ABSTRACT

The first 19 pages of the document describe a study carried out to examine the feasibility of using health intervention as a means of increasing entry of welfare clients into job training. Objective screening procedures were used to define physical and mental health problems and handicaps in a New York State sample population. Common health disabilities identified in the experimental group included emotional handicaps such as sick-role behavior, aversive handicaps including obesity, dental decay, and locomotor handicaps with limited mobility. Health intervention included treatment of sick-role behavior and other emotional problems by group counseling, weight reduction, exercise classes, and treatment of specific medical and dental problems. Job motivation classes were also provided. Improvement in health status and solution of problems was correlated with compliance in relation to treatment. Clients with initial medical handicaps, successful in the health rehabilitation program, entered CETA job training and gained employment, doing as well as controls without chronic health problems over the same period. Appended materials include: all forms used, a short job motivation course outline, 70 case resumes, code words and definitions, and tables summarizing all measures (educational, social, personal, and medical) and correlations between all measures. (Author/BP)

Documents acquired by ERIC include many informal unpublished materials not available from other sources. ERIC makes every effort to obtain the best copy available. SUMMARY OF SALIENT FINDINGS

1. Finding: A significant number of persons having non-health eligibility characteristics for local job training and placement programs (CETA) claim medical problems as a reason for non-participation.

Implication: Registrants for job training should have health evaluation to determine actual health status and particularly the feasibility of remediable treatment to foster employability.

2. Finding: Among the health problems cited as reasons for non-participation in job training, those for which it is difficult to exclude some degree of disability figure largely. These include back problems, recurrent black-outs, migraine and nervousness.

<u>Implication</u>: Health evaluation must include testing procedures which can distinguish these conditions which confer a real handicap from those associated with hypochondriasis or malingering.

3. Finding: Sick role behavior is frequently found among welfare clients and is associated with long-term underemployment or unemployment, extrinsic handicaps including long-standing poverty situations, and family disharmony. Persons playing a sick role tend to have passive-dependent personalities. Sick role behavior is associated strongly with unemployment.

Implication: It is most important to use evaluation procedures which accurately delineate sick role behavior. Group therapy aimed at combatting sick role behavior must be provided to allow persons exhibiting such behavior to become employable.

4. Finding: Perceived health related job restriction by the client has been related to the number of current complaints, the hypochondriasis score, and negatively to performance in exercise tests. Measures of physical fitness as well as of intrinsic health handicaps have been found to have a predicted value in deciding whether clients are likely to respond to rehabilitation.

Implication: Objective definition of health status including motivation must continue to be a prominent feature of health intervention programs related to job training under the Manpower Administration. Reproducible measures of physical and mental health status of clients should be used to generate prognostic information for WIN/CETA agency personnel.

5. <u>Finding</u>: Aversive handicaps are similar in frequency to emotional problems in contributing to the health disorders of welfare clients. The commonest aversive handicap is obesity. Long-term obesity is particularly resistant to intervention in this population.

Implication: Programs for the treatment of obesity have to be designed by a nutritionist and physicians familiar with weight reduction programs for low income - low education groups.

6. <u>Finding:</u> Adequate health evaluation may require consultant opinion from medical and/or dental specialists for which ADC clients can be covered by Medicaid.

Implication: In establishing a health rehabilitation unit for ADC clients it is necessary to negotiate with the local Department of Social Services to

insure that they will understand the necessity of referrals to area health services for evaluation as well as treatment purposes.

7. Finding: Non-compliance for prescribed therapies is characteristic of some clients, this detracting from the success of health intervention.

Implication: Contractual arrangements must be made with clients so that they have a time schedule in which to accomplish therapeutic goals. Token rewards should be offered for session attendance and expected achievement.

8. Finding: Clients geared to patch-up medicine and dental treatment are unfamiliar with the advantages of health rehabilitation, nor do they know how to seek or obtain optimal community health care.

Implication: Health education must have high priority with particular reference to upgrading health practices.

9. Finding: Non-attendance and/or lack of progress in therapeutic sessions after 3 months has been associated with overall failure to reach job readiness.

<u>Implication</u>: All clients should be re-evaluated after every 3 morths. Those who fail to comply with advised treatment despite all encouragement and social assistance should be dropped from job related health intervention programs, except under extenuating circumstances.

10. Finding: Clients receiving active health intervention had more medical problems initially, were more likely to have emotional and aversive (unsightly) handicaps, and were less likely to be employed. In spite of these disadvantages, with rehabilitation, the success of the group on entering job training and/or employment was similar to that of a control group without such problems.

<u>Implication</u>: Based on this initial experience, it is projected that ajob oriented health intervention program can increase employability.

11. Finding: As far as this feasibility study can show, successful health intervention does contribute to the employability potential of welfare clients.

Implication: It is highly recommended that the role of health rehabilitation as a means of returning unemployed persons to the work force should be further investigated.

12. Finding: It has been shown that health intervention for welfare clients can be established at moderate costs in a small town community.

<u>Implication</u>: It is recommended that similar units be established in other communities, more particularly in a large urban community, in order to evaluate whether the establishment of such health programs is an appropriate function of WIN.

CONCLUSIONS

Chronic medical problems have been identified among a group of welfare recipients which were related to job restrictions and unemployment. The most common health handicaps found in this group were emotional and aversive; the latter extegory including obesity and gross dental decay. Sick role behavior was common, as shown by hypochondriasis scores, and the total number

of complaints. Physical performance was negatively related to obesity, hypochondriasis score, the number of current complaints, job restriction, age, and in general to the presence of emotional or aversive handicaps.

Decision to employ health intervention was based upon the finding of remediable disabilities. Distinguishing characteristics of the active intervention group included that they had more medical problems initially, they were less likely to be working initially, they had overall higher handicap scores, they were more likely to have emotional or aversive handicaps, they performed less well on physical performance tests, they had fewer years of education, and they had incurred more Medicaid costs than the non-intervention group during the pre-study period. Health intervention included group and individual mental health counseling, weight reduction, exercise classes, and medical or dental referral for treatment.

Change in work status during the 8 months of the study was related in the intervention group to number of medical problems solved. In spite of their initial handicaps the overall changes in work and training status in the active intervention group were no worse than those of the controls who had less medical problems during the same period. It has been shown that, given the opportunity for comprehensive health intervention, as provided by the Cornell Health Rehabilitation Program, the chances of handicapped welfare recipients entering the job training programs and obtaining jobs may be increased to the level of those not having such health handicaps. Given the findings of this feasibility study, it is recommended that a demonstration project be established to show whether, in similar groups of ADC recipients with health handicaps, those receiving active health intervention have a greater chance of entry and success in WIN/CETA job training and ongoing employment. By including a larger population with differing demographic characteristics, it should be possible to determine whether it is an appropriate function of WIN/CETA to provide job related medical programs.

