of schools, taken increasingly seriously, will be to insure that each pupil is prepared, at the upper school levels, either to continue in school or to support himself by employing his personal resources usefully in the economy. To achieve this and other goals, schools will try to pattern each student's educational program after his own abilities, interests, and goals. There will accordingly be greater diversity in teaching methods and in the time patterns of schooling. Students at the upper levels may freely intersperse on the job training, travel, military service, or leisure with their schooling—even on a day-to-day basis. At all levels, a much greater part of the effort of teachers and administrators will be devoted to frequent counseling of individual pupils—keeping abreast of their changing interests and goals, advising them in educational matters, and planning their curriculum for the short and the long run. Counselors will seek out pupils on a regular basis as well as be available for special problems, as they are in most current-input schools.

Today many school administrators would make these changes if sufficient resources—particularly personnel—were available. Whereas most cannot now afford them, we foresee five developments which will make these changes possible.

• First, relatively low-cost instructional television and computer-assisted instruction will come into widespread use freeing instructional personnel from some classroom responsibilities. Multi-channel cable television networks with digital or voice feedback have enormous capabilities for providing varied and extensive instruction at all levels and in most subjects. The weight of experimental evidence indicates that many kinds of material can be taught just as well over television, and at lower cost per pupil. As cable systems proliferate and as knowledge about teaching by television accumulates, instructional television will become increasingly cost-effective.

Similarly, computer-assisted instruction has been shown effective in teaching a limited but important set of subjects; its fuller possibilities are unknown.²⁶ These capabilities and possibilities, along with the costs of experimental systems now in existence, give us reasonable confidence that computer-assisted instruction will be commonplace in the United States in 30 years.²⁷ To the extent that television and computers are adopted in the schooling process, the time of teachers will be freed for the individualized instruction and counseling discussed above. Although it is possible in these circumstances that school administrators will employ fewer instructional personnel, experience indicates that they will not do so.²⁸ Instead, existing teachers will probably spend more time with individual pupils and, upon retiring, be replaced by more specialized instructors and counselors.

- A second development that will facilitate the broad changes we expect schools to undergo is *increasing use of specially trained paraprofessional instructional personnel*. Many of these people will have completed a six-month to two-year training program after high school and will be prepared to assist in specific facets of instruction and classroom administration. Their efforts, which may be of particular use in supervising instructional television classes and computer-assisted instruction, will enable professional teachers to spend more time with individual pupils.
- A third contributing factor will be the *increasing allocation of schooling resources to the lower levels*. Many children will begin formal schooling as early as age

three,²⁹ and expenditures per pupil will grow more rapidly at the lower two levels than at the upper two.

- Fourth, it seems very likely that schools at all levels will increasingly find ways to use their physical plant and equipment for more of the calendar year. 30
- A final factor is the expected proliferation of so-called extended campus programs in which students can take courses and earn degrees while physically removed from the classroom. Instructional television and remote-access computer-assisted instruction may enable people to continue their schooling while living at home or holding a full-time job. With periodic visits to a school or campus for counseling and testing, these programs will surely be less expensive than conventional schooling.

All these changes should enable pupils to learn much of the material covered today in college survey courses while still in high school or to devote considerable time to learning skills that can be used in jobs after graduation. We accordingly anticipate that such survey courses will be offered typically at the secondary level and that academically prepared high school graduates will be able to earn a Bachelor's degree in an average of two years. Further, we foresee the development of well-organized work-study programs affording students a variety of work experiences and perhaps the opportunity to learn several trades before finishing high school. Business firms, unions, and schools may establish mutually advantageous cooperative programs to accomplish this end.

Most high school graduates who continue in school will attend two-year degree-granting community colleges, after which they may join the labor market, travel, or continue their education in graduate universities or professional schools. On the average, therefore, college graduates will begin their productive careers two years earlier than at present. Their lifetime incomes will be increased on this account, and society will reap the benefits of their longer participation in productive activities. The discounted value of their additional output is part of society's payoff for its allocation of resources to schooling in the early years.

PREKINDERGARTEN SCHOOL CHARACTERISTICS 31

More than at the elementary and secondary levels, prekindergarten instructional programs differ markedly in their organization, methods of teaching and learning, and types and amounts of materials and equipment. Since information about these factors and the expenditures they imply has not been systematically collected as for higher level institutions, we have derived estimates of expenditures per pupil in current-input schools from the experiences of several federally funded programs and from elementary school estimates. These per-pupil expenditure figures for prekindergarten programs are listed in Table 2.32 They suggest the important roles of paraprofessional instructional personnel and of medical, dental, and nutritional services which are included in "other expenditures." Professional teachers and equipment, on the other hand, account for smaller proportions of total expenditure than in elementary and secondary schools.

Table 2

SOURCE: Appendix A.

Future prekindergarten schools can best be characterized by their objectives: to prepare children for future social interaction in school and to provide rudimentary language, counting, and study skills.³³. Peer group and "next cohort" associations, and free exploration of the adult world of reading, writing, speaking, and computing via frequent presentation of artifacts and activities are the main instruction methods. Children who did not learn at home to speak "standard English" are exposed to it here as a second language, and all pupils have televised instruction for an average of one hour daily. There is a minimum of IQ categorization, overt testing, and discipline control whereas talking and group play are encouraged. Intensity of participation in new activities is an important part of learning at this level, and the children's progress is appraised in written reports by teachers and parateachers who observe their daily activities.³⁴

Preschool systems are administered locally and share, where possible, the medical, custodial, secretarial, cafeteria, and transportation services of existing primary schools.³⁵ Physical facilities are in full use for 240 days of the year and may be available to the community from early morning to late evening for custodial care of children.

Although the size of classes varies widely among schools and even from day to day within the same school, it is useful here to think of an average class as consisting of 20 children. A professional teacher is in charge of three such classes. He has at least a Lachelor's degree in child education including training in child and group psychology, the use of instructional equipment and techniques, paramedical practice, the counseling of parateachers and parents, and the management of school activities. Each class under his supervision has two parateachers and a teacher aide.

The parateachers have high school diplomas and certificates of completion of or examination from a six-month to two-year course in prekindergarten education including child and group psychology, fixed raining, and familiarity with two instructional specialties—for example stable sual techniques and handicrafts. Teacher aides are high school or college stable or parents who volunteer their time.

Classrooms consist of an open area containing most of the tables and chairs and a quiet corner for reading and puzzles. Along one wall is a work surface with running water and electricity. Every two classrooms share an audio-visual area which offers a television, and a tape/ cassette/record playing machine with a speaker and five to ten headsets. They also share a handicraft area containing potting wheels and various art materials.

Costing these resources at 1970 prices and augmenting the resulting figures for anticipated increases in the costs of educational inputs during the next three decades gives the exp nditure estimates listed in Table 2. These figures suggest that future prekindergarten schools will devote a much larger proportion of their total expenditure to paraprofessional instructional personnel than do current-input schools.

ELEMENTARY SCHOOL CHARACTERISTICS 36

More than half the per-pupil expenditure of current-input elementary schools was devoted in 1970 to professional instructional personnel. A large proportion was also spent on physical plant, as Table 3 indicates, but relatively little on equipment and paraprofessionals.

For future elementary schools, these proportions would be considerably altered, reflecting differences in objectives, organization, and methods. The objectives of future elementary schools are the following: to help children understand the philosophy and basic skills of research and acquisition of knowledge; to provide settings and accessories with which children can acquire specific skills in language and computation; to encourage understanding of the universe and man's social relationships and responsibilities; and to insure adequate nutrition. To accomplish these goals, future elementary schools emphasize interaction and self-instruction among pupils, encouraging development of interests and knowledge in specific areas selected by the individuals themselves. To this end there is less rigid scheduling of specific activities and freer and more random access to literary, audio-visual, graphic, and mechanical materials. The pupils, individually or in groups, pursue their own interests during part of the school day with teacher's observing, asking questions, and suggesting related activities the children might also want to investigate. During the rest of the day teachers direct group activities, with the same child belonging to different groups for different subjects, depending on his interests and abilities. Rather than a complex structure of specific skills, the school seeks to teach affection for the learning process itself.

SOURCE: Appendix A.

Overt testing and IQ categorization are minimized; instead, teachers evaluate pupils' and groups' total progress relative to "where they were." Nevertheless, the learning of students and classes is compared at several points with preestablished goals, and administrators periodically evaluate the use and success of school resources in meeting these goals. Evaluations by secondary school administrators of their incoming students' preparation is another useful check on elementary schooling.

The ratio of pupils to professional instructional personnel seems likely to continue falling, reaching 20:1 in future elementary schools. It stood at 24:1 in 1970. These professional teachers have at least a Bachelor's degree in primary school education, and each is assisted by a parateacher and teacher aide, who have qualifications similar to those described in the prekindergarten section.

