ABSTRACT
        The purpose of the study reported here was to assess
the various decentralization efforts as they occurred in different
services and in different cities. The study reviewed
decentralization's record in terms of five outcomes: (1) Increases in
the flow of information between servers and served; (2) Improvements
in service officials attitudes; (3) Improvements in client attitudes;
(4) Improvements in services delivered; (5) Increases in client
control. The study was based on an assessment of 215 previously
written case studies of decentralization, collected from published
sources as well as from federal agency records. The case studies
covered such innovations as police-community relations programs, team
policing, neighborhood health centers, new neighborhood multiservice
facilities, little city halls, ombudsmen and complaint procedures and
district control of schools. The Community Action and Model Cities
programs prepared the groundwork for urban decentralization. However,
each of these federal programs emphasized only one of the two
dimensions of decentralization. The first dimension of
decentralization, coming mainly from the Community Act Program,
involves a client imperative. A second, equally important dimension
coming more from the Model Cities experience invokes a territorial
imperative. (Author/JM)

PREFACE

This report serves as the executive summary for *Street-Level Governments: Assessing Decentralization and Urban Services*, R-1527-NSF, October 1974. The summary presents the basic findings from a recently completed study, but the interested reader should refer to the full report for further discussions of the research methods, service contexts, and more detailed discussions of such topics as citizen participation.

An adapted version of this executive summary will appear as a special article in *Nation's Cities Magazine*.

STREET-LEVEL GOVERNMENTS: ASSESSING DECENTRALIZATION AND URBAN SERVICE

INTRODUCTION

In the 1960s, decentralization suddenly became a major and much de-
bated innovation in urban administration. Advocates claimed that de-
centralization would dramatically revitalize the urban scene, while
critics believed that it would do great damage to the ord·rly process
of government. In most cases, the goal of decentralization was either
to improve services or to provide the recipients of services with a
greater measure of control over service delivery. Where government was
unresponsive or did not provide a needed service, decentralization also
included the call for new neighborhood institutions to serve public
needs--institutions that did not necessarily have to be built within
the municipal bureaucracy. But whatever the form of decentralization,
its central theme was to bring government closer to the people being
served, and the consequent focus of decentralization was on the social
relationship between those providing urban services and those receiving
them.

The purpose of the present study was to assess the various decen-
tralization efforts as they occurred in different services and in dif-
ferent cities. The study reviewed decentralization's record in terms of
five outcomes:

1. Increases in the flow of information between servers and
   served. Decentralization often improves information and
   communication, so that those providing services know
   more about service needs and those using services know
   more about services provided. The calling of frequent
   meetings and distribution of printed materials would be
   examples. However, in the long run this outcome actually
   becomes a means for achieving the next four, and hence it
   is not considered as important as the next four.

2. Improvements in service officials' attitudes. Decentralization can lead to service officials having a more positive view of their own role, of the service being provided, or of clients and their needs.

3. Improvements in client attitudes. Decentralization can similarly lead to clients having a more positive view of their role, of the services being provided, or of the server group and its problems.

4. Improvements in services delivered. Decentralization may produce better services, as judged by output (e.g., higher reading scores) or by input (e.g., more teachers per student).

5. Increases in client control. Finally, decentralization can result in clients having the power to implement their own ideas in service delivery. For example, a local school board can be client-dominated and act as a governing body for the school district.

The study was based on an assessment of 215 previously written case studies of decentralization, collected from published sources as well as from federal agency records, and was supported by the Research Applied to National Needs program of the National Science Foundation.[1] The case studies covered such innovations as police-community relations programs, team policing, neighborhood health centers, new neighborhood multiservice facilities, little city halls, ombudsmen and complaint procedures, district control of schools, and community development corporations.

DEFINING DECENTRALIZATION

The Community Action and Model Cities programs prepared the groundwork for urban decentralization. However, each of these federal

---

[1] The full study is reported in Robert K. Yin and Douglas Yates, *Street-Level Governments: Assessing Decentralization and Urban Services*, The Rand Corporation, R-1527-NSF, October 1974. In all, 269 case studies were originally gathered, but 54 were discarded because they did not meet our criteria for research quality.

