ABSTRACT

This document reports the tabulations of a national study sponsored by the Office of Child Development of the U.S. Department of Health, Education and Welfare to determine exactly how children are cared for, how often child care services are purchased, at what costs, for what reasons and with what accompanying problems or barriers. Of related interest are the preferences, opinions and attitudes of consumers. Tabulations are based on 4609 personal interviews conducted in 1975 from a national probability sample of households with children under 14 years of age. The data are organized under the following headings: (1) Design and Methodology, (2) Characteristics of the Sample Households, (3) Measures of Child Care Usage, (4) Reasons, Satisfaction, Preferences and Prior Usage, (5) Cost and Transportation, (6) Opinions and Attitudes. A sample questionnaire is included. (MS)

FOREWORD

This report is comprised of a basic compendium of data gathered from a national probability sample of households with children under 14 years of age. Tabulations presented are based on 4,609 personal interviews conducted during the late spring and early summer of 1975 as part of a contract sponsored by the Office of Child Development of the U.S. Department of Health, Education and Welfare to determine national levels of child care usage as well as consumer needs, preferences and attitudes on child care.

The primary purpose of this volume is to provide a full accounting of all the basic questionnaire items and variables encompassed by the survey including marginal distributions and sample dispositions. As such, the report represents a limited, preliminary examination of the data, not a final analysis.

Given the sheer volume of the data, it is all too easy to lose continuity and topical perspective. Consequently, the report has been organized along four substantive themes—the characteristics of the households; levels of usage; measures of satisfaction and preference; and cost and transportation—supported by very brief explanatory narratives. Simplicity has been sought throughout with most cross-tabulations and higher-order tables relegated to the various appendices for those who wish to explore further the nuances of the data.

Two additional volumes based on this survey are planned for the future. Volume II is an analysis of the patterns and trends of child care usage. Volume III is a treatment of the opinions, attitudes and typologies of child care consumers.

Section I INTRODUCTION

SECTION I

INTRODUCTION

A Perspective

United States with at least one child 13 years old or younger. Of these households, nearly 90% use some form of child care arrangement—whether formal or informal, by using a family or non-family member, regularly or occasionally, in a home or in an institutional setting—when the mother or other adult assuming primary responsibility for care is not available. Six million households rely exclusively on members of the immediate household (e.g., siblings or spouses) or schools, while some 16 million engage a relative, babysitter, nursery school, family home proprietor, day care center or other external arrangement. By far the highest incidence of usage can be attributed to what most of us would call babysitting.

There is nothing particularly startling in the "bottom-line" statistics from this survey. Indeed, the broad picture portrayed is the very character of the study, for we are concerned not just with low-income households, with working mothers, with exceptional children, with day care centers nor with any other single target group or method of care. Rather, the study was designed to find out, from a national viewpoint, just how children are cared for, how often child care services are purchased, at what costs, for what reasons and with what accompanying problems and barriers. Of related interest are the preferences, opinions and attitudes of consumers.

3

To be sure, there are population subgroups of special interest, particularly those for whom culture or economic circumstance may pose different hardships or impediments. Hence, ethnic minorities and low-income households were intentionally overrepresented in the sample to bolster the capability for analyzing such trends, but weighting techniques have been employed to preserve the essential national perspective.

Abstracted Summary

Except where editorially irresistible, this report does not seek to draw conclusions. The report sections, however, may be summarized by topic as follows:

- II. Design and Methodology. The survey universe consisted of households with telephones. A sample frame for in-person interviews was developed by computer-generating 25,000 random telephone numbers under a stratified national probability design, and screening those who answered to determine if the household contained any children under 14. Names and addresses volunteered over the phone were used to obtain face-to-face interviews of about an hour in length. A specimen questionnaire is included in the appendix to Section II.
- III. Characteristics of Sample Households. Over 99% of the respondents were females. Over 80% of respondents were married. Most of the households consisted of nuclear families, and only about 2% of the children were not some or daughters of respondents. The overall household income distribution was decidedly "middle class" with about 15% (weighted) falling below the poverty level. Just under two-thirds of the "mothers" were employed neither full nor part-time.

- Measures of Child Care Usage. Although nearly 90% reported using some form of child care, only about two-thirds use care provided by someone outside of the family nucleus. The most frequent external arrangement is care by a relative in the relative's home (35.2% of households). About one in four use care in the child's home by a non-relative. About one in eight of all children receive full-time-equivalent care (30 or more hours a week), but the majority of children receive care so infrequently as to average less than an hour per week.
- Reasons, Satisfaction, Preferences and Prior Usage. About 40% of the households use child care related to the parents' employment or education. The most frequent reason for care is so the parent can "go out" (e.g., social reasons, shopping, entertainment). The most "satisfying" care arrangements from the parents' viewpoint are those provided by relatives. The least satisfactory tends to be care in the child's home by a non-relative. There is substantial latent demand for nursery school and day care center care, most often barred by high cost. Care in the child's home is preferred over care in the homes of others.
- VI. Costs and Transportation. Approximately 55% of those using child care pay in cash. The remainder compensate by services or favors or receive free care. Day care centers represent the nost expensive method used while relatives are the most economical. Nane of tenchildren receiving care away from home are transported by family members.
- VII. Opinions and Attitudes. This section consists of miscellaneous data for which no observations are provided.

Section II DESIGN AND METHODOLOGY

SECTION II

DESIGN AND METHODOLOGY

Overview

Data presented in this report were collected from a stratified national probability sample of telephone house olds with children 13 years old or younger. The sample frame was obtained by screening some 24,900 randomly selected households by telephone to identify those with children, resulting in an available sample of 9,075 households.