Future elementary schools are within walking distance of children's homes in most areas and are used at full intensity for 240 days of the year. For each class of 20 children there is a large classroom with movable wall partitions. In their normal state these rooms have, in addition to an open central section, a quiet corner for individual activities, and audio-visual and laboratory areas. Contained in the latter are a television, a tape/cassette/record playing machine, a microfiche reader-printer, two or three typewriters, several Bunsen burners, chemistry laboratory equipment, and a small electric motor. Additional materials can be borrowed from the school library.

Instructional television and computer-assisted instruction are used, on the average, for two hours every school day by each student. Regional and national programming networks supply schools' needs in regard to both these capabilities.

Costing these resources at 1970 prices and correcting for anticipated increases in the costs of all educational inputs yields the expenditure estimates listed in Table 3. Paraprofessional teachers and equipment account for a larger proportion of expenditure in future schools, whereas professional teachers and physical plant are less important than in current-input schools. Overall, the savings from more intensive operation of the fixed physical facilities go into both personnel and equipment.

SECONDARY SCHOOL CHARACTERISTICS 37

Future secondary schools are designed to accept pupils who have progressed through prekindergartens and elementary schools of the future type. The objectives of these secondary schools are interrelated: to encourage individual pacing of learning in various disciplines, to offer structured training in fields of individual interest, to encourage a comprehensive appreciation of the interrelationships among facts and disciplines, to prevent students from committing themselves to specific life goals without exposure to many areas of skill and knowledge, to develop understanding of the operations and requirements of their social, political, and biophysical environment, and to insure that each person is prepared to employ his resources usefully upon graduation, either in a job or in additional schooling.

School organization and curriculum are arranged to achieve these goals. In particular, academic and vocational education are much less distinctly separated than in current-input schools. All education is directed toward achieving students' goals, whether they be extensive higher education or development of special skills which can be put to direct use in working and living. In this sense, schooling in fine arts, music, cinematography, and chiropractic are "vocational."

Similarly, future secondary education provides much of the basic knowledge previously taught in required lower-division college courses. Formerly upper division college courses of a "how to" nature are now also taught in high schools. These include nursing, computer programming and operation, and medical technology. To aid in learning these and other skills, off-campus apprentice practicums are widespread. Students with every kind of interest, including academic, may spend part of each month in a training program or job, though these experiences are concentrated during vacation periods which come during any part of the calendar year, leaving school facilities in year-round use. Through these practicums and other means, students and other members of the community have varied school-related contacts which should make school more a part of real life for students.

Learning-by-doing is also emphasized within the school by extensive use of literary, audio-visual, mechanical, electronic, and graphic materials. Students pursue their own interests with these materials but are encouraged to relate their interests to other disciplines and to general techniques of research and investigation. Individual work is not necessarily a virtue; studying, working, and testing together are encouraged.

Students are counseled frequently concerning their interests, short and long

term goals, and current and planned activities. Instead of being categorized by currently perceived potential and objectives, they are given every opportunity to change interests and goals. Upon 'eaving high school, they receive complete placement services—for college, specified training programs, jobs, and independent study and travel. At this point, e. In pupil has had many opportunities to do what he enjoys doing, pursuing these interests as far as he wishes with the assistance of teachers and others in the community. In cooperation, they have charted courses of skill acquisition or research in his interest areas. But he has been free to change interests and to learn at his own pace. Each student has also learned something of how skills and knowledge are acquired in many different disciplines; all his schooling has been directed toward skill in asking questions and finding answers in a variety of disciplines. Most important, he is now prepared to do something with his life which is both personally satisfying and useful to his community.

The pupil-professional teacher ratio remains at 20:1, the level at which it settled in the late 1960s in current-input secondary schools. These teachers are more highly trained than their prekindergarten and elementary colleagues since they teach many courses formerly offered only in colleges. A higher proportion of them are specialists—in audio-visual techniques, computer-assisted instruction, and counseling, for example—than in current-input secondary schools. For every three professionals, there is a parateacher who assists primarily in administrative and record-keeping matters.

Libraries and laboratories are upgraded to levels found in 1970 junior colleges, and equipment and materials needed for career education are much more extensive. In addition to these resources, the average student uses instructional television and computer-assisted instruction for two hours daily. Each student may have sufficient disc storage at his disposal to facilitate on-going computer research projects. The schools are in full use for 240 days of the year and may be used to varied extents by persons not directly in pursuit of a diploma.³⁸

Table 4 lists the expenditure estimates generated by costing all these resources at 1970 prices and adjusting for the anticipated increases in the prices of all educational inputs. Current-input and future schools at this level differ chiefly in the proportions of expenditure devoted to physical plant and to equipment.

HIGHER EDUCATION CHARACTERISTICS 39

The major difference between current-input and future institutions of higher education is organizational. The latter institutions consist of two types: colleges with two-year programs leading to Bachelor's degrees and various certificates of competency, and universities which offer advanced research and professional degrees.

With most of the required survey course work completed in high schools of the future type, undergraduate education in two-year colleges concentrates from the beginning on the student's primary fields of interest. Upon completion of a two-year degree program, he is prepared to (1) immediately enter useful employment, holding

either a certificate of competency in some set of skills or a Bachelor's degree, (2) enter a university to begin professional study leading to a Master's degree, professional degree (LL.B., M.D., and so on), or certificate of competency in an advanced skill, or (3) enter a university to begin study toward an advanced teaching or research degree (D.Phil., Ph.D.).

In most respects these two-year colleges resemble the middle two years of our present colleges⁴⁰ in which students are usually clear about their broad areas of interest (for example, physical science, literature, business) but are not encouraged to specialize further. For example, a student interested in doing graduate work in anthropology would cover a wide range of topics in the social sciences during his two college years. Survey courses in the arts and physical and biological sciences are behind him already, though he may take more work in these areas if he wishes. Another student, planning to get a job after two years of college, may specialize in social work or economics or may study for a teacher's license.

These examples illustrate the major objective of future higher education: to insure that each person, upon graduation, is prepared to employ his resources usefully, either in a job or in additional schooling. To reach this objective, good teaching, rather than research, is emphasized in colleges, and students are counseled frequently regarding their goals and present and planned progress.

In the graduate universities and professional schools where teaching is more a matter of example and individual guidance, research and its direction is a more important responsibility of the faculty than classroom teaching. These universities receive students who are already familiar with the areas of knowledge and methodology on the periphery of their fields of primary interest. They are now ready to specialize.

from future—stitutions of higher education there is considerably more opportunity—people of any age to enroll. They may study for a year, work or travel for one or—ny year—and then return. As a result, a much higher proportion of people learn result in secondary schools, work for several years, and then enter college. Similarly—course—maminations are not as important as subject matter proficiency tests, which is a statent may take whenever he feels prepared. He need not have any particular classes.

one-fifth of the students are enrolled in extended-campus degree programs; which day-to-day instruction is received at their homes via television. They are able to respond to questions through digital feedback cable television capabilities and to practice and request additional information by using a computer terminal in their home or community which is on-line to central processing and storage facilities at the college or university. These students return periodically to the campus or a regional center for counseling and testing, though much of this is also accomplished by television and computer.

At the college and university level the caveat in footnote 32 concerning perstudent expenditure figures becomes particularly important. Because student education is only one product of these institutions—new knowledge through research, and community service through extension activities are two other important outputs—the level of expenditures may not be as closely related to the number of students as at the lower levels. We have therefore not broken down our expenditure estimates at the higher education level into broad categories. Instead, results dependent on forecasts by these categories are based only on the more meaningful figures pertaining to the lower levels.

Expenditure per student in 1970 current-input institutions of higher education is \$3435. Future undergraduate colleges and graduate universities are estimated to spend \$8400 and \$13,455 per student, respectively. Anticipating that one-fourth of all students in future institutions of higher education will be enrolled in graduate universities, total expenditure per student in both kinds of institutions is \$9665. These estimates are the basis of our forecasts of total expenditures of colleges and universities, but it should be borne in mind that society's future demand for the products of research and extension activities will affect the true course of these expenditures quite independently of enrollment growth.

THREE PROJECTED RATES OF SCHOOL QUALITY IMPROVEMENT

The foregoing discussions describe two types of schools at each level. One type, current-input schools, is representative of actual schools in 1970. The other type, future schools, uses different kinds and amounts of educational resources, reflecting the schools' changed objectives and operations. Although all schools in 1970 are of the current-input type by definition, it is impossible so predict the speed at which our schools will change and improve. Three alternative assumptions about this rate of change are therefore made. The first is that schools will continue to employ the

same resources in the same proportions as in 1970. The prices of these resources will rise and they may become more productive for reasons discussed above on pages 2-4, but the magnitude of resources devoted to each pupil will not change, according to this assumption.

The second assumption is that by the year 2000, 30 percent of American schools will be of the future type. This possibility, referred to hereafter as *medium rate of improvement*, entails year-by-year changes in the kinds and amounts of resources per pupil employed in our nation's schools. The third assumption is that 80 percent of the schools will be of the future type by the year 2000. This *high rate of improvement* implies more rapid change and more expensive schooling in every year of the forecast period. The compound growth of expenditure per pupil implied by each of the three alternative projections is shown in Table 5.