8

programs emphasized only one of the two dimensions of decentralization, and the federal activities themselves were not the main subject of the current study.

The first dimension of decentralization, coming mainly from the Community Action Program, involves a *client* imperative. Decentralization thus focuses on the status, rights, responsibilities, and powers of client groups served by public programs, regardless of residential location. *Decentralization here has meant the transference of responsibility and power to those very people who are affected by the program or innovation in question.* The client dimension of decentralization has led to a general association between any decentralization attempt and the increase in responsibility and power of those being served, especially low-income and disadvantaged groups.

But the client dimension has not been the only one. A second, equally important dimension of decentralization coming more from the Model Cities experience invokes a *territorial* imperative. That is, the target of decentralization is also a particular neighborhood--its physical assets and resident population. *Decentralization here has meant the redeployment of resources and efforts, from whatever out-side agency or source of government, to a small geographic area.* The territorial dimension of decentralization has led to a general association between any decentralization attempt and improvement in the physical and social conditions of specific neighborhoods. Thus, decen-tralization has come to be associated with specific neighborhoods such as Harlem, the Lower East Side, Hough, Watts, Hyde Park-Kenwood, Roxbury, and the like.

Both of these dimensions of decentralization were found in varying degrees in each project or innovation. In some cases, such as decen-tralization to local school boards, both the territorial and client dimensions were maximally decentralized, and the innovation was intended to produce both increases in client control and improvements for the neighborhood. In other cases, as in a city-wide grievance procedure that gave a larger role to clients or in the strict physical redeployment of services or facilities, decentralization was really occurring along one dimension but not the other. The fact that these

9

two dimensions have generally not been explicitly contrasted in the past may account for some oi the confusion over the term "decentralization." For some observers decentralization automatically connotes the client dimension and raises one set of expectations regarding the transference of political power; for other observers decentralization automatically connotes the territorial dimension and raises another set of expectations regarding neighborhood issues.

These two dimensions allowed us to categorize the decentralization efforts into three groups:

o   Those that were *weak* forms of decentralization because significant decentralization was not intended on either territorial or client dimensions (physical redeployment, administrative decentralization, and grievance mechanisms were the weaker forms, with community relations being the weakest of all);

o   Those that were *moderate* forms because some decentralization along both dimensions was intended (indigenous employment and new neighborhood institutions were the moderate forms); and

o   Those that were *strong* forms because substantial decentralization along both dimensions was intended (political decentralization).

The terms "weak," "moderate," and "strong," in other words, were applied throughout the present study as descriptions of the intended degree of decentralization and did not refer to the effects of decentralization. In total, 66 case studies fell into the weak category, 56 into the moderate category, and 93 into the strong category.

RESEARCH QUESTIONS AND METHOD

The study dealt with the following major questions:

o   What have been the outcomes of the decentralization innovations, as reported by the case studies?

o What was the relationship between these outcomes and
the attempt to implement weak, moderate, and strong
decentralization strategies?

o What was the relationship between these outcomes and
other factors such as the type of service being
decentralized, the availability of federal funds to
support the innovation, and the role of the mayor in
supporting the innovation?

o What have been the lessons and effects of the decen-
tralization experience?

The answers to these questions were based on the aggregation of
215 case studies of urban decentralization efforts in five service
areas: public safety, health, multiservice programs, education, and
economic development (see Figure 1 for a sample list of studies).
The application of a *case survey method* provided the means for aggre-
gating the characteristics from these case studies. The case survey
called for a reader-analyst to answer the same set of questions, or
checklist, for each case study of decentralization, with a case study
being defined as *any description of a site-specific organizational
change in an urban area.*[1] These checklist data then served as the
basic body of evidence resulting from our review of the decentralization
literature.

