ABSTRACT

This report presents the childbearing experience and fertility expectations of American women based on data collected in the June, 1976, Current Population Survey. Survey findings include the birth expectations of young single women who, as they marry, will contribute a major portion of the births in the United States within a few years. An introductory section summarizes significant trends. Of the 13.5 million future births expected by 18 to 24 year old white women reporting in the survey, over one-half are expected to be contributed by currently single women, and 43% by currently married women. The fertility rate has dropped in women 18 to 24 years of age from 3.1 in the early 1960 to 2.1 in 1976. This may be due to temporary postponement of childbearing on the part of young wives. For married women of all races 14 to 34 years old in 1971, fertility rates for the five years ending in 1976 are about 88% of the rates expected for that period in 1971. For comparable age groups, single black women have significantly higher levels of childbearing than do single white women. Data indicate an inverse relationship between fertility and educational attainment. The bulk of the report consists of tables of data. Two appendices define terms such as "birth cohort" and "parity" and review the source and reliability of data presented in the report. (Author/AV)

ACKNOWLEDGMENTS

This report was prepared in the Fertility Statistics Branch by **Martin O'Connell**, with the collaboration of **Peggy Payne**, and under the supervision of **Maurice J. Moore**, Branch Chief. Statistical and clerical assistance was provided by **Sharon Phipps** and **Carol Smith**. **Howard N. Kaufmann** and **Richard Jaronski**, Demographic Surveys Division, designed the computer programs to meet both editing and tabulating specifications. Statistical review was performed by **Paul Makens** and **Diana Harley**, Statistical Methods Division. Content review was contributed by **Charles E. Johnson, Jr.**, Assistant Division Chief (Demographic and Social Statistics Program) and **Paul C. Glick**, Senior Demographer. **Karen M. Mills** assisted in the preparation of textual materials.

FERTILITY OF AMERICAN WOMEN: JUNE 1976

INTRODUCTION

This report presents the childbearing experience and fertility expectations of American women based on data collected in the June 1976 Current Population Survey. An advance report based on this survey (*Current Population Reports, Series P-20, No. 300*) has previously described the decline in birth expectations among currently married women 18 to 39 years of age between the first Census Bureau study of birth expectations in 1967 and the present 1976 survey (see also table 6 in this report).

Survey findings in the text of this final report include the birth expectations of young single (never-married) women who, as they marry, will be contributing a major portion of the births in the United States within a few years. The consistency between the birth expectations of married women in 1971 and actual fertility for the 5-year period 1971 to 1976 will also be examined. Finally, there will be a brief review of some new data on the fertility of single women which are available for the first time from the June 1976 Current Population Survey.

BIRTH EXPECTATIONS

Birth expectations of single women. One criticism of the usefulness of the data collected in previous birth expectations surveys for fertility projections and analysis has centered on the omission of young single women in the sample universe.¹ Since women currently single will contribute substantially to the number of births in future years, an examination of the fertility prospects for these women should aid in the evaluation of future fertility trends.

¹For a discussion of these shortcomings, see Norman B. Ryder and Charles F. Westoff, *Reproduction in the United States 1965* (Princeton: Princeton University Press, 1971); and Jacob S. Siegel and Donald S. Akers, "Some Aspects of the Use of Birth Expectations Data from Sample Surveys for Population Projections," *Demography*, Vol. 6, No. 2 (May 1969), pp. 101-115.

Figure 1 on the cover illustrates the relative importance of the contribution of currently single women to the number of future expected births. Of the 13.5 million future births expected by 18 to 24 year old White women reporting in the survey (table 1), over one-half (54 percent) are expected to be contributed by currently single women; 43 percent of these births are expected to be contributed by currently married women (excluding separated); and the remaining 3 percent are expected to be contributed by women currently widowed, divorced, and separated. Among Black women 18 to 24 years old, approximately two-thirds of the future births to be born to that cohort of women are expected to be contributed by women who have not as yet been married.

Of course, the expectations of these single women are closely related to the probability that they will eventually marry in future years. Since the probability of eventual marriage declines with age for single women beyond their early twenties,² the number of children expected by single women 25 years old and over is substantially smaller than that expected by single women 18 to 24 years old. Table 1 shows that single women 18 to 24 years old in 1976 expect to complete their fertility with approximately 1.9 children per woman; however, those 30 to 34 years old in 1976 who were still single anticipate a final average of only 0.9 children per woman.