Table 5

COMPOUND GROWTH RATE OF PROJECTED ANNUAL PER-PUPIL EXPENDITURE

	Compoun	d Growth Rate	(percent)
Level	Current Inputs	Medium Rate of Improvement	High Rate of Improvement
Prekindergarten Elementary Secondary Higher	2.7 2.7 2.7 2.7	3.1 3.1 2.9 2.5	3.5 3.7 3.2 2.1

SOURCE: Tables 2, 3, 4, and text.

The growth rates for higher education expenditures are computed on the basis of students ever attending an institution of higher education. Although future institutions at this level spend more per year for every enrolled student than do current-input institutions, the total amount spent for each student who ever attends a college or university is actually lower. This is because the average time required to earn a Bachelor's degree is two years less for students who came up through the future education system. How this adjustment was made in projecting aggregate expenditures is summarized in Appendix A, p. 38.

III. THE IMPACT OF FUTURE DEMOGRAPHIC TRENDS ON EDUCATION

Appendix Tables C-5 to C-30 give the detailed annual projections of expenditure per student and total expenditures by school level and cost category derived in this study. Projections of requirements for professional and paraprofessional instructional personnel are detailed in Appendix Tables C-31 through C-40. These data are the central product of this research and constitute raw material for many comparisons and contrasts concerning resource requirements of American education during the next three decades. In order to characterize the most important features of the projections and the manner in which some of our assumptions affect them, we will highlight the most important comparisons in the text.

EDUCATIONAL EXPENDITURE PROJECTIONS

According to Fig. 2, differences in population growth will affect relative spending by school level during the next three decades. Population Series B (column 5) will create requirements for relatively more expenditure at the prekindergarten and elementary levels and relatively less at the higher education level than will population Series E (column 3).⁴³ This result is due to the fact that higher fertility causes a lower population age structure and applies equally to the case of low enrollment rate growth (compare columns 4 and 6).⁴⁴

Columns 3 and 4 or 5 and 6 indicate the effects of enrollment rate growth, holding constant the underlying population growth rate. In both comparisons, a relatively large proportion of total spending is at the lowest and highest levels when enrollment rates grow more rapidly (columns 3 and 5). For example, with population Series E, elementary and higher schooling combined account for 47 percent of total educational expenditure when enrollment rates grow quickly (column 6) but for only 38 percent when they grow slowly (column 5). These variations arise because by far the largest differences between the fast and slow enrollment rate projections occur at the prekindergarten and higher education levels. These results, as well as those

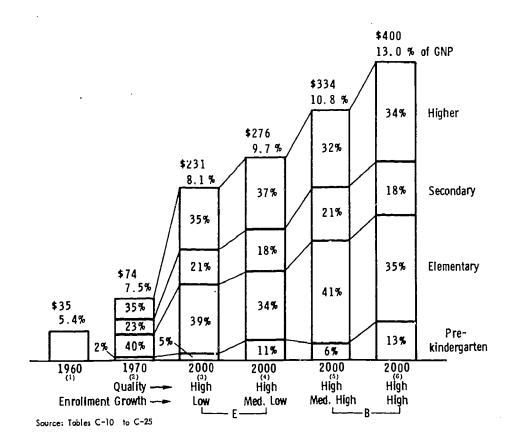

Fig. 2—The effects of population and enrollment growth on expenditures by level

(In \$ billion)

due to population growth differences, are substantially unchanged in the cases of current-input schooling and medium rate of improvement schooling (not shown). Furthermore, expenditures on prekindergarten schooling are a higher proportion of the total, and expenditures on secondary schooling a lower proportion in the year 2000 than in 1970, if schools improve at the high rate. This is true for all four enrollment projections.

The top of the columns in Fig. 2 indicates how various combinations of population growth and enrollment rate growth would affect total expenditures. Even for the high rate of improvement and the highest projected population growth (column 6), expenditures in the year 2000 would be less, relative to GNP, than the expenditure which results from simply projecting forward the growth of educational expenditures as a percent of GNP between 1960 and 1970. The latter proportion would be 13.8 percent in the year 2000. Of course, a slower rate of improvement, slower enrollment rate growth, or slower population growth will all reduce the level of expenditures in 2000. Based on our assumptions, then, educational expenditures are likely to grow less rapidly relative to GNP than they have in the past decade.⁴⁶

In 2000, a high rate of school improvement could be bought for only 8.1 percent of GNP if enrollment grows at the lowest projected rate (column 3). However, providing higher quality at about the same relative cost of society's resources as in 1970 must be balanced against the costs borne by persons who depend, directly or indirectly, upon the education sector for their livelihood. Some of these people—teachers, contractors and construction workers, manufacturers and sellers of educational equipment and materials, and their employees—will feel the pinch generated in an industry whose rate of growth is steadily declining. Indeed, many are already feeling it. In the long run—that is, by the year 2000—it is likely that requirements for instructional personnel will have continued to grow and that manufacturers and suppliers will have adjusted to changing market conditions in education and the rest of the economy. In the interim, however, the recent decline in numbers of children reaching school age is causing and will continue to cause economic and social problems, as in any industry whose growth levels sharply.

Turning now to Fig. 3, note first that with a high rate of improvement at the lower three school levels (columns 2 and 4), relatively less would be spent in the year 2000 on physical plant and "other resources," but relatively more on personnel and equipment than in current-input schools in 1970 or 2000 (columns 1 and 3). Furthermore, it appears that the rate of population growth does not influence the proportion of spending allocated to each category. For high enrollment rate growth this can be seen by comparing column 2, based on population Series E, with column 4, based on population Series B. A similar comparison for low enrollment rate growth (not shown) yields the same result.

Figure 3 also suggests the projected magnitude of the tradeoff between the quality of education and the number of people to be educated. Our projections indicate that by the year 2000 it will cost society \$32 billion more to support a school system characterized by current inputs (column 3) than one resulting from high rate of improvement (column 2), if in the first case population grows at the highest projected rate and in the second case at the lowest projected rate, and if enrollment in both cases grows at the high rate.

The variety of such choices that will face society is indicated in Fig. 4. Until 1983 it will be less expensive to provide current-input schooling for a rapidly growing enrollment than to assure medium or high rate of improvement schooling for an enrollment resulting from the lowest projected population growth. After 1983, on the other hand, medium rate of improvement schooling for a slowly growing enrollment becomes less expensive than schooling of a lower improvement rate for a apidly growing enrollment. Even high improvement rate schooling is less expensive under these conditions after 1991. And by the year 2000, current-input schooling for the most rapidly growing enrollment is clearly the most expensive of these three alternatives.

Table 6 provides a summary of these tradeoffs by showing the percent of GNP in 2000 that will be spent on education under various assumptions concerning population growth, enrollment rate growth, and the improvement rate achieved for schooling. Looking down the columns, one sees that for the same enrollment growth, educational expenditures will be somewhat higher for higher rates of school im-

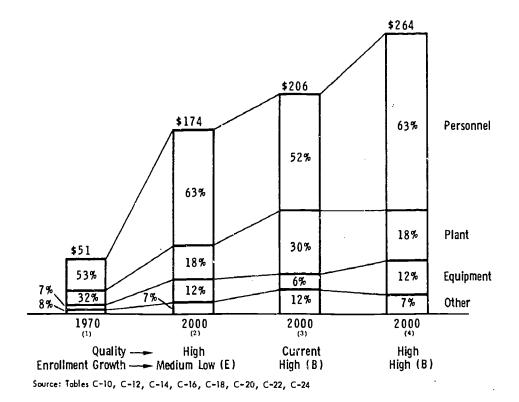

Fig. 3—The effects of quality and population growth on types of non-college expenditures (In \$ billion)

SOURCE: Table C-30.

provement. Now looking across the rows, note that educational expenditures will be a larger proportion of GNP if either enrollment rates or the population grow more rapidly. Of the three factors—rate of quality improvement, enrollment growth, and population growth—population growth clearly makes the largest difference in the size of educational expenditures in 2000.

Comparing cells in different columns and rows of Table 6 shows that schooling of superior quality can be had for a lesser proportion of our national output if population grows less rapidly. This point can be illustrated more vividly by assuming that we will spend 10 percent of our GNP on education in the year 2000. What type of education would this buy under the two population projections if enrollment rates increase relatively rapidly? With the larger population (Series B) this expenditure would provide 7 percent of the students with our assumed high quality education, while 93 percent would receive education characterized by the same kind of school inputs used in 1970. With the same proportion of GNP spent on education of the smaller population (Series E), all students could receive high quality schooling.