ACKNOWLEDGEMENTS

This report has been made possible through the collaborative activity of people who functioned as the active Project staff as well as others who worked with us, advised us or supplied us with needed information. All of these people contributed to the success of the Cornell Health Rehabilitation Project, designed to test the feasibility of providing health evaluation and intervention for welfare recipients with medical job restrictions, in order to potentiate entry into job training and employment.

I am first of all indebted to the professional staff of the Project. Without the efforts of Mrs. Nancy Brown, the Project coordinator, this program would not have been possible. She established liaison with area agencies, secured client referral, initiated the job motivation course, and worked with clients at all stages of their progress to further their entry into CETA job training and employment. Mrs. Muriel Dickey, nurse-educator, cooperated with me to set up the medical unit, carried out the health evaluation procedures, administered questionnaires, obtained objective health evaluation of clients, supervised in-house health intervention programs and

4

worked with clients to obtain their compliance with prescribed treatment. She also worked with Mrs. Brown on home visits, transportation, child care and client referral to area health professionals. More recently Mrs. Sally Nation has replaced Mrs. Dickey and has taken on the follow-up of clients. Dr. Curtis Hanners, the Project psychologist, has been a most active member of the team, developing innovative psychological testing techniques and being responsible for individual and group counseling of clients. He trained area paraprofessionals (nutrition aides) to work with him in counseling sessions, and to encourage clients' attendance at these sessions. Further, he has made the evaluation of psychological tests, thus contributing very significantly to the value of this report. Mrs ! Julie Bleier, a graduate student in the Division of Nutritional Sciences and a trained dietitian, established and supervised the weight reduction and worked with clients to obtain their cooperation. Dr. Kathleen Eickwort worked closely with me in the design of the Project and, more especially, in all phases of data analysis. She supervised data coding, the writing of computer programs, designed scores of variables, carried out computer analysis, and provided me with the factual substance of this report.

Among the clerical staff employed on the Project I would first of all like to thank my secretary, Mrs. Beverly Hastings, for her unstinting efforts on communications, questionnaires, staff meetings, and in typing the progress and final reports. Ms. Gail Neimith did particularly good work as clerical assistant to the unit. She manned the telephone, answering many clinits queries, analyzed Medicaid records, and assisted in data analysis. In the later phase of the feasibility project she was ably assisted by Ms. Ruth Barton, an undergraduate at Williams College.

My colleagues in the Division of Nutritional Sciences, as well as other members of the faculty of Cornell University, have contributed significantly to the design of this Project. I am particularly indebted to Professor Marjorie Washbon, Program Coordinator for the Expanded Food and Nutrition Education Program, who advised us on the utilization of indigenous aides, Professor David Levitsky who suggested contractural arrangements for weight reduction, and Professor Harrison Trice of the College of Industrial and Labor Relations, who worked with us on plans for job motivation. I am also indebted to the staff of the Division of Nutritional Sciences, especially Mr. Kenneth Gilbert, Administrative Aide, and other persons in the Business Office who kept our financial records and provided us with budgetary data.

I am grateful to Mr. Glenn Cline, Co-Coordinator of Cooperative Extension for Tompkins County, who arranged for our rental of the Project premises in the 4-H Cooperative Extension Building. He made it possible for us to make such changes in this space so as to make it possible to carry out a health program. Mr. Tom Gibson, Nutritionist for Tompkins County, arranged for us to secure the services of nutrition aides under his direction. Our thanks are due to those fine nutrition aides who have contributed to the program.

Our Project was dependent on the excellent cooperation we received from the directors, managerial staff, and personnel of area agencies. I am particularly grateful to Mr. Joseph Greenberger, Manager of the New York State Employment Service, and to Mr. William Gilmore, a job counselor under his

direction. These men have identified the need for health rehabilitation for their clients and have done everything possible to offer successful clients, coming from the Project, entry into CETA job training and employment. I would like to thank Mr. Hugh Hurlbut, Commissioner for Personnel Cervices and CETA Director, for his willingness to facilitate client referral. I am also most grateful to Commissioner Richard Wagner of the Department of Social Services, Mrs. Marjorie Beggs, also of this agency, and Mrs. Florence Mahoney in charge of the Medicaid program at the local level, for their insurance that our clients obtained the financial benefits of Medicaid, for assistance to clients in order to obtain Medicaid benefits, and for the provisions of social and Medicaid records for

Area health professionals have been particularly helpful to our Pro-I am especially indebted to Dr. Francisca Racker, Director of Physical Rehabilitation Unit for Tompkins County, who carried out all the evaluations of locomotor handicaps and musculoskeletal problems among our clients, and supervised the necessary treatments. Other area health professionals who have cooperated with us to the great benefit of our program have been Wendall Bryce, M.D., physician to Tompkins County, Edward E. Hart, M.D., ophthalmologist, who with his colleagues have evaluated clients for visual impairment, Richard Salerno, M.D., who has evaluated clients for deafness, David Safadi, M.D., Director of the Pathology Department at Tompkins County Hospital, where all laboratory tests were carried out, and dentists John Gibson, Robert Duthie, Roland Uris, J. Dix Wayman, Patrick LaForte and James Siefried, who have carried out dental examinations and treatments. The staff of the Mental Health Department for Tompkins County have been most helpful. I would particularly like to thank Dr. Roberta Batt, Director of the Tompkins County Mental Health Clinic, and Mr. Tom Jackson, Director of Meadow House, a half-way house for mental health clients. Finally, I would like to express my appreciation to the staffs of two Family Practice Clinics to whom we have referred clients requiring acute health care.

FIELD SURVEY

Background Information

analysis.

In a number of studies, poor health status has been associated with unemployment or underemployment. Health problems are a particular deterrent to employability among those with few job skills. During the years 1971-1973 the present Principal Investigator carried out a health survey in Upstate New York. The sample population consisted in 469 middle-aged rural-urban fringe women who were, or had recently been, recipients of ADC. In this group, current medical complaints, nervous symptoms, and physical and mental disabilities were associated with unemployment. Most medical findings were preventable chronic ailments. Dental decay and untreated dental disease was prevalent. There was a high incidence of obecity which was associated with unemployment, an association explained by secondary disabling diseases including hypertension, diabetes, and non-rheumatic cardiac disorders. Disabilities arising in early life

12

influenced current work status. Past employment was related directly to education and job skills, and inversely to the number of pregnancies.