A total of 4,609 interviews were obtained from a sample space of 6,850, exceeding the original survey goal of 4,500. A specimen instrument is included in the appendix to this section. For the reader preferring to relate data to the exact questions asked, a cross-index appears at the beginning of this appendix.

Interviews were conducted in person at the respondents' homes by the field interviewing staff of Chilton Research Services, Inc., under subcontract with Unco. The average administration time was approximately one hour.

Only scanty discretion is devoted in this section to the sample design and field management produces since each has been the topic of detailed reports previously submitted to the Office of Child Development under this contract. Consistent with the objectives of this report, no higher-order statistical techniques, save probability sampling and weighting, have been employed.

Sample Design

There were three basic steps to the sample design: selection of primary sampling units (PSUs), selection of central offices (telephone exchanges), and determination of sampling rates within central offices.

In the first step, all PSUs were categorized as being in one of four Census-defined regions—Northeast, North Central, South and West. Within each region, PSUs were further stratified according to whether or not they were in Standard Metropolitan Statistical Areas (SMSAs), with an additional distinction made within SMSAs between center-city and outside-center-city areas. The selection of PSUs, therefore, was a function of a 12-level plan across four regions and three residential strata. Within the 12 strata, central cities were oversampled, such that the residential distribution was 50% central cities, 33% SMSA-other and 17% outside SMSAs.

The second step in the sample design was the selection of central offices. For each primary sampling unit, four central offices were randomly selected. However, to improve the efficiency of screening, the sampling rates within the selected central offices emphasized blacks and Spanish-Americans and households near or below the poverty line. During screening, updated demographic records were kept on the yields from each central office.

Central offices were oversampled in cases in which there were relatively high observed proportions of minority groups or households near or below the poverty line, so as to guarantee sufficient raw interview records among minority and poverty households to conduct analysis of differences between racial and economic subgroups.

In addition to the differential sampling rates among central offices, a third step was introduced in the sample design, also to assure adequate representation of the target groups, using the following proportions:

TABLE II-1

White	49	% -
**	Below poverty	7%
	Poverty to 200% poverty	16
i	Over 200% poverty	27
Black	337	X.
	Below poverty	11%
	Poverty to 200% poverty	11
	Over 200% poverty	-11
Spanis	h-American 11%	ć i
•	Up to 200% poverty	7%
	Over 200% poverty	4
Other	7%	
	100%	

To develop the sample frame, centralized to phone screening was used. Screening interviewers worked from batches of randomly generated telephone numbers using the area codes and prefixes of the central offices selected. A five-minute questionnaire was developed to establish if the household was eligible to participate in the study (i.e., containing at least one child under 14), to identify the person responsible for care of the children, and to obtain the needed demographic information.

Approximately 25,000 screening interviews were completed, of which 9,075 identified households having children under 14. These households were then divided into two matched groups of roughly equal size for use by

the field interviewers in conducting the in-person interviews. That is, the households were assigned as matched pairs in which the interviewers attempted to obtain an interview with the first of the pair (up to four attempts each for setting an appointment and for actually carrying out the interview) before replacement with the second name. This procedure was used as one of several to minimize bias in the overall methodology. Altogether, 6,850 households were used in obtaining the 4,609 interviews (the remainder were either back-up pairs, as described, or upper income whites for which a portion of the sample was not mailed to the field due to the more than ample yield from telephone screening).

An overall completion rate of 67% was achieved with 953 (13.9%) refusals and 1,288 (18.8%) failures to locate an eligible respondent.*

Use of Weighted Data

Under a controlled probability sample, all households enter into the survey with a known probability of selection. In the case of "overrepresented" (or certainty) primary sampling units and central offices, households are selected under greater probability than in "normal" or undersampled areas. Consequently, since the probabilities of selection can be determined, unequal weights may be calculated to compensate for disproportional sampling and to project an unbiased estimate of the population universe.

^{*}Included in this category are (1) moved from area, (2) youngest child turned 14 and (3) unable to contact after four tries.

The basic approach used in deriving weights in this study involved a three-stage process summarized (indeed oversimplified) as:

$$\star W = \left\{ \frac{1}{P_1} \cdot \frac{1}{P_2} \cdot \frac{1}{P_3} \right\} \cdot R$$

where:

P₁ is the probability of selection of the respondent's primary sampling unit (PSU)

P₂ is the probability of selection for the respondent's central office

P₃ is the ratio of completed interviews in the respondent's central office over the size of the subsample frame (# of telephone numbers available)

R is a ratio estimator based on known population proportions in the stratum.

In order to minimize the possibility of extraordinary sample errors caused by very high weights, an exponential smoothing process was applied to the vector of weighting factors, controlling for the total weighting within each of the target sample cells.

As a result, each observation received a final weighting factor projecting, in a rough conceptual sense, the number of U.S. households represented by a given number.

Unless otherwise noted all data reported herein are population estimates derived as the sum of the applicable weights and reported in thousands. The fact that one or two observations with high weights may suggest apparent anomolies in extremely small cells should be kept in mind, particularly when interpreting numbers occurring in the tails of distributions.

Missing Date

Always a troublesome problem in survey research, missing data or item non-response results from refusals, "don't knows" and occasionally collection, coding and keypunching errors. Whenever weighting is used to project actual estimates of the universe, non-response not only introduces bias in estimates of population means and proportions, but also has the additional effect of lowering absolute projected numbers.

Fortunately, the observed non-response for most of the questionnaire items in this study is near trivial. Household income constitutes the most serious problem with a non-response rate of 11.5%, most of which involves refusals. A commensurate non-response rate was experienced when respondents using day care centers, nursery schools or care by non-relatives in other than the childrens' own homes were asked if the provider was licensed. The relatively low completion rates experienced here were generally due to lack of knowledge.