PROJECTIONS OF REQUIREMENTS FOR INSTRUCTIONAL PERSONNEL 49

The detailed projections of instructional personnel requirements which occupy Appendix Tables C-31 through C-40 are summarized in Fig. 5. A comparison of the four columns representing the year 2000 suggests that prekindergarten teachers and prekindergarten parateachers, combined, will be a larger proportion of the total if either population or enrollment rates grow rapidly. In any case, they will consti-

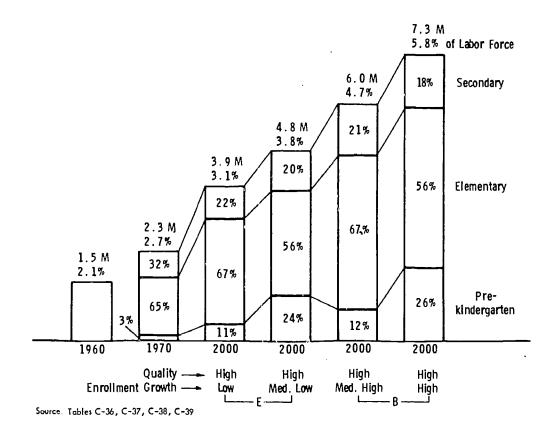

Fig. 5—The effect of population and enrollment growth on requirements for instructional personnel

tute a much larger proportion than in 1970, and secondary school teachers and parateachers will constitute a much smaller proportion. As in the case of expenditures by school levels (Fig. 2), the reasons for these relationships are that (1) the two enrollment rate assumptions differ more markedly at the prekindergarten level, and (2) faster growing populations have lower age structures. A figure drawn for current-input schooling or medium rate of improvement schooling would show similar percentage distributions, though the height of the year-2000 columns would be somewhat reduced.

At the top of the columns are the numbers of instructional personnel in millions at the lower three school levels, as well as corresponding percentages of the labor force. Series B population growth, with either of the enrollment rate assumptions, implies that instructional personnel will be a larger proportion of the labor force in the year 2000 than would be expected on the basis of projecting their growth between 1960 and 1970. Such a projection yields a figure of 4.5 percent in 2000. Hence, although it is anticipated that a higher proportion of the labor force will be employed

as instructional personnel at these school levels 30 years hence, the rate of population growth will make a considerable difference, in both the proportion and the absolute number.⁵⁰

Although we have not projected requirements for instructional personnel in institutions of higher education, several speculations seem warranted. First, to the extent that society rapidly adopts schools of the future type, these requirements should be lessened. This is expected because of (1) the elimination of two years of college work in Bachelor's degree programs in future colleges and (2) the participation of up to one-fifth of all students in extended-campus programs which make extensive use of television and computer-assisted instruction. ⁵⁰ Second, more rapid enrollment rate growth will induce higher requirements for instructional personnel, as will increased population growth with an 18 to 25 year lag. ⁵¹ Third, it is an entirely different matter to speculate about society's future demand for the products of research and extension activities. And this factor, perhaps as much as population and enrollment rate trends, will influence the number of "instructional" personnel in colleges and universities of the future.

On balance, it seems reasonable to expect that classroom teachers in institutions of higher education will decrease as a percent of the labor force and perhaps absolutely if society adopts a high rate of schooling improvement and if population and enrollment rates grow slowly. Nevertheless, the number of professional personnel employed by these institutions may grow, even in this situation, if society's demand for the products of research and extension rises sufficiently quickly.

IV. CONCLUSIONS

The projections resulting from this research suggest the following conclusions:

- 1. Expenditures on education in the United States will be very sensitive to population growth during the next 30 years. For given rates of school quality improvement and enrollment rate growth, total expenditures on education in the year 2000 will be about 45 percent higher with population growth implying an average three-child family in 2000 (Series B) than with population growth implying an average two-child family (Series E).
- 2. Educational expenditures will be significantly affected by enrollment rate growth. Expenditures in 2000 will be about 20 percent higher if enrollment rates increase at the faster pace, given the same rates of school quality improvement and population growth.
- 3. Expenditures at the lower schooling levels—prekindergarten and elementary—will be a larger proportion of total educational expenditures if population growth is rapid than if it is slow.
- 4. Similarly, the proportion of prekindergarten, elementary, and secondary instructional personnel who are employed at the lower two levels will be larger for higher population growth and enrollment rates.
- 5. The distribution of non-college educational spending among broad categories—instructional personnel, physical plant, and equipment—does not appear sensitive to population growth or enrollment rate variations.
- 6. Educational expenditures are unlikely to rise as fast, relative to GNP, as they did in the decade of the 1960s, even with substantial infusions of new technology and even at the highest projected enrollment growth rate. If the educational improvements identified in this report are adopted relatively quickly, rapid growth in school enrollment (based on Series B) will require about 13 percent of GNP to be spent on education in the year 2000. Slow enrollment growth (based on Series E) will require about 8 percent, an increase of only one-half percent over the 1970 figure. Slower adoption of improved methods and technologies will slow the growth of educational spending accordingly.
- 7. There will be a large financial tradeoff in the coming decades between the quality of education and the number of people to be educated. This tradeoff can be illustrated by assuming that enrollment rates will increase relatively rapidly and

that we will spend 10 percent of our GNP on education in the year 2000. With the "three-child" population (Series B) this expenditure would provide 7 percent of the students with all of the educational improvements identified in this report, while 93 percent would receive education characterized by the same kind of school inputs used in 1970. With the same proportion of GNP spent on education of the "two-child" population (Series E), all students could receive high quality schooling.

NOTES

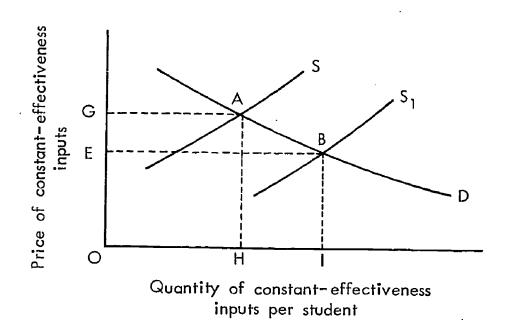

- 1. The best entries into this field are *Education Daily*, Capital Publications, Inc., Suite G-12, 2430 Pennsylvania Ave., N.W., Washington, D.C. 20037, and the monthly "Education in America" supplement in *Saturday Review*. Vance Grant, *Digest of Educational Statistics*, 1970 Edition, Department of Health, Education and Welfare, Office of Education, National Center for Fducational Statistics, September 1969; and other publications of the Office of Education.
- 2. Much of the research is summarized and reviewed in Harvey Averch et al., How Effective is Schooling? A Critical Review and Synthesis of Research Findings, R-956-PCSF/RC, The Rand Corporation, Santa Monica, January 1972. In addition, the last several years have witnessed considerable critical writing based on observation and opinion rather ian formal research. Particularly important are: "85 Theses to Stimulate Academic Reform," Assembly on University Goals and Governances, reprinted in The Chronicle of Higher Education, January 18, 1971. John I. Goodlad, "A Radical Concept of 'School' in A.D. 2000," Washington Post, December 13, 1970. Less Time, More Options: Education Beyond the High School, by the Carnegie Commission on Higher Education, McGraw-Hill, New York, 1971. Open Door, Center for Urban Education, Washington, D.C., 1971. Report of the Governor's Commission on Educational Reform, State of California, Sacramento, January 1, 1971. Charles E. Silberman, Crisis in the Classroom, Random House, New York, 1970. Urban School Crisis: The Problem and Solutions, Final Report of the Task Force on Urban Education of the Department of Health, Education and Welfare, January 5, 1970; and the works of George Dennison, Caleb Gattegno, Paul Goodman, James Herndon, and John Hold.
- 3. Much technical information and informed speculation in this area is contained in Roger E. Levien (ed.), Computers in Instruction: Their Future for Higher Education, R-718-NSF/CCOM/RC, The Rand Corporation, Santa Monica, July 1971, and Sidney G. Tickton (ed.), To Improve Learning: An Evaluation of Instructional Technology, R. R. Bowker Company, New York, Volume I, 1970 and Volume II, 1971.
- 4. All prices and expenditures in this report are in dollars of constant 1970 purchasing power.

5. William J. Baumol and William B. Bowen have analyzed the general phenomenon of rising input prices in industries which experience insufficient corresponding productivity increases. They apply their insights in an exhaustive study of the performing arts; see Baumol and Bowen, *Performing Arts—The Economic Dilemma*, The M.I.T. Press, Cambridge, 1966, especially pages 162-172.

6. Resources are drawn into the industry that pays them a higher price. Consequently, the supply of these resources to other industries is reduced, and their price rises there as well. In the case of labor resources, a higher wage for similarly trained people in other industries is often a powerful bargaining tool in union negotiations.

7. Increased effectiveness of educational inputs can be interpreted as an increase in the supply of constant-effectiveness inputs from S to S_1 . The quantity purchased then rises from OH to OI. If the demand

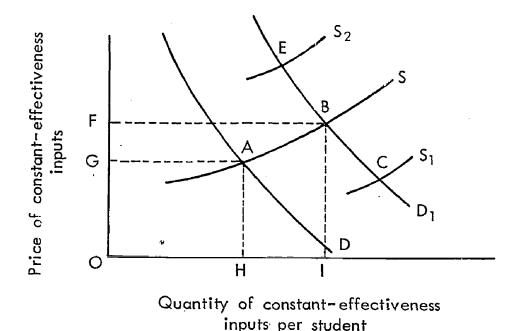

for these inputs is elastic over the relevant input range, expenditure on inputs increases from AGOH to BEOI. Even though the price of an input of constant effectiveness has fallen from OG to OE, actual inputs have increased in quality and now command a higher price. The increase in total expenditure is shared among them.

