ABSTRACT

The volume of test-norms and expectancy tables is intended as a tool for counselors in counseling individuals. The work contains a chapter on test interpretation to assist the counselor in relating individual test scores to other information about the individual. In the Minnesota Norms section of the tables, there are no data at the elementary level. At the secondary level there are two types of tests: scholastic aptitude (Lorge-Thorndike, and Differential Aptitude), and achievement (Iowa Tests of Basic Skills; Stanford Achievement, both advanced battery and high school battery; Iowa Tests of Educational Development; and the Minnesota English Test). Tests for post-high school include Minnesota Scholastic Aptitude, High School Percentile Rank by type of Minnesota College, and General Aptitude Test Battery by Training Groups. There are expectancy tables for the various campuses and colleges of the Univ. of Minnesota and other Minnesota colleges grouped according to the categories: Private Liberal Arts Colleges, State Colleges, and Junior Colleges. Finally, there are two interest tests results: Strong Vocational Interest Blank and Minnesota Vocational Interest Inventory. (AG)

## FOREWORD

The purpose of this loose-leaf publication, *Minnesota Test-Norms and Expectancy Tables*, is to provide counselors working in all settings with test results that should be useful in counseling with individuals. However, the value of any individual's test score depends upon the manner in which it is used. A single test score used in isolation could prove harmful to some students and in such cases students would be done a disservice. Test results must be considered together with all other information about students to be helpful in the development of their vocational-educational plans. Dr. Dallis Perry's chapter on test interpretation was written especially to assist the counselor to take all these factors into consideration in the utilization of test data for individuals.

The booklet is loose-leaf so that it may be kept current by adding new test information as it is developed.

### ACKNOWLEDGEMENTS

This publication is a revised and expanded version of the earlier edition, published in 1961 with later supplements which were distributed to the schools and related agencies.

The normative data and expectancy tables were made possible through the cooperation and support of the Minnesota Association of Colleges, Minnesota State-Wide Testing Programs, and the Minnesota Research Coordination Unit in Occupational Education. The latter unit, sponsored by the Division of Vocational-Technical Education, Minnesota Department of Education and the University of Minnesota, provided the normative data on the General Aptitude Test Battery (GATB) and the Minnesota Vocational Interest Inventory (MVII).

Individuals singled out for their contributions include Dr. Gary Joselyn, Minnesota State-Wide Testing Programs, who compiled and edited the entire publication; Dr. Dallis Perry, Assistant Director, Student Counseling Bureau, University of Minnesota, Minneapolis who wrote the chapter on test interpretation; Dr. David Pucel and Dr. Howard Nelson of the Minnesota Research Coordination Unit in Occupational Education for data from project MINI-SCORE training norms, and the Student Counseling Bureau's Technical Division staff who prepared the many tables and figures.

The members of the Ad Hoc Committee on Testing of The Pupil Personnel Services Section, State Department of Education, participated in planning the content and organization of this revision. Their assistance is gratefully acknowledged.

Members of the Committee:

Dr. Paul Ingwell, Chairman  
Professor of Psychology  
St. Cloud State College, St. Cloud

Dr. Roger M. Adams, Director  
Personnel Services  
Wayzata Public Schools, Wayzata

Robert J. Casanova, Principal  
De La Salle High School, Minneapolis

Donald Clauson, Director  
Curriculum Development  
State Department of Education, St. Paul

Dr. E. Gary Joselyn, Editor, and  
School Testing Consultant  
State-Wide Testing Programs  
University of Minnesota, Minneapolis

Julius Kerlan, Consultant

## INTERPRETING STANDARDIZED TEST SCORES

Dallis K. Perry

### Uses of Tests

Standardized tests are used to assist in making a wide variety of educational decisions:

Which students should be selected for Special Program A?

What educational and vocational plans are reasonable for Student B?

For what level of instruction in mathematics is Student C ready?

Has Class D made the expected progress in science?

How successful is the new social studies curriculum in School E?

Test scores provide just one of many kinds of information that must be evaluated and integrated to answer these questions. The ways in which such information is used in educational administration, instruction, and guidance is the subject of such disciplines as educational evaluation, teaching methodology, and counseling and is beyond the scope of this discussion; but, before we use test results in any way, we must understand what information is contained in the test scores -- what it is they do and do not tell us.

Cronbach's (1970) definition of a test as "a systematic procedure for observing a person's behavior and describing it with the aid of a numerical scale or category system" is perhaps as satisfactory as any. The tests with which we are concerned are standardized tests -- standardized both with respect to the presentation of the stimuli (items) that elicit the behavior that is observed and with respect to the reference data by which the numerical results are interpreted. The score that results directly from a test operation is ordinarily an arbitrary and quite meaningless figure. A considerable portion of test technology is concerned with procedures for transforming such "raw" scores to scales that "build in" significance through their relation to one or more kinds of reference information. Two general classes of transformed scores are "norm-referenced" scores, which indicate relative standing in comparison with a specified reference group, and "criterion-referenced" scores, which relate test performance to the kind of behavior exhibited by, or expected from, the examinee. Underlying the interpretation of both kinds of scores are the concepts of validity and accuracy of measurement and the assumption that the tests have been presented to students in a standard manner. The following sections discuss test administration circumstances and the concepts of measurement accuracy, validity, norm-reference, and criterion-reference as they influence the interpretation of standardized test scores.

### **Test Administration**

Fundamental to a standardized test is the equivalence of test content from one student to another, which makes possible comparison of scores. It is essential that this standardization not be compromised by special instructions, assistance, or failures in test security that may effectively alter the content in unknown ways for some students. Testing conditions cannot, of course, be identical for all examinees, but they should be comparable in every way possible. Because most educational tests are regarded as measures of maximum performance, each student must have an opportunity to do his best. Satisfactory physical conditions of lighting, heating, ventilation, space, and work surfaces are assumed, as well as rigid adherence to specific directions and time limits. Equally important, and much more difficult to control, are the internal conditions that each student brings to the test. If a test score is to represent maximum performance, the effort and therefore the motivation to do well on the test must be comparable to that expected in the situations to which the test score is related. Test manuals and administration directions give little attention to pre-test preparation and instruction of examinees. A clear explanation of the purpose and significance of the tests, without resorting to exhortation, is preferable to presentation of the tests as unexplained but unexplained task. Motivation cannot be completely standardized, of course, and the counselor or teacher with specific knowledge of each student as well as of the testing situation can best judge whether a given test score should be accepted at face value, regarded with extra caution, or disregarded completely because of the circumstances in which it was obtained.

### **Accuracy of Measurement**

No single test score is completely representative of the "universe" of behavior for a person. A test score is based on a sample of behavior, and scores based on different samples can be expected to vary. Interpretation of the score must take into account the amount of such variation to be expected under given circumstances. This variation is usually expressed as "error of measurement", considered to be the difference between the observed score and a hypothetical "true" score consisting of the mean of a very large number of measurements of the same kind on the same person.

### **Standard Error of Measurement**

The standard deviation of the distribution of measurements on a person, of which the person's true score is the mean (or equivalently the standard deviation of the differences between true and observed scores), is called the standard error of measurement (s.e.m.) for that person. Although the s.e.m. on a test varies from one person to an-

other, in practice the average s.e.m. over a sample of persons is determined as an estimate of the s.e.m. on the test for each person.

The s.e.m. of a test indicates the extent to which a person's scores obtained by repeated measurement of the same kind would vary around the person's true score. It may be pictured as shown in Fig. 1. Within the range of  $\pm 1$  s.e.m. from a person's true score will fall 68% of his obtained scores, and 95% will fall within  $\pm 2$  s.e.m. If the s.e.m. is 3, for example, the probability is 68% that any observed score is within 3 points of the true score.

Figure 1. Standard error of measurement in relation to observed score distribution.

The s.e.m. of a test is important because it emphasizes that an observed test score is just an estimate and not a precisely determined number, and at the same time it quantifies the dependability of the score. Test scores are sometimes reported as ranges or bands, typically extending 1 s.e.m. above and below the observed score, with or without the observed score indicated. Although the interpretation of such ranges is difficult to specify precisely in probability terms, they have the advantage of emphasizing to users the limits of score dependability.

In evaluating scores on a test with reference to its s.e.m., two points should be considered:

1. The reported s.e.m. is an estimate of the *average* s.e.m. for all persons who take the test. Individuals differ in their variability as well as in their true scores, so the actual s.e.m. is not the same for all persons. The s.e.m. of a well-constructed test should not be correlated with test scores, but in practice persons near the extremes of a distribution are less likely to be measured accurately than those near the middle. This situation may arise, for example, if the test has insufficient "ceiling" so that differences among the more able students cannot be detected, or if it is so difficult for some students that they respond randomly or by excessive guessing.

2. Different procedures used to estimate the s.e.m. of a test ascribe different sources of observed score variance to error. It is important to keep in mind the sources of variance represented in the s.e.m., and, therefore, the generalizability of the score. Internal consistency procedures (Kuder-Richardson formulas, split-half, odd-even) or alternate form correlations generally include as error that variance due to sampling of test content and that due to momentary factors that differentially influence performance during a single testing occasion. Factors that would differentially affect scores on another occasion are ascribed to "true" score variance. Retesting at a different time with the same instrument leads to the inclusion of differences due to testing occasions, but not differences due to content sampling, in the error variance estimate.