On the basis of these findings, it was recommended that a necessity existed for the development of positive health attitudes in low income populations, as well as the provision of early and preventive medical and dental care, health education, the development of exercise and diet programs, to control obesity, and comprehensive rehabilitation by a team approach. It was suggested that these medical services be provided as a component of federal job training programs (Roe, D. A. and Eickwort, K. R. Health and nutritional status of working and non-working mothers in poverty groups. Research & Development Contract No. 51-36-71-02, Manpower Administration, USDL, 1973).

Sample Population

The caseload has consisted in 12 male and 59 female clients between the ages of 18 and 52 years, eligible except for health problems, for CETA job training programs. These persons were all residents of Tompi ins County, New York. Client referral was from area agencies including the Tompkins County Department of Social Services, Cooperativ Extension of Tompkins County, New York State Employment Service, the Tompkins County Personnel Office, EOC, OVR, Mental Health Rehabilitation, as well as via area health personnel including public health nurses and private ph. sicians. Clients also came to the program through hearing of its existence via news media (see Table 1, Progress Report, June 1975). In all, 71 persons have been seen, of whom 1 did not complete a health evaluation, and 10 have not been in the program long enough for adequate follow-up. Demographic characteristics of the subsample of 60 persons for whom we have follow-up are shown in Tables 1-5 inclusive.

Description of the Project

The feasibility study was carried out between December 8, 1974 and August 15, 1975. During this period, the clients were interviewed, examined, and given health rehabilitation in the facility at the 4-H Cooperative Extension Building on Fulton Street in Ithaca, New York. Within the facility a room was equipped for physical examinations, and space was adequate for interviews and for group therapy sessions. Initial interviews were held with each client and at that time, health histories and work histories were obtained (Appendix 1). Indices of hypochondriasis were obtained using the questionnaire and scoring system from the MMPI Handbook (Dahlstrom, G. W. and Welch, G. S. An MMPI Handbook. The University of Minnesota Press, Minneapolis, 1960, p. 560). Motivation was assessed by the internal-external scale of Rotter, which determines predominance of internal motivation vs. passive dependency (Rotter, J. ... et al. Internal versus external control of reinforcement and decision time. J. Personality & Social Psychol. 2: 598-604, 1965) (Appendix 2). Intelligence tests were carried out including the Wechsler test and the Shipley-Hartford test (Wechsler, D. The Adult Intelligence Scale. New York: Psychological Testing Corp., 1944; Bartz, W. R. and Loy, D. L. The Shipley Hartford as a brief IQ screening device. J. Clin. Psychol. 26: 74-75, 1970). Current health complaints were obtained using

a structured list. Physical examinations performed by the Project Director assisted by Mrs. Muriel Dickey, nurse-educator included a systems review, anthropometric measurements and an assessment of exercise performance using a Harvard Step Test, and hand grip as measured with a calibrated dynamometer (Appendix 3). Routine ancillary investigations of health status included laboratory studies (blood counts, biochemical profiles, tuberculin tests, sickle cell tests, serological tests for syphilis, and special tests relating to nutritional status), also routine chest x-rays and electrocardiograms where indicated by the health history or physical examination. Clients were referred to area physicians or clinics outside the Project for special systems evaluation. Dental examinations were carried out by consultant dentists, unless the client was able to furnish evidence of recent evaluation and/or treatment.

At the completion of health evaluation a staff meeting was held to decide on the need of individual clients for health intervention. quirement for health intervention was based on the presenting symptoms, the findings on physical examination, psychological investigation, the ancillary testing procedures, and the results of diagnostic services. Participation in physical or mental health rehabilitation was, voluntary. In-house health intervention included a weight reduction program, super-_ vised by the nutritionist, Mrs. Julie Bleier, and exercise and health education program under the direction of Mrs. Muriel Dickey, and group or individual counseling supervised by Dr. Curtis Hanners, the Project psychologist. In each of these programs the number of projected treatment sessions was pre-defined. On an individual basis, medical treatment, . surgical procedures, physical therapy, prescription spectacles, hearing aids or prostheses were provided through area physicians and dental treatment was carried out as required. Clients receiving health intervention were those who had remediable disabilities. Those having severe chronic mental or physical health problems which were not believed to be amenable to rehabilitation under the program were referred to area health agencies and/or to the local Office of Vocational Rehabilitation, or to the County Mental Health Department. Clients having no demonstrable health problems were directed into CETA job training or employment as openings became available.

Clients participating in the Project were assisted by the Project Coordinator in obtaining aid from local social as well as health programs in order to facilitate job training and employment, thus clients were taken to the Planned Parenthood Clinic of Tompkins County, legal aid was provided where needed, as well as child care and transportation. The services of county nutrition aides were obtained and these women worked closely with participants, making house-calls, giving dietary information, encouraging ongoing attendance for rehabilitation procedures, and assisting Dr. Hanners in the group counseling sessions. All medical services, other than those provided in-house, were covered by Medicaid except in those few instances where clients were not yet receiving such assistance. In these latter circumstances, medical services were covered by the Project.

All participants within the Project were invited to take part in three weekly job motivation classes. These sessions were conducted by Mrs. Mancy Brown and Dr. Curtis Hanners. They were designed to prepare clients for

the work world and more specifically, to give them information on the requirements for job training, how to handle a job interview, as well as work attitudes and applications and employer-employee relationships. Particular attention was given in these sessions to the problem of how clients should handle health problems in the job interview and work situation. Short presentations were made by area employers, job counselors, by members of the Cornell Health Project team, including the Director, and by CETA job holders. Movies were shown and participants engaged in role-playing dialogues (Appendix 4).

Participants were interviewed and re-examined three months after the initiation of health intervention and then again after another three months, or at the completion of the feasibility project. At the time of these follow-up sessions, progress was evaluated as well as job readiness; the latter being assessed independently by the clients and by the Project staff (Appendix 5). Participants whose health problems were solved at the time of the first follow-up, or before that time, or between the time of the three months and the latter follow-up, were referred for CETA job training or job placement.

Detailed findings described below relate to the 60 clients for whom we had a period of not less than three months follow-up,

Employment History

In general, it was found that clients had poor work histories, having been employed for a short period of time in low paying jobs. The fact that four clients had never worked, and that 50 clients had worked for not more than five years totally, can only be explained in part by the number of young adults in this sample. Clients had most frequently held unskilled. jobs as operatives or service workers, or they had been in semiskilled jobs, particularly in clerical work (Tables 6-10).