In actuality, although school inputs may have become more productive during the last decade, it is unlikely that demand for them has remained constant and that it is sufficiently elastic for all inputs and at all school levels to account for the observed behavior of expenditures and resources per pupil.

8. An increase in demand from D to D₁ raises expenditures on educational resources from AGOH to BFOI, while the amount of resources used increases

from OH to OI and their price rises from OG to OF. However, the same expenditure increase could also have resulted from increasing demand accompanied by growing productivity of school inputs (shifting the supply curve out to S_1) r rising prices of inputs without corresponding productivity gains (shifting the supply curve back to S_2).

In the special case of unitary demand elasticity, the demand shift produces the same expenditure change, regardless of supply shifts. However, the nature of the supply shift determines the amount of additional resources bought with the greater expenditure. If rising resource productivity increases the supply of constant-effectiveness inputs, the amount of those resources per pupil increases to the level corresponding to point C. Alternatively, if pressures from other sectors cause input prices to rise without corresponding productivity increases in education, the same expenditure increase raises resources per pupil only to the level corresponding to point E.

In the general case, different combinations of demand and supply shifts are required to produce the same expenditure change, but the conclusion is unchanged. The only quantity we are able to observe—expenditure per pupil—is the same in any case, but differences in the quality of schooling may be substantial. Without better conceptual and statistical measures of input effectiveness, we can only guess the extent to which we have bought better educational resources with our rising expenditures.

9. For a short and perceptive discussion of some of these problems, see June O'Neill, Resource Use in Higher Education: Trends in Output and Inputs, 1930-1967, Carnegie Commission on Higher Education, Berkeley, 1971, Chapter 5. Also of interest is Harvey Averch et al., op. cit. Problems of defining and measuring outputs

in several other service industries are analyzed in Victor R. Fuchs (ed.), *Production and Productivity in the Service Industries*, Studies in Income and Wealth, No. 34, hational Bureau of Economic Research, New York, 1969.

- 10. This number is the mean of the eight annual growth rates implied by the income projections prepared as of March 10, 1971 by the Department of Commerce for the Commission on Population Growth. The eight projections are based on the B, C, D, and E population projections and two assumptions concerning future reductions in annual hours of work per man.
- 11. One might expect that such increases in real prices would be more likely for personnel than for buildings and equipment, since the latter are produced in industries that presumably share in general technological improvement. New buildings and equipment should accordingly be increasingly productive at the same prices. In fact, however, all broad categories of physical plant and equipment have grown more expensive, in real terms, during the decade of the 1960s, as we indicated above on page 2. There seems no reason to assume that this trend will change.
- 12. T. W. Schultz estimates that foregone earnings were about 60 percent of total expenditures on education at both the high school and college levels in the United States in 1956. See *The Economic Value of Education*, Columbia University Press, New York, 1963, pp. 27-32. W. Lee Hansen and Burton A. Weisbrod in a study of California higher education indicate that the same proportion in 1964-65 ranged from 49 percent for lower division students at the University of California to 70 percent for students at California junior colleges. *Benefits, Costs, and Finance of Public Higher Education*, Markham, Chicago, 1969, pp. 41-49.
- 13. Administrative costs were less than 4 percent of the current expenditures of U.S. public elementary and secondary schools in 1967-68, the latest year for which data see available.
- I Furthermore, we know of no evidence to suggest that the lost of providing comparative schooling varies widely by regions of the country. Nevertheless, since the projections presented later in the report are reported for alternative rates of quality improvement in education, one could evaluate their relative likelihood according to his expectations about the speed of population movements to areas with better mality schools.
- 123. See Appendix A for data sources and methodology for the enrollment projections. The annual projections appear in Tables C-1 through C-4.
- 13. In this study, we follow the Census convention of restricting prekinder-garten schools to institutions having instruction as an important and integral part of the sprograms.
- IT. At the high growth rate, the prekindergarten enrollment rate will reach in 2000 the low rate of enrollment of children aged five in kindergarten and elementary school projected by the Bureau of the Census for that year. These year-2000 percentages correspond to pupils attending a full six-hour school day. The expenditure projections for the slow enrollment rate increase apply to a 60 percent half-day enrollment rate in 2000 as well as to a 30 percent full-day rate. Similarly, the projections for the fast enrollment rate increase are consistent with 66 percent of the pupils attending full day and 34 percent attending half day.

- 18. Most of the 4.4 percent not enrolled in 1970 are institutionalized children not capable of attending regular elementary schools. Any decreases in this number will result essentially from reductions in congenital health defects and early environmental deprivation.
- 19. These figures represent the number enrolled in the most important age group (5 to 13 for elementary, 14 to 17 for secondary, and 18 to 24 for higher education) as a percent of total population in that age group. The actual projections for each level include pupils outside these age limits.
- 20. Paraprofessionals are defined in this study as persons directly involved in the instructional process who are not licensed teachers.
- 21. The tendencies and goals summarized in the following paragraphs have been widely discussed in the popular and professional literature concerning education. They can be found repeatedly in the references cited in footnotes 1, 2, and 3. We will accordingly try neither to trace each idea to its original source nor to give the impression, by citing lists of supporting sources, that informed opinion overwhelmingly agrees with our predictions. The first effort would be impossible; the second misleading. Further, it is not argued here that these changes are necessarily desirable, only that they are probable.
- 22. The importance of this function has been stressed with increasing frequency in the last several years, particularly with regard to the place of vocational or career education in the secondary curriculum. For example, U.S. Education Commissioner, Sidney P. Marland, Jr., has often emphasized this function (see summaries of his speeches in *Education Daily*, op. cit., January 25, 1971 and May 7, 1971), as did the 1971 California Governor's Commission on Educational Reform (see their *Report*, page 32).
- 23. Breaking of the so-called "educational lockstep" has been proposed by, among others, the Higher Education Secretariat, an informal group including 12 major organizations such as the American Council on Education and the Association of American Universities. See *The New York Times*, August 8, 1971, page E7.

Stauffer, "Instruction in Initial Reading Under Computer Control: The Stanford Project," Educational Technology Research Reports Series, Englewood Cliffs, N. J., Educational Technology Publications, 1971; Lawrence Parkus, "Computer Assisted Instruction in Elementary/Secondary Education: The State of the Art," in Tickton, op. cit., 1970. F. W. Blackwell, "The Probable State of Computer Technology by 1980, with Some Implications for Education," P-4693, The Rand Corporation, Santa Monica, September 1971; K. L. Zinn, "List of Projects Using Computers in Instruction" (unpublished paper), 1969.

- 27. Our confidence is not complete. See Appendix B.
- 28. See page 2.
- 29. The Bureau of the Census reports that the proportion of children aged three to five enrolled part or full time in any preschool program rose from 25 percent in 1964 to nearly 38 percent in 1970.
- 30. The Wall Street Journal, September 14, 1971, reports that about 100 school districts now have some sort of a year-round program, whereas only a few had such programs five years ago. More than 1000 other districts are studying their feasibility. Also see Thomas R. Driscoll, "School Around the Calendar," American Education. March 1971.
- 31. Appendix A gives data sources and methodology for the prekindergarten expenditure estimates.
- 32. Measures of inputs or expenditures per pupil are in general not very reliable guides to school decisionmaking or to cross-school comparisons. See Sue A. Haggart et al., Program Budgeting for School District Planning: Concepts and Applications, RM-6116-RC, The Rand Corporation, Santa Monica, November 1969. However, these measures produce usefully broad comparisons and contrasts for our specific purposes—i.e., to study aggregate tradeoffs between future enrollment and future school quality.
- 33. The proponents of early childhood education argue not only that young children are able to learn much more than they are customarily exposed to, but also that early learning tends to produce better adjusted persons with larger capacities to continue learning. See Robert D. Hess and Roberta Meyer Bear (eds.), Early Education: Current Theory, Research, and Action, Aldine Publishing Company, Chicago, 1968. There is, in addition, a very different benefit to society when facilities for the care and schooling of young children are widely available. This benefit arises from the opportunities mothers then have to continue their own schooling or work outside their homes, thereby enriching their own lives and incomes as well as society's stock of productive resources and output of goods and services. On the other hand, economic theory suggests that average family size will be larger than it would have been in the absence of widely available prekindergarten programs. These effects may be substantial and important; they should certainly be considered in any evaluation of the desirability of various prekindergarten programs. Even for our present purposes they should ideally be taken into account since they affect the size of future population and per-capita GNP. However, limitations of our current research effort have precluded this possibility.
- 34. Some of these features of future prekindergarten schools, as well as of future elementary schools, considered below, are prominently discussed in the "open classroom" literature. See, for example, *Children and Their Primary Schools* (Plowden Report), A Report of the Central Advisory Council for Education (England), Vol. 1, The Report; and Vol. 2, Research and Surveys, Her Majesty's Stationery Office, London, 1967; and *Open Door*, Center for Urban Education, Washington, D.C., 1971.
- 35. Although federal prekindergarten programs have induced most of the increased enrollments of recent years and promise to expand in the future, a variety

of delivery modes for prekindergarten instruction may well arise. Programs may be organized, for example, by unions or employers at work sites, by national franchise organizations, by cooperative neighborhood groups, by individuals for profit, or by the public school system. Public funds may subsidize any of these. Features of federal and state legislation in this area will certainly affect these delivery patterns. Even without subsidization, some employers have been turning to instructional day care programs as a way of attracting female workers and reducing absenteeism.