There are at least three common ways of dealing with missing data.

First, an additional cell ("non-response" or "missing") can be added to each class variable. We do not favor this approach because, although marginal totals are preserved, proportions (e.g., percentages) are distorted.

Secondly, non-response can be artificially allocated according to observed proportions. Although we plan to employ allocation by computer in subsequent phases of the research, it was decided that this report, as a "first cut" at the data should retain the maxim of simplicity. This leads us to the third method of treating non-response—to ignore missing data dufing tabulation and evaluate its impact during analysis.

As an aid to interpreting the results as well as an informative description of the data, a sample disposition table, expressed in unweighted (raw) observations, is provided for every questionnaire item.

However, if the reader wishes to venture further than the analysis provided in text, particularly in interpreting the supplemental cross-tabulations included in the various appendices, he or she is advised to use, where possible, proportions or percentages. If an absolute projected population estimate is needed, it is a good idea to refer to appropriate sample disposition tables to assess possible effects of missing data.

ow, we would like to talk to you about what standards there should be, if any, for arious kinds of childcare.

- 9. Thinking about childcare provided in someone else's home, in your opinion which of the following aspects of childcare should be regulated by standards? (HAND RESPONDENT CARD Q. 29) (CIRCLE AS MANY AS APPLY. RECORD IN Q. 29 COL.)
- O. Thinking about childcare provided by daycare centers and nursery schools, which of the following aspects should be regulated by standards? (CIRCLE AS MANY AS APPLY) (RECORD IN Q. 30 COL.)

	Q. 29	Q. 30
1) Fire and building safety		
2) Cleanliness and sanitation of facilities		
3) Number of children per responsible adult		
4) Training and qualification of staff		
5) Food and nutrition		
6) Program content and activities		1
7) Space per child, and physical surroundings and equipment	,	
8) Counseling and referral services for family and child problems		
9) Health condition of staff and children		
10) No standards should be set		

31. Do you think there should be personal qualifications set for non-related people who care for children in the children's own home? In other words, should sitters be required to pass health exams, education requirements, or meet some other kind of standard if they were providing care in your home?

Yes	
No	
Don't Knew	

(ASK Q. 32 AND Q. 33 ONLY FOR THE AGE GROUP(S) IN WHICH THE RESPONDENT HAS CHILDREN. REFER TO FLAP FOR APPLICABLE AGE GROUPS)

32. We would like to talk to you about the number of children a responsible adult can reasonably handle. If you placed your child age(s) (0-2), (3-5), (6-9), (10-13) in someone else's home and assuming that the home and caregiver are acceptable, how many children altogether should this person be able to care for?

Number of Children per Adult				
	0-2	3-5	6-9	10-13
1	,			,
2-3				
4-5				
6-7				
8-9

42. Now, I'm going to read 5 features of childcare. After I finish reading them, please tell me which one is <u>least</u> important to you. The five features are: (READ LISTED FACTORS IN SUCCESSION)

(CIRCLE THE ONE FEATURE LEAST IMPORTANT)

Features	Least 1
Cost	
Convenience of hours available	
Convenience of location	
Provides child development activities and instruction	
Agrees with my views on child- rearing	

We would now like to find out more about the ways in which parents participate in their childcare arrangements.

43. Please tell me in which of the following ways you would like to be involved in your child's arrangement. (HAND CARD Q. 43 TO RESPONDENT) (CIRCLE AS MANY AS APPLY)

1)	Talk regularly with person who cares for my child about his/her activities and development	
2)	Spend time in home, daycare center, or nursery school with my child to see how things are done	
3)	Work as a volunteer member of staff in a daycare center, nursery school or family daycare home	
4)	Talk to parents whose children are in this arrangement	
5)	Help decide what kinds of activities and programs will be provided	
6)	Help decide on selection of staff for daycare center, nursery school or home where there is more than one person who cares for my child	
7.)	Learn more about effective ways of raising children	
8)	Receive counseling about child and family related problems	 ·
9)	Help decide on how available funds should be spent, e.g., types of equipment pur- chased, field trips, staff salaries, etc.	
10)	Work as a paid staff member in a daycare center, nursery school or family daycare home	

(ASK ONLY THOSE RESPONDENTS CURRENTLY USING CHILDCARE IN THEIR OWN HOMES. CODES 1 OR 2 IN Q. 7. OTHERWISE SKIP TO Q. 45)

44. People look for many things when they select someone to provide in-home care for their children. (HAND OUT DECK OF CARDS, Q. 44. SAY:) On each of these cards is a factor which some people think is important in selecting someone to come into their home to provide care for their children. I'd like to know which of these factors is most important to you. Take a minute to look through the cards, and then pick out the seven most important ones and set them aside. 60. I am going to read you two ways that childcare funds can be used. Which one of the two ways would you most like to see used? (READ LIST)

	1) Direct cash payments to working parents for childcare	
	Direct cash payments to the person or agency providing the childcare for the working parents	2
DO NOT READ	3) Neither	3

61. I'm going to read 3 statements. After I finish reading them, please tell me which one of these statements best describes your preference on the way to handle the costs of childcare in general: (READ CATEGORIES)

Childcare should be free for all those who might need it regardless of income	1
The costs of childcare should be adjusted according to parents' ability to pay (sliding scale)	2
Parents should pay all costs of the childcare they use?	3

PART II

ATTITUDE, VALUE, OPINION STATEMENTS

We are also interested in your feelings and impressions about childcare and topics related to childcare. I am going to read several statements aloud to you. Please tell me how you feel about each statement, using one of the five categories shown on your card. Just tell me the letter beside the feeling that comes to mind when you hear the statement. It is not necessary to take a lot of time thinking about the statement; your first reaction is all that we need. Please respond to each statement even if you have only limited experience with the topic -- based on anything you may have seen or heard. There are no right or wrong answers. Do you have any questions?