Medical History

The medical history of each client from birth was obtained. Each illness or accident was tabulated by diagnosis according to the International Classification (Eighth Revised International Classification of Diseases (ICDA), PHS Publ. No. 1693, USDHEW/PHS, Washington, D. C., Vol. 1, 1967, Vol. 2, 1968).

Most of the medical problems cited in the history had arisen in adult life, and in this period mental health problems had frequently occurred including predominantly neuroses, variously described as nervous breakdowns, anxiety, depression, and nervousness. Most physical problems mentioned as occurring in adult life were of long-standing, including back problems, as well as late effects of injury and surgical procedures (Tables 11-14). The medical history score for each period of the person's life was calculated as follows: 4 points for each problem causing permanent major disability; 2 points for each problem not causing major disability, but recurrent, continuous or lasting more than 6 months; and 1 point for each other problem mentioned. The overall medical history score equals the sum of the scores at birth, preschool, during the school years, post-school, and during the past year.

ç

Current health complaints were frequently multiple. The most common symptoms were frequent nervousness, frequent tiredness, breathlessness on exertion, frequent urination, frequent headaches and tender guis; also frequent backaches (Table 15).

Physical Examination

Physical examination showed a rather low frequency of severe abnormalities. Among the commoner abnormalities encountered were dermatoses, limitation in movements of one or more parts of the body, deformities, usually minor, and other musculoskeletal problems (Table 16). Dental decay (dental caries and/or periodontal disease) and obesity were prevalent and frequently so severe as to constitute an unsightly appearance which would provide a handicap to employment (Tables 17, 18). Measures of obesity included weight and triceps skinfold thickness. Triceps skinfold thickness was negatively correlated with performance on the Harvard Step Test (r = .43, p < .001). On the other hand, the taller the client, the better they performed on the Harvard Step Test (r = .45, p < .001).

Mental Health Assessment

As anticipated from the medical history and the number of nervous complaints, psychological problems were frequently identified among the clients. There were two with mild to moderate, and 13 with severe, neuroses. Ten persons showed evidence of emotional immaturity, and in two cases this was severe. Two clients had severe behavior disorders, and one was psychotic. Three clients had mild to moderate degrees of mental retardation. Five persons had an impaired learning ability, which includes those with mental retardation. Some degree of intellectual handicap was found in eight clients, and of these, three had severe intellectual handicaps (Tables 19-26). The hypochondriasis score was very highly correlated with the number of current symptoms (r = .83, p < .001), and with the health related job restrictions cited by the client (r = .42, p < .001), and with the degree of emotional handicap (r = .38, p < .001).

Intake of Medication

Fifty percent of the sample were taking medications. The commonest groups of prescribed drugs being taken were analyssics and tranquilizers. It was also found that 38.3% of the sample were taking over-the-counter drugs to relieve frequent headaches. This rather high usage of pain killers and psychoactive drugs may be associated with the prevalence of emotional problems (Tables 27-29).

Assessment of Handicap

Handicaps encountered among clients were classified according to the system developed by Agerholm (Agerholm, M. Handicaps and the handicapped. A nomenclature and classification of intrinsic handicaps. Roy. Soc. Health J. 1: 3-8, 1975). This system offers a method for the identification and grouping of medical handicaps which is valid for the individual regardless of his/her age; of the circumstances in which he/she lives, and of the context in which he/she is reviewed. Handicap or intrinsic handicap is

identified in this system as a long-term disadvantage which adversely affects an individual's capacity to achieve the personal and economic independence which is normal for his/her peers. Key handicaps within this system include locomotor, visual, communication, visceral, intellectual, emotional, invisible, and aversive handicaps. Any one person can have one or several handicaps, or components of handicaps. A handicap score was developed by counting one for each mild to moderate component of each intrinsic handicap, and two for each severe component under the Agerholm system. By this method it was found that 31 clients (51.7% of the sample) had aversive handicaps which included gross obesity, dental decay, deformity or macceptable smell. Twenty-eight persons (46.7% of the sample) had emotional handicaps, and 15 of these had neuroses. Intellectual handicaps were found in 8 persons (13.3%); invisible handicaps including pain disorders occurred in 6 persons (10%), locomotor handicaps in 12 persons (20%), communication handicaps in 5 persons (8.3%), visceral handicaps including disorders of ingestion or excretion in 3 persons (5%), and visual handicaps including severe visual restriction in 1 person (Table 30).

Height as an Indicator of Physical and Work Performance

In our sample population the taller clients were healthier and had a better history of work performance. Height was directly related to ability to perform in the Harvard Step Test and to the level of performance with the hand-grip dynamometer (HEIGHT vs. STOPWHEN r = .45, p < .001, HEIGHT vs. HANDGRIP r = .53, p < .001). The taller members of the sample also had less initial medical problems, lower hypochondriasis scores (a measure of sick role), less emotional handicaps and less perceived job restrictions (NUMINFR r = -.47, p < .001, HYPSCORE r = -.33, p = .005, EMOTIONL (Handicap) r = -.34, p = .004, r = -.25, p.= .026). Those who were relatively taller also had less health complaints (r = -.22 p = 0.45), were thinner (SKINFOLD r = -.23, p = .043), and had less overall handicaps as determined by the Handicap score (HANDSCORE r = -.30, p = .01). It is also significant that height was related directly to education (r = .27, p = 0.19), and negatively to age (r.= -.27, p = .018).

Inverse relationships between height and early neglect associated with malnutrition have previously been identified. In our previous study conducted between 1971 and 1973, including a sample population of very low income women, it was found that height was related to education (r = .12, $p \leq \gamma O1$); to the total number of years employed as a percentage of potential years of employment (r = .11, $p \le .01$). It was also negatively related to the number of medical problems at birth (r = -.08, p < .05) and to the number of health problems in the medical history (r = -.08, p < .05). Further height was directly related to total income (r = .11, p = .007). From these findings it was concluded that the shorter the woman was, the more likely she was to have been unemployed, low in income, poorly educated, and to have had medical problems at birth and during later life (Roe, D. A. and Eickwort, K. R., cited previously). It has been shown by other studies that, whereas height is determined by genetic factors, early malnutrition and difease including infection and interactions between these variables can result in stunted growth (Bakwin, H. and McLaughlin, S. M. Secular increase in height: is the end in sight? Lancet 2: 1195, 1964; and Chavez, H. Ecological factors in the nutrition and development of children

רר

in poor rural areas. Proc. Western Hemisphere Nutrition Congress III, 1971, Futura Publ. Co., 1972, p. 265).