#### Reliability Coefficients

As Fig. 1 implies, the error variance ordinarily is much smaller than the total variance on a test. If it were not — if all the variance were error variance — there would be no true score variance and the test would have no value. Interpretation of the s.e.m. of a test depends in part on *how much* smaller than total score variance it is. An s.e.m. of 3 has quite different significance for a test with a standard deviation of 4 than for a test with a standard deviation of 40. The variance of a group of test scores is composed of the error variance plus the true score variance, or

$$S^2_{\text{observed}} = S^2_{\text{true}} + S^2_{\text{error}} \quad (1)$$

The relationship of these variances is usually expressed as the *ratio* of true score variance to total score variance, called the reliability coefficient,

$$r = S^2_{\text{T}}/S^2_{\text{O}} \quad (2)$$

Because true score variance, and therefore total observed variance, is a function of the heterogeneity of the group being measured, a reliability coefficient reflects both group and test characteristics, whereas the error component of scores on a test, (s.e.m. squared) is regarded as a characteristic of the test, fixed for all groups. In interpretation of an individual test score the s.e.m. most directly indicates the confidence that can be placed in the score, but the stability of the score with respect to an entire group of scores, as indicated by the reliability coefficient, also should be known. Given the standard deviation of the group in question one can, from (1) and (2) above, compute either s.e.m. or  $r$  from the other according to the familiar formulas

$$\text{s.e.m.} = S_0 \sqrt{1 - r} \quad (3)$$

$$r = 1 - \frac{(\text{s.e.m.})^2}{S_v^2} \quad (4)$$

Internal consistency reliability of the Minnesota Scholastic Aptitude Test (MSAT) was found to be .93 (Layton, no date), which indicates, according to formulas (3) and (4), a s.e.m. about one-fourth as large ( $\sqrt{.07} = .26$ ) as the standard deviation of 13.5, or about 3.7. Referring to the MSAT norm table we find that, if, for example a student's "true" score is at the 71st percentile ( $RS = 44$ ), about two-thirds of the time in repeated testing his observed MSAT score would be between the 63rd and 79th percentiles. He would obtain a score below the 54th percentile less than 3% of the time.

### Validity

The most critical information underlying the interpretation of test scores is how well the scores measure the characteristic the test is being used to measure, i.e. how *valid* is the test for the purpose to which it is being put. Because a test may be used for many purposes, it may have many validities and even several different kinds of validity. Different kinds of validity are generally classified into three categories: content validity, criterion-related validity, and construct validity.

#### Content Validity

When a test is used to determine a person's current knowledge or performance in a domain represented by the test, evidence of how well the test actually represents the domain is required to establish the *content validity* of the test. Such evidence usually takes the form of an analysis of the domain into subdivisions, description of the subdivisions, and identification of the items related to each subdivision. In educational achievement tests such subdivisions usually correspond to educational objectives. It is important that both subject matter content and process be included in the analysis and description of the test.

Establishment of a test's content validity requires demonstration not only of what the test does measure but also of what it does not measure. Extraneous factors that are measured by a test but are not conceptually a part of its content lower its content validity. Two of the most common such influences are reading skill and working speed, because so many achievement tests are composed of written items and are given with time limits.

The careful analysis and description of the measurement domain which characterize the establishment of content validity distinguish it from "face validity", which refers to the superficial appearance, or even name, of a test. Motivation may be better if test items appear to

examinees to be relevant to the purposes of testing; therefore, face validity may be desirable, but it is not the same as content validity.

### **Criterion-related Validity**

When a test is used to predict a specific kind of performance other than that measured by the test itself, evidence is required that the test scores are indeed related to the other, criterion, performance. Such evidence is most commonly presented in the form of a coefficient of correlation between test and criterion scores.

Clearly, a test has as many validities as criteria. Thus the median correlation of MSAT scores with grades of freshmen in Minnesota colleges is .43, which demonstrates its validity as a measure of scholastic aptitude; but the coefficients in individual colleges vary from .10 to .76.

Adequate evidence of criterion-related validity requires not only a validity coefficient of sufficient size to be useful but also a criterion measure that truly represents the behavior or performance to be predicted. School marks or grades are the most commonly used educational criteria, and tests validated against such measures must be used with awareness of the limited scope of relevant behavior represented in the criterion. Nevertheless, because grades do represent a significant aspect of achievement and one that may be critical in determining continuation and completion of an educational program, correlation of test scores with grades is an important and meaningful indication of validity.

### **Construct Validity**

Criterion-related validity is invaluable for use of a test to aid in reaching a decision, e.g., choice of college, regarding a specific course of action, the outcome of which can be measured in some way, e.g., by subsequent course grades. However, we cannot expect that tests will have been specifically validated against criteria for all decisions of all students who may be aided by a better understanding of their capabilities and characteristics as measured by tests. For effective counseling use of tests to help understand students and to help students understand themselves we must know "what the test measures", apart from its prediction of behavior in specific situations. Evidence of the meaning of test scores in terms of the psychological characteristics, or constructs, represented by the scores is termed "construct validity". Such evidence may take the form of analysis of the content of the test, synthesis of criterion-related validity coefficients, correlations with other tests, factor analysis, differences or similarities of scores of specified groups (e.g., age or educational levels), item analysis, observation of test-taking behavior, and influence of training or experience on

scores. As with evidence of content validity, demonstration of what the test does not measure is as important as demonstration of what it does measure.

Interpretation of the Differential Aptitude Tests (DAT) for counseling secondary school students, for example, depends largely on construct validity. Although the DAT manual reports more than 5,000 predictive validity coefficients, few counselors will have such evidence available for their students and for criteria specifically relevant for their students. Focusing on the Mechanical Reasoning (MR) test we find by examining the items that they deal with gears, levers, pulleys, the application of forces, and similar principles that are part of the content of physical mechanics. The items are presented pictorially, with verbal questions about the pictures, so the test requires some reading ability; but the questions and the words in them are short and should be easily understood. Correlations of about .5 to .6 with the Verbal Reasoning test and with various intelligence tests indicate that MR is measuring something different than verbal ability, and item analyses of the very similar Mechanical Reasoning Test indicate that it is measuring a general mechanical ability, not separate "levers ability", "gears ability", etc. (Cronbach, 1970). On the average MR correlates higher with high school grades in science than in other subjects (although it is not the best DAT predictor of science grades), and it was found to be an effective predictor of vocational school performance of machine shop students but not of auto mechanics students. Girls' scores on the test tend to be substantially lower and less reliable than boys' scores and to have higher correlations with grades in "unrelated" high school courses such as English and social science, suggesting that the test functions somewhat differently for the two sexes. Because MR is a revision of earlier Mechanical Comprehension Tests, evidence that scores on the latter are related to evaluations of training and job performance of various jobs concerned with machinery supports the construct validity of MR. Finally, MR scores are correlated about .4 with mechanical and scientific interests of boys as measured by the Kuder Preference Record and negligibly with other interests. Again, the relationships for girls are lower. Taken together the evidence briefly summarized above supports the notion that MR measures a meaningful characteristic of students, one that is appropriately labeled "mechanical reasoning", is not the same as general intelligence, and is important in certain scientific and mechanical pursuits though not in every activity labelled "mechanical".

Establishment of construct validity in a different domain is illustrated by the development of the Academic Achievement (AACH) scale for the Strong Vocational Interest Blank (Campbell and Johansson, 1966). This scale was developed by selecting SVIB items that significantly differentiated between students with high grades in

college and high school and those with low grades. The scale correlated about .35 with high school and college grade averages in a cross-validation sample drawn from the same population as that on which the scale was constructed and also in a 25-year-old sample of college freshmen tested in the 1930's. Low correlations with MSAT scores show that the scale is not just another measure of scholastic aptitude, and the AACH score adds slightly to the multiple correlation of HSR and MSAT with college GPA. In 10-year and 25-year follow-up groups the scale showed substantial differences between students who dropped out of college and, in order, those who obtained BA, MA, and PhD degrees. Scores were found to increase until about age 28 and then remain relatively stable. Examination of the item content indicates that items scored positively represent scientific, aesthetic, and intellectual activities, whereas those scored negatively involve sales, business, and manual skills. AACH scores of occupational groups are ranked very much like the average educational levels of the groups, with scientists (biologists, mathematicians, psychiatrists, physicists) at the top and policemen, forest service men, pilots, and office workers at the bottom. Scores of outstanding persons in 10 occupations showed similar differences, with outstanding composers, novelists, astronauts, and psychologists scoring high and outstanding life insurance salesmen, military men, and football coaches scoring low. In summary the AACH scale appears to measure interest in activities that lead to getting good grades and continuing in school, but it is not a measure of scholastic aptitude as such nor a predictor of success within occupations.

#### **Norm-Referenced Scores**

A norm-referenced score indicates an individual's standing in comparison with a standard reference group of persons who have taken the same test. In the interpretation of norm-referenced scores both the nature of the score transformation and the nature of the reference group must be considered.

#### **Score Transformations**

The most commonly used norm-referenced scores are *percentiles*, *standard scores*, and *grade equivalents*.

**PERCENTILES.** Percentile scores indicate relative standing in a group in very much the way rank ordering does, and they are often called percentile *ranks*. Because the meaning of a given rank depends on the size of the group ranked, percentiles adjust for group size by, in effect, indicating the equivalent of rank order in a standard group of 100 scores. The concept of rank order and the analogy of "a ladder with 100 rungs" are easy to understand, and percentiles are much used

because of the ease with which their meaning can be communicated. The most likely misunderstanding of percentiles is an interpretation of them as indicating "percent correct", and in reporting test results to students and parents it is important to insure that this interpretation is not made.