OUTCOMES OF URBAN DECENTRALIZATION

In the aggregate, what were the decentralization outcomes reported
by the case studies? Five different checklist questions served as the
keys to the five decentralization outcomes. An affirmative answer to any

---

[1]The checklist questions were closed-ended, allowing the answers
to be aggregated in a simple manner. The questions covered the major
characteristics of decentralization, divided into four sections: the
nature of the case study, the background characteristics for the
innovation, the characteristics of the decentralization innovation,
and the outcomes of the decentralization innovation. In all, there
were a total of 118 questions that the reader-analyst had to answer.

one of these questions meant that a positive outcome was tallied.
(See Figures 2-6 for examples of the case study evidence.) Individual
studies could obviously report more than one outcome or none at all.

Based on these tallies, the two c   .. outcomes were improved
services and increased flow of information. About 66 percent of all
the studies reported an association between decentralization and an
improvement in services, whether of a major or minor sort, and about
61 percent of the studies reported an association between decentrali-
zation and an improved flow of information. The other three outcomes
each occurred in less than 25 percent of the studies (see Figure 7).
These rates of outcomes, especially of improvec services, suggest that
*the case studies have on balance reported a fairly positive picture of
the decentralization experience.* Certainly the results do not warrant
any of the strongly negative interpretations of the overall decen-
tralization experience, a point to be discussed further at the end of
this report.

The five outcomes were also examined for potential tradeoffs.
That is, a prevailing question about decentralization is whether
certain outcomes tend to occur only at the expense of other outcomes.
In particular, increased citizen control may occur to the exclusion
of improved services, or vice versa. To test this and similar
hypotheses regarding the relationship among the five outcomes, cross-
tabulations were carried out for the 215 case studies, with each paired
combination of the five outcomes being examined. The results showed
the following statistically significant relationships:

o Increased client control, as an outcome, was *positively*
   related to improved services; and

o Improved agency attitudes were *positively* related to
   improved client attitudes.

None of the other cross-tabulations among the five outcomes showed a
significant relationship, in a positive or negative direction, indi-
cating that there were no negative tradeoffs among any of the out-
comes as the only significant relationships were positive.

Fig. 2 -- INCREASED FLOW OF INFORMATION

One question in the checklist dealt with increased social contact or passage of information between servers and served. Examples of evidence from specific case studies were:

"The Public Information Office handles some 4,000 complaints and 8,000 walk-in requests for information annually."

"During the first three months, the paraprofessional receptionists served 20,000 clients."

". . . outreach workers helped clients to complete forms and prepare letters on the client's behalf . . ."

". . . the health education _des carried out a community survey to determine residents' perceived health problems . . ."

"The school . . . produced a widely acclaimed community information manual which was distributed to every parent or family . . ."

A total of 132 or *61.4 percent of all the studies indicated that an increase in information had occurred* as a result of the decentralization innovation.

Fig. 3 -- IMPROVED SERVICE OFFICIALS' ATTITUDES

A second checklist question dealt with any evidence that service officials had a more positive attitude toward either the service being rendered or the clients as a result of the innovation. Examples of evidence of positive and negative outcomes were:

"[As assessed on a questionnaire], teachers and administrators perceived [the decentralized schools] to have a stronger, freer intellectual atmosphere and a more growth-inducing climate."

". . . police officers responded 'yes' when asked whether they thought [the unit] had improved police-community relations."

"The [new decentralized police] teams never became popular with non-team members, . . . and [there were] recruiting difficulties."

". . . [survey results show] agencies which work within little city hall facilities generally feel the program has helped them relate to the city and reach citizens more effectively by their proximity."

A total of 27 or *12.6 percent of the studies indicated that service officials' attitudes had improved* as a result of the decentralization innovation.

Fig. 4 -- IMPROVED CLIENT ATTITUDES

A third question dealt with changes in client attitudes, either toward service officials or the services rendered. Examples were:

". . . [A majority of the] residents surveyed expressed agreement with the statement, 'I believe the program makes my neighborhood safe.'"

"Citizens view branch city halls as a convenience to them in those areas where service is good. The branches reinforce community identity . . ."

". . . students [in the decentralization program] responded positively to forty statements about the police, requiring responses from favorable to unfavorable on an 11-point scale . . ."