Current fertility trends and prospects. An overview of fertility trends in the United States for the period 1960 to 1976 is presented in table A. The two fertility measures shown in this table are the total fertility rate and the average number of lifetime births expected per currently married woman 18 to 24 years old. The latter measure is based on privately conducted fertility surveys in

²For estimates of marriage probabilities, see Robert Schoen and Verne E. Nelson, "Marriage, Divorce, and Mortality: A Life Table Analysis," *Demography*, Vol. 11, No. 2 (May 1974), pp. 267-290.

1960 and 1962 to 1965, on the Survey of Economic Opportunity conducted in 1967, and on June Current Population Surveys conducted from 1971 to 1976.

The total fertility rate for a given year is based on annual birth registrations compiled by the National Center for Health Statistics and indicates the current rate of childbearing. The rate for a given year may be interpreted as the number of births a woman would have by the end of her childbearing period, if,

during each year of her reproductive life, she were to experience the age-specific fertility rates that occur in that given year.

On the other hand, the average number of lifetime births expected in a given year are composed of all births to date, and all additional births expected in future years. Unlike the total fertility rate, the average number of lifetime births expected used in this section refers only to currently married women between 18 and 24 years old. Since the data

Table A. Annual Total Fertility Rate, and Lifetime Births Expected by Wives 18 to 24 Years Old, for Selected Years, 1960 to 1976

¹The numbers of births a woman would have in her lifetime if, at each year of age, she experienced the age-specific fertility rates occurring in the specified calendar year. This rate is derived from births registered as occurring to women 10 to 49 years old.

²Average for the period 1962 to 1964.

Source: Total fertility rates for 1960 to 1973 (which are adjusted for population undercounts) are from Robert L. Heuser, Fertility Tables for Birth Cohorts by Color: United States, 1917-1973, (Washington: U.S. Government Printing Office, 1976), p. 4; the rates for 1974 and 1975 are from National Center for Health Statistics, Monthly Vital Statistics Report, "Advance Report, Final Natality Statistics, 1975," Vol. 25, No. 10 (December 1976), p. 10; the rate for 1976 is an estimate provided by Census Bureau statisticians.

Lifetime expected births for 1960 are from Pascal K. Whelpton, Arthur A. Campbell, and John Patterson, Fertility and Family Planning in the United States, (Princeton: Princeton University Press, 1966); the rate for the 1962-64 period is from Ronald Freedman and Larry Bumpass, "Fertility Expectations in the United States: 1962-1964," Population Index, Vol. 32, No. 2 (April, 1966), table 3; the rate for 1965 is from unpublished data from the 1965 National Fertility Study; the rate for 1967 is from the Survey of Economic Opportunity analyzed in Current Population Reports, Series P-20, No. 211; data for 1971 to 1976 are from Current Population Reports, Series P-20, No. 300.

are not for all women 18 to 24 years old, the lifetime expectations analyzed in this section slightly overstate expectations for all women of that age.³ Women 18 to 24 years old were chosen since they have most of their reproductive lifespan ahead of them and are currently making very large contributions to the annual number of births. Currently married women in this age group in 1976 have borne only 38 percent of their total number of expected children (table 6). In addition, children born to all women 18 to 24 years old accounted for 46 percent of all births in 1975.⁴

Although the total fertility rate and birth expectations data are not strictly comparable because of the conceptual differences between the two fertility measures, both the total fertility rate and the average number of lifetime births expected were quite high in the early 1960's. During this period at the end of the baby boom, women were bearing sufficient numbers of children to produce annual total fertility rates in excess of 3.0. At the same time, young wives 18 to 24 years old were expecting approximately 3.1 lifetime births. In more recent years, childbearing has declined to such an extent that the total fertility rate has been below 2.0 since 1972, with the average number of lifetime births expected per currently married woman 18 to 24 years old in 1976 around 2.1.

This decline in the total fertility rate to its current level of about 1.8 is not necessarily inconsistent with the realization of current lifetime expectations of over 2.0 births per woman, at least in the short run. Although it is true that women 18 to 24 years old contribute a large proportion of births during any given year, what may be happening is that there is some temporary postponement of childbearing on the part of young wives. If, in the coming years, wives continue to expect an average of more than two children and actually live up to their expectations, the annual total fertility rate is not likely to persist very long at its current low levels.

Reliability of short term birth expectations. Considering that various demographers have predicted a coming rise in fertility within the next few

³Currently married women 18 to 24 years old in 1976 expected 2.1 births per woman, whereas all women 18 to 24 years old regardless of marital status expected 2.0 births per woman (table 1).

