ABSTRACT

The relation ship of population characteristics to school and college enrollments in Illinois are discussed. Emphasis is placed on the numbers of youth and educational attainment. The author suggests that although the Illinois high school graduation rate is lower than that for the nation, the college participation rate of people who do graduate from Illinois high schools is higher than the national average. The need for public policy in the area of college enrollment is recommended. Appendices include statistical data. (MJM)

POPULATION CHARACTERISTICS - THEIR PULLTONSLIP TO DONOL & COLLEGE ENROLLMENTS

At no time in the history of Illine's has the demand upon clucational services been as great as it has been during the past two decades. Two factors are a sponsible for this phenomenon; (a) a dramatically increasing number of youth in our population now representing a large proportion of the total population, and (b) increased retention of these youth in the educational pipeline.

Numbers of Youth

The increased birth rates experienced after 1945 continued at a high level until 1965 when they dropped to the birth rates typical of the depression years. The higher birth rates experienced during the twenty year period following WW II have created a "bulge" of young people (See Figure 1), and this "bulge" of ages 5 through 24 in 1970 represents 37° of the State's total population.

The 17-year-old population (defined as the average of 17 and 18-year-olds) provides a convenient group to study in detail. They can be compared to high school graduation races because high school completion is normally accomplished within the state of residence; the 17-year-old population forms the base for policy regarding higher education enrollments; and the characteristics of the Illinois 17-year-old population can be studied through 1988 by utilizing the recent census tabulation of the live population by age group.

Figure 2 presents the growth of the 17-year-old population from 1930 through 1970, and it projects this age group through 1988. The 17-year-old population is not projected to peak until 1978. It will decrease by approximately 20% between 1978-1986 then include again when the children born to the members of the post WW II "Laby boom" (who are now child bearing adults) begin to create a new bulge in the 17-year-old population.