"Community board members surveyed gave a high rating for the community officer program . . ."

"Patients were asked to rate their satisfaction with services and to note whether they knew the staff person who had served them . . ."

A total of 53 or *24.7 percent of the studies indicated that client attitudes had improved* as a result of the decentralization innovation.

Fig. 5 -- IMPROVED SERVICES

The fourth outcome concerned improvements in public services that could be attributed to the decentralization innovation. Examples were:

"Over a three-year period roughly $2 million [in loans] have been provided to forty-eight local firms."

". . . more than 1,450 houses have been renovated in a program that has employed over 900 formerly unemployed and unskilled youths."

"[Before the clinic was expanded, there were] 350 patients per month. Afterwards, the average was 550 patients per month."

"1,000 patient visits were analyzed for the average number of diagnostic and treatment actions, and the results compared with those of three non-poverty clinics."

"For calendar 1970, 1,887 individuals were registered at the center and participation [in its service activities] totaled 47,438."

"[The program has resulted in] . . . 135 ditches being cleaned, 55 streets repaired, 45 lots cleared, . . ."

A total of 142 or *66.1 percent of the case studies indicated an improvement in services* attributable to the decentralization innovation.

Fig. 6 -- INCREASED CLIENT CONTROL

The fifth and last outcome was reflected in the checklist question on the clients' ability to implement their own ideas in organizing services. An affirmative answer to this question meant that the case study had pointed to some decision that had been made or heavily influenced by the clients. Examples of this evidence were:

"When the School Board proposed that a community school coordinator should have a salary of $14,000 and academic requirements that would have eliminated [neighborhood] residents from consideration, the [local board] came in with a counterproposal. Finally, a compromise was reached that there should be a $10,000 coordinator and a $6,000 assistant coordinator as a resident-in-training for the job."

"Residents helped to develop the neighborhood youth center and the drug abuse and new careers programs."

"The [citizen board] chose the site . . . and reviewed staff appointments for the new health center . . ."

". . . the community boards won the right to appoint their own local superintendent to either 2- or 4-year contracts. Previously the local superintendents were named, virtually for life, by the central board."

". . . forty [neighborhood] residents elected in neighborhood elections and seventeen appointed agency representatives serve on the . . . board, which plans and governs the . . . program."

A total of 48 or *22.3 percent of the case studies indicated an increase in client control* as a result of the decentralization innovation.
Fig. 7 -- Results for Five Decentralization Outcomes (n = 215)

Finally, when the weak, moderate, and strong categories of decentralization efforts were compared in terms of the frequency of the five outcomes, the results (see Figure 8) showed that:
o *Strong forms of decentralization were associated with higher frequencies of improved services and increased client control;*

o *Weak forms were associated with increased information; and*

o *No significant differences were observed for improved agency attitudes and improved client attitudes.*

In other words, strong decentralization was more successful in a hieving *both* the service improvement and client control outcomes.

The lack of any relationship between the strength of the decentralization strategy and either servi·e officials' or clients' attitudes is consistent with a theme found in the past—that decentralization innovations probably have little effect on attitudes about government. Such attitudes appear to be based on many factors, not merely those concerned with specific local service, and cannot be expected to be changed on the basis of innovations in a specific service. Media coverage, national and even foreign affairs, and simple awareness of local events and service changes are all as likely as the innovation itself to be important in shaping attitudes toward a specific local service such as police protection, education, or health services.

STREET-LEVEL GOVERNMENTS: THE SERVICE HYPOTHESIS

If strong decentralization strategies were so clearly related to positive outcomes for improved services and increased client control, then it is important to understand the conditions under which strong decentralization took place. One of the most important factors here appeared to be the nature of the service bureaucracy and the specific service being decentralized. In other words, urban decentralization can occur only within the context of a specific municipal service—for example, police or fire protection, education, and social services. Each

*p < .01.

Fig. 8 -- Weak, Moderate, and Strong Decentralization
Strategies, by Five Outcomes

-14-

service has different traditions and ground rules, and these affect any
decentralization innovation attempted in that service.