⁴National Center for Health Statistics, *Monthly Vital Statistics Report*, Vol. 25, No. 10, "Advance Report, Final Natality Statistics, 1975."

years,⁵ it is especially interesting to assess the reliability of birth expectations data as predictive statistics. To test the ability of married women in 1971 to predict the number of births they expected in the next 5 years, information was used from the June 1976 Current Population Survey for women who had been married at the time of the 1971 survey to discover how many children they had borne in the last 5 years. Table B shows the comparison of expected births with actual births for the same cohort of women at two points in time—in 1971 when the first sample of women reported on how many children they expected to have in the next 5 years and again in 1976 when the second sample reported on the number of children that they had actually borne in the preceding 5 years.⁶

The last column in table B shows the rates of children actually born since 1971 as a percentage of the number of additional births expected in 1971. For married women of all races 14 to 34 years old in 1971, the fertility rates for the 5 years ending in 1976 are about 88 percent of the rates expected for that period in 1971. White women between the ages of 20 and 29 years in 1971 recorded fertility rates which were significantly lower than the corresponding expectations. This finding reflects the observed fertility decline that has occurred since 1971 for these women.⁷ However, for married women age 14 to 17 and 18 and 19 years old in 1971, no statistically significant differences emerged between expected and actual fertility.

Regarding the fertility patterns among Black women, the sampling errors for the various rates are so large that none of the differences shown in table B between expected and actual fertility during the 5 years qualify as being statistically significant.

To judge from the results in table B, expectations of births in the next 5 years are not a very precise analytical tool for short term fertility projections. Short term birth expectations may be especially

⁵The recent opinions of certain demographers are summarized in Linda Wolfe, "The Coming Baby Boom," *New York*, January 10, 1977, pp. 38-42.

⁶Since the 1971 data on birth expectations were based on reports from 81 percent of the wives in the sample, the 1976 data on children ever born between 1971 and 1976 were also restricted to the 86 percent of the wives in the sample reporting on birth expectations. The purpose of this was to make the two sample universes as comparable as possible, although it is uncertain that any biases due to nonreporting were the same in both surveys.

subject to revision due to changing social and economic conditions. The value of lifetime birth expectations as predictors of completed cohort fertility, however, still awaits an adequate assessment.

CHILDREN EVER BORN TO SINGLE WOMEN

Data in table C on the number of children ever born to single women indicate that for comparable age groups, single Black women have significantly higher levels of childbearing than do single White women. Single Black women 30 to 44 years old in 1976 had an average of 2.0 children per woman with approximately one-third of the women in this age

group having borne three or more children to date. The corresponding statistics for single White women in the same age group were 0.2 births per woman and only 2 percent reporting having borne three or more children. Overall, the data show that 44 percent of single Black women, 18 to 44 years old have had at least one child as compared to 5 percent for single White women of the same age.

These large fertility differentials by race are consistent with data collected from annual birth registrations and published in annual reports on vital statistics in the United States. The latest available data for 1975 from this source indicate that 49

percent of all Black children were born out of wedlock, as compared with 7 percent of White children.⁸

Socioeconomic differentials. Differentials in average numbers of children ever born to single women by selected characteristics are shown in table D. The socially disadvantageous aspects of premarital childbearing are evident when comparing levels of fertility among single women by years of school completed and labor force status. Regardless of race or age, in the statistics shown in table D an

inverse relationship is observed between fertility and educational attainment. This differential is in part produced by the fact that a childless single woman has fewer obstacles to surmount in furthering her educational career than does an unwed mother.⁹ Having a child at an early age often results in a permanent educational handicap that a single woman must bear for her entire life. Another factor

⁹Harriet Presser discusses the obstacles faced by unwed mothers regarding socioeconomic advancement in "Social Consequences of Teenage Childbearing," in W. Petersen and L. Day, eds., *Social Demography: The State of the Art* (Cambridge, Massachusetts: Harvard University Press, 1977).

contributing to differences in fertility according to educational level is that women with lower educational attainment often have a more limited knowledge of contraceptive practices than women with higher attainment; consequently, those with lower levels of schooling may be subject to higher pregnancy risks.¹⁰

Regarding the higher levels of children ever born to women not in the labor force (table D), this differential may be attributed in part to the difficulty encountered by the unwed mother in finding a job or in locating adequate child care facilities in

order to look for work. Even if a job can be located, the burden of caring for her child probably influences not only the type of work a single mother can accept, but also the amount of time she has available to support herself and her child.