- 36. Appendix A gives data sources and methodology for the elementary school expenditure estimates.
- 37. Appendix A gives data sources and methodology for the secondary school expenditure estimates.
- 38. The Census projections of enrollments at the secondary grades unfortunately do not take account of possible rapid increases in the number of adults who use secondary school facilities, whether for vocational retraining or personal satisfaction.
- 39. Appendix A gives data sources and methodology for the higher education expenditure estimates.
- 40. Under the pressure of increasing costs, colleges and universities around the country are now experimenting with shortened degree programs. California's state colleges and the State University of New York, the Nation's largest higher education systems, began pilot three-year programs in Fall 1971. Among others, Harvard and Princeton Universities are seriously studying such possibilities. Moves in this direction may received support from such study teams as the Carnegie Commission on Higher Education (Less Time, More Options: Education Beyond the High School, op. cit.) and the HEW task force on higher education headed by Frank Newman (see, for example, The New York Times, March 9, 1971, page 45). Moreover, both these study teams have urged the rapid creation of many new two-year community colleges, and the Carnegie Commission predicts that these institutions will be the fastest growing institutions of higher education in the decade of the 1980s, in terms of numbers of students ("New Students and New Places," Carnegie Commission on Higher Education, October 1971).
- 41. These ideas recur frequently in the writings of leading educators and education critics. Charles Silberman, the Newman Task Force, the Carnegie Commission on Higher Education, the Higher Education Secretariat, Dr. William J. McGill (President of Columbia University), Dr. John I. Goodlad (Dean of the Graduate School of Education, UCLA), and a study panel of the American Association of Arts and Sciences have been among those calling for greater diversity and flexibility in our processes of higher education.

The English Open University is an early model for extended-campus instruction via television. In this country the Chicago City Junior College has offered such a program for 15 years (*TV College—The Fifteenth Year*, the Chicago Educational Television Association, Chicago, Illinois, September 1970), and the TAGER network in Texas is five years old (*Annual Report, 1969-70*, The Association for Graduate Education and Research of North Texas, Southern Methodist University, Dallas, Texas, October 1970). The University of Maine and the new Empire State College

of New York are planning similar programs. For further information, see *Multi-Media Systems*, 11 Project Descriptions of Combined Teaching Systems in Eight Countries, Internationales Zentralinstitut Für Jugend-und Bildungsfernsehen, 8 München 2, Rundfunkplatz 1, 1969 (?), English.

- 42. June O'Neill estimates that student instruction may currently account for only half of the output of average institutions of higher education. This proportion may have declined over time, and it varies widely among schools. (Resource Use in Higher Education: Trends in Output and Inputs, 1930 to 1967, op. cit., page 1.)
- 43. To the extent that children in prekindergarten schools would otherwise have been schooled at home, expenditures of these schools overstate the true cost of this schooling to society. Some of the resources that would have been required for home schooling can now be allocated to other productive pursuits. The time of mothers is such a resource. Nevertheless, school expenditures, which are the focus of this research, will increase with the growth of prekindergarten enrollment.
- 44. See Donald J. Bogue. Principals of Demography. Wiley, New York, 1969, Figure 7-1, p. 149.
 - 45. See Table 1.
- 46. The GNP projections used to calculate these percentages were made by the Department of Commerce based on alternative assumptions about population growth and reduction in hours of work. They do not take account of two factors which will raise GNP in a society where schooling is improving at a high rate, as we define it. First, labor force participation of mothers will be higher because the availability of prekindergarten schools frees some of timeir time for work outside their homes. Second, most college graduates will have two additional years in the labor market during a very productive period of their lives. The resulting additions to GNP cause educational expenditures to be lesser proportions of GNP in the year 2000. The percentages corresponding to the year 2000 in Fig. 2 are, on this account, biased upward.

The magnitude of the part of the bias resulting from neglecting the additional working years of college graduates can be roughly suggested. Assume that one-third of the undergraduates enrolled in any year will graduate in that year, that all graduates are employed in the labor market, that the annual salary foregone at this age by staying in school is \$6000 in 1970 prices, and that salaries increase during the 30-year period at the same rate as real per-capita disposable income. Under these conditions, if all schools are of the future type, GNP in the year 2000 will be 3 to 5 percent higher than the Department of Commerce projection.

- 47. See Fig. 5.
- 48. See Fig. 1.
- 49. These projections assume that three-fourths of the instructional personnel in future schools will choose to work for the full 240-day school session while the remainder continue to work 180 days.
- 50. For reasons discussed in footnote 46, the Department of Commerce projections of the labor force, on which the percentages in Fig. 5 are based, are biased downward if schools improve at the fast rate. This bias should cause all the year-

2000 labor force percentages to be slightly below those given in Fig. 5, but it should not affect the differences implied by varying rates of population growth.

51. Since secondary school teachers employed in future schools will be more highly trained, the total number of teachers demanding a given level of graduate education may not change much, for given population growth, if schools improve at the high rate.

Appendix A

METHODS OF PROJECTING ENROLLMENTS AND ESTIMATING EXPENDITURES PER PUPIL

ENROLLMENT PROJECTIONS

A. Prekindergarten enrollment projections. Full-day equivalent enrollment in prekindergarten institutions of children aged three to six was estimated for 1970 as the sum of full-day enrollment and one-half of part-day enrollment. (Department of Health, Education and Welfare, Office of Education, *School Enrollment*, October 1970, Table 6, page 24.) The sum, 986,000, was 6.3 percent of the population aged three through six in 1970. The high enrollment rate projection assumes that this percentage will be augmented annually by 2.55 percent, reaching 83 percent in the year 2000. At this rate of growth, the prekindergarten enrollment rate in 2000 will reach the low rate of enrollment of children aged five in kindergarten and elementary school projected by the Bureau of the Census for that year. The low prekindergarten enrollment rate projection assumes that the 1970 rate of 6.3 percent will grow annually by 0.79 percent, reaching the arbitrary level of 30 percent in the year 2000.

Each of these two enrollment rate projections was multiplied for each year by the number of children aged three to six in Census population projections B and E. The four resulting projections, designated as high, medium-high, medium-low, and low, are defined and listed in Table C-1.

These figures refer to full-day equivalent enrollment of children in prekinder-garten institutions having instruction as an important and integral part of their program. (*Current Population Reports*, Series P-20, No. 222, June 28, 1971, page 8.) One may roughly compare these projections with past trends by noting that the proportion of children aged three to five enrolled part or full time in any preschool program (including purely day care) rose from 25 percent in 1964 to almost 38 percent in 1970 and an estimated 40 percent in 1971 (Bureau of the Census).

B. Elementary and secondary enrollment projections. The projections listed in Tables C-2 and C-3 were made by the Bureau of the Census for the Commis-

sion on Population Growth. Two enrollment rate assumptions were applied to each of the B and E population projections. The high assumption is an extrapolation of the trends in age-sex-specific enrollment rates between 1950-52 and 1967-69. The low assumption was formulated by averaging the high projected rates and the enrollment rates for 1967-69. It was assumed that the distribution by school level would remain constant within age groups.

C. Higher education enrollment projections. Four projections were constructed by the Census Bureau using population Series B and E and two enrollment rate projections formulated as in the elementary and secondary cases. Unlike these two latter cases, however, our conception of higher education in the year 2000 implies a change in the Census enrollment figures. Specifically, students in this future school system will, on the average, earn a Bachelor's degree or its equivalent in two, instead of four, years. Since there are other differences, as well, between current input institutions and future institutions of higher education, we have, for ease of calculation, included all the effects of society's adoption of the future institutions in the rate of change of expenditures per student. Hence, Table C-4 lists the Census projections, but the aggregate expenditure figures for the medium and high trends in school improvement are consistent with enrollments which have been reduced to correspond with our description of future higher education institutions and with the alternative speeds of adoption. In all cases, however, our projections imply the same numbers of people having attended college as do the corresponding Census projections.

ESTIMATES OF EXPENDITURES PER PUPIL

A. Definitions of expenditure categories:

Professional instructional personnel includes all personnel who are licensed to teach except school system administrators. These include counselors, various specialists, and principals.