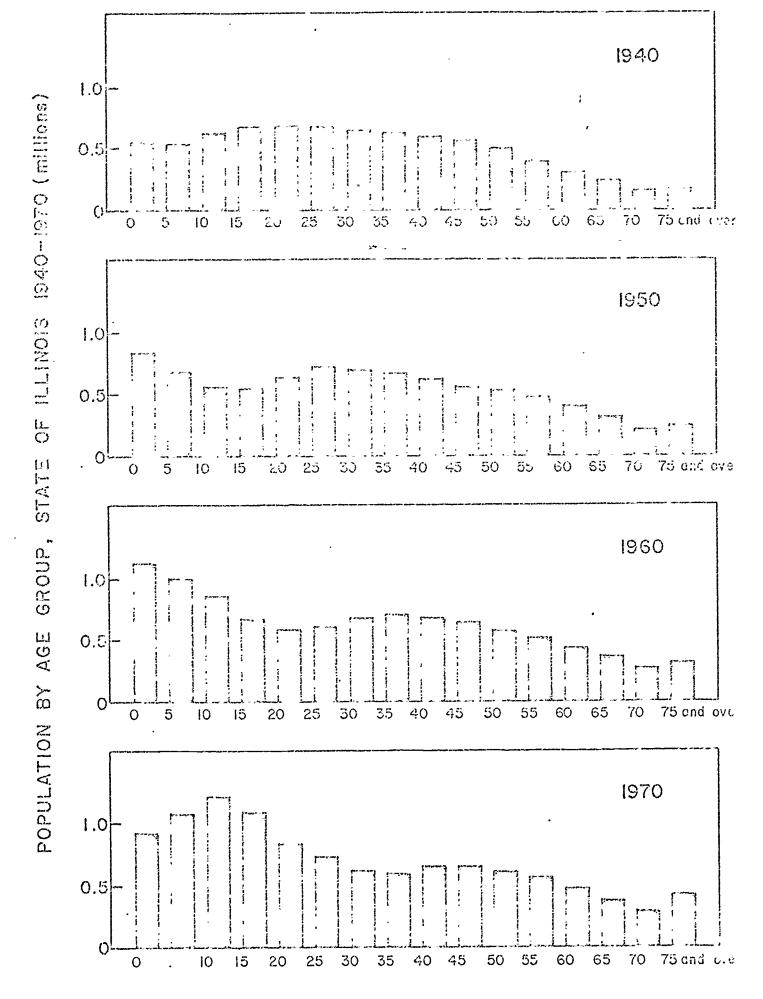

FIG. 1

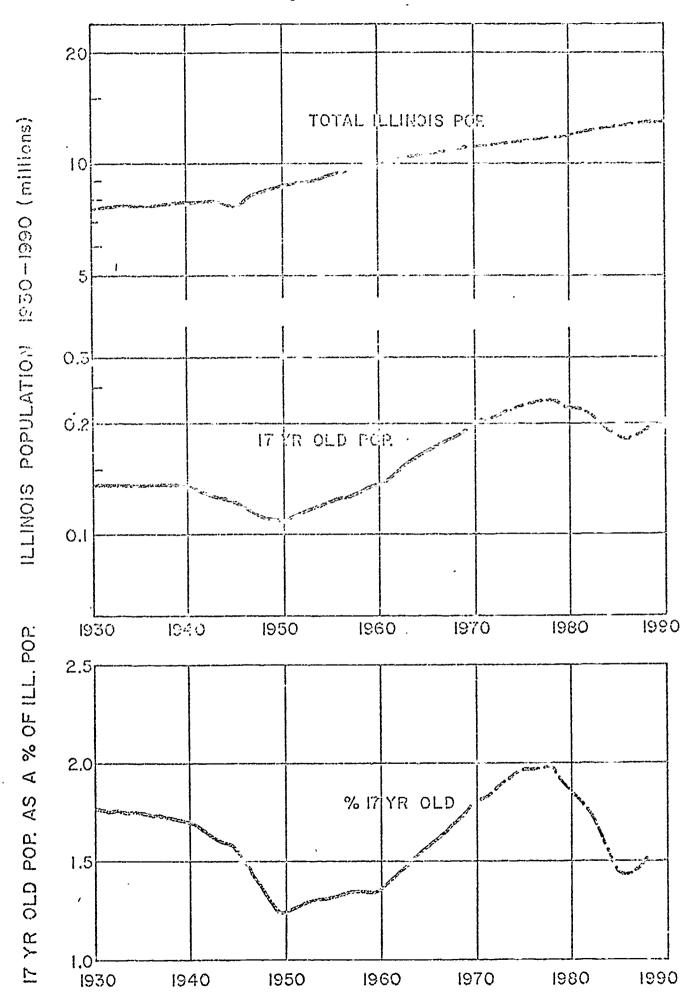

FIG. 2

the population profile of the 5-year-old population. (That is, the 17-year-old population of 1960 was the 5-year-old population of 1948. The people who graduated from high school in 1960 began their school careers in 1948.) It is interesting to trace the past elementary school enrollment prosumes which began in the early 1950's, and to observe the fact that while elementary school enrollment presumes which began in the early 1950's, and to observe the fact that while elementary school enrollment pressures have legun to decrease in the past few years, they will head up again by 1975. Even if the birth rate continues to decline during the 1970's, the total number of children born to the members of the post k. II "balge" will very likely continue to increase through 1990.

Educational Attriment

Within the last three decades, a high school education has become the norm of educational attainment for the youth of the State and the Nation. Figure 3 presents for the State of Illinois a comparison of the 17-year-old population to the number of high school degrees awarded over time. The proportion of high school graduates among the 17-year-old population has doubled since the late 1930's and stands at a current graduation rate of approximately 80%. The important feature of this figure is the fact that high school graduates derived from the 17-year-old population are leveling off. Increases will continue to occur more slowly in the proportion of students obtaining high school degrees, but the number of people achieving this level of educational attainment will peak in the late 1970's, decrease for approximately a decade, then rise again to a new high before the end of this century.

How does the Illinois experience compare with national trends? Table 1 presents for each of the census years since 1930 a comparison of the high school graduation rates for the State of Illinois and for the Nation. It demonstrates that while Illinois' high school graduation rate lagged the Nation's graduation rate through the 1940's and