RELATED REPORTS

Advance data on birth expectations and fertility as of June 1976 were presented in **Current Population Reports, Series P-20, No. 300**. Data from the June 1972, June 1973, June 1974, and June 1975 surveys appeared in Series P-20, Nos. 248, 265, 277, and 301. The report on the June 1971 survey, which includes data on childspacing and on cumulative fertility by age for birth cohorts and by interval since first marriage for marriage cohorts, is No. 263. Data on fertility by ethnic origin as of November

¹⁰See Farida Shah, Melvin Zelnick, and John F. Kanter, "Unprotected Intercourse Among Unwed Teenagers," **Family Planning Perspectives**, Vol. 7, No. 1 (January/February 1975), pp. 39-44.

1969 were presented in report No. 226. January 1969 survey data on fertility appeared in report No. 203. Birth expectations and fertility data from the 1967 Survey of Economic Opportunity were published in report No. 211. Detailed information on childspacing collected in June 1965 appeared in report No. 186.

Statistics on fertility by social and economic characteristics from the 1970 census were published in Final Report PC(2)-3A, Women by Number of

Children Ever Born, and PC(2)-3B, Childspacing and Current Fertility, and from the 1960 census in Final Report PC(2)-3A, Women by Number of Children Ever Born and PC(2)-3B, Childspacing. A special study entitled "Premarital Fertility," based on the data from the 1970 census, was published in Current Population Reports, Series P-23, No. 63.

For references to census and survey data on fertility for earlier years, see the publications cited in the Bureau of the Census catalogues.

Numbers refer to women in the sample population and are not inflated estimates of the national population.
 Percentages not reporting includes any woman under 26 years old who reported a number of children ever born which would imply an average of more than one birth a year since age 15.
 Percentages not reporting includes any woman 15 years old who reports a number of children ever born.
 Percentages not reporting includes any woman 15 years old who reports a number of children ever born, a number was imputed by matching her on the basis of similarity in selected characteristics with a woman who did report.

APPENDIX B

DEFINITIONS AND EXPLANATIONS

Population coverage. The data from the Current Population Surveys and from the Survey of Economic Opportunity (1967) are for the civilian noninstitutional population of the United States. Because only a small proportion of women are inmates of institutions, (less than 1 percent of women 15 to 44 years old being institutionalized), the data for the civilian noninstitutional population have a high degree of comparability with data for the total population. The censuses of 1970, 1960, 1950, and 1940 show data for the total population; Alaska and Hawaii are included beginning with 1960.

Birth expectations. Women 14 to 39 years old who were currently married (spouse present or spouse absent excluding separated) and women 18 to 34 years old who were not currently married (including women widowed, divorced, separated, and never married) who were asked the following questions:

1. Looking ahead, do you expect to have any (more) children?

Answer: Yes, No, Uncertain.

If the answer to the first question was "Yes," the second and third questions were asked.

2. How many (more) do you expect to have?
3. How many (more) do you expect to have in the next 5 years?

These questions were asked only of the women to whom they pertained, i.e., responses were not accepted from another household member on behalf of a woman if she was not available.

Reporting on birth expectations. A woman was counted as "reporting" with respect to birth expectations under the following conditions:

1. If currently married, either she both answered "Yes" to question 1 and provided numerical answers to questions 2 and 3, or she answered "No" to question 1.

2. If widowed, divorced, separated, or never married, the conditions were the same as currently married, except that a "Yes" response to question 1 required a positive response only to question 2.

If the conditions were not met, a woman was counted as "not reporting." Data on birth expectations were not allocated for nonreporting women.

Births to date. In some tables showing the birth expectations of wives, the number of "births to date" is also shown. This term has the same meaning as the number of children ever born.

Additional births expected. Information on additional births is derived from the questions on birth expectations (see above). These births are called "additional births" when the women in question are ever married, since information on births to date is available for these women. In this case, births expected in the future are additions to those known to have been born to date, although some ever-married women are childless at the time of the survey.

Lifetime births expected. This term is used with respect to ever-married women to refer to the sum of births to date and additional births expected. The sum represents the total number of births a woman expects during her lifetime.