Findings from the present study serve to emphasize the fact that those who come from a low socioeconomic group may not only have suffered physical disadvantages in early life including primary and secondary malnutrition, which had an adverse effect on growth, but more importantly that these persons may have later disadvantages in motivation for, or performance in, work or physical work performance. From the available information it is, of course, not possible to say that association of shortness, poor education and numerous health problems through life are individual factors predictive of social failure, but rather that such factors taken together may indicate a had prognosis with relation to employability. In support of the latter statement, it was found in the present study that height was related directly to the maximum pay categories in previous employment (r = .23, p = .038), and that progress under health intervention conducted by the Project was also directly related to height, i.e. the number of medical problems remaining at follow-up was inversely related to height (progress score r = -.32, p = .013).

Handicaps of the Obese

Evidence was obtained from the present study that obesity confers physical, emotional, and social disadvantages. The overall handicap score was directly related to fatness (r=.34, p=.005). Physical performance as reflected by the Harvard Step Test was negatively related to obesity (r=-.43, p<.001). Although it was found that the fatter the client, the greater the number of visits they made to the Project (r=.39, p<.001), remaining problems after health intervention were greater in the fatter clients (r=-.28, p=.032). Change in welfare status during the period of study was inversely related to fatness (r=-.30, p=.012).

Relationships Between Job Restrictions and Health Handicaps

Job restrictions cited by the clients were very significantly related to age (r = .48, p < .001), to the handicap score (r = .47, p < .001), to the number of medical problems occurring in adult life (r = .49, p < .001), and to the number of initial health problems defined (r = .42, p < .001). There was also a very significant relationship between job restriction and staff time spent with each client (r = .39, p < .001). A significant inverse relationship was found between the perceived job restrictions and education (r = -.30, p = .01); also an inverse relationship to previous earnings (PAYCAT r = -.31, p = .01). Previous Medicaid costs were very significantly related to job restriction, (m + .45, p < .001).

Relationship Between Previous Earning and Health Parameters

Levels of pay in previous jobs were inversely related to the number of previous medical problems (MEDHISSC r=-.20, p=.07), to the presence and severity of aversive handicap (r=-.25, p=.035), to the number of initial medical problems (NUMINPR r=-.24, p=.054). Total Medicaid

charges before entry into the Project (DAYACOST r = -.30, p = .016) and to costs for Medicaid after entry into the Project (DAYBCOST r = -.29, p = .017). Education showed a direct relationship to previous pay categories (r = .28, p = .02), and those with higher previous pay categories were more likely to be working at follow-up (r = .30, p = .013).

These correlations show complex relationships between health and social factors in defining previous work and work potential.

Characteristics of Clients in the Health Intervention Program

Health intervention was made available to clients on the basis of the presence of remediable health problems and acceptance by the client of recommended treatment modalities.

Differences between the "active intervention group" and the others ("controls") were examined by rank correlations (Spearman's r). Differences which resulted in their being chosen for active intervention were as follows:

- 1. This group had more medical problems initially (r = .3, p < .001).
- 2. They were less likely to be working initially (r = -.40, p < .001).
- 3. They had higher overall handicap scores (r = .63, p < .001).
- 4. They were more likely to have an "intrinsic emotional hamdicap" (r = .41, p < .001) or an intrinsic aversive handicap (r = .54, p < 1001).
- 5. They had a higher "medical history score" since leaving school till the past year (r = .48, p < .001), a larger total number of problems mentioned on the medical history (r = -.36, p = .002), and a higher overall medical history score (r = .46, p < .001).

Other incidental distinguishing characteristics of the active intervention group were:

- 1. They were shorter (r = .35, p = .003).
- -2. They were fatter (thicker triceps skinfold, r = .44, p < .001).
- 3. They stopped after a shorter time on the Harvard Step Test (r = .51, p < .001).
- -4. They had higher hypochondriasis scores (r = .44, p < .001).
- 5. They had more children (r = .39, p < .001).
- 6. They had completed fewer years of formal education (r = -.36, p = .002).
- 7. They had incurred more costs per day on Medicaid than the others during the control period (re. Jan. 1, 1974 Dec. 1, 1974, r = .38, p = .004).

Results of Health Intervention

Differences between the health intervention groups and the controls during the duration of the study were examined. It was found that the health intervention group

1. Had more phone calls and personal calls as well as other contacts with the Project staff (phone calls r = .57, p < .001); personal calls

r=.57, p <.001). They also initiated more self contact (r=.52, p < .001); received more staff-initiated contacts (r=.50, p <.001); and took up more hours of staff time (r=.61, p < .001).

- 2. They incurred more costs per day on Medicaid than others during the Project period (r = .37, p = .002); and more costs per day on Medicaid that were traced to Project referrals or costs (r = .40, p < .001).
- 3. They showed a greater decrease in hypochondriasis scores than the non-intervention group (r = .43, p < .001):

At three months, the active intervention group still had a greater percentage of their medical problems not yet solved (r = -.58, p < .001). Many of those in the non-intervention group had one or no medical problems initially.

In spite of their initial handicaps, as documented above, by August, the overall changes in work and training status in the active intervention group were similar to that of the control adring the same time (defining variable WORKAUCH as: -1 -left job or training, now not employed and not in training; 0 -no change; +1 -got job or entered training, we find that the rank correlation of WORKAUCH with INTRVENE is .01, p = .5, n.s.).

It is necessary to delineate the health problems that were easiest to solve, and the clients who benefitted most from health intervention. In general, it was found that clients with easily definable single health problems, without overlay of sick role behavior, were easiest to treat. Clients in this category were closer to work readiness on entry into the Project and also had the advantages of better health and work histories. Conversely, those with multiple health problems on entry into the Project, including overt sick role behavior, responded less well to treatment. Another question which we have had to ask is whether solution or partial solution of health problems contributed to or promoted entry into job training and employment.

Results of Health Intervention

We have obtained both direct and indirect evidence that health intervention contributed to employment at the time of follow-up. Clients working at the three months follow-up period were more likely to have received health intervention and less likely to have residual health problems.

Problems and Progress

We must address ourselves to consideration of the specific problems encountered which were a hindrance to the performance of the feasibility study. At the beginning, client referral was slow, and those clients who were sent to see us were those who had made little or no progress with other agencies. They were multi-problems people with numerous health problems, a poor work history including very limited job skills, and they had been in receipt of welfare over a long period of time. Thus, we started out with nard to reach, hard to teach clients whose motivation to overcome

20

health problems was not well developed. We found ourselves adopting a custodial care role with those clients least likely to succeed. This meant that these persons were most likely to take up staff time with phone calls, visits and other supportive activity. Another problem which we encountered was the limited number of job training programs in the area, which clients could enter through the aegis of CETA. Indeed, initially job training other than OJT was limited to courses at the Tompkins-Cortland Community College where clerical skills were offered. Limitation in job openings was also apparent. Initially some of our clients did poorly in job interview, either because they presented themselves badly, or because they referred back to previous health problems which had previously been work deterrents.