A distribution of percentile scores from a group comparable to that on which the percentile norms are based will be rectangular, that is, will have about the same number of cases at each score. There will be, for example, about the same number of scores at the 98th percentile as at the 50th. Because there are far more cases near the middle of the raw score distribution than near the extremes, a small raw score change results in a much larger percentile change near the middle than near the extremes. This tendency to accentuate differences among mid-range scores and de-emphasize differences among extreme scores is a major disadvantage of percentiles.

**STANDARD SCORES.** This disadvantage is avoided by standard scores, in which differences are proportional to raw score differences. Standard scores are anchored at the mean of the norm group distribution, with units proportional to the standard deviation of the norm group distribution. The basic standard score transformation (z-score) is made by subtracting the mean from each score and dividing the remainder by the standard deviation, producing a score with mean of zero and standard deviation of 1. Because the fractional and negative scores produced by the z-score transformation are inconvenient, transformations that assign more units to the standard deviation and a positive score to the mean are usually used for score interpretation. Some standard score transformations commonly encountered by Minnesota test users, are:

Score	Mean	S.D.	Relation to z
Stanine .....	5	2	$2z + 5$
ITED, ACT .....	15	5	$5z + 15$
T-Score (Stanford HS) .....	50	10	$10z + 50$
GATB .....	100	20	$20z + 100$
CEEB .....	500	100	$100z + 500$

Because standard score differences are proportional to raw score differences, comparisons of scores in different parts of the distribution are less subject to misinterpretation than comparisons of percentiles; and standard scores can be manipulated mathematically to obtain meaningful averages, correlations, etc. The meaning of a standard score is not immediately clear, however, without some understanding of its relation to a normal distribution of scores. Fig. 2 pictures this relationship for several standard score scales as well as for percentiles.

Figure 2. Common score scales and the normal distribution.

**GRADE EQUIVALENTS.** Whereas a percentile or a standard score indicates the location of a score within one specified norm group distribution, a grade-equivalent score identifies a specific score distribution for which the obtained score is the median. The score distribution is for students at a particular grade level. For example, if the grade equivalent for a raw score of 38 is 4.0, 38 would be the median score of the norm group of beginning 4th-graders. Decimal parts are added to represent fractions of a 10-month school year, so that a grade equivalent of 4.2, for example, represents the median of students tested at the end of the second month of the 4th grade. Although there is a hypothetical norm group for each separate grade equivalent, in practice only a few levels are tested within the range of grade equivalents reported. A junior high school achievement test might be normed on students tested in the middle of the seventh (7.5), eighth (8.5) and ninth (9.5) grades, for example. Intermediate grade equivalents are determined by interpolation, and equivalents below the lowest group tested and above the highest group tested are determined by extrapolation.

Because grade equivalents are especially convenient for measuring progress, and because the significance of the score that is "built in" in the form of reference to educational levels seems especially easy to

understand, grade equivalents are widely used. They have some disadvantages, however, that should cause users to interpret them with special caution. Although the meaning of a grade equivalent of 6.6 for a student in the middle of the 6th grade is clear, the meaning of the same score for a student in the middle of the 4th grade is less clear because we have no guidance as to whether such a deviation from the "expected" score is rare and significant or common. Certainly the two scores represent different kinds of achievement and have quite different meanings for the two students. Because students do not progress at the same rate in different subjects nor in the same subject at different levels, comparisons across subjects are difficult to interpret. At the high school level, where students are not taught every subject every year, grade equivalents have largely been abandoned for this reason. Finally, grade equivalents seem especially likely to be misinterpreted as performance standards. It seems easier to accept the notion that, on the average, half the students in the class must be below the 50th percentile than that half must be below "grade level".

Perhaps the simplest source of misunderstanding of a test score to be guarded against is confusion among the concepts underlying the various score transformations. A score of 75, for example, might be a grade equivalent with the decimal point omitted (common practice), a percentile rank, a standard score: mean 50, or a standard score: mean 100. Knowledge and understanding of the specific transformation is obviously essential to correct interpretation of the score.

### **Norm Groups**

Because the meaning carried by norm-referenced scores is relative standing in a defined reference group, the characteristics of the reference group are most important.

**SIZE.** The group must have adequate size to provide stable results. If the norm group is a sample from a large population, it must be large enough so that variations due to sampling are minimized. Even when the norm group can be regarded as the entire population, as, for example, with school or class norms, anomalous and possibly misleading norms may be obtained if the group is very small. For this reason, local norms computed in the Minnesota High School Statewide Testing Program are based on two years' testing if possible when the size of a single class is less than 50.

**REPRESENTATIVENESS.** Adequate size does not insure that a norm group will be adequately representative of the population specified. Norm groups are frequently difficult to obtain, and it is rare that samples can be randomly selected. The factors that do influence selection are likely to cause the norm group to be unrepresentative in unknown ways. Norms for the MSAT are based on the scores of nearly

every Minnesota high school junior in a given year, and their representativeness is thereby assured. Minnesota norms for tests in the High School Statewide Testing Program, on the other hand, must be based on substantially less than the total population of Minnesota students in a given class because testing practices vary considerably among schools. To provide more assurance of representativeness norms for these tests are based on scores of students from schools whose combined MSAT score distribution is the same as that of the state as a whole. To the extent that the distributions of ability being normed parallel the distribution of scholastic aptitude measured by MSAT, this procedure increases the representativeness of the norms. "User norms", which are based on all the students from a defined population who happen to have taken the test, should be especially suspect.

**CURRENCY.** Norms must be representative not only at the time they are developed but also at the time they are used. Norms that are not current may be misleading because they do not reflect educational and occupational changes. The MSAT, for example, was normed in 1959 on entering Minnesota college freshmen who had been tested as high school juniors. To provide consistency of interpretation from year to year this norm has been continued even though it cannot be relied on to represent the present Minnesota college population. Consequently, more current norms for high school juniors and various types of colleges also are presented.

**APPROPRIATENESS.** Given technical soundness in the form of adequate size, representativeness, and currency of a norm group, it is also important to consider the appropriateness of a norm group both for the student and for the decisions to be made. The student may be currently a member of the populations represented by some norms, so their appropriateness for the student is assured. A 9th-grade Minnesota student who has taken the Lorge-Thorndike Intelligence Test (LTIT) and the Iowa Test of Educational Development (ITED) is a member of the populations represented by local school, Minnesota, and national norms for each test, all of which are appropriate for him. For decisions about his educational experiences in the immediate future, the local norms would be most appropriate because they indicate how he compares with his classmates in various areas. For longer-range planning the Minnesota norms, because they represent the students with whom he would most likely be compared in other high schools or post-high school institutions, would be more helpful. National as well as state norms might be used in evaluating how well the school's educational program achieved in various domains the kind of educational development expected for students with ability levels like those in the school.

For example, Alice's LTIT Verbal and Non-verbal scores of 59 and 52 put her at the 73rd percentile according to 9th-grade Minnesota

norms, indicating an above-average student. On local norms for her school, however, these scores are at the 99th and 93rd percentiles, respectively, which suggest that she is likely to move much more rapidly than most of her classmates and may require special material to enable her to apply her abilities appropriately. In another school Brian's 9th-grade LTIT scores of 60 and 51 give him local percentile scores of 49 and 46, indicating an average student who should progress with the rest of the class. His percentiles of 75 and 70 on state norms, however, show above average ability, suggesting that his educational program should be one that will support many possible post-high school options.

Some norms represent populations of which the student is only potentially, not currently, a member. The MSAT, for example, offers both types. Each student who takes the test is clearly a member of the high school junior norm group, but only potentially a Minnesota college freshman. Similarly, the Minnesota Vocational-Technical School norms for scores on the General Aptitude Test Battery (GATB) and Minnesota Vocational Interest Inventory (MVII) represent applicants who successfully completed various training programs. Such norms indicate not only relative standing in the norm population, but also whether it is reasonable to consider the student as a member of the population in the first place. Cathy's MSAT score of 32 is average (53rd percentile) among high school juniors and also among Minnesota junior college freshmen (51st percentile), somewhat below average among State College freshmen (35th percentile), and substantially below average among liberal arts college freshmen (11th percentile). Nevertheless, Cathy clearly is a potential member of any of these groups, and it is reasonable to explore additional information about all three types of college. Douglas' MSAT score of 20, however, giving him a liberal arts college percentile of 1, indicates not only that Douglas' chances of successful performance in most Minnesota liberal arts colleges are quite low but also that his more specific estimates of performance in such colleges (see "Criterion-Referenced Scores") may not be applicable to Douglas because he is quite unlike the populations on which they are based. He is, however, a potential member of the junior college population (12th percentile), and performance estimates based on this group would be meaningful. It is important to note that, although members of such norm groups are identified after they become members of the defined population, their status at the time they were tested was the same as that of the students to whom the norms are applied. Thus the Minnesota college freshmen norm groups were tested as high school juniors, and the vocational-technical program graduates were tested as applicants for the programs. Some norms, such as those often reported for employees in various occupations, are based on groups of persons already in the defined popula-

tion at the time they are tested. In applying such norms to persons who are only potential members of the norm population, the influence on the test results of status at time of testing must be considered.