The problems of service delivery at the street-level are not the
problems of a single governmental structure, but are those of different
street-level governments. For instance, the police service is a sep-
arate entity that operates rather independently of and in a different
manner from the school system or the health care system. These street-
level governments differ in their decisionmaking processes, their internal
relations of authority, their ethnic, age, and sex composition of employ-
ment, and, most important, in their openness to the participation and
demands of the governed in influencing service policies.

Police protection and health services are dominated by highly pro-
fessional server groups that set the rules for service delivery. Cli-
ents have traditionally had little policy influence over these services,
even though considerable discretion may be exercised in individual police-
citizen or doctor-patient relationships. In multiservice programs, there
is no dominant professional erver group, but there have also been no
traditional mechanisms available for clients to participate in policy-
making, as a strong bureaucracy has traditionally minimized client in-
fluence. In contrast, in education and economic development, clients
have had greater opportunities to influence policymaking. In education,
the traditional openness of the service to parents and the establishment
of joint parent-teacher organizations and activities have provided a basis
for an exchange of ideas and for the potential influence by parents over
school policy. In economic development, the public service is fairly new
on the urban scene, but the basic tenet of organization has been an even
stronger sharing of responsibility between servers and served.

In contrasting these services, there are two important elements
at work: the degree of professionalism and the scope of bureaucratic
control. The more a service area possesses both of these elements,
the more *closed* it is to client influence; the less a service possesses
them, the more *open* it is. Given these two elements, the five services
in our study were ranked as shown in Table 1. The service hypothesis

is therefore that this basic nature of the service bureaucracy not
only affects the outcomes of any decentralization, but also affects
the types of decentralization innovations tried in the first place.

Table 1

RANKING OF FIVE SERVICE AREAS BY SERVER-SERVED RELATIONSHIP

Service	Degree of Server Control over Policies	
	Professional	Bureaucratic
Safety	High	High
Health	High	Moderate
Multiservice programs	Low	High
Education	Moderate	Moderate
Economic development	Low	Low

The case survey revealed that each of the five services was marked
by characteristically different strategies and outcomes. In particular,
the safety, health, and multiservice areas had high occurrences of weak
decentralization strategies, whereas the education and economic
development areas had high occurrences of strong strategies. Table 2
summarizes the frequency of occurrence of weak, moderate, and strong
strategies for each service area and shows that the relationship between
services and type of strategy was highly significant. In this relation-
ship, the more open the service in terms of the degree of professional
and bureaucratic control, the more frequently strong decentralization
strategies were tried; conversely, the more closed the bureaucracy,
the more frequently weak strategies were tried.

Because of these service variations in strategies attempted, it
was not surprising that the five services also varied significantly in
the frequency of positive outcomes. Figure 9 shows the success rates
for each outcome by service area. The safety and multiservice areas
had high rates of increased flow of information but low rates of
increased client control. Education and economic development showed
distinctively high rates of increased client control. Health had

Table 2

WEAK, MODERATE, AND STRONG DECENTRALIZATION STRATEGIES
BY SERVICE AREA
$(n=215)^a$

Service Area	Total Number of Studies	Type of Decentralization Strategy		
		Strong	Moderate	Weak
Safety	38	4	10	24
Health	48	13	21	14
Multiservice	41	8	10	23
Education	34	26	3	5
Economic development	54	42	12	0
Total	215	93	56	66

[a] $\chi^2 = 92.09$, df = 8, p < .001.

moderate outcome levels in comparison with the other service areas for
all the outcomes. For each outcome, the service variation was statis-
tically significant.

These findings fit into a single general explanation for the
decentralization outccmes. The first part of the explanation is that
stronger decentralization strategies were more successful than weak
ones in improving services and increasing client control because the
stronger strategies (new institutions, employment, and political decen-
tralization) put greater political and economic resources in the hands
of service deliverers and clients, and constituted potent instruments
for reshaping the service relationship. By contrast, the resources
and administrative leverage provided by the weak strategies (community
relations, grievance mechanisms, physical redeployment, and admini-
strative decentralization) were less substantial. Thus, one might
simply conclude that the stronger the decentralization strategy, the
more successful it was for improving services and increasing client
control.