Non-compliance with prescribed treatment was not uncommon. Less motivated clients missed appointments whether these were for health groups working within the Project or outside medical visits on referral.

Greatest progress and health change was achieved in relation to dental problems, visual impairment (provision of corrective glasses), hearing difficulties (provision of hearing aids), musculoskeletal problems (physical therapy), and overcoming sick role behavior (innividual or group counseling). Progress in weight reduction was modest, and this may be attributed in part to the fact that the program was only offered for 12 weeks as active intervention, and because our clients had very long-term obesity. Treatment progress at the end of the three months follow-up period is shown in the following tables (Tables 31-35).

In examining the number of medical problems solved or partially solved at the end of three months (Table 36), as well as the number of old problems unchanged at three months, it can be seen that clients' progress has been slow (Table 37). Residual medical problems consisted chiefly of emotional disabilities and obesity. Slow response of these health problems to therapy was not unexpected, more especially because of their chronicity.

Despite slow improvement in the health of some clients, entry of clients into job training and/or employment increased with time of Project participation. Whereas initially 39 of the 60 clients were not working and 21 were working, and at 3 months the same number were working or in job training, as of August 15, 1975 24 clients were working, 32 not working, and for 4, status was unknown. It is more meaningful to state that as of August 15th, 8 persons were in training or working who initially had been outside the work force. However, as of the latter date, 3 persons who were initially working or in training were now unemployed, and 45 of the clients had stayed in their original employment or non-employment status. It is to be noted that 11 of the clients who were working at the time of entry into the Project had health problems, and would not have been able to maintain their training or work status but for the availability of the program (See also Table 38 showing employment status as of Sept. 1).

Participation of Clients in CETA Job Training or Employment

Participation of Cornell Health Rehabilitation Project clients in Tompkins County CETA programs was such that between January, 1975 and

September, 1975, 23 clients held CETA jobs (Titles I and VI), 4 clients were enrolled in the Spring 1975 secretarial course at the Tompkins-Corthand Community College, 3 took part in a summer remedial reading program, and 4 are participating in the Fall 1975 secretarial course at the Community College. The total Tompkins County CETA program population were as follows:

Title I, Spring 1975 secretarial course -15 Summer remedial reading - 4 Fall 1975 secretarial course - 17 Title VI, approved for training - 23.

Indicators of the Effectiveness of Health Intervention in Terms of Employability

Changes in health status brought about by intervention range from solution of physical problems to conquest of sick role behavior. The professional team had a strong impression that as health problems were overcome, so the clients felt they could play a role in determining the direction of their lives or life style. In support of these impressions, verbally communicated by the staff, it was found that change in the internal-external score indicating increased self-confidence was directly associated with the reduction in the number of complaints between the initial visit and the three months visit (r = .26, p = .045). Further, those who showed a change in the internal-external score in the direction of self-reliance were more likely to be working in August (r = .39, p = .005).

Medicaid Expenditures and Client-Related Medical Charges to the Project

Medicaid charges were obtained for each client for a control period before the entry into the program, and for the duration of the Project. Medicaid charges as computed from records obtained from the Tompkins County Department of Social Services were divided as follows:

- 1. Costs during the control period before the Project started, viz. January 1, 1974 December 1, 1974.
- 2. Medicaid charges after initial contact of the client with the Project until the termination of the feasibility study or the last billed item on Medicaid records.
- 3. The costs during the latter period for which the Project was responsible because of referrals.
- 4. Costs for which the project was responsible but were not yet billed.

These charges in the four different categories are itemized in Table 39. In examining the costs in Category 1, it can be seen that the items requiring the greatest expenditure per client were doctors' office visits, pharmacy charges, hospitalization, and appliances. During period 2 after the clients had begun to attend the Project, the Medicaid paid costs appeared to be reduced for doctors' office visits and accident room visits. In view of the dissimilar periods for which Medicaid costs were obtained

before and after the Project, these differences must be interpreted cautiously. Medicaid costs for which the Project was responsible through referrals were chiefly in the categories of hospitalization, dental visits and charges for appliances.

Medicaid charges for clients during the period before the Project started were very significantly related to the charges for these clients after the Project started (DAYACOST vs. DAYBCOST r = .55, p < .001). DAYACOST was also very significantly related to the medical history score during the school period (r = .39, p < .001), to the medical history score during adult life (r' = .58, p < .001), and to the number of medical problems cited in the last year (r = .45, p < .001). The higher the Medicaid expenditures for clients prior to entry into the Project, the greater number of contacts and visits they made to the unit (NUMCALLS r = .47, p < .001; NUMVIST r = .49, p < .001; STAFINIT r = .56, p < .001; NUMSUPP r = .38, p < .001). Those working at the three-month follow-up visit were less likely to have sustained high Medicaid expenditures prior to entry into the Project (WORKIN2 r = -.07, p < .001).

Medicaid costs totally during the period of the Project for clients were directly related to health referrals made by the Project team (r=.54, p<.001). Medicaid costs during the study were also very significantly correlated with the total number of medical problems (r=.43, p<.001), to a number of medical problems occurring in adult life (r=.49, p<.001), and to the total medical history score (r=.46, p<.001). Clients working at the three months follow-up incurred lower Medicaid expenditures during this period (r=-.39, p<.001).

Medicaid costs attributable to our referrals were related very significantly to the total number of initial medical problems (r = .50, p < .001). It is of particular importance to note the Medicaid costs attributable to Project referrals were higher also in those who had more medical problems remaining at the three months follow-up visit (r = .39, p < .001), and were inversely related to whether the client was working at the time of follow-up (r = -.31, p < .009). From this it is inferred that those with multiple initial health problems are not only more costly with respect to health intervention, but also that their chances of being rehabilitated so that they can enter the work force within a short period of time is less than that of other clients with less health handicaps. However, the percentage of medical problems solved was also related to the Medicaid referral costs attributable to the Project (r = .24, p = .053). Change in hypochondriasis scores was inversely related to Medicaid costs attributable to the Project, which suggests that a persistent sick role behavior may have accounted for some of the referrals.