(IF RESPONDENT IS MALE, SAY:) Some of the statements that I am going to read refer to "mothers" or "working mothers." This is because many of the people we are talking to are mothers. For any of these items, try to think about parents who have the main responsibility for raising their children, regardless of whether they are mothers or fathers.

(ANSWER ANY QUESTIONS BY REPEATING PORTIONS OF THE INSTRUCTIONS AND/OR GIVING A SIMPLE EXAMPLE.) (FILL IN THE LETTER OF THE RESPONSE BESIDE THE STATEMENT.)

HAND RESPONDENT PART II RATING CARD.

- A Strongly Agree
- B Agree
- C Neither Agree or Disagree
- D Disagree
- E Strongly Disagree

IF RESPONDENT SAYS "DON'T KNOW", RECORD THE LETTER F.

Section III

CHARACTERISTICS OF THE SAMPLE HOUSEHOLDS

SECTION III

CHARACTERISTICS OF THE SAMPLE HOUSEHOLDS

Overview

This section is devoted to a statistical description of the households surveyed. For the most part, projections given can be interpreted as being representative of U.S. households including one or more children under 14 years of age. Included in this discussion are the primary demographic variables (i.e., age, race, sex, household size, marital status and kinship structure), general economic indicators (i.e., income, poverty status and sources of economic support), employment characteristics of respondents and, where applicable, their spouses.

Characteristics of the Respondents

Respondents were selected under n extreme sex bias. That is, the preferred respondent was defined, in all cases, as the female primarily responsible for care of the children. Married males in two-parent households were interviewed in only a handful of cases (n = 19).

The weighted distribution of respondents by sex is reported on the following page as Table III-1. Given the overwhelming proportion of females shown, together with the distribution of household relationships presented subsequently in this section, it can reasonably be construed that, for analytical purposes, the term respondent is virtually synonymous with "mother." Only

SOURCE: Question 1

BASE: All households with children under 14

100%

22 interviews involved households headed by unmarried males. Of the 4,609 households interviewed, 4,539 included a son or a daughter under 14. Approximately 2% of the respondents were grandparents, with most of the remaining households exhibiting other close relationship structures (e.g., respondents' siblings, nieces, nephews within the household).

It is important to underscore that households, not "families, "constitute the unit basis for interviews in this study. For many variables, this fact tends to hinder comparison with census data. However, the study design presupposes that an understanding of the overall household, particularly the availability of proximate adults as caregivers, is critical to the analysis of child care practices.

The definition of respondent bears great impact on nearly all of the data collected. For example, consumer preferences, attitudes and opinions reported in the sections below are primarily those of mothers and should not be generalized to the entire adult population. Similarly, questions keyed on the respondents' spouse (e.g., "Is your spouse employed?") can be interpreted generally, but not exclusively, to denote the status of husbands.

A weighted distribution of the ages of respondents is given in Table III-2 (on the following page). The mean age is 33.8 years, with approximately 90% falling within the customary childbearing ages of 18-45. Nearly half (47.4%) are included in the modal category "26-35."

The great majority (82.2%) of respondents were married at the time of the survey. (Table III-3). Less than one percent reported spouses who were physically absent from the household.

The educational level of respondents is presented in Table III-4. This distribution, which includes large proportions of high school drop-outs, high school graduates and those with post-secondary educations, portrays a broad typological cross-section.

Race and Ethnicity

As we have noted in Section II, the sampling plan was designed to embrace disproportionally large numbers of minority and low-income interviewees via planned oversampling. In both cases, the goal of attaining sufficient raw interviews to support detailed analysis of these population subgroups was achieved.

Race was recorded from observation where the interviewer was able to make certain determinations. Where there was doubt, the respondent was asked to select the appropriate racial category.

Race and ethnic characteristics were recorded only for respondents. It is therefore an explicit analytical assumption throughout this report that the respondent's race may be attributed to all members in the household, particularly where patterns of child care usage have been expressed as distributions of children by race or ethnicity.

Both raw and projected distributions of respondents by race are given in Table III-5 due to the import of the oversampling. In our opinion, the unweighted sample space for racial minorities (n = 1,602) is demonstrably adequate for the partitioned analysis intended.

A second item (question 66) was included in the questionnaire to identify respondents who perceived themselves as Spanish in ethnicity. Results from this question are given in Table III-6. The question was not asked of American Indians or Asian-Americans.

Finally, a summary variable was constructed from both the race and the Spanish ethnicity variables as shown in Table III-7. The logical methodology used-in combining these items held that Spanish-ethnicity takes priority in summary classification over race.

Household Size and Structure

The sample households range in size from two (by definition) to fifteen (Table III-8). The modal size is four members (mean = 4.46), tending to confirm the image of the "typical American family." Fewer than one in twenty (4.2%) consist only of mother and child, a structure which may be assumed to represent a care-demanding circumstance, at least for non-public-assistance households.

In the broadest sense, the concept of "household" is very nearly synonymous with that of "family" since fewer than one percent contain unrelated members. The proportional distribution of relationships shown (Table III-9) merits clarification since percentages do not reflect the absolute proportions of household members of a given relationship. Instead, figures represent the probability of a sample household containing at least one member of a certain relationship. For example, while an estimated 77.6% include at least one son, some include more than one son. Given that the categories are not exclusive, the percents do not, of course, add to 100%.