The second part of the explanation, however, concerns the service
conditions for decentralization. Here, the thesis is that there was

Fig. 9 -- Decentralization Outcomes, by Service Area

an obstacle to decentralization that hinged on the openness or closed-
ness of the service bureaucracy. Any decentralization strategy will
encounter opposition in the more bureaucratic and professionalized
(and hence closed) services. Closed bureaucracies therefore tended
to permit only weak strategies to emerge. Conversely, strong
strategies emerged and were successful in such open bureaucracies as
education and economic development. In sum, the success of decen-
tralization depended on *two* factors:

(1) *Successful decentralization was directly related to
the strength of the decentralization strategy;* and

(2) *Successful decentralization was inversely related to
the degree of professional and bureaucratic control
over service policies.*

THE NON-SERVICE VIEW: INFLUENCE OF EXOGENOUS FACTORS

In contrast to the interpretation that successful decentralization
was determined in part by the strategy and in part by the service,
other analysts have frequently cited exogenous, non-service-specific
factors as being most highly associated with success. These factors
deal primarily with the preconditions for decentralization. Two pre-
conditions in particular have been thought to be related to successful
decentralization experiences:

o Financial support of the innovation by the federal govern-
ment; and

o The support of the innovation by the mayor or municipal
executive.

The case survey showed that these factors did not account for the pattern
of decentralization outcomes and hence could not be used to negate the
strategy-service interpretation.

Figure 10 shows the decentralization outcomes in relation to the
presence of federal support. The results indicated that there were no
significant differences for any of the five outcomes, and hence *the*

Fig 10 -- Relationship of Federal Financial Support to Decentralization Outcomes

-20-

*presence of federal support made little difference for the decentrali-
zation outcomes.* These results do differ from those reported by others,
but the explanation of the difference appears quite simple. Previous
studies have focused primarily on CAP and Model Cities efforts, whereas
our study focused on decentralization in specific urban services.
Thus, although the proportion of federal funds may be an important
factor in building citizen participation in new programs such as CAPs
and Model Cities, the presence of such funds did not influence and
should not be expected to have influenced the outcomes of decentrali-
zation in existing service bureaucracies.

A second factor that has been considered very important to
successful decentralization is the active participation of the mayor
or municipal executive in the innovation. The interpretation has been
that a mayor's commitment to an innovation may mean the availability
of more local resources; but at a minimum, his support means that city
hall will probably not try to undermine the innovation.

The case survey included a question regarding the role of the
mayor or municipal executive. However, the answers were quite sensitive
to the completeness or focus of the original case study, and there were
89 studies, or over 40 percent of the cases, in which "no information"
was given as the answer to this question. This "no response" rate was
much higher than that of any other question reported throughout this
entire study, and the results should therefore be interpreted with
extreme caution.

The results showed that the only decentralization outcomes for
which mayoral or municipal executive activity appeared to make a dif-
ference were increased flow of information and improved services (see
Figure 11). Mayoral activity was *not* related to increased client
control. The interesting aspect of these findings is that mayoral
activity was inversely related to improved services and positively
related to increased information, suggesting that mayoral participation
was associated with weak decentralization strategies. In general, *the
case survey, with a high "no response" rate on this question, showed no
positive relationships between mayoral activity and improved services
or increased client control.*

Fig. 11 -- Relationship of Mayor's Role to Decentralization Outcomes

*p < .05

Similar analyses were carried out with two other exogenous conditions, the size of the target population and the occurrence of pre-implementation conflict within the community. However, only a moderate- to small-sized target population appeared to have any relationship to both the improved services and increased control outcomes. Except for this finding, the exogenous factors did not account for the pattern of decentralization outcomes. In other words, the availability of federal funds, the active participation of the mayor, and the occurrence of pre-implementation conflict did not have the requisite relationships to the outcomes. As a result, our interpretation of the importance of strategy and service factors remains as the main conclusion regarding urban decentralization.