Project Costs (December 1, 1974 - August 1, 1975)

The costs of undertaking the feasibility study were moderate and less, than those anticipated. Savings relative to the Project budget were made in the personnel category, by reduction in the total number of staff. Two full-time staff worked with the Project; that is, the nurse-practitioner, Mrs. Muriel Dickey, and the Project coordinator who also acted as social

worker, Mrs. Nancy Brown. The position of mental health counselor, as invisaged by the original budget, was replaced by the Project psychologist, Dr. Curtis Hanners, who worked half-time and was paid by combining the projected budgeted salaries for the mental health counselor and a physical therapist. No physical therapist was employed, since it was possible to refer clients under Medicaid to the Rehabilitation Unit of Tompkins County Hospital. A dental hygienist was not employed, because clients were referred to area dentists for evaluation as well as treatment. Parttime secretarial help was obtained through employment of sevaral persons on an hourly basis. The statistician who worked with the Project on a 50% time basis received the salary payment originally intended for the statistician, as well as the coder-keypuncher. An office cleaner was not required, since these services were carried out by the personnel at the 4-H Cooperative Extension Building. Although it was found that this staff could manage the Project and carry out the necessary duties efficiently, a need for further clerical assistance and the expertise of a social worker was particularly identified as the Project proceeded.

Savings on the original budget were also made in the categories of consultants, supplies, travel and services, as well as communication. Lower costs in these categories were only maintained because of the temporary nature of the Project. For example, purchase of medical equipment was held at a minimum although it is now considered highly desirable that further equipment and supplies for health evaluation should be obtained in order to obtain an adequate objective estimate of health status of clients. Structure alterations in the Project facility which are urgently required to offer privacy to staff and clients as well as proper accommodations for group health intervention sessions were not carried out because the principal investigator was unsure of the continuity of the Project.

Nevertheless, it has been demonstrated that health evaluation and rehabilitation can be carried out in relation to a work training program using a small professional staff, aided as was the case in the feasibility study, by paraprofessionals (Table 40).

OUTCOME AND RECOMMENDATIONS

Owing to the short duration of this feasibility study, we were not able to assess the long-term effects of health intervention on clients' work potential. In our sample population, it was clearly demonstrated that health handicaps which limit or prevent entry of welfare recipients into job training or employment are complex, being conditioned by sick role behavior, lack of motivation, long neglect, emotional problems, and obesity. Unless welfare clients are desirous to enter the work force, they are not anxious to obtain optimal health. Indeed, the prominence of sick role behavior suggests that health complaints are used as a means of excusing social and economic failure. In order for these people to acquire physical and emotional fitness for work, they must first be helped to understand the nature of their disabilities. They must be encouraged to see work as a positive personal advancement. Client profiles and their

intervention are given in Appendix 6. They must also have available a health team who can fully evaluate their problems, offer remedial health intervention, and act as advocates for them in the established health care delivery systems.

Routine health screening, as available in most communities, is frequently inadequate to the needs of welfare clients who are potential WIN/CETA registrants. In order to understand their health complaints and reactions to these problems it is necessary to know that symptoms may often be cited for which it is difficult to exclude some disability in relation to employment. Recognition of sick role behavior is not easy, nor is the recognition of the symergistic effects of social (extrinsic) and health (intrinsic) handicaps. In the feasibility study we have developed methods for obtaining information which can be used in developing a complete health evaluation. Measures of physical fitness as well as of intrinsic health handicaps have been found to have a predictive value in deciding whether clients are likely to respond to rehabilitation. Common intrinsic handicaps encountered include emotional problems and aversive handicaps, and in the latter category, the most common has been obesity.

Full health evaluation has required the collaborative efforts of the professional team of the Project, as well as area dental and medical professionals. Outside services have been covered by Medicaid, in the case of our welfare clients. Referral of clients to these local health professionals and actually taking them to meet medical or dental appointments has been an integral function of the Project.

Beneficial effect of health intervention with respect to employability has often not become immediately apparent. Clients geared to patch-up medicine and dental treatment are slow to learn the advantages of full-health rehabilitation.

Non-attendance and non-compliance have also been problems. However, we have established that whereas clients who entered our active health intervention program had more medical problems initially, and were more likely to have emotional and aversive handicaps, and were less likely to be employed at all on entry, the success of this group on entering job training and/or employment was similar to that of a control group without such problems. It was further shown that the expenses of health intervention for welfare clients can be established at moderate costs in a small town community.

Based on the findings of this feasibility study, it is recommended that a full scale demonstration project be established forthwith, with essential objective of developing a model health care delivery system designed precisely to the needs of WIN/CETA clients. In order to establish the practical value of such a program to a variety of communities, it is recommended that units be established in a semi-rural community (Ithaca) and also in an urban community (Syracuse). It is recommended that the demonstration project be concerned with 1) health evaluation; and 2) health intervention.

Methods must be developed for the precise and rapid assessment of health status and for success of health for intervention. A health intervention system must be developed such that client compliance is optimized and health care be directed towards employment needs.

Under the auspices of the demonstration project it should be possible to determine to what extent ADC recipients with health-related work disabilities can be returned to the labor market through physical and mental rehabilitation: the hypothesis being that these health disabilities need to be corrected before a job can be held successfully. It has to be proven whether or not expenditures to health rehabilitation, facilitating employability, will be a cost-benefit overlying ADC recipients with health problems to remain outside the work force or to take care of their own health difficulties. It must further be established whether health rehabilitation for remediable disorders is an appropriate function of the WIN/CETA programs and to what extent health rehabilitation is an overall function of projected Manpower programs. Implementation of these recommendations is the objective of the demonstration project which has recently been funded by the Manpower Administration of the United States Department of Labor.