(In any event, it is somewhat enigmatic that there are substantially more households (5.4%) that contain sons than contain daughters. Perhaps daughters are more likely to occur in pairs?! On the other hand, all other sex-linked relational pairs favor females. This phenomenon, if intellectually interesting, has little direct analytical import.)

From this probability distribution, it is clear that at least nine of ten families are styled after the traditional nuclear model consisting of parents and children. Yet 212 interviews do describe households including five or more relationships, a fact which may make some analysis of "complex families" possible in the future.

A second similar probability—of— relationship distribution (Table III-10) is limited to children under 14. Except sons and daughters, the only children that are represented at greater than a 1% probability are grandchildren.

The average number of children under 14 per household is 1.96 with an observed maximum of nine children (Table III-11). The estimated distribution by age is prenated as Table III-12.

As a topic of ancillary interest, respondents were asked if any of their children had disabilities or special problems. Fully 8.6% (projected n = 2.06 million) answered affirmatively. These respondents were then asked the ages of the applicable disabled or "special" children. The resultant distribution is given by age in Table III-13.

Economic and Employment Characteristics

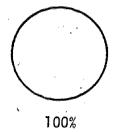

More than 90% (22.2 million) of households with children under 14 receive at least some economic support from one or more household members (Table III-14). Of these, approximately 87% contain male respondents or husbands contributing support and 41% include breadwinning female respondents or wives. No other household member, related or unrelated, contributes with sufficient frequency to merit generalization. Three-quarters report no financial support from external sources (Table III-15).

A fourth, or roughly six million, receive additional financial support from outside the household. Among the sources tabulated are support from an estranged spouse (6.9%) and Aid to Families with Dependent Children (AFDC-6.7%). The categories "other public welfare" (4.5%) and "other government source" (6.9%) are generally undefined, including food stamps, the "adult" welfare categories (blind, disabled, old age assistance), social security, veterans' benefits, general assistance, Medicaid and myriad other assistance programs. Finally, the category "income tax deductions" may not have been stated entirely clearly and may yield a suspect statistic although it is reported in Table III-15 without note.

A distribution of the gross annual household cash income is shown in Table III-16. This item (question 67) yielded the lowest response rate (88.5%) of all the basic survey variables, due primarily to refusals. The reader is therefore cautioned that non-response is not allocated in the projected distribution.

A second income variable, poverty status (Table III-17), was constructed as a function of gross income and household size using the interagency government poverty-level tables of April 30, 1975. Since farm households could not be identified on the basis of questionnaire data, figures for non-farm families were applied to all households.

The three categories shown (below poverty, above poverty to 200% of poverty and above 200% of poverty) are particularly relevant to federal policy-related research since eligibility for various programs and benefits is determined by the poverty level. Furthermore, the three classes correspond, if only very roughly, to the vernacular notion of "poor," "marginal" (or "near poor") and "non-poor" (or "middle-class") households. Consequently, this contrast variable is and will continue to be used more prominently than simple income in our analyses.

₹**.**

Because child care usage, particularly of the more formal methods, is so often job-related, household employment characteristics assume a quintessential role in our attempt to describe the sample universe. With this in mind, it is important to note that over a third of the respondents are employed at least part-time, with nearly a quarter assuming full-time jobs (Table III-18). Including respondents who are enrolled in school or job training programs (Table III-19), some 9.6 million estimated households have primary caregivers with work or educational commitments.

Both the distribution of earned income (Table III-20) and the Bureau of Labor Statistics taxonomy of job classifications (Table III-21) for respondents paint woefully stereotypical portraits of the American Woman. Only 1.2 % of respondents (versus 17% of households) earn over \$20,000 with nearly half (45% versus 9.6% for households) earning under \$5,000, albeit true that about one-third of those employed work only part-time. By the same token, the majority are employed in service or clerical positions.

In analyzing many of the attitude variables and in assessing previous child care usage experience (see Section IV), it is worth noting that about half of those respondents not currently working have worked at some time since having children (Table III-22).

On the other hand, nine out of ten of the spouses (i.e., "husbands") are currently employed on a full-time basis (Table III-23). An estimated 6.4% are not employed, a figure roughly commensurate with the national unemployment rate."

Section IV MEASURES OF CHILD CARE USAGE

SECTION IV

MEASURES OF CHILD CARE USAGE

Overview

In this section, levels of child care usage are presented from two statistical perspectives: households and children. Furthermore, four basic definitions of consumption are proffered for use throughout the remainder of the report as follows:

- Total Methods Used. Under this definition, any household which uses any form of child care, even if very occasionally, including casual care by the spouse, an older sibling or even the respondent at her or his place of work. This of finition, obviously, is only of passing interest from an analytical viewpoint and embraces about 90% of households.
- Users of a "Principal" Method. Households or children using or receiving care from one or more of nine types of caregivers or institutions not included in the immediate family nucleus. These principal types are (1) in-home care by a relative, (2) in-home care by a non-relative, (3) other-home care by a relative, (4) other-home care by a non-relative, (5) nursery and pre-schools, (6) day care centers, (7) cooperative programs, (8) before and after school care programs and (9) Headstart. Unless otherwise noted, the term "user" in this report refers to any household reporting at least one child receiving one or more of these types of care, even if infrequently.

`IV-1

- Main Method. Respondents using more than one of the nine/principal types listed above were asked to select one as their most important or "main" method. This variable is useful in its own right as an indicator of importance and is, in addition, used as a key or frame of reference in the structure of the questionnaire.
- Children Receiving One or Mora Hours of Care per Week.

 Some respondents reported that their children received given types of care so infrequently as to "average" less than an hour per week. Where distributions and mean levels of usage are given, these observations were intentionally dropped as being insubstantial.