INTERPRETING THE DECENTRALIZATION EXPERIENCE: ITS SUCCESS AND FAILURE

Where these findings provide room for viewing decentralization innovations as a partial success given the nature of the different services, the general view held by *reformers, participants,* and the *majority culture* has been that decentralization has failed to produce the anticipated changes. An attempt to reconcile this seeming contradiction between the apparent success and failure of decentralization provides an opportunity for summarizing the major lessons to be learned from the urban decentralization experience.

The *reformist critique* is straightforward: Except for a very few cases, decentralization innovations have not given clients substantial authority. It is not surprising, then, that substantial client control has not occurred either, and thus, for the reformists, decentralization has simply not yet been put to a full test. This view of the decentralization experience is certainly a valid one. A significant shift in power from servers to served, for instance, would not only result in the emergence of new and powerful client-dominated organizations, but also in the waning of existing provider-dominated organizations; and such changes in the institutional balance of power have not occurred. What the reformers have themselves failed to demonstrate, however, is whether there are any viable means of achieving their goals.

28

The problem varies considerably by service area, and only in education has there been any evidence of frequent (though not necessarily substantial) increases in client control. Even in education, however, no successful reform strategy has emerged; the current guidelines still do not adequately assure that new decentralization attempts will not also be accompanied by a more than compensatory surge of union or centrist power. For other service areas, the lack of a viable strategy is an even greater deficiency. There are no demonstrable mechanisms for substantially increasing client control, for instance, over such closed bureaucracies as the police or fire departments. The only alternative would appear to be the establishment of new organizations that would provide the same services and be client-controlled. However, this alternative must be discarded on the basis of the experience with the economic development cases. The reformers have failed to address the question of why substantial community control did not emerge even here, but one suspects that the development of a new institution may not be the phase during which client control can work effectively.

In short, the reformers have not developed a strategy for creating client-controlled urban services in the variety of organizational circumstances in which such services are delivered. Given the lack of such a strategy, the reformists' critique of the decentralization experience has been somewhat utopian. The failure of decentralization has been a judgment based on the failure to attain unachievable goals.

The *participants' critique* stems from the fact that most people who have participated in decentralization innovations, whether as service officials or as consumer representatives, tend to have negative feelings toward decentralization. The personal or collective benefits from decentralization have failed to justify the heavy personal "costs" of participation. The "costs" include the endless hours spent, emotions invested, and conflicts and frustrations produced.

The participants' critique is valid and cannot be discarded. Most of the benefits from decentralization that our study uncovered were minor and certainly were not likely to justify heavy participant "costs." So although in our terms decentralization may have succeeded,

in the participants' terms it did not succeed nearly enough. And
future decentralization efforts must keep this implicit calculus in
mind: Whatever the projected benefits, they must outweigh the costs
of participation.

Finally, the *majority critique* is captured by the declining public
interest in decentralization. The critique is implicitly based on a
certain view of the city of the 1960s, which was that the city was
burdened with increased crime and drug addiction, declining quality
of inner-city education and health, high rates of unemployment and
welfare dependency, and residential abandonment and decay.

Many of the proposals for decentralization stemmed from a desire
to deal with these urban problems and the quality of life. In fact,
decentralization today is still associated with vague but important
expectations that one's city or neighborhood will become a more
pleasant place in which to live. The majority critique of decentrali-
zation, then, is that decentralization failed to produce visible changes
in the quality of urban life. Obviously, our own results have not
dealt with this level of outcome but have focused on less visible
service changes. However, the majority critique is based on one
important and, we feel, unproved assumption. Although there is some
evidence that the *business* of both the federal government and local
governments can affect the quality of urban life, we know of little
evidence that suggests that the *organization* of government, at either
level, can have such effects. Decentralization, after all, has to do
with the reorganization of political procedure, whether entirely within
the bureaucracy or involving external citizen control mechanisms. Such
reorganization can rightly be expected to have administrative effects
(shifts in power, greater efficiency, more pluralistic decisionmaking,
or changed physical location of governmental offices), but one has to
withhold judgment about its potential quality-of-life effects (increased
safety, health, and economic opportunity). Thus, the matter of the
relationship between the organization of government and quality-of-life
effects is a topic for further research. Whether a mayor is building
superagencies, inducing massive horizontal integration and services
coordination, or decentralizing offices, there is a need for some

evidence that any such organizational changes make a difference beyond purely operational effects.