	•			
1.a	Children get into trouble because their parents punish them too much.		b. :	The trouble with most children nowadays is that their parents are too easy with them.
	a.		• •	/b.
2.a	Tany of the unhappy things in people's lives are partly due to bad luck.	•	b.	People's misfortunes result from the mistakes they make.
	a.			/ b '.
3.a	One of the major reasons why we have wars is because people don't take enough interest in politics.	•	b.	There will always be wars, no matter how hard people try to prevent them.
4.a	In the long run people get the respect they deserve in this world.	. ,	b.	Unfortunately, an individuals's worth often passes unrecognize no matter how hard he tries.
	a			b
5.a	The idea that teachers are unfair to students is nonsense.	44	b.	Most students don't realize the extent to which their grades are influenced by accidental happenings.
	a.	•		/
6.a	Without the right breaks one cannot be an effective leader.	,	-	Capable people who fail to be- come leaders have not taken advantage of their opportunities
	a.	,		
7.a	No matter how hard you try some people just don't like you.		b.	People who can't get others to like them don't understand how to get along with others.
	a.		•	

8.a Heredity plays the major role in determining one's personality.	b. It is one's experience in]
a.	which determine what they'r like.
9.a I have often found that what is going to happen will happen.	b. Trusting to fate has never turned out as we. 1 for me a making a decision to take a definite course of action.
10.a In the case of the well prepared student there is rarely if ever such a thing as an unfair test.	b. Many times exam questions to to be so unrelated to course work that studying is really useless.
a.	b.
ll.a Becoming a success is a matter of hard work, luck has little or nothing to do with it.	b. Getting a good job depends many converse in the right planet time.
12.a The average citizen can have an influence on government decisions.	b. This world is run by the few people in power, and there is not much the little guy can about it.
a.	
3.a When I make plans, I am almost certain that I can make them work.	b. It is not always wise to plan too far ahead because many things turn out to be a matte of good or bad fortune anyhow
a.	The state of the s
4.a There are certain people who are just no good.	b. There is some good in every-body.
a.	· / b.
5.a In my case getting what I want has little or nothing to do with luck.	b. Many times we might just as well decide what to do by flipping a coin:
	/

16.a Who gets to be the boss often depends on who was lucky enough to be in the right place first.	b. Getting people to do the right thing depends upon ability, luck has little or nothing to do with it.
a.	b.
17.a As far as world affairs are concerned, most of us are the victims of forces we can neither understand, nor control.	b. By taking an active part in political and social affairs the people can control world events.
a.	b. +
18.a Most people don't realize the extent to which their lives are controlled by accidental happenings.	b. There really is no such thing as "luck".
a	b.
19.a One should always be willing to admit mistakes.	b. It is usually best to cover up one's mistakes.
a.	,b:
20.a It is hard to know whether or not a person really likes you.	b. How many friends you have de- pends how nice a person you are
a.	b.
21.a In the long run the bad things that happen to us are balanced by the good ones.	b. Most misfortunes are the result of lack of ability, ignorance, laziness, or all three.
a.	b.
22.a With enough effort we can wipe out political corruption.	b. It is difficult for people to have much control over the things politicians do in office
a.	b.
23.a Sometimes I can't understand how teachers arrive at the grades they give.	b. There is a direct connection between how hard I study and the grades I get.
	

24.a A good leader expects people to decide for themselves what they should do.	.	A good leader makes it clear to everybody what their jobs are.
a.		b.
25.a Many times I feel that I have little influence over the things that happen to me.		It is impossible for me to be lieve that chance or luck plan important role in my life.
26.a People are lonely because they don't try to be friendly.	b.	There's not much use in tryi too hard to please people, i they like you, they like you
27.a There is too much emphasis on athletics in high school.		Team sports are an excellent way to build character.
28.a What happens to me is my own doing.	6.	Schettles I feel that I don't have enough control over the direction having is taking.
29.a Nost of the time I can't understand why politicians behave the way they do.	1	In the long run the people ar responsible for bad governmen on a national as well as on a local level.
	. C. S.

ERIC

April 15, 1975

development of employment skills and attitudes.

There will be films about working, interviews with persons who have 'made it' to successful employment, a session led by an employment expert, hints from an Ithaca employer, and a tour of your choice of a place of local employment.

This project is now ready to offer you a short course on

Our aim is to demonstrate how a person can develop his employability and show why he might want to do so. Any change is a
result of committment by the individual.

As the course dates are not yet set, we ask you to sign below if you are interested, so that we may know you want to be notified of the starting date.

TEARN TO EARN

SESSION I

Plan and Process

Purpose: Arrousal of hope - work as a reality.

Self image of employability - employment as a goal.

- Plan: 1. Establish comfortable atmosphere, conversation.
 - 2. Introduction of principles

 Cornell Health Rehabilitation Project session leader

 Cooperative Extension Communications Assistant

 Staff Psychologist
 - 3. Leader short statement about intensions, lead-in for film:
 - 4. Coop Ass't film- "You Pack Your Own Chute" as basis for examination of our own fears as deterrants to success.

 Discussion of film; participation.
 - 5. Leader's lead-in to panel presentation play tapes of
 "What work means to me" (made by secretarial CETA students)
 Talks by persons who are working.

 Feedback to and from participants
 - 5. Leader Wind-up Observations, conclusions, invitation to next session What Jobs? and How to Get One.

80

LEARN TO EARN SESSION II

WHAT work? - and how to get it

Program plan

Introduction of today's leaders.

Introduction: (CHRP leader) Today we will work with these questions:

"What kind of job will I be best at?"

"Where is it?"

"How can I find it?"

"How can I GET it?"

Let's watch a short film that shows some people finding the answers.

Film: Your Job: Applying For It. 132 minutes. Tells how five young people got jobs as stock clerk, secretary, salesman, beautician and draftsman. Describes their procedures, problems & experiences.

Manu Layer
Co-op Extension leader: Reviews the points the film makes.

Leads discussion if audience wants to make comments.

Wm. Gillmore - NYSES Job Counselor:

WHAT work? - and how to get it.

Review of kinds of work available in Tompkins County now.

Suggestions of ways a persons can decide what kind of work they want. Reinforces film on subject of job search, and employment interview. Indicates the place of health problems in the interview.

Activity: by Extension leader. Divided into teams of two, everyone writes a resume to present at an interview. One person can'draw the other out, thus increasing the scope, and perhaps the validity of the resume.

Recap by CHRP leader. Invitation to next week's session...On The Job -

LEARN TO EARN

SESSION III

On the Job - To Stay and Grow

Program Plan

Iced Coffee and lemonade available
Copies of 'To think about' and pencils also

Introduction

Short, making the speakers and topics known to the audience.

Film:

I Want to Work For Your Company - 10 min. An excellent reinforcement of last session's subject - the employment interview.

Discussion of film to be kept to 5 min.

Speaker: NYSES Director - Joseph Greenberger on Making a Success of Your Job. Discussion period following. 15 min.

Speaker: DOL Manpower (State) - Frances Fenner

Film:

Person to Person - Making Communications Work For You - 10 min. How your attitudes show, and the value of positive attitudes on the job. Brief or no discussion.

Speaker: Ardella Blandford - C.U. Personnel Director as local employer on What I Want in an Employee. Discussion following. 15-20 min.

Speaker: Project Director - Daphne Roe on Your Health and Yorr Job Discussion invited.

Critique of LEARN TO EARN to be completed by audience.