Also included in this section are the schedules and times of day various types of care are used, usage of special summer care arrangements and, for three more formal methods (in-home by non-relative, nursery schools and day care centers), licensure status of the caregiver where known. Supplemental cross-tabulations and tables of mean usage by poverty status, race/ethnicity, and summary marital/employment status are included in the appendix at the end of the section.

Maximum Usage Estimates

After listing all members of the household by age and relationship, interviewers asked, for each child under 14, what methods of child care were used for that child, no matter how infrequently, including even very informal arrangements within the household. Fully 88% of the children (Table IV-1) representing 89.7% of the households (Table IV-2) reported some usage of care. An estimated 15.8 million (64.7%) reported using at least one of the nine principal methods.

IV-4

The logical presence of some usage is given by method as a distribution of children (Table IV-3) and households (Table IV-4). To the surprise of no one, care by the spouse leads the list.

In general, both tables are dominated by providers related to the shild, including care in a relative's home and in the child's home and informal care by siblings. Only about 7% of children receive "formal" care in nursery schools or day care centers. Perhaps the most important observation to be made from these tables concerns the availability of relatives as child care providers.

When users of any of the principal (first nine) methods were asked what they considered to be their "main method," nearly half (48.2%) identified a "non-nuclear" relative as the provider (Table IV-5).

At this point, it should be noted that the difference between nursery school and day care center care is not entirely clear, since a given facility could provide full-time care and possess all the attributes of a day care center but simply be titled a "nursery school." If there is a single important categorical difference between these methods of care (other than local nomenclature), it probably lies in the respondent's perception of the mode of usage. Under this hypothesis, two users of the same facility—one part-time in order to provide social contact for the child, the other full-time because the parents work—might identify the method of care as nursery school and day care center respectively. In any event, overall users of "day care centers" are nearly twice as likely to identify that method as their "main method" as are "nursery school" users.

Measures of Usage

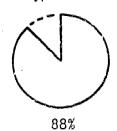

As we have noted, a great proportion in the overall distribution of children "using" child care consists of marginal (very infrequent) users. Only about 26.4 million children (62.5% of the gross "sometimes use" population) receive

care (under one or more of the nine principal types) with sufficient regularity to "average" an hour or more per week (Table IV-6). Even within this group of "regular users" (under a very liberal assumption indeed), most (53.6%) average less than 10 hours a week. About 21%, or an estimated 5.6 million of these children, representing just under 12% of all children under 14, receive full-time-equivalent care (defined as 30 or more hours per week).

The distribution of usage levels is, as one would expect, very strongly tied to the method used (Table IV-7).* Most (56%) day care-center-using children utilize the services at a full-time-equivalent rate, whereas about three-quarters of all the home-based-care users (methods 1-4) receive care less than 10 hours a week.

Children receiving care in another home by a non-relative are of particular interest in this analyses, since regulated "family day care homes" would generally fall under this heading. But given the proportion of "light" users (67.2% receiving less than 10 hours), it is probable that at least half of the "other home by non-relative" group represents informal arrangements among friends and neighbors rather than the more structured "family day care home." This inference is supported in part by the proportion of respondents who exchange services and favors for care rather than cash (cf., Section VI on costs).

Regardless of the structural characteristics of "other home by non-relative" care, it is interesting that the distribution of usage is among the flattest (most broadly distributed) of the methods. This would tend to confirm speculations that this method embraces a variety of usage modalities.

^{*}Sample dispositions for each method are included in the appendix to this section.

Usage Schedule

Our analysis of the mode and significance of usage is greatly augmented by three additional variables, also collected by both child and method. First, respondents were asked when, during the day or night, each applicable child usually received a given type of care. The results (Table IV-8) reinforce the developing pattern that nursery and day care centers are most likely to be used on a regular, full-time basis. "Other home by non-relative" is broadly distributed and encompasses a broad range of usage modalities, and most home-based care can probably be termed "babysitting." The distribution for "before and after school program" is suspect (e.g., "evenings" at 6.5% and "whole day" at 3.9%) and may reflect misinterpretations by some respondents.

A second schedule-related question, days of the week used, yields a congruent distribution (Table IV-9), with nursery schools, day care centers, before and after school programs, and Headstart most frequently used during the week. Care by relatives and all in-home care is used either on weekdays or weekends with approximately equal probability. Once again, however, other home care by non-relatives is unique, occurring more frequently during weekdays but still meeting broad, divergent needs.

A third variable, "general usage schedule" can be interpreted as a measure of regularity (Table IV-10). The same general patterns noted above are evident here, also by method.

Licensure

Respondents were asked, for each child using other home by non-relative, nursery school or center care, if the provider or facility was licensed. Based upon the valid answers attained, nearly all day care centers (97%) (Table IV-11) and 86% of nursery schools (Table IV-12) used are licensed.

It should be underscored, however, that about one in ten eligible respondents either did not know whether the facility was licensed or refused to answer the question, thus presenting a relatively high probability for bias in the estimate

By contrast, "other home by non-relative" care is seldom (10.3%) licensed. (Keep in mind, once again, that a high proportion of the responses represent informal babysitting arrangements (Table IV-13). Just under 10% of the eligible sample space is item non-response.

Summer Care

To round out our overall picture of child care, respondents were asked what special care arrangements they made during the summer months when school is out and occupational vacations are usually taken. The results from this question are summarized by Table IV-14 and sample dispositions by applicable age groupings are presented as Tables IV-15 through IV-18.

Section V

REASONS, SATISFACTION, PREFERENCES AND PRIOR USAGE

SECTION V

REASONS, SATISFACTION, PREFERENCES AND PRODUCT SAGE

Overview .