THE LASTING EFFECT OF DECENTRALIZATION

This discussion of success and failure does not provide a full assessment of decentralization. That is, it is important not only to see what decentralization has achieved to date but also to consider albeit in a more speculative way, decentralization's potential future effects. The urban decentralization experience may influence urban and national policymaking in four ways.

The first effect lies in the improved understanding of neighborhood institutions and citizen participation. Decentralization has shown that intricate and dynamic political forces continually operate in the neighborhood and between neighborhoods and city government, and that attempts to install major organizational changes inevitably lead to secondary effects that may offset the initial changes. Nowhere is this "balance of power" notion more relevant than at the neighborhood level. An improved understanding of neighborhood institutions is extremely important because the institutions provide a persistent opportunity and point of entry for citizen participation. To move beyond erratic protest efforts, citizens need institutional structures through which they can channel their energies and in which they can find a ready vehicle for expressing their views. Thus, building new neighborhood institutions or replacing old ones will be of continuing concern, whether government is involved in the building process or not.

A second potential effect of urban decentralization is that it may serve to sustain a strong, human service orientation in urban policy. Only in recent years has the quality of municipal service delivery in general received more than sporadic attention from policymakers both in the city and in national government. Decentralization, along with other organizational innovations, has helped to call attention to the intricacies of service delivery. But the distinctive contribution of decentralization is to emphasize the street-level relationship between the servers and the served. Since this human relationship lies at the heart of urban services, a solidification of the service focus

31

through decentralization will perform the useful function of anchor-
ing urban administration to specific social relationships.

A third effect of decentralization bears directly on the relation-
ship of the servers and the served in urban services. Although one
would probably not go so far as to claim that client participation has
been institutionalized in the sense that formal mechanisms for
participation will always be provided, the decentralization experience
has probably counteracted the previous trend in which service bureau-
cracies were becoming increasingly accountable to themselves alone.
And what may have become institutionalized is the notion that clients
have a right to significant influence over service delivery, as well
as the ever-present threat that client power can be called upon to act
as a curb whenever service bureaucracies become unresponsive.

Finally, one of the most significant implications of decentrali-
zation is that it has brought the analysis of service problems down to
the street-level. That is, decentralization entails a view of urban
problems that is unusually sensitive to block and neighborhood needs
and problems. Such a street-level analysis of service problems is a
rare element in public planning and policy analysis. Typically, the
dominant concern in public policymaking has been to increase the
planning and analytical capacities of city hall or of the federal
government. By contrast, decentralized service delivery makes the
particularity of neighborhood services its central concern, and it
highlights the important variations in the supply of and demand for
services between neighborhoods.

In summary, our study suggests the following choices for future
decentralization efforts: First, given a choice between a federally
or a locally initiated policy, the results support locally based
policies. On the one hand, federal support was not a major condition
of success and, on the other hand, the complexity of the neighborhood
service setting calls for a hand-tailoring of an innovation to its
local environment. Second, given a choice between comprehensive and
service-specific strategies, our findings indicate that decentralization
strategies must be tailored to fit particular services. Decentralization
should not be thought of as a single policy instrument but as an array

of instruments, some of which are better suited than others to particular services. Finally, given a choice between strong and weak strategies, no decisive answer or policy recommendation can be given. Strong strategies produce a higher rate of positive outcomes, but they may also meet intensive resistance in "closed" service environments. This does not mean that strong strategies should not be tried in closed environments, but rather that the probabilities of their working are low and the cost of making them work high. A more confident conclusion is that both strong and weak strategies do work, although in different ways, and therefore a combination of strategies might be tried in most neighborhoods and service areas.
