ABSTRACT

The development of effectiveness criteria for APROTC detachments, and relationships between the criteria and various environmental and program characteristics are described. The objective of the study is the development of a method for estimating student enrollments and total operating costs at perspective host-site institutions by using institutional measures which can be easily updated. Standard multiple regression techniques are used in the analysis. The predictors were chosen for their high validity and their easy access in an operational setting. Utilizing the equations and procedures set forth in the report, cost and enrollment figures can be derived for potential APROTC host sites. (Author/JMF)

A PROCEDURE FOR ESTIMATING ENROLLMENT AND COST FACTORS AT POTENTIAL AFROTC HOST-SITES

I. INTRODUCTION

The objective of this research was to develop a method for estimating student enrollments and total operating costs at prospective Air Force Reserve Officer Training Corps (AFROTC) host-site institutions that would be both reasonably accurate and simple to implement. Initial efforts in this area documented by Alley and Berberich (1975) indicated substantial relationships between various measures of detachment performance and characteristics of the host college. For practical purposes, however, some of the predictor variables used in that study were of limited value, either because they were unavailable for certain schools or were difficult to update on a periodic basis. In response to immediate requirements outlined by HQ AFROTC for an operational prediction system, the feasibility of revising the predictor base was explored with the intent of converting to more readily accessible institutional measures while maintaining the accuracy of estimation obtained in the earlier study.

II. APPROACH

The initial pool of predictor variables included in the analysis is shown in Table I. The information was obtained from three standard reference books available in most academic libraries: (a) American Universities and Colleges (10th ed, American Council on Education, 1968); (b) The College Blue Book (14th ed, CCM Information Corporation, 1972); and (c) Earned Degrees Conferred (1970-71, National Center for Educational Statistics, 1973).

Degrees Awarded in 24 Selected Areas	Literal	Office of Education (HEW)

The criterion variables of principal interest were student enrollments in Air Science (AS) 300 and total detachment operating costs (excluding funds associated with the college scholarship and flight instruction programs). To insure stability in these measures, enrollment and cost data for the two most recent school years were averaged and the composites used in the actual analysis.

Individual detachments constituted the sampling units. To be included in the analysis sample, a detachment had to have been in continuous operation for at least five years and must have offered AFROTC training on an optional rather than a compulsory basis. In total, approximately 150 detachments met the dual standard for inclusion.

After the data were assembled into computerized format for all valid detachments, a standard multiple regression analysis was performed to select and weight the predictor variables appropriately. In these exercises, institutional measures which did not contribute uniquely to predicting either the enrollment or cost criteria were subsequently dropped from the final equations.

For each criterion, two models were developed. The first permitted information about degree orientations to enter the equations while the second did not. Of all the predictor variables, the data on degrees awarded in selected areas was the most time-consuming to obtain from a clerical standpoint. Thus, serviceable predictions were desired both including and excluding this information.

III. MODEL SPECIFICATIONS

Variables selected from those contained in the initial pool, as providing the most accurate composite predictions of AS 300 enrollment and total detachment costs, are listed in Table 2 with associated coding definitions. The accuracy of the final equations is summarized in Table 3 which also shows means, standard deviations, and zero-order correlations between selected variables and the criteria. A composite validity of .65 was obtained in predicting AS 300 enrollments, accounting for approximately 42% of the criterion variance. A restricted model excluding degree orientation data yielded a correlation of .63. Similar validities were noted for equations predicting total detachment costs where the full and restricted models yielded correlations of .64 and .62. Each of the four coefficients was statistically significant beyond the .01 level. However, in neither case did degree orientations add significantly to prediction when considered in the context of the other variables. Raw score regression weights for predictor variables included in the final equations are shown in Table 4.

IV. DISCUSSION

Results from this analysis suggest that an appreciable amount of the variance in AS 300 enrollments and total detachment costs can be accounted for by considering various characteristics of the host college at which the detachments are located. These would include geographic region, total school enrollments, proportion of male enrollments, students per faculty member, institutional type and public versus private control. Degree orientation data as defined in this study appears to be more or less redundant with the other more readily accessible information just described. For practical purposes, the restricted models excluding the degree data yield equivalent predictions with greater efficiency; especially in view of the clerical processing needed to retrieve the number and proportion of degrees awarded.

The accuracy of prediction associated with both the enrollment and cost models compares quite favorably with that obtained in prior analyses. Previously, correlations of .71 and .75 had been reported using approximately 30 independent predictors and a single year of enrollment and cost data (Alley & Berbench, 1975). Some shrinkage was expected due to the fact that 2-year composite criteria were used and that only 26 of the revised predictors had been retained for simplicity of implementation.