This section contains topical data and related discussion on the reasons for child care usage, leve's of parental satisfaction with current methods, preferences and factors in selecting arrangements, past usage experience and the frequencies of and reasons for child care arrangement changes.

Reasons for Using Child Care

Users of any of the principal methods of care were asked to select, from a list, the reasons why they use care (Table V-1). Having chosen one or more reasons, they were then asked to select the single most important reason (Table V-2).

In general, the distribution of reasons can be grouped into three conceptually different summary categories: work, school or job-training (items 1, 8 and 9); adult-oriented factors, psychological or social (items 2, 3, 4 and 10); and child-development-related factors (items 5, 6 and 7). Measured only by frequency of response (not adjusting for the amount of usage), a plurality (43.7%) give, as the most important reason, one of the several adult-oriented factors. This group, then, undoubtedly consists largely of "occasional babysitting" consumers (Table V-2).

 V_{-}

Of perhaps greater significance, nearly 40%, or about 6.3 million bouseholds, use child care as an adjunct to employment or education. Only cloud one in ten gives one of the child-oriented developmental reasons as a primary response. However, an important cavent must accompany this observation. The child-oriented factors (e.g., help child learn, be independent or get along with others) are likely to assume greater prominence among the parents of pre-school-age children.

Furthermore, the frequency of child-oriented responses rises dramatically as a proportion of total responses to the "all-reasons" question (Table V-1). This can probably be construed to mean that at least a quarter of the population of users perceive child care to be a positive influence, not a merchy a "necessary gvil." The converse inference, that three-quarters see no developmental value, is patently invalid; this proportion, the refore, must be interpreted as extremely conservative.

Satisfaction

For each child using each of the nine principal care types applicable, respondents were asked to rate their level of satisfaction using the categories "very satisfied," "satisfied," "not completely satisfied" and "dissatisfied." Symmary results, shown in Table V-3, portray a clear pattern of differences in satisfaction by method, but not an overwhelmingly strong one.*

Using a mean rating based on assigning of corresponding values to the ordinal categories (i.e., 1 for "very satisfied" through 4 "dissatisfied"), the most favorable rating is attributed to arrangements in the child's own home

^{*}Sample dispositions are provided for each method in the appendix to this section.

Question 13 SOURCE:

BASE:

Children receiving care in the respective types.

**For frequencies, sample disposition and other information, see tables on the following pages.

by a relative (1.2) followed by "in other home by non-relative" (1.3) and nursery schools (1.3). The least favorable rating (1.5) was reported by users of arrangements in the childrens' own homes by non-relatives.

The observation that care in the child's own home by a relative is among the most satisfactory to parents is confirmed in part by a second questionnaire item in which users were asked if, given the hypothetical choice of using any type of child care (implicitly disregarding availability or cost), they would prefer some other type over their current main method. Just under a quarter (23.9%) indicated a propensity to change. When the distribution of answers is examined against the current main methods (Table V-4), users of arrangements in other homes, whether by a relative or non-relative, are the most likely to prefer some other method, at 32.2% and 26.8%, respectively. The method "in home by a non-relative" is a close third. Of all the home-based care types, "in home by a relative" is, once again, the most highly rated. On the whole, nursery schools and day care centers both appear to be generally satisfactory as measured by the tendency of users to prefer another method.

The questionnaire panel on preference over current main method led logically to the question of what type of care would be most preferred by those who would change. This question, represented by Table V-5, resulted in a rather dramatic bimodal pattern. There are two clear tendencies: (1) nearly 30% preferred some form of in-home care (confirming, perhaps, a residual dissatisfaction with other-home care) and (2) approximately 40% expressed a latent demand for formal, institutional care (i.e., nursery schools or centers). Both forms of other-home care were infrequently preferred, although the notion of availability in the case of relatives renders the respondent's perspective somewhat problematical. In any event, the current policy trend toward

increasing and strengthening family day care home care is apparently short on "product concept acceptance," in the parlance of advertising.

Selection Factors

Current users of in-home care, nursery schools or day care centers and family day care homes were asked to choose, in rank order of importance, seven factors in selecting their child care arrangement. Tables V-6, V-7 and V-8 present the results from these questions expressed as percentages of the eligible response. An additional column, labelled weighted rank, was calculated by multiplying the value 7 by the proportion ranked first, 6 by the proportion ranked second and so forth, finally using unity as the multiplicand for the proportion of observations ranked seventh.

For in-home as well as family day care users, the "reliability" and "warmth" of the caregiver were deemed, in the aggregate, to be the most important factors followed closely by the child's level of satisfaction. Although "availability" is relatively prominent, the responses indicate a very strong pattern of child-orientation from a common sense as opposed to procedural viewpoint. Such issues as licensure, health examinations for staff, qualifications and convenience are not highly ranked. Yet it is only fair to point out that users of these two methods of care are more likely to be casual, occasional users than, say, day care center users.

The taxonomies for each principal type referenced are different, as are the patterns of usage. Yet it can be said that center and nursery school users are somewhat more likely to identify programmatic and procedural factors (e.g., "frequent information," "planned and supervised play") than are home-care users. The differences between methods are, however, neither imminently clear nor strong.

C.

The logical inverse, that is, the least important factor in selection, was also included in the questionnaire (Table V-9), using an abridged response taxonomy. The results of this question, asked of all users, indicate that users tend to de-emphasize cost and convenience. Yet the welfare of children, like mom, apple pie and, allegorically, the flag, seldom comes last in our hearts.

Insight into the way in which consumers select a method of care is perhaps best gleaned from a questionnaire panel asking from a historical perspective, what arrangements current users actually did consider. First, users of the principal methods were asked if they considered any other method, and three-quarters reported that they had not (Table V-10). It is unclear, from a behavioral viewpoint, what constituted "consideration," but it is probable that for the 25.7% who had considered other methods, genuine decision-making had not been arbitrarily or circumstantially precluded.