**Multi-Score Tests**

**PROFILES.** Although the principles of test interpretation apply whether there is a single score or several, additional considerations are involved in tests or test batteries that produce multiple scores. Such scores are commonly presented on *profiles*, which offer a convenient means of displaying several items of information. A test profile is simply a graphic representation of several scores on comparable scales. Fig. 3 is an example of one such profile, showing Edwin's

Figure 3. Edwin's DAT profile

Minnesota percentile scores on the DAT plotted as vertical bars extending above or below the midpoint of the score range for each test. Profiles are often prepared also with adjacent scores connected to each other, rather than to the midpoint of the scales, with straight lines, as in Fig. 4. The key word in the definition of a test profile is "comparable". It is inappropriate to profile raw scores because there is no basis for comparing raw scores on one test with those on another. The raw scores must be transformed to scales with comparable units, such as percentiles or standard scores. Furthermore, the transformations for all tests must be based on the same norm group. The provision of such comparability was an important objective and is now a basic feature of standardized batteries of aptitude and achievement tests.

**DIFFERENCE SCORES.** Because profiles do make score comparison easy, it is important to guard against over-interpretation of the differences that appear. The concept of error of measurement is especially important in evaluating differences in scores because the measurement errors cumulate, making the differences less reliable than the separate scores. In psychometric terms the standard error of the difference, S. E.<sub>D</sub>, is given by

$$S. E._D = \sqrt{S_{e1}^2 + S_{e2}^2} \quad (5)$$

where  $S_{e1}$  and  $S_{e2}$  are the standard errors of the two tests whose scores are being compared. If the two standard errors are equal, formula (5) indicates that S.E.<sub>D</sub> is about 1.4 times the standard errors of the individual tests. Computation of S.E.<sub>D</sub> is cumbersome, and test publishers commonly offer convenient guides to the significance of score differences. When scores are reported as percentile bands, as on School and College Ability Tests and Sequential Tests of Educational Progress, bands that do not overlap are regarded as representing reliably different true scores. The manual for the High School Stanford Achievement Test (SAT) includes a table of standard errors of difference for each pair of tests in the battery, which should be consulted in evaluating SAT profiles. The reported S.E.<sub>D</sub> of 5 for Spelling and Numerical Competence, for example, indicates that only one-third of the time would differences as large as 5 be obtained if the true scores for these abilities are equal, and only 5% of the time would differences as large as 10 be obtained.

Nearly all of the SAT S.E.<sub>D</sub>'s range from 4 to 6, although a few are as small as 3. Standardized tests used for individual student diagnosis and guidance should generally have reliabilities close to .9, which will provide S.E.<sub>D</sub>'s of about half a standard deviation (5 points on the SAT standard score scale). Following a practice established by the publishers of the DAT, the profiles for the multi-score tests in the

Minnesota Statewide Testing Program are printed with 1 inch  $\approx$  1 S.D.  $\approx$  2 S.E.<sub>p</sub> (approximately), so that differences of one inch or more correspond to a critical ratio of 2 (5 percent significance level) and may be regarded as significantly different. It is suggested that differences of one-half inch be interpreted if confirmed by other evidence. Comparison of Edwin's DAT scores in Fig. 3 with the 50th percentile reference line indicates that his scores are generally low, only the score on Mechanical Reasoning reaching the average level. Of the individual scores, Mechanical Reasoning is significantly different from all except perhaps Space Relations; whereas the others, despite their apparent differences, are sufficiently similar that differences among them should not be emphasized.

The "one-inch rule" is approximate, of course. It is conservative when the reliabilities of the tests exceed .9; and, of the tests in the Minnesota Statewide Testing Program, the Arithmetic Applications Test in the Stanford Advanced battery, Iowa Tests of Basic Skills Arithmetic Problems and Work-Study Skills subtests, and DAT Mechanical Reasoning test (for girls) have reliabilities too low for score differences to be interpreted in this way.

**PROFILE APPLICATIONS.** Profiles conveniently display both the overall level of a student's scores and areas of strength or weakness. Thus Frank's 11th-grade ITED scores in Fig. 4 show generally superior performance, with special strength in mathematics and some weakness in English expression, literature, and vocabulary. The scores provide a basis for discussion with Frank of his high school program for the remainder of his junior and senior year and of his post-high school plans. The counselor may wish to suggest that Frank concentrate on improving his communication skills in preparation for college work. Fig. 4 illustrates another use of profiles, namely for examining change. Frank's performance is very consistent from the 9th- to the 11th-grade, except for a fairly sizable improvement in his social studies score. This change may reflect an unusual course sequence in Frank's case, or perhaps the development of new interests.

A test profile is a convenient way to summarize group as well as individual test performance. Overall performance of a school or class can be evaluated in comparison with the norm-group average, and strengths and weaknesses can be noted in the same way as with individual scores. Similarly the scores of the same group at two different times or of two different groups at the same time can be plotted on one profile to facilitate group comparisons and reveal changes. Special care must be taken in evaluating the magnitude of group differences in terms of score scales based on individuals, because the mean scores of groups are much less variable than individual scores. Whereas an individual percentile score of 60 differs rather inconsequentially from the midpoint of the norm group, a group mean at the 60th percentile

is likely to be extremely high in comparison with other groups. Precise interpretation of such differences requires norms of group means.

Figure 4. Frank's ITED scores

To learn more about the nature of group differences revealed by the profile it may be helpful to examine the distributions of scores for individual tests. Fig. 5 shows 9th-grade percentile scores for the Minnesota norm group and the local percentiles for one school plotted against raw scores on the SAT-HS English Test. (Either percentile scores or cumulative percentages can be used, but both groups must be represented in the same way.) The school's average score is somewhat below the state mean, but the graph shows that this difference appears almost entirely in the lower part of the score distribution. This evidence does not explain the lower mean score, of course. One possibility is that the curriculum or the instruction is such that insufficient attention has been given to the less able students. An equally tenable hypothesis is that the English achievement scores reflect a similar distribution of learning ability of the students in the school.

This hypothesis could be checked by examining scores of the same students on a general intelligence test such as LTIT in comparison with state norms.

Figure 5. SAT-HS English score distributions for state and a local group.

**SIMILARITY INDEXES.** We sometimes wish to compare a student's scores with each of several reference groups. This may be done either by transforming the student's scores into standard scores or percentiles based on each reference group in turn, or by displaying the reference group distributions as well as the student's performance in terms of a single norm. Minnesota vocational training program norms for the GATB and MVII are of the latter type. As a student's scores are compared with each of several groups and similarities and differences are noted, questions of *how* different the student is from a given group, or *which* group he is most like, arise; and the multiple comparisons produce more information than even profiles can conveniently summarize. To summarize such comparisons and obtain answers to questions like those above, indexes of profile similarity are used. One such

index, the centour score, is reported as part of the Statewide Vocational Testing Program. Centour scores are like the scores on a target, where the bullseye, or the *center* (not the top) of the reference group, gets a score of 100, and the rings successively further in any direction from the center get successively lower scores. A centour score of zero, like missing the target completely, corresponds to a set of test scores outside of the "test space" occupied by any scores in the reference group. (In actual use centour scores are usually based on more than two test scores, and therefore more than two dimensions, and take into account not just differences in individual scores but also in score combinations. Consequently the "target" is elliptical rather than round, and multi-dimensional rather than flat.) Just as a student's percentile gives the percentage of scores in the norm group *lower* than his, the centour score gives the percentage of score combinations in the norm group "further out" than his. Like all summaries, centour scores both reveal and conceal information. A student's centour scores reveal his similarity simultaneously to a large number of reference groups in which he may be interested. At the same time they conceal the specific ways in which he is similar to and different from each of them. Centour scores of 50 for three different groups may result from a student's having all higher scores than the average for one group, all lower scores than the average for another, and some higher and some lower than the average for the third. The differences are important, and to discover them we must go back to each profile and consider it in detail.

For example, Greg's centour scores (Table 1) show little similarity to any of the 18 Minnesota Vocational School training programs for which the scores are reported. Examination of his aptitude scores indicates that they are all lower, some of them substantially lower, than average for students in these programs. These are not the only training programs available, of course, nor do these tests measure all important abilities. It will be necessary for the counselor to explore with Greg his possible strengths in other areas and the ways in which these strengths match possible training or job opportunities.

Helen's scores, like Greg's, are dissimilar to those of graduates of all 18 programs, but the reason is quite different in her case. Most of her aptitude scores are quite high in comparison with the vocational school population. Helen may want to start with a more academic program, perhaps in a junior college, where she would have an opportunity more gradually to narrow her focus on a career program or a college transfer curriculum.

Although none of Irene's centour scores is high, she does have several — Agri-technology, Clerical training, Cosmetology — that suggest a careful look at these fields. Her weakest ability, according to

**TABLE 1**  
**SVTP Scores for Five Students**

Centours	Greg	Helen	Irene	Jerry	Karen
1. Aircraft Meechanics.....	0	0	1	50	1
2. Agri-Technology.....	0	9	21	30	7

4. Spatial.....	97	117	94	137	101
5. Form Perception.....	84	129	107	111	140
6. Clerical Perception.....	100	129	115	118	139
7. Motor.....	82	103	101	111	132

the aptitude scores, is in working with numbers (which also influences the G score). Neither the centour scores nor the aptitude scores provide any information about the relative importance of this weakness for various occupations, but both the "construct validity" of numerical ability and the lower mean N score of the Cosmetology students suggest that it may be less significant in the Cosmetology program than in either of the other two.