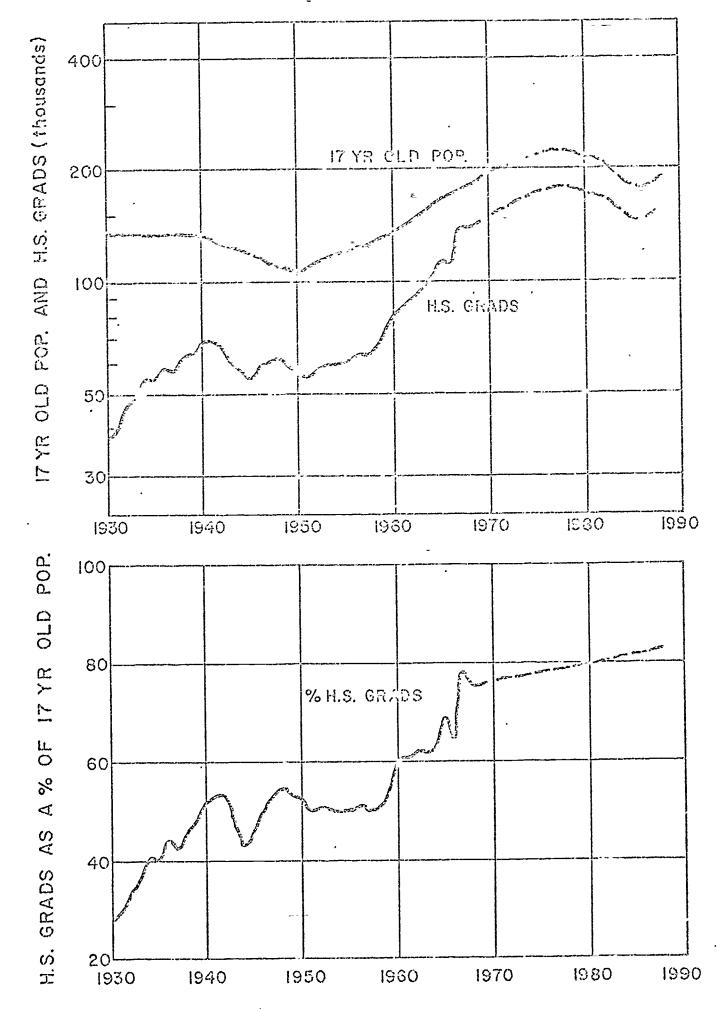

FIG. 3

1950's, a reparkable "catch up" period commed in the 1960's. This catch up reflects the primary and secondary school enrollment pressures in the 1950's and 1960's and it is at least partially responsible for the college level enrollment pressures of the 1960's. During the next decade, the Illinois high school graduation rate is projected to centimes to lag behird the intional graduation rate.

Projected 1980	4,042	221	3,386	1.76	84	80

An increasing proportion of Illinois high school graduates have sought some education beyond the 12th grade and this has been especially true during the last decade. College attendance statistics are not as easily related to the college age group because many students elect to attend college in states other than their home state. However, Illinois has historically exported more of its college age youth than have migrated into Illinois from other states, and while approximately 5% of the Nation's college age population are residents of Illinois, our colleges and universities enroll 6% of the Nation's college students. Add to this the net number of students migrating out of the State to enroll in colleges, and it is obvious that while our primary and secondary schools are not as degree-productive as the national average, those who do graduate from Illinois high schools enjoy a higher college participation rate than the national average.

Table 2 presents a comparison of the growth in the college age population for the Nation and the State of Illinois during the past decade. And it presents fall college enrollment statistics for the same period. While the size of the college age population increased by approximately 50% over the decade, the number of chrolled college age youth more than doubled.

ţ,

Future college enrollments are more uncertain. While the college age population can be projected from live births which have already occurred, a range of college enrollments must be projected because college enrollments are influenced by many factors including the state of the economy, changing attitudes toward education, financial support for college students, the changing structure of higher education, changes in admissions practices, etc. Table 3 presents estimates of the college age population through 1985 and a range of enrollment estimates for the Nation and the State of Illinois. It shows that (a) the college age population will not increase as much during the 1970's as it did during the 1960's; (b) college enrollment during the 1970's will increase at

least as rapidly as the age group increases; (c) college enrollment during the 1970's could possibly increase at a rate more than double the increase in the age group.

Conclusions

1. The birth rates between 1915 and 1965 created a youth bulge in our population which has in ourn created increased demand upon the State's educational services from kindergarten through college. During the past decade, the college age population of Illinois has increased by about 505. During the next decade, the college age population in the State of Illinois will increase by about 206. In 1960, 615 of Illinois' 17-year-old population graduated from high school and in 1970 763 of Illinois' 17-year-old population graduated from high school and in 1970 763 of Illinois' 17-year-old population graduated from high school. During that period, an increasing proportion of those high school graduates have enrolled in institutions of higher education. The high school participation rates have reached near saturation, and by the middle of this decade the real numbers of 17-year-olds will begin to decrease, reflecting the declining birthrates which ushered in the decade of the 1960's. However, before the end of the

-9-

 \mathbf{O}

century, enrollment demand will sebside then increase apain at different times for each segment of the educational pipeline.

- 2. As the children of the youth hulge mature, they create differential denoid upon each segment of the educational pipeline from kinder arten through college. And it can be anticipated that in the late 1970's the leading edge of a second bulge will begin in kindergarten as the trailing end of the first bulge ends in college.
- 3. During the past few decades increasingly more people have been educated and the average person has been enrolled longer in the educational pipeline.
- 4. We are approaching the end of the exponential expansion of "consumption" of education:
- (a) Projections of enrollment in the primary schools will depend entirely upon the numbers of births during the 1970's and not on changes in rates of enrollment since nearly all persons of compulsory school ages are enrolled.
- (b) Projections of enrollment in secondary schools will increase until the mid 70's, decrease for approximately 10 years, and thereafter be dependent upon the number of births during the 1970's. Increases in the proportion of students of high school age attending and graduating from high school will very likely be small.
- (c) Projections of college enrollments are most uncertain but it can be assumed that college enrollment pressures will continue to increase at a declining rate until the end of the 1970's. During the 1970's and beyond, college enrollment will depend upon a myriad of factors and the most significant of these factors is public policy yet to be developed.
- 5. While the Illinois high rehool graduation rate is lower than that for the Nation, the college participation rate of people who do graduate from Illinois high schools is higher than the national average.