Those who had considered other methods were then asked to name up to four methods considered and the respective "main reason" why they did not use each method. Cross-tabulated results of this question are presented on three successive pages (Table V-11) and include multiple responses.

While small cell sizes presage caution in drawing inferences from this table, several patterns are very clear. Foremost, nursery schools and day care centers were the most frequently chosen. Third in frequency was "own home by a non-relative," thus verifying very satisfactorily, the distribution of preferred methods (c.f., Table V-5, supra).

In all three instances, cost is an important barrier, constituting the modal cells for nursery schools and centers and a very strong second factor for in-home care by a non-relative.

From these data, it is difficult to avoid concluding, if prematurely, that (1) there exists a substantial demand suspense for nursery and center, care, caused by cost and programmatic barriers (as opposed to availability per se) and (2) difficulties in obtaining "reliable in-home care, coupled with "high" cost. also result in demand suspense.*

Past Experience and Change

As a measure of stability, respondents using child care were asked how many times they had changed their main method during the past year (Table V-12). About one in ten had changed. Significantly, over half (53.8%) gave as their reason for changing (Table V-13) either some problem with the arrangement (e.g., transportation, inconvenience, discipline, program, facility or staff inadequacies or special problems as opposed to cost (10.5%) or such usual external reasons as the child's aging (6.5%), moving (8.1%) or change in the respondent's employment status (18.0%). The modal reason is availability (18.7%). Given that over 60% of those changing identified their old method as one of the "in-home" or "other home" care types (Table V-14), it is possible that some respondents misinterpreted the question to mean a change in provider instead of method.

Before one leaps to the conclusion that the distribution in Table V-13 represents reasons for discontinuing care types on the whole, it is useful to examine the usage history of the entire sample. All respondents were asked if they had used any types of care in the past which they are not using at present.

Just under half reported having discontinued some method in the past (Table V-15).

^{*}It is interesting that when asked to choose from among possible funding options for child care, respondents most frequently chose "referral service" (cf., Table VII-14, p. VII-15).

SOURCE: Question 20

BASE: All households with children under 14

Unweighted Sample	Disposition
Valid answers Non-response	4,585 24
TOTAL	4,609

These respondents were asked to identify up to four previously applicable types together with the main reasons for stopping. This distribution, presented on the three successive pages as Table V-16, shows a more "normal" pattern of termination, with "child too old," "I stopped working," and "I moved" assuming greatest prominence among the reasons given. Yet, again notwithstanding the small cell sizes, there is ample evidence to infer that a great deal of flux and discontinuance is caused by (1) dissatisfaction with providers or their programs, (2) difficulties in making and maintaining arrangements and (3) cost.

Section VI COST AND TRANSPORTATION

SECTION VI

COST AND TRANSPORTATION

In this section costs, including in-kind compensation, are presented by type of care. Supplemental cross-tabulations are included in the appendix at the end of the section by marital/employment status, race/ethnicity and household poverty status. Cost thresholds and transportation-related variables are also reported since each has a direct role in determining resources allotted for care.

Costs

About one in ten users, most of whom receive services from relatives, Headstart or before and after school programs, report no compensation whatsoever for child care (Table VI-1). Over half of all users (55.2%), notably those using home-based care by non-relatives, nursery schools or day care centers, pay in cash. Approximately the same proportion receive some services in exchange for services or favors, with about one in five paying cash for one arrangement and "in-kind" for another. The relatively low proportion (43.7%) paying cash for care in the other home by non-relative category indicates that caution should be used in equating this method with the concept of "family day care home."

The distribution of total costs paid by method (Table VI-2) is analytically useful not only as an economic measure, but also as a supplementary partition between casual and formal users. Only approximately 3.8 million (23.7%) of the user households pay \$15 per week or more, and nearly half (47%) report no cash expenditures for child care.

Question 25 SOURCE:

Households using the respective types of care BASE:

One of the future goals of this study is to compare current payments against the respondents' stated upper limit or budget threshold for care. A distribution of the "most [users reported] they would be able to spend altogether for all of [their] child care needs on a weekly basis" is given in Table VI-3. This variable is of limited analytic use in simple marginal form.

Transportation

Ignoring in-home users, about 90% of child care-related transportation is performed by a family member including respondents (Table VI-4). In most of the remaining cases, the child walks. Two-thirds of those who travel require less than 10 minutes travel time (Table VI-5), with about 5% traveling 30 minutes or more. In over 85% of the cases in which a family member is responsible for transportation, the traveling is considered to be "out of the way" (Table VI-6).

As we have seen in Section V, convenience and transportation problems were not particularly highly ranked as problems or barriers to care. The maximum travel time expressed as the maximum time respondents were willing to have children travel to a child care arrangement lends at least a partial clue. Viewed on the whole, the distribution of current travel times is substantially lower than the threshold limits given in Table VI-7. The two questions, however, are not parallel in concept as they do not measure the respondents willingness or capability to perform the transportation.

Section VII OPINIONS AND ATTITUDES

SECTION VII

OPINIONS AND ATTITUDES

Phase III of this study will consists of a rigorous examination of consumer opinions and attitudes. The principal goal of this stage of analysis will be the development of consumer typologies based upon attitudinal patterns as well as manifest usage and independent demographic variables.

Consequently, a series of attitude scales were included in the instrument as were several opinion questions of possible policy-related value. Simple tabulations of these variables, therefore, are included in this section only as a matter of interest, exclusive of comment, explanation or analysis.