In contrast to the other students, Jerry's scores fall in the area where all the training groups overlap. As a result, all of his centour scores are high, including several that are very high. Although the high centour scores provide some guidance, Jerry's ability pattern fits well into all the training groups, and other considerations than his abilities will likely determine his choice.

The pattern of Karen's scores is similar to Irene's, but all of her aptitude scores are higher, and this difference is reflected in higher centour scores in more areas. In addition to clerical and cosmetology training, practical nursing and secretarial training offer good possibilities.

It is important to note that similarity indexes, like all norm-referenced scores, do not in themselves indicate the likelihood of behavior of any kind other than that required by the tests themselves. To predict from the test scores to behavior in other situations we must rely on information about test validity, which is not introduced or represented by the norming process.

**INTEREST PROFILES.** Interest profiles are a special case of score representation by profile. Because of the way occupational scales are constructed, the practice has developed of norming each scale on its own occupational group, rather than on a single standard reference group for all scales. On the SVIB and MVII the scores are standard scores with an occupational group mean of 50 and S.D. of 10; on the Kuder Occupational Interest Survey the scores are, in effect, correlations between the students' responses and those of each reference group. Such profiles must be interpreted somewhat differently from those based on a single norm group. To provide a comparable reference point the SVIB and MVII profiles show the mid-third range of scores for a standard men-in-general group on each scale. These considerations do not apply to the Basic Scales of the SVIB or the Homogeneous Scales of the MVII, which in each case are all normed on a single reference group.

### Criterion-Referenced Scores

Whereas norm-referencing procedures provide meaning to test scores in terms of relative standing in a defined group of *persons*, criterion-referencing provides meaning in terms of expected *behavior*. The behavior may be defined by the test content itself, in which case we have content scores, or by a separate (criterion) measure, in which case we have predicted scores.

### Content Scores

Scores on a content-referenced scale are summaries of the behavior on the test. Rate scores (e.g. reading rate, typing speed) and percentage scores are commonly used to represent performance, but to have meaning such scores must be accompanied by definitions of the content itself. Thus we have a "reading rate of 247 wpm on passages from *The Readers' Digest*," or "83 percent accuracy on 2-digit by 2-digit multiplication problems". If brief descriptions do not suffice to define the content, samples or examples may be used, such as "ability to spell 77 percent of words such as ambitious, anticipate, disappoint, eligible, indefinite, liability, miniature, oblige, sympathy, treasurer". To be most useful the content referred to should be not just described but scaled, so that mastery of a specified level implies mastery of all easier levels. Such scaling is just beginning in some fields, and few standardized instruments are available that reflect it. A fundamental requirement for the use of content-referenced scores, of course, is satisfactory content validity.

### Predicted Scores

If criterion-related validity has been demonstrated, the validity relationship can be used to report test performance directly in terms of expected criterion behavior. This is usually done in the form of either criterion estimates or expectancy tables or graphs.

**CRITERION ESTIMATES.** Given a linear relationship between a test score (or scores) and a criterion variable, as reflected by a significant validity coefficient, an individual's expected score on the criterion variable can be predicted by the corresponding regression equation. From the correlation of .60 between College Aptitude Rating (CAR) and first-term grades (GPA) of University of Minnesota-Duluth freshmen, for example, we obtain the following equation for predicting GPA from CAR, where CAR is one-half the sum of high school rank (HSR) plus MSAT college percentile:

$$\text{GPA} = .74 + .02 \text{ CAR} \quad (6)$$

From this equation we learn that the predicted UMD GPA corresponding to the minimum acceptable CAR of 40 is 1.54.

Like any test scores predicted scores are accompanied by uncertainty. In the case of predicted scores, however, this uncertainty is caused not only by the error of measurement of the test score, but also by measurement error in the criterion and by lack of perfect correlation between the true scores of the two measures. The combination of these three sources of error usually results in considerable imprecision in prediction, and it is important that this uncertainty be recognized in interpreting predicted scores. It is usually expressed as the standard error of estimate, computed as

$$S.E._{est} = S_c \sqrt{1-r^2}, \quad (7)$$

where  $r$  is the validity coefficient and  $S_c$  is the criterion standard deviation, and interpreted as the standard deviation of observed criterion scores around each predicted score. Fig. 6 portrays the standard error of estimate in relation to the standard deviation of criterion scores.

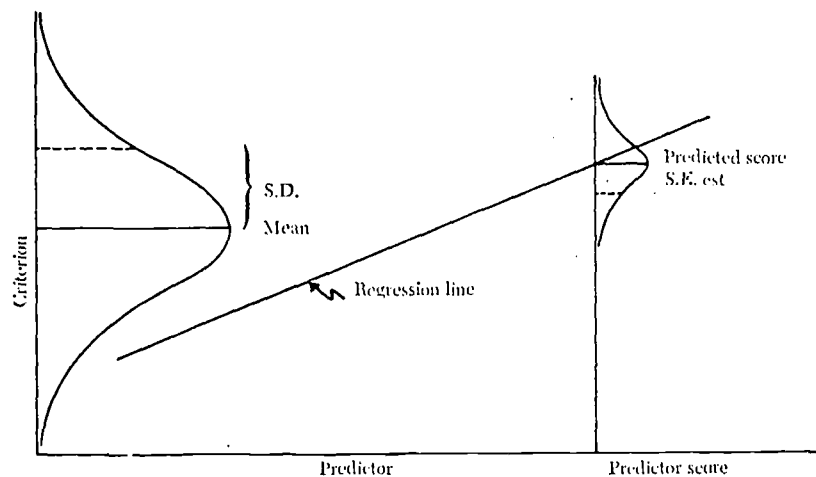

Figure 6. Relation of standard error of estimate to criterion standard deviation.

In the case of the UMD regression equation discussed above the standard error of estimate is computed from the validity coefficient and the criterion S.D. to be .60. This figure, combined with the predicted GPA obtained above, indicates that of students with a CAR of 40 two-thirds will obtain GPA's between .94 and 2.14 and 95% will obtain GPA's between .34 and 2.74. The importance of taking into account the error of estimate in interpreting predicted scores is indicated by the width of the range needed to provide considerable assurance that the criterion score will indeed be included in the predicted range.

Predicted scores are used, of course, not for persons whose criterion scores are known, but for a new group of individuals (e.g., applicants) who have not been measured on the criterion. The standard error of estimate does not take into account sampling error in determining the regression equation. Interpretation of a predicted score and its associated estimate of precision assumes that the score comes from the same population represented by the sample on which the regression equation was determined and that this sample is large enough to provide accurate estimates of the regression parameters for the population.

#### **Expectancy Tables**

Instead of predicting a specific criterion score and accompanying confidence band corresponding to each test score, a common practice is to report the probability of obtaining a criterion score within certain fixed ranges or above certain points. The criterion ranges for which probabilities are given are the same for all test scores, and the probabilities usually are reported for test score ranges rather than for individual scores. The Minnesota State-wide Testing Program expectancy tables relating high school rank (HSR) and MSAT score to first-term grades in each Minnesota college are examples of this method of criterion-referenced score interpretation. These tables were produced by determining the proportions of students in each fifth of the predictor distribution who obtained a college grade average of C or better and of B or better. Application of the tables can be illustrated with the scores of Linda, who has always done above average but not outstanding work in school (HSR=63) and has been developing a serious interest in art, in which she seems to have some talent. She wants a "good, general education" and plans to obtain it at the University of Minnesota, which she can attend while living at home. Her MSAT score of 36 is consistent with her high school record (junior percentile=68), and is sufficient to enter the College of Liberal Arts (college percentile=58). Linda's HSR is in the 60-79 range of the CLA expectancy table, which is clearly below average for CLA females (above 12% and below 59%) but indicates a reasonable probability (67%) of obtaining at least a C average. Her chances of getting a B average or better are not high (10%). Information provided by the MSAT expectancy table is consistent. Her college percentile, in the 40-59 range, is in the lowest quarter of entering CLA students and shows grade probabilities nearly identical to the HSR table. Linda has been considering, besides CLA, the applied arts program in the School of Home Economics. According to the AFHE expectancy tables Linda's scores are below average for entering freshmen here also, but not quite so far below, and her chances of getting satisfactory grades are somewhat higher (79% and 80%). Properly interpreted these data can help Linda understand some differences

between the two colleges, consider the kind of program and level of intellectual challenge most appropriate for her, and stimulate her to seek further information to help her resolve the choice.

In the Minnesota expectancy tables the HSR ranges are based on the within-school HSR percentiles, whereas the MSAT ranges are based on the percentile scores for entering college freshmen. Thus, the sets of tables for the two variables present somewhat different information, not only because of their different content but also because they use different divisions of the total ability range. If the tables for each college were based on score ranges dividing the entering students in that college into approximately equal proportions, the tables would be more useful for that college; but, because the Statewide expectancy tables are intended for use in guidance of students considering attendance at various colleges, the same predictor ranges are used for all colleges to facilitate comparisons and avoid confusion. A compromise is offered for the more selective institutions by dividing the top range into two, making six ranges in all. Caution should therefore be used to avoid comparing grade expectations for scores in the top category (upper 10%) for these schools with expectations for scores in the top category (upper 20%) for the other colleges.