Children ever born. The question "Has . . . ever had any babies (Do not count stillbirths)?" was asked of all women 14 to 59 years old who were reported as married (including separated), widowed, or divorced, and all women 18 to 59 years old who were reported single (never married). If the answer for the woman in question was "yes," the further question "how many" was also asked. When asking about children ever born, interviewers were instructed to include children born to the woman before her present marriage, children no longer living, and children away from home as well as children who were still living in the home. It is possible that some never-married mothers living with one or more of their natural children reported themselves as having been married. In addition, many mothers who first

married after the birth of one or more children counted those children, as they were expected to do. Nevertheless, data are probably less complete for births out of wedlock than for births within wedlock.

In filling out the interview schedule, the interviewer entered the number of children ever born from 0 to a terminal category of "10 or more." For purposes of computing the total number of children ever born, the terminal category was counted as 10.

Parity. Parity is the number of children ever born to a woman. In some cases, use of the term "parity" provides a less cumbersome expression, e.g., "two-parity women" as opposed to "women with two children ever born."

Birth cohort. A birth cohort is a group of persons who were born in a specified calendar period.

Marital status. Data refer to present marital status. All women may be categorized as either single (never-married) or ever married, the latter consisting of women who are married, widowed, or divorced. In this report reference is made to various subgroups among married women. In the section on birth expectations, "currently married" refers to all married women except those who are separated; separated women are classified along with the widowed and divorced. In the section on children ever born, two categories of married women are shown, "husband present" or "husband absent" (including separated), in order to show whether or not the husband is a member of the household.

Household. A household consists of all the persons who occupy a housing unit. A house, an apartment or other group of rooms, or a single room, is regarded as a housing unit when it is occupied or intended for occupancy as separate living quarters; that is, when the occupants do not live and eat with any other persons in the structure and there is either (1) direct access from the outside or through a common hall or (2) a kitchen or cooking equipment for the exclusive use of the occupants.

A household includes the related family members and all the unrelated persons, if any, such as lodgers, foster children, wards, or employees who share the housing unit. A person living alone in a housing unit, or a group of unrelated persons sharing a housing unit as partners, is also counted as a household. The count of households excludes group quarters.

Family. A family is defined as a group of two or more persons residing together who are related by blood, marriage, or adoption. A lodger and his wife who are not related to the head of the household, or an employee and his wife both residing in the household, are considered as separate families and not as part of the head's family. On the other hand, a household head living alone or a household head and one or more unrelated persons is regarded as a household but not as a family. Thus, some households contain more than one family and some do not contain any families.

Primary family. A family that includes among its members the person reported as the head of the household.

Household Relationship

1. **Female head, no husband present,** is a woman reported as head of a household in which no one is listed as her husband. Such a woman may be single, married, widowed, or divorced. She may live alone, with relatives, and/or with nonrelatives.
2. **Wife in husband-wife primary family** is a woman living with her husband in a primary family. This category includes women in common-law marriages as well as women in formal marriages.
3. **Other primary family member** is a person living in the household who is related by blood, marriage, or adoption to the person reported as the head of the household and who is not included specifically in another category.
4. **Not a member of primary family** is a person living in the household who is not related by blood, marriage, or adoption to the person reported as the head of the household.

Geographic regions. The four major regions of the United States, for which data are presented in this report, represent groups of States, as follows:

Northeast: Connecticut, Maine, Massachusetts, New Hampshire, New Jersey, New York, Pennsylvania, Rhode Island, and Vermont.

North Central: Illinois, Indiana, Iowa, Kansas, Michigan, Minnesota, Missouri, Nebraska, North Dakota, Ohio, South Dakota, and Wisconsin.

South: Alabama, Arkansas, Delaware, District of Columbia, Florida, Georgia, Kentucky, Louisiana, Maryland, Mississippi, North Carolina, Oklahoma, South Carolina, Tennessee, Texas, Virginia, and West Virginia.

West: Alaska, Arizona, California, Colorado, Hawaii, Idaho, Montana, Nevada, New Mexico, Oregon, Utah, Washington, and Wyoming.

Metropolitan-nonmetropolitan residence. The population residing in standard metropolitan statistical areas (SMSA's) constitutes the metropolitan population. Except in New England, an SMSA is a county or group of contiguous counties which contains at least one city of 50,000 inhabitants or more, or "twin cities" with a combined population of at least 50,000. In addition to the county or counties, containing such a city or cities, contiguous counties are included in an SMSA if, according to certain criteria, they are essentially metropolitan in character and are socially and economically integrated with the central county. In New England, SMSA's consist of towns and cities, rather than counties. The metropolitan population in this report is based on SMSA's as defined in the 1970 census and does not include any subsequent additions or changes.