Table 2. Definition of Predictor Variables Selected for Final Equations

Variable	Definition
Total Male Enrollment	Literal coding format. Includes the total number of full-time male undergraduate enrollments.
Total Enrollment	Literal coding format. Includes the total number of full-time male and female enrollments at the undergraduate and graduate levels.
Average ACT Composite	Literal coding format. This number reflects the average ACT composite for entering freshmen. For schools at which the SAT mathematics and verbal scores only are available, reference is made to conversion tables found in Alexander Astin's, <i>Predicting Academic Performance in College</i> , American Council on Education, 1971
Students Per Faculty Member	Literal coding format. Obtained by dividing the total enrollment by the total full-time faculty.
Geographic Region	Categorically coded 1 if applicable, 0 otherwise. States included in each region are listed below.
New England	CT, ME, MA, NH, RI, and VT
Mid East	NY, PA, NJ, DE, MD, WV, and DC
Great Lakes	OH, IN, MI, IL, WI, and MN
Plains	ND, SD, NB, IA, MO, and KS
South East	VA, NC, SC, GA, FL, AL, TN, MS, AR, LA, and KY
South West	TX, OK, NM, and AZ
Rocky Mtns	MT, WY, CO, UT, and ID
Far West	NV, CA, OR, WA, HI, and AK
Institutional Type	Categorically coded 1 if applicable, 0 otherwise.
University	
Liberal Arts College	
Teachers College	
Technical Institute	
Public Control	Categorically coded 1 if the institution is under public control; 0 if private.
Predominantly Male	Categorically coded 1 if the percentage of males in the undergraduate student body is greater than 75%; 0 if predominantly coed. Note that this variable does not include provisions for predominantly female institutions since at no time have AFROTC detachments operated in this type of environment.
Predominantly Black	Categorically coded 1 if the percentage of black enrollments is greater than 75%; 0 otherwise.
Collocated ROTC	Categorically coded 1 if the institution does not presently offer an ROTC program of any type; 0 if either the Army, Navy or both are represented.
Degree Orientation	Literal coding format. Represents the total percentage of degrees offered in 24 specialties grouped into seven broad areas. Career fields included in each area are listed below. Note: Totals add to 100%.
Realistic	Agriculture, Architecture, Engineering, Geology
Scientific	Biology, Computer Sciences, Mathematics, Physical Science
Social	Education, Health, Psychology, Social Sciences
Conventional	Business, Home Economics
Enterprising	Area Studies, Banking and Finance, Law, Economics, History, Political Science
Artistic	Fine and Applied Arts, Foreign Languages, Letters
Aerospace	Aerospace Engineering

It is interesting to note the measures which did not appear to contribute uniquely to predictive accuracy in the context of those selected. Variables dropped from the system included female enrollments, total number of PhDs awarded, number of undergraduates on scholarship, average worth of undergraduate scholarships, total number of full-time faculty members, number of library volumes, and miscellaneous revenue data. Similarly, religious affiliation and land-grant status were shown to provide little in the way of incremental validity. This does not imply that these factors taken individually were unrelated to the criteria; only that any predictability associated with them was shared in common with one or more of the variables selected for the models. The same might be said for the degree orientation variables which, in these analyses, did not contribute significantly to predictive accuracy.

As noted in previous studies (Alley, 1974, Alley & Berberich, 1975), there appears to be some similarity between the enrollment and total cost prediction systems. This may be attributable to the fact that certain components of the total cost estimates vary proportionally with the number of cadets enrolled in the program.

V. ILLUSTRATION

Since it is sometimes difficult to conceptualize the combined effect of a large number of variables weighted simultaneously in a prediction model, some additional insight into the procedure used might be gained by reviewing the characteristics of a simpler model. Suppose that only three items of information were available about a potential host-site: (a) the total number of male enrollments, (b) whether it was under public versus private control, and (c) whether or not it was located in the Southwest. The general form of a regression equation utilizing this information might be as follows:

$$\hat{Y} = C + a_1 X^1 + a_2 X^2 + a_3 X^3 \text{ where}$$

Y = the criterion of interest (e.g., AS 300 enrollments)

C = a constant term

X¹ = the number of male enrollments

X² = 1 if the institution is publicly controlled; 0 otherwise

X³ = 1 if the institution is located in the Southwest; 0 otherwise

a₁, a₂, a₃ unknown least-squares regression weights

The coefficients a₁ - a₃ are estimated by observing the effects of the three predictor variables on AS 300 enrollments at current operational detachments. Moreover, the values associated with a₁ - a₃ are such that no other values would provide more accurate predictions. The next equation shows the values of a₁ - a₃ as computed on the analysis sample (R = .50).

$$\hat{Y} = 12.73 + (.00076)X^1 + (10.22)X^2 + (12.55)X^3$$

By generalizing to schools which do not yet host detachments, it would be possible to estimate the expected AS 300 enrollments. If, for example, a candidate school had a total of 15,000 male enrollees, was privately controlled, and was located in the Southwest, the best estimate of its expected AS 300 enrollment would be:

$$\hat{Y} = 12.73 + (.00076)(15000) + 10.22(0) + (12.55)(1) \text{ or}$$

$$\hat{Y} = 37$$

The relationships identified in this equation are shown graphically in Figure 1. The procedure for estimating the joint influence of 26 predictor variables (as opposed to 3) would be identical in both analytical form and subsequent applications.

VI. CONCLUSIONS/RECOMMENDATIONS

These analyses support the technical feasibility of establishing an objective, quantifiable procedure for evaluating any potential host-site institution. It is recommended that a data file be assembled containing all schools in which it might be desirable to establish an AFROTC detachment. Information for each school would include but not necessarily be limited to those measures specified in Table 2. The selection process could then be supplemented with expected enrollment and total cost data based on past experience with similar institutions.

Figure 1. Estimating AS 300 enrollments on the basis of host-site male enrollment, control and location data.