In comparison with criterion estimates based on regression equations, expectancy tables do not require a normal bivariate distribution underlying their interpretation, and they avoid an unwarranted appearance of precision. The uncertainties associated with measurement error and degree of relationship between the variables are reflected by the probability figures themselves. However, there are important cautions to be observed in using expectancy tables, cautions which reflect the fact that the tabled figures are actually proportions of previous classes rather than probabilities of future performance. (It has been suggested that they be called experience tables rather than expectancy tables.) First, in interpreting the figures as expectancies for new students we must assume that the composition of the new classes will be the same with respect to academic ability as the classes on which the tables are based and that they will be treated the same, i.e., that grading practices will remain the same. (Theoretically, it is unnecessary to assume that class composition remains the same if absolute marking standards do not change; but, because most grading is at least partly relative, it is more realistic to expect that a marked change in class composition will change the expectancies.) Entering classes will differ somewhat from year to year; but, unless there is a definite change in policy, such as an increase in admission standards, the differences are likely to be slight enough to maintain the validity of the expectancy tables. Over a period of years, however, such changes can cumulate, so the tables must either be reasonably current or be accompanied by evidence of consistency, such as predictor and

criterion distributions that remain the same from year to year, if they are to be relied on. Second, it is important that each table be based on a group large enough to provide stable proportions. Like the standard error of estimate the expectancies reflect uncertainty due to measurement and prediction error but not that due to sampling variation. The number of cases in each predictor range (i.e., each row of the Statewide tables) determines the stability of the proportions for that range. It is for this reason that predictors are grouped into just five or six categories rather than a larger number that would permit more discriminating probability estimates. As it is, some ranges for small schools and even for large schools with skewed predictor distributions have too few cases for the computation of reliable proportions. The tables contain no expectancies for predictor ranges with fewer than 10 cases, but even with an N of 10 the standard error of the percentage may be as large as 16. With an N of 50 the standard error is not larger than 7. Because the classes on which the percentages are based are obviously not random samples from the schools' populations of entering students, interpretation of the standard error in terms of expected variation for future classes is not possible; but it is clear that the expectancies based on small N's should be used with extra caution. Finally, expectancy tables are necessarily based on the experiences of enrolled students; and these students form populations that differ from high school seniors in ways varying from one college to another as a result of both college admissions policies and practices and students' college selection decisions. To refer a student's score to a given expectancy table it must be reasonable to consider him a potential member of the population on which the table is based. If the table shows no scores in the range containing the student's score, it is clear that the table is not applicable to him. Even if a small percentage of the class had similar predictor scores, these students were atypical of their classmates with respect to these scores; and, inasmuch as they were enrolled despite this atypicality, they are likely to be atypical in unknown ways of students with similar scores. Thus, not only expectancies based on small N's, but also those based on small proportions of the class, should be viewed with caution.

Consider, for example, Michael's HSR of 36. The expectancy table for the U of M College of Liberal Arts indicates that Michael's chances of obtaining passing grades (57%) or a B average or better (11%) are slightly larger than those of boys with HSR's in the range of 40-59. The first explanation to be considered for anomalies of this kind in the tables is a small number of cases, but in this case the N of about 70 (4% of 1981) should be sufficient to avoid fluctuations of this size merely because of sampling error. As noted above, students who enroll in a college despite very low predictor scores are likely to have special strengths in other areas or high scores on other predictors.

Unless Michael has such strengths he would be unwise to rely too heavily on the tabled expectancies. For CLA, of course, because of the admissions requirement of an average HSR and MSAT percentile of 50, enrolled students with HSR's of 20-39 can be expected to have MSAT percentiles of at least 61-80.

When predictions of the same criterion are made from more than one predictor, the results will not always agree. Norma is thinking of going to St. Cloud State College, and referral of her MSAT percentile of 40 to the expectancy table indicates that her chances of obtaining passing grades on the average are 70%, but according to her HSR of 39 her chances of getting a C average are only 30%. Which is correct? Part of the discrepancy may be ascribed to the fact that Norma's scores are at the upper edge of one interval and at the lower edge of the other. The course grouping results in some inaccuracy. Thus Norma's chances for a C average are undoubtedly more like those of a student with HSR of 40, for which the tabled probability is 57%, than like those of a student whose HSR is 20, which is in Norma's interval with 30% probability. Some interpolation of probabilities may be made to adjust for this phenomenon, but even with such adjustments Norma's two predictions are discrepant. To determine which is more valid, Norma should consider with her counselor such information as whether special problems or responsibilities, which would not affect her college work, have held her high school grades down; whether her other test scores confirm the ability indicated by the MSAT score or suggest that it is singularly high; whether Norma's academic motivation and study habits have changed in such a way as to give her a better chance of success in college than her high school grades indicate.

As the considerations above suggest, the expectancy tables do not in themselves decide whether or not a student should attend a given college. The same probability of success that leads one student to choose a college may lead another to look elsewhere. A 30% chance of success may encourage one student, whereas a 70% chance may discourage another. Nor should the tables be used to "shop" for a college by seeking to identify the college in which the student has the best chance of obtaining good grades. But they do provide information, suggest additional questions, and supply some answers to help clarify tentative choices or narrow the field of possibilities.

**DISCREPANCY SCORES.** Expectancy tables may be used not only to help reach decisions about the future but also to help explain the past. In the latter application, comparison of actual performance with expectancies based on previous scores may aid a counselor in understanding that performance. Quite different explanations of a student's failing grades, and different courses of action, may be indicated if

his probability of a passing average were, say 17%, than if it were 70%.

Expectancy tables especially intended for this kind of interpretation, rather than prediction, of performance are sometimes provided for combinations of ability and achievement test scores. The manual for the SAT High School Battery presents quartile scores for each achievement test based on the distributions of scores for students in each stanine on the Otis Gamma Mental Ability Test. Orley's standard score of 57 on the English test puts him well above average (national norms) for 11th-graders in general, but more than three-fourths of 11th-grade students with Otis scores in the 8th stanine, as his is, score higher. This information may lead the teacher or counselor to a different interpretation of his English score than its percentile equivalent alone. Because the interest in expectancy tables of this kind is on the discrepancy between the ability and achievement scores, they are discussed here under the heading of "discrepancy scores"; but in reality such expectancy tables do not give criterion-referenced scores at all. Neither the ability test nor the achievement test is a criterion. The ability test, rather, is used to divide the norm group into more homogeneous subgroups so that more specific norms can be provided. Emphasis on the norm-referenced character of this kind of information may help to avoid reification of score differences into concepts such as "underachiever" and "overachiever". At the very least it is important to be aware of the differences between criterion-referenced and norm-referenced expectancy tables. Thorndike (1967) has pointed out a paradox in connection with the latter, namely that their value depends on the existence of moderate, rather than very high or very low, relationships between ability, and achievement scores. If the relationship is very low, of course, achievement norms for low-ability students will not be appreciably different than those for high-ability students; and subdivision of the norm group will be useless. If the relationship is extremely high, on the other hand, the tests will be measuring much the same thing; and discrepancies between scores on the two instruments will be due largely to measurement error and not subject to meaningful interpretation. For prediction purposes, of course, the higher the relationship represented in an expectancy table, the more helpful is the information.

#### Selected References

This summary of test interpretation principles is clearly no more than an overview of the psychometric technology that test users should understand if they are to interpret and apply test results effectively. It is hoped that it will serve both as a quick reference and as a review and reminder. For more detailed exposition both of general principles

and of specific information about tests commonly used in Minnesota, the following references may be consulted.

**Minnesota State-Wide Norms**  
**for**  
**LORGE-THORNDIKE INTELLIGENCE TESTS**

**Form 1, Level E (Grades 7 & 8) and Level F (Grade 9)**

1966

*Males and Females Combined*

These norms are for pupils who took the Lorge-Thorndike Intelligence Tests (LTIT) in the fall of 1965, through the Minnesota High School State-Wide Testing Program and are based on the "Multi-Level Edition" published in 1964.

Grade	N (Schools)	N (Students)
7	147	9,899
8	68	4,997
9	31	2,671

Tables are provided for the two batteries, Verbal and Nonverbal, and for the Total Score. The Total Score is the sum of the Verbal and Nonverbal raw scores.

The representativeness of these norms was checked by comparing the Minnesota Scholastic Aptitude Test (MSAT) distribution for schools using LTIT at each grade level with the appropriate MSAT distribution for all Minnesota high schools. MSAT is administered to virtually every Minnesota high school junior and is a good scholastic aptitude "bench mark" against which to judge the representativeness of any Minnesota norm group. After some slight adjustments, the distribution of MSAT means for schools using LTIT at each grade level very closely approximates the distribution of MSAT means for all Minnesota high schools. These LTIT norms thus appear to be quite representative of Minnesota students in general.

**Minnesota State-Wide Norms  
for  
IOWA TESTS OF BASIC SKILLS**

**Males and Females Combined**

**1969**

The Minnesota norms for ITBS are based upon scores of students who took the battery in Fall, 1969.

	N (Schools)	N (Students)
Grade 7	34	3,432
Grade 7	24	1,690

Not all schools which administered ITBS in Fall of 1969 are included. A few were eliminated so that the final norm group represents a good cross-section of the State in terms of school size and geographical location.

Additional adjustments were made so that the distribution of Minnesota Scholastic Aptitude Test (MSAT) scores in the schools making up the norm group closely approximate the distribution of MSAT scores for the entire Minnesota population.