Paraprofessional instructional personnel includes all persons directly involved in the instructional process who are not licensed teachers. In the future schools described in the text, these people have successfully completed post-high school training programs of six months to two years.

Physical plant expenditures include operation and maintenance of plant, fixed charges, capital outlay minus expenditures on new equipment, and debt service.

Expenditures on *equipment and other instructional resources* include current funds expenditures on books, laboratory supplies and other instructional materials, as well as capital expenditures on new equipment.

Other expenditures include school system administration, and health, attendance, transportation, and food services.

B. Expenditures per prekindergarten pupil. Expenditure per pupil in current prekindergarten schools is given in Table 2 as \$830 and is estimated as follows. Expenditure per pupil in Headstart schools for 1969 was for three quarters,

and total Headstart expenditures allocated to pupils was \$208.5 million. Alternatively, ESEA Title I preschool programs expended \$348 per pupil for three quarters. (Evaluations of the War on Poverty: Education Programs, Resource Management Corporation, March 1969, Tables 18 and C-2.) Full-day-equivalent enrollment of children aged three to five was estimated for 1969 by assuming that part-day pupils attend one-half day, on the average. (Full- and part-day enrollments of children aged three to five are given in Department of Health, Education and Welfare, Office of Education, Preprimary Enrollment Trends of Children Under Six: 1964-1968, 1969, Table 9, page 18.) This enrollment figure was augmented by 3 percent to account for six year olds in prekindergarten programs. This seems reasonable since 10 percent of those enrolled were aged five to six in 1969. Then, assuming that ESEA Title I expenditure per pupil was the average for all non-Headstart prekindergarten programs gives an estimate for 1969 expenditures on non-Headstart prekindergarten schooling of \$237.2 million. The sum of Headstart and non-Headstart expenditures is thus \$445.7 million. Dividing by estimated 1969 full-day equivalent enrollment of pupils aged three to six, 573,000, yields an estimate of 1969 expenditure per pupil of \$777. This figure was converted to the 1970 estimate of \$830 by applying the 1969-70 percentage increase in per-capita disposable income in current dollars (a 7 percent increase).

Because of the great variety among prekindergarten institutions and the lack of detailed cost data, we have estimated the expenditure breakdown for current-input schools by adjusting the percentage distribution for current elementary schools according to generally observed differences between the two levels of schooling. Expenditure on professional personnel, those with the equivalent of a college degree and a teacher's license, is reduced from 52 percent for elementary schools to 17 percent for prekindergarten schools, while expenditure on paraprofessional people is increased from 2 to 32 percent. Expenditure on physical plant is reduced somewhat, and expenditure on other inputs is increased substantially to reflect the nutritional, medical, and dental programs in most federally supported prekindergarten programs.

Expenditure per pupil in future prekindergarten schools is also listed in Table 2 and is estimated in two steps. First, we estimate expenditures on five categories of inputs having 1970 productivity and costs. Second, we increase all these expenditures to the level that would result from an annual cost increase of 2¾ percent. Specifically, professional instructional personnel expenditures assume one professional teacher for every 60 pupils, paid at the 1970 elementary rate of \$9025 for a 180-day school year. Expenditures for paraprofessional personnel pay for two paraprofessionals, each paid \$5000, for every 20 pupils. Physical plant expenditures are anticipated to be the same as in elementary schools, with facilities in use 240 days of the year. In addition to the \$42 per pupil spent on equipment and other instructional resources in current-input schools, future schools spend \$25 per pupil for one hour daily of instructional television for each pupil, \$1.50 for language laboratory equipment, and \$1.50 for art and handicraft materials. (The last two figures each reflect the use of \$300 worth of equipment for each two classes of 20 students, with the equipment having an average life of five years. See Appendix B for derivations

of the instructional television expenditure estimate.) Finally, expenditures on other inputs fall to the same percentage as in future elementary schools, reflecting an anticipated shift of expenditures on medical and dental care from school budgets to other public or private accounts.

All expenditure figures are then augmented by a factor corresponding to average yearly cost increases of 2% percent.

C. Expenditures per elementary pupil. Since there exist no national expenditure data for elementary and secondary schools separately, we have had to estimate the figures for current-input schools that appear in Tables 3 and 4. First the 1970-71 expenditure per pupil enrolled in regular public and nonpublic elementary and secondary schools, \$917 (Department of Health, Education and Welfare, Office of Education, Digest of Educational Statistics, 1970, Table 22, page 18), is allocated among the five expenditure categories according to the percentage breakdown of 1967-68, the latest year for which figures are available (calculated from Department of Health, Education and Welfare, Office of Education, Statistics of Local Public School Systems, 1967-68, Finances, Table C, page 6; Table F, page 9; and Table G, page 10).

For each category of expenditure, separate estimates for elementary and secondary schools were then obtained by applying the ratio of elementary to secondary expenditures of that type in California schools in 1968-69 (California State Department of Education, *California Public Schools Selected Statistics, 1968-69*, Table IV-6, page 76; Table IV-7, page 77; and Table IV-8, page 78), and by constraining these estimates so that the implied sum of total elementary and secondary expenditures equals the total expenditure of that type obtained by multiplying the original combined per-pupil figure by combined national elementary and secondary enrollment. In algebraic terms, if, for some expenditure category

```
E_{t,u.s.} = total elementary and secondary expenditures, U.S. 

E/N_{e,cal} = expenditures per pupil in California elementary school districts 

E/N_{e,u.s.} = estimated expenditures per pupil in elementary schools, U.S. 

E/N_{s,u.s.} = estimated expenditures per pupil in secondary schools, U.S. 

N_{e,u.s.} = elementary school enrollment, U.S. 

N_{s,u.s.} = secondary school enrollment, U.S.
```

then we calculate the numbers of interest, $E/N_{e,u.s.}$ and $E/N_{s,u.s.}$, as follows.

$$\begin{array}{lll} K = E_{t,u.s.} \div [(E/N_{e,cal}) \times (N_{e,u.s.}) + (E/N_{s,cal}) \times (N_{s,u.s.})] \\ E/N_{e,u.s.} = K \times (E/N_{e,cal}) \\ E/N_{s,u.s.} = K \times (E/N_{s,cal}). \end{array}$$

These equations imply that

$$(E/N_{e,u.s.}) \, imes \, (N_{e,u.s.}) \, + \, (E/N_{s,u.s.}) \, imes \, (N_{s,u.s.}) \, \, = \, E_{t,u.s.}$$

These calculations yield estimates of 1970 total expenditures per pupil in elementary and secondary schools of \$830 and \$1130, respectively. The estimates by expenditure categories are listed in Tables 3 and 4. According to these estimates, expenditure per elementary pupil is 73 percent of expenditure per secondary pupil. We attempted to check this proportion by making use of the identity

$$(E_e/N_e) \times (N_e) + (E_s/N_s) \times (N_s) = E_t$$

where

 E_e/N_e = state expenditure per pupil in elementary schools E_s/N_s = state expenditure per pupil in secondary schools

 E_t = state total expenditures on elementary and secondary education

 N_e = elementary enrollment in the state N_s = secondary enrollment in the state

 N_t = total elementary and secondary enrollment in the state.

Rearranging terms gives

$$E_t/N_t = E_s/N_s + (E_e/N_e - E_s/N_s) \times (N_\epsilon/N_t).$$

This equation was estimated by ordinary least squares regression using 1969 data on total expenditure per pupil, E_t/N_t , and elementary enrollment as a proportion of total elementary and secondary enrollment, N_e/N_t , for the 50 states. The coefficient estimates were unfortunately not statistically significant and so could not be compared to our previous estimates.

Another independent check, however, does give us some confidence in our estimates. In both the elementary and secondary cases, the estimates of expenditures on professional instructional personnel are close to the figures obtained by multiplying the appropriate teacher-pupil ratio by the appropriate average national salary. These figures, \$376 and \$477, respectively, are somewhat below the professional instructional personnel expenditures listed in Tables 3 and 4, as indeed they should be since counselors, specialists, and principals, who are more highly paid, are included among instructional personnel but were not counted in computing average teacher salaries. In 1970, pupil-teacher ratios in elementary and secondary schools were estimated to be 24:1 and 20:1, respectively, at the national level. (Department of Health, Education and Welfare, Office of Education, *Statistics of Public Schools*, *Fall 1969*, Table 1, page 8.) Respective salaries were \$9025 and \$9540. (National Education Association, *Economic Status of the Teaching Profession, 1970-71*, Table 22, page 28.)

Expenditures per pupil in future elementary schools reflect the changes described in the text. Expenditure on professional instructional personnel reflects an anticipated fall in the pupil-teacher ratio to 20:1, while the higher paraprofessional figure is due to the addition of one paraprofessional, paid \$5000 for a 180-day school year, for each class of 20 pupils. In addition to the \$35 spent on equipment and other instructional resources in current-input schools, the following additions are made:

\$80 for one hour daily of individualized computer-assisted instruction. (See Appendix B for the derivation of this estimate.)