**Minnesota State-Wide Norms**  
**for**  
**STANFORD ACHIEVEMENT TESTS,**  
**ADVANCED BATTERY**

**Males and Females Combined**

The Minnesota norms for SAT(AB) are based upon scores of students who took the battery in Fall, 1969.

	N (Schools)	N (Students)
Grade 7	8	1,224
Grade 8	22	3,488

Schools included in the norm group were chosen to be as representative of the State as possible in terms of size and geographical location.

The distribution of Minnesota Scholastic Aptitude Test (MSAT) scores for the students from the norm group schools is almost identical to the MSAT distribution for all Minnesota Juniors indicating that the SAT norm group is probably quite representative of the entire Minnesota student population.

**Minnesota State-Wide Norms for  
STANFORD ACHIEVEMENT TEST, ADVANCED BATTERY  
Forms W, X**

**Minnesota State-Wide Norms**  
**for**  
**THE IOWA TESTS OF EDUCATIONAL DEVELOPMENT**

**Forms X-4 and Y-4**  
**Full Length and "Class Period" Versions**

**Revised 1965**

**Grades 9, 10, 11, 12**

**Males and Females Combined**

The following tables contain Minnesota norms for the Iowa Tests of Educational Development. These norms are based on the scores of Minnesota high school students tested in the fall of 1964.

Grade	N (Schools)	N (Students)
9	155	11,555
10	138	9,108
11	125	8,565
12	54	2,942

These norms were revised in 1965 by the Student Counseling Bureau at the University of Minnesota, which administers the Minnesota State-Wide Testing Programs. Forms X-4 and Y-4 were first used in the Program in the fall of 1964, replacing Forms X-3 and Y-3, upon which the previous, 1956, Minnesota norms were based.

The representativeness of these norms was checked by comparing the Minnesota Scholastic Aptitude Test (MSAT) distributions for schools using ITED at each grade level with MSAT distributions for all Minnesota high schools. MSAT is administered to virtually every Minnesota junior each year and thus serves as a good scholastic aptitude "bench mark" against which to judge the representativeness of any Minnesota norm group. From this and other checks the 1965 ITED norms appear quite representative of Minnesota students at each respective grade level.

The scores used in the norms are standard scores. Although the various forms of ITED are equated through the use of standard scores and a single norm table should suffice for all forms, enough differences exist between Forms 3 and 4 so it is not advisable to use these tables with the old Forms X-3 and Y-3. Users are cautioned that equal standard scores on two or more subtests does *not* necessarily represent

equivalent performance (See pages 33-34, "How to Use the Test Results," ITED Manual).

When ITED was restandardized nationally in 1963, the publishers adopted the commonly accepted convention of computing norms to the midpoint of the class interval. Therefore, the same convention has been adopted in the preparation of these norms.

The Iowa Tests of Educational Development, Form 4, have nine subtests and a Composite Score.

Test 1 Understanding of Basic Social Concepts

Test 2 Background in the Natural Sciences

Test 3 Correctness and Appropriateness of Expression

Test 4 Ability to do Quantitative Thinking

Test 5 Ability to Interpret Reading Materials in the Social Studies

Test 6 Ability to Interpret Reading Materials in the Natural Sciences

Test 7 Ability to Interpret Literary Material

Test 8 General Vocabulary

Composite The Composite Score is based on a combination of the scores on Tests 1-8. Each test receives approximately equal weighting in determination of this score.

Test 9 Use of Sources of Information

**Minnesota State-Wide Norms for the  
MINNESOTA ENGLISH TEST  
1965-66**

**ELEVENTH GRADE  
MALES AND FEMALES, COMBINED**

These are the official norms used for MET in the Minnesota High School State-Wide Testing Program.

These norms are based on 1,009 juniors from fourteen Minnesota high schools selected from those which took MET the fall of 1965 as part of the Minnesota High School State-Wide Testing Program. Size of junior classes in these selected high schools ranged from 12 to 152. The Minnesota Scholastic Aptitude Test (MSAT) scores of the schools taking MET the fall of 1965 were carefully studied and the group selected to be representative of all Minnesota high school juniors. Studies of groups selected because they are representative of the entire state on MSAT have shown that we obtain norms representative of the entire state on other tests. Because the fourteen schools are representative on MSAT, as shown below, we are quite confident they are also representative on MET.

**Minnesota Scholastic Aptitude Test Data on Fourteen High Schools  
in MET Norms Group and for All Juniors**

	<u>Juniors from Fourteen Schools in MET Norms Group</u>	<u>All Juniors 1965-66</u>
Number	1,009	61,919
Mean	34.7	34.7
Standard Deviation	14.1	14.7

For a further description of MET see: Swanson, Edward O., "The Minnesota English Test," *Student Counseling Bureau Bulletin and Occupational Newsletter*, 17:7-8, January, 1965.

\*MSAT, Form C, was first administered to all Minnesota high school juniors in 1966-67. It superceded MSAT, Form A, used with juniors 1957-58 to 1965-66.

\*\*These are the "official" percentiles included on the reports sent to high schools and colleges. These norms are equated to the original MSAT, Form A, norms based on 3,401 entering freshmen to the University of Minnesota in the fall of 1959. Thus, these percentile ranks are equivalent to the MSAT percentile ranks which were reported from 1959-66.

\*\*\*N = 65,830; Mean = 32.47; Standard Deviation = 13.19

### HIGH SCHOOL PERCENTILE RANKS (HSR)

HSR's corresponding to the percentiles for the median, the middle two-thirds (bold bars), and the middle 90% (light bar) for freshmen entering various types of Minnesota Colleges in fall, 1968.  
 (With all Minnesota Juniors included for comparison)

**GENERAL APTITUDE TEST BATTERY (GATB)**  
**and**  
**MINNESOTA VOCATIONAL INTEREST INVENTORY (MVII)**

**Norms for the Curriculum or Occupational (Training) Areas in  
Minnesota Area Vocational-Technical Schools**

The GATB and MVII norms on the following pages were furnished by Dr. David Pucel and Dr. Howard F. Nelson of the Department of Industrial Education, University of Minnesota. The norms were generated as a part of their Project MINI-SCORE\* (Minnesota Student Characteristics and Occupationally Related Education).

All of the 17,500 applicants to the full-time, day trade programs conducted in the Area Vocational-Technical Schools of Minnesota during the period from September, 1966 to October, 1968 took the paper and pencil portions of the GATB as part of an extensive battery used in the Project MINI-SCORE research.

In Project MINI-SCORE the training courses offered in Minnesota Area Vocational-Technical Schools were grouped into 63 relatively homogeneous groupings by personnel from the Minnesota State Department of Vocational Education and the Department of Industrial Education at the University of Minnesota. Presently, GATB, B-1002, Form B, training norms have been developed for 27 of these groups which attract a large proportion of students. Norms for additional training groups are being prepared and will be included as they become available. The 27 current training groups have been put into two clusters as follows:

<b>Cluster I</b>	<b>Cluster II</b>
Air Conditioning, Refrigeration and Appliance Repair	Accounting
Aircraft Mechanics	Chefs and Cooks
Agri-Technology	Clerical Training
Architectural Drafting	Cosmetology
Automotives	Data Processing
Diesel Mechanics	Dental Assistant
Electronics	Interior Design and Sales Assistant
Carpentry	Medical Laboratory Assistant
Farm Equipment Mechanics	Practical Nursing
Fluid Power Technology	Sales
Machine Shop	Secretarial Training

\*Project MINI-SCORE (Minnesota Student Characteristics and Occupationally Related Education) is supported by a grant from the Division of Comprehensive and Vocational Research, Office of Education, U.S. Department of Health, Education, and Welfare under the formal title "The Characteristics of Full-time Students in Post Secondary Trade Schools." Project No. HRD 5-0148.

### Cluster I -- Continued

Mechanical Drafting and Design  
Plumbing and Sheetmetal  
Power and Home Electricity  
Printing and Graphic Arts  
Welding

### Cluster II -- Continued

The specific courses which are included in each of these 27 area are listed on the following pages.

Notice that Cluster I contains occupations usually referred to as trade or technical occupations which attract predominantly males. Cluster II contains occupations related to business and social service and tend to enroll mostly females or both males and females.

The norm groups for the 27 Training Area are made up of students who *successfully completed courses in the particular training programs*. While these are important and useful norm groups, it is important to remember that success in training does not necessarily mean success on the job. Project MINI-SCORE is assembling follow-up data to examine the relationship between test scores and job success and satisfaction. These data will be available soon and will be published as a supplement to this book. Until they are available, however, counselors and students should keep in mind the distinction between training-success and job-related norms.

### **Project MINI-SCORE used only the written portions of GATB in its test battery.**

The omission of the GATB manipulative performance tests from the Project MINI-SCORE Battery means that data relating scores from these tests to training experience in Minnesota Area Vocational-Technical Schools and to subsequent job experience are not available or forthcoming.

Counselors may encounter students whose other scores or tentative vocational plans would make the manipulative scores useful, however. Many Minnesota counselors who have completed Employment Service GATB training programs and who are certified to administer GATB will want to administer the manipulative tests to such students. Schools who do not have a personnel with this training may be able to send selected students to their local Employment Service Office to have the tests administered.

### **AREA VOCATIONAL-TECHNICAL SCHOOL TRAINING AREAS**

The 27 training areas for which GATB norms are available are listed below.

1. AIR CONDITIONING, REFRIGERATION AND APPLIANCE REPAIR
2. AIRCRAFT MECHANICS
3. AGRI-TECHNOLOGY
  - Agri-Chemicals and Fertilizers, Sales and Service
  - Agricultural Technician (Animal Science)
  - Agriculture Technician (Plant Science)
  - Agricultural Sales Technician
4. ARCHITECTURAL DRAFTING
5. AUTOMOTIVES
  - Auto Mechanic
  - Auto Body Repair
  - Automobile Management
  - Automobile Technician
6. DIESEL MECHANICS
  - Diesel Mechanics
  - Diesel Mechanics Technicians
  - Truck and Diesel Mechanics
7. ELECTRONICS
  - Electronics
  - Electronics, Communications
  - Electronics, Computer Maintenance
  - Electronics, Industrial and Home Entertainment Service
  - Electronics, Industrial Technical
  - Electronics, Radio and Television
  - Electronics, Technician Communications
  - Electronics, Technician Industrial
  - Electronics, Technician
  - Electronics, Technology
8. CARPENTRY
  - Building Construction
  - Carpentry
9. FARM EQUIPMENT MECHANICS
  - Farm Equipment Mechanics
  - Farm Mechanics
10. FLUID POWER TECHNOLOGY

11. MACHINE SHOP
  - Machine Operator
  - Machinist
  - Production Machinist
12. MECHANICAL DRAFTING AND DESIGN
  - Engineering Drafting
  - Industrial Drafting
  - Industrial Drafting Technology
  - Machine Drafting
  - Technical Drafting
  - Design Technology
  - Drafting and Design Technology
13. PLUMBING AND SHEETMETAL
14. POWER AND HOME ELECTRICITY
  - Electrical
  - Electrical, Construction
  - Electrical, Maintenance
  - Electrical, Technology
  - Lineman Electrician
  - Power Plant Operation
15. PRINTING AND GRAPHIC ARTS
  - Graphic Arts
  - Photolithography and off-set printing
  - Offset Printing
16. WELDING
17. ACCOUNTING
18. CHEFS AND COOKS
  - Chef
  - Cook, Institutional
  - Hotel and Restaurant Cooking
19. CLERICAL TRAINING
  - Clerical Record Keeping
  - Clerk, General Office
  - Clerk-Typist
  - Clerk-Typist Machine Operator
20. COSMETOLOGY
21. DATA PROCESSING
  - Clerical Training and Data Processing
  - Clerical Training and Key Punch
  - Tabulating Machine Operator

- 22. DENTAL ASSISTANT
- 23. INTERIOR DESIGN AND SALES ASSISTANT
- 24. MEDICAL LABORATORY ASSISTANT
- 25. PRACTICAL NURSING
- 26. SALES
  - Sales Management
  - Sales and Marketing
  - Sales Training
- 27. SECRETARIAL TRAINING
  - Educational Secretary
  - Hospital Station Secretary
  - Secretarial Training, General
  - Secretarial Training, Medical
  - Stenographic Training
  - Medical Office Assistant
  - Medical Office Service
  - Legal Secretary

**GENERAL APTITUDE TEST BATTERY (GATB)**  
**Project MINI-SCORE Training Success Norms**  
**for**  
**Minnesota Area Vocational-Technical Schools\***

**Description of the Profiles**

The Aptitude Score Scale is plotted along the left side of each page. A bar for each of the seven aptitude scores represents the range of scores for *students who have successfully completed courses in that area*. The bold part of the bar represents the range of scores for the middle two-thirds of these students. The light portion of the bar represents the middle 90 per cent of the group. That is, 90 per cent of the students in the Project Mini-Score research who successfully completed courses in a particular area had GATB Aptitude scores which fell between the top and bottom ends of the light bars, and two-thirds of the students had Aptitude scores which fell between the top and bottom of the bold portion of the bars.

The seven GATB Aptitudes for which Minnesota Norms are available are as follows:

**Aptitude G – General Learning Ability (Intelligence)**

The ability to “catch on” or understand instructions and underlying principles and the ability to reason and make judgments.

**Aptitude V – Verbal Aptitude**

The ability to understand the meaning of words and the ideas they stand for, and to use them effectively.

**Aptitude N – Numerical Aptitude**

Ability to perform arithmetic operations quickly and accurately.

**Aptitude S – Spatial Aptitude**

Ability to think visually of geometric forms and to comprehend the two-dimensional representation of three-dimensional objects.

\*Please refer to Page 101 for a discussion of the Project MINI-SCORE Project and a description of the norm groups.

**Aptitude P – Form Perception**

Ability to perceive pertinent detail in objects in pictorial or graphic material.

**Aptitude Q – Clerical Perception**

Ability to perceive pertinent detail in verbal or tabular material.

**Aptitude K – Motor Coordination**

Ability to coordinate eyes and hands or fingers rapidly and accurately in making precise movements with speed.

**Air Conditioning, Refrigeration and Appliance Repair**

**EXPECTANCY TABLES FOR FRESHMEN  
ENTERING MINNESOTA COLLEGES**

The expectancy tables on the following pages are similar to tables published in earlier editions. For each group there are two tables for predicting first year college marks, one based on high school percentile ranks (HSR) and one based on the Minnesota Scholastic Aptitude Test (MSAT).

The user is referred to Dr. Perry's chapter on test interpretation for a further discussion of the use of these tables.

## FREQUENCY OF STRONG VOCATIONAL INTEREST BLANK (SVIB) SCORES AMONG MINNESOTA HIGH SCHOOL SENIORS\*

Edwin Gary Joselyn

Students and their counselors interpreting SVIB profiles often wonder how a profile compares with that of a "typical" senior. There seems to be a need for some kind of reference or norm to help determine whether a student's interests are quite different from those of his peers, and various reports of normative data have appeared in the SVIB literature from time to time. ° °

Tables 1 and 2 present percentage distributions of letter grades for Minnesota seniors who took SVIB through the Minnesota High School State-Wide Testing Program in 1966-67. Of the 310 schools which used SVIB with their seniors through the Program that year, 250 administered the instrument to all senior boys and 245 to all senior girls, a total of 8,168 boys and 7,263 girls. Only seniors from schools which tested all the boys or all the girls are included in the distributions in Tables 1 and 2. This was done to obtain a better cross-section of Minnesota seniors since schools which use SVIB with less than the entire class tend to test only brighter, "college-bound," seniors.

There may be some bias in these data, however, since the schools whose seniors are included represent a higher proportion of smaller, out-State communities. Nevertheless, because of the large N's (about one-quarter of the entire Minnesota class of 1967) and because the data include only schools where all seniors were tested, these tables are believed to be a good representation of Minnesota seniors.

These tables should help students and their counselors spot ways in which their interests are alike or different from other Minnesota seniors. For example, "A" scores on the Social Worker or Minister scales are much rarer among boys than "A" scores on the Farmer or Printer scales, and are probably more important.

High school senior boys tend to get high scores in Group IV, the Technical-Outdoor group, while many girls score high on the Secretary, Office Worker, and Housewife scales. Both boys and girls get their lowest scores on the Social Services areas. (Other studies have shown that men and women receive considerably higher scores in the Social Services area by age 25.) Notice that there are few scales on which many girls get very high scores. "A's" other than in the Secretarial and Housewife scales are fairly rare for girls.

## MINNESOTA VOCATIONAL INTEREST INVENTORY (MVII) PROJECT MINI-SCORE TRAINING SUCCESS NORMS FOR MINNESOTA AREA VOCATIONAL-TECHNICAL SCHOOLS\*

### Description of the Profiles

The MVII Raw Score is plotted along the left side of each page. A bar for each of the nine area scales represents the range of scores for *students who have successfully completed courses in that area*. The bold part of the bar represents the range of scores for the middle two-thirds of these students. The light portion of the bar represents the middle 90 per cent of the group. That is, 90 per cent of the students in the Project

Mini-Score research who successfully completed courses in a particular area had MVII scores which fell between the top and bottom ends of the light bars, and two-thirds of the students had Aptitude scores which fell between the top and bottom of the bold portion of the bars.

The nine "Area Keys" of the MVII are as follows:

#### H-1: *Mechanical*

Indicates interests in mechanical things, machine operation and design, or about home repairs of mechanical and simple electrical gadgets.

#### H-2: *Health Service*

Expresses interests in medical and hospital services, activities and occupations, or in working in medical, biological or chemical laboratories.

#### H-3: *Office Work*

Indicates interests in general clerical work and office machine operation, bookkeeping and accounting, and office management practices.

#### H-4: *Electronics*

This key expresses an interest in the maintenance, operation

\*Please refer to Page 101 for a discussion of the Project MINI-SCORE Project and a description of the norm groups.

and construction of electronic equipment, and the repair and construction of electrical systems and devices.

H-5: *Food Service*

Indicates interests in the preparation of food and menu planning.

H-6: *Carpentry*

This cluster deals primarily with interests relating to carpentry, cabinet making and furniture construction.

H-7: *Sales-Office*

Two clusters of interests are indicated here. The larger deals with a variety of verbal activities, while the other relates to aesthetic interests. High scores are made by retail sales clerks, new-car salesmen, printers, and persons engaged in office work.

H-8: *Clean Hands*

Indicates an interest in those occupations which possess "clean hands" kinds of activities.

H-9: *Outdoors*

This key reflects an interest in athletics and other outdoor activities.