\$25 for one hour daily of instructional television for each pupil. (See Appendix B for the derivation of this estimate.)

\$3 for language laboratory equipment (\$300 worth of equipment, having an average life of five years, for each class of 20 pupils).

\$5 for microfiche reader-printers (one reader-printer, costing \$1000 and lasting an average of 10 years, for each class of 20 pupils).

\$3 for laboratory equipment (\$120 worth of equipment, lasting an average of two years, for each class).

\$2 for typewriters (\$200 for three typewriters, lasting an average of five years, for each class).

\$2 per pupil for carpentry, mechanics, electronics, and handicraft materials (\$400 worth of equipment, lasting an average of five years, for every two classes of 20 pupils each).

Expenditure on physical plant decreases by one-third due to an increase of the same proportion in the number of days plant is in full use. Expenditure on other inputs is assumed to remain the same. Finally, all expenditure figures are augmented by a factor corresponding to average yearly cost increases of 2% percent.

D. Expenditures per secondary pupil. The figures for current-input schools, listed in Table 4, were derived by the procedures described in the preceding section of this appendix.

Expenditures per pupil in future secondary schools reflect the changes described in the text. Expenditure on professional instructional personnel is higher due to a rise in teacher salaries consistent with the increased breadth and depth of courses taught. Salaries in future secondary schools are hence commensurate with those of full-time teachers in public junior colleges in 1970—\$11,600. (Professional salaries are increased to a level also consistent with the assumption (true in California schools in 1969-70) that secondary teachers are 90 percent of professional secondary instructional personnel.) Expenditures on paraprofessional instructional personnel also increase, in this case because of the addition of one parateacher, paid \$5000, for every three professional instructional personnel.

In addition to the \$90 spent on equipment and other instruction: resources in current-input schools, the following additions are made:

\$80 for one hour daily of individualized computer-assisted instruction. (See Appendix B for the derivation of this estimate.)

\$25 for one hour daily of instructional television for each pupil. (See Appendix B for the derivation of this estimate.)

\$5 for microfiche reader-printers (one reader-printer, costing \$1000 and lasting an average of 10 years, for each class of 20 pupils).

\$30 for libraries and equipment of a type found in 1970 in two-year colleges and for equipment and materials for extensive vocational training. \$95 was spent per student by two-year colleges in 1967-68 for equipment and corresponding maintenance and for libraries. (Department of Health, Education and Welfare, Office of Education, Financial Statistics of Higher Education: Current Funds, Revenues and

Expenditures, 1967-68, Table 2, page 11, and Table 5, page 127.) Multiplied by the growth in per-capita disposable income, in current dollars, the estimated 1970 figure is \$120. Subtracting the equipment expenditures of current-input secondary schools gives an additional \$30 per pupil. The same amount is assumed spent on vocational training equipment for pupils enrolled in these programs.

Expenditure on physical plant decreases by one-third because of an increase of the same proportion in the number of days plant is in full use. Expenditure on other inputs is assumed to remain the same. Finally, all expenditure figures are augmented by a factor corresponding to average yearly cost increases of 234 percent.

E. Expenditures per student in institutions of higher education. The expenditure stim is for current-input institutions, \$3435, is the sum of current funds expenditure per student and additions to plant assets per student, both for all institutions of higher education in 1970. Total expenditures in these two categories were \$26.1 billion (Digest of Educational Statistics, 1970, Table 22, page 18), and enrollment was 7.7 million.

The expenditure figure for future institutions, \$9665, is calculated as follows. The sum of current funds expenditure per student and additions to plant assets per student, both for "other four-year institutions" in 1970, is reduced by one-tenth because of the anticipated enrollment of one-fifth of the students in off-campus programs which cost only half as much. Three-fourths of this amount is then added to one-fourth of an amount calculated in the same way for private universities in 1970. This sum reflects our anticipation that one-fourth of all students in institutions of higher education will be enrolled in post-graduate programs at costs commensurate with those of private universities in 1970. (1968-69 expenditure data for "other four-year institutions" and "private universities" are in *Financial Statistics of Higher Education: Current Funds, Revenues and Expenditures, 1968-69*, Table C, page 8. These figures are adjusted to 1970 by applying the growth rate of per-capita disposable income in current dollars.) Finally, these expenditure figures are augmented by a factor corresponding to average yearly cost increases of 2¾ percent.

Appendix B

ESTIMATES OF EXPENDITURES ON INSTRUCTIONAL TELEVISION AND COMPUTER-ASSISTED INSTRUCTION

Our estimate of per-pupil expenditure on instructional television (ITV) is derived from estimates made by Herbert J. Kiesling ("On the Economic Analysis of Educational Technology," in Sidney G. Tickton (ed.), To Improve Learning, Vol. II, 1971, op. cit., pages 981-997). Considering the characteristics and costs of several existing ITV systems and the results of other studies, Kiesling estimates the costs of a system that delivers nationally and locally produced programming to a district of 20,000 pupils, with each pupil receiving about 35 minutes of ITV each school day. Using Kiesling's guides concerning economies of scale, our estimate for a system providing one hour of ITV per day is \$25.

The estimate of per-pupil costs of computer-assisted instruction (CAI) is by far the most conjectural expenditure estimate in this research. Existing computer systems currently in active educational use are clearly too expensive to be adopted in any but well-funded experimental programs. Three such systems would cost in 1970 between \$480 and \$900 per pupil per school year, under the assumptions of our future elementary and secondary schools (Lawrence Parkus, "Computer-Assisted Instruction in Elementary/Secondary Education: The State of the Art," in Tickton (ed.), *To Improve Learning*, 1971, op. cit., pages 333-335). Comparing these numbers with the estimated expenditures on equipment in current-input schools (Tables 3 and 4) is more than sobering.

Expert opinion concerning the future course of these costs is widely varied. (For example, see Dean Jamison, J. Dexter Fletcher, Patrick Suppes, and Richard Atkinson, "Cost and Performance of Computer-Assisted Instruction for Education of Disadvantaged Children," draft paper, June 4, 1971, National Bureau of Economic Research, Inc., New York. Dean Jamison, P. Suppes, and C. Butler, "Estimated Costs of Computer-Assisted Instruction for Compensatory Education in Urban Areas," Educational Technology, September 1970. Herbert J. Kiesling, "On the Economic Analysis of Educational Technology," in Tickton (ed.), To Improve Learning, op. cit., pages 981-997. Richard E. Speagle, "The Costs of Instructional Technology," in

Tickton (ed.), To Improve Learning, op. cit., pages 1061-1074.) However, the existence of several prototype systems capable of delivering instruction in the tutorial and problem-solving modes for less than 50 cents per student contact hour (including terminal equipment, CPU, multiplexing and communication equipment, and curriculum preparation) has nudged us toward optimism. A brief description of two of these systems must suffice here. One of these prototypes, the PLATO IV system at the University of Illinois, is being built to provide a key set, graphical display device, and slide selector at each terminal. Each pupil is assigned approximately 300 words of extended core memory. With a central computer having two million words of extended core memory connected by telephone or coaxial cable system to 4000 student terminals within a 100 mile radius, this system is expected by its designers to produce a yearly total of 10 million student-contact hours at a total cost of 34 cents per hour-or \$61 per pupil per year if each pupil uses the system for 180 hours a year. Under these conditions, five-sixths of the computer's capacity is available for other uses at no cost. These specifications imply the system's use for 8 hours daily, 300 days a year. (Donald L. Bitzer and Dominic Skaperdas, "The Design of an Economically Viable Large-Scale Computer-Based Education System," in Tickton (ed.), To Improve Learning, op. cit., pages 439-454.) Adjusting the figures to be consistent with our future-schools assumptions-six hours daily, a 180-day school year for each pupil, facilities in use for 240 days-yields an approximate per-pupil expenditure of \$80 per year.

The PLATO IV system will be extraordinarily large and achieve its expected low cost largely through economies of scale. The recent development of another CAI system suggests, however, that low cost may not be dependent on such economies. The TICCET system developed by the MITRE Corporation features a computer with only 64,000 words of core memory serving 120 terminals, each having an ordinary television receiver with voice, picture, and text. All 120 pupils who use the system simultaneously can be working on different lessons. (Kenneth J. Stetten, "The Technology of Small, Local Facilities for Instructional Use," in Levien (ed.), Computers in Instruction, 1971, op. cit., pages 35-41.) Assuming that each pupil uses the system for one hour daily in a 180-day school year and that all facilities are used for 240 days of the year, the terminal-hour cost of 26 cents implies an annual per-pupil cost of less than \$50.

In view of the capabilities and costs claimed for these two prototype systems and of the reservations expressed by other experts, we estimate per-pupil expenditure on CAI in future schools to be \$80 per year. This estimate is subject to question, however, both by those who doubt that such systems can eventually be put into operation at such low cost and by those who feel that their instructional effectiveness and political acceptability will be insufficient to warrant widespread adoption, even at the costs we have projected.