Central cities. Each SMSA must include at least one central city, and the complete title of an SMSA identifies the central city or cities. If only one central city is designated, then it must have 50,000 inhabitants or more. The area title may include, in addition to the largest city, up to two city names on the basis and in the order of the following criteria: (1) The additional city has at least 250,000 inhabitants or (2) the additional city has a population of one-third or more of that of the largest city and minimum population of 25,000. An exception occurs where two cities have contiguous boundaries and constitute, for economic and social purposes, a single community of at least 50,000, the smaller of which must have a population of at least 15,000.

Farm population. In the Current Population Survey and the 1960 and 1970 Censuses of Population the farm population consists of all persons living in rural territory on places of 10 or more acres if as much as \$50 worth of agricultural products were sold from the place in the reporting year. It also includes those living on places of under 10 acres if as much as \$250 worth of agricultural products were sold from the place in the reporting year. Persons in institutions, summer camps, motels, and tourist camps, and those living on rented places where no land is used for farming are classified as nonfarm.

Age. The age classification is based on the age of a woman at her last birthday. Age of woman at first marriage was determined by subtracting the date of birth of the woman from the date of first marriage. Likewise, age of a woman at birth of a child was determined by subtracting the date of birth of the woman from the date of birth of the child.

Race. The population is implicitly divided in this report into three groups on the basis of race: White, Black, and "other races." The last category includes Indians, Japanese, Chinese, and any other race except White and Black. The tables in this report show data for all races, Whites, and Blacks.

Spanish origin. Persons of Spanish origin in this report are those persons who indicated that their origin was Mexican, Puerto Rican, Cuban, Central or South American, or some other Spanish origin. The latter category includes persons from Spain as well as persons with combinations of types of Spanish origins. Persons who reported that they were of one of the specific Spanish origin categories and a non-Spanish category were included in the specific Spanish category. Persons of Spanish origin may be of any race.

Years of school completed. Data on years of school completed in this report were derived from the combination of answers to questions concerning the highest grade of school attended by the persons and whether or not that grade was finished. The questions on educational attainment apply only to progress in "regular" schools. Such schools include graded public, private, and parochial elementary and high schools (both junior and senior high), colleges, universities, and professional schools, whether day schools or night schools. Thus, regular schooling is that which may advance a person toward an elementary school certificate or high school diploma, or a college, university, or professional school degree. Schooling in other than regular schools was counted only if the credits obtained were regarded as transferable to a school in the regular school system.

Labor force and employment status. The definitions of labor force and employment status in this report relate to the population 14 years old and over.

Employed. Employed persons comprise (1) all civilians who, during the specified week, did any work at all as paid employees or in their own business or profession, or on their own farm, or who worked 15 hours or more as unpaid workers on a farm or in a business operated by a member of the

family, and (2) all those who were not working but who had jobs or businesses from which they were temporarily absent because of illness, bad weather, vacation, or labor-management dispute, or because they were taking time off for personal reasons, whether or not they were paid by their employers for time off, and whether or not they were seeking other jobs. Excluded from the employed group are persons whose only activity consisted of work around the house (such as own home housework, painting or repairing own home, etc.) or volunteer work for religious, charitable, and similar organizations.

Unemployed. Unemployed persons are those civilians who, during the survey week, had no employment but were available for work and (1) had engaged in any specific jobseeking activity within the past 4 weeks, such as registering at a public or private employment office, meeting with prospective employers, checking with friends or relatives, placing or answering advertisements, writing letters of application, or being on a union or professional register; (2) were waiting to be called back to a job from which they had been laid off; or (3) were waiting to report to a new wage or salary job within 30 days.

In labor force. Persons are classified as in the labor force if they were employed as civilians, unemployed, or in the Armed Forces during the survey week. The "civilian labor force" includes all civilians classified as employed or unemployed.

Not in labor force. All civilians who are not classified as employed or unemployed are defined as "not in labor force." This group who are neither employed nor seeking work includes persons engaged only in own home housework, attending school, or unable to work because of long-term physical or mental illness; persons who are retired or too old to work, seasonal workers for whom the survey week fell in off season, and the voluntarily idle. Persons doing only unpaid family work (less than 15 hours during the reference week) are also classified as not in labor force.

Occupation. Data on occupation are shown for the employed and relate to the job held during the survey week. Persons employed at two or more jobs were reported in the job at which they worked the greatest number of hours during the week. The major groups used here are generally the major groups used in the 1970 Census of Population. The composition of the groups is shown in 1970 Census of Population, Vol.1, Characteristics of the Population, chapter C, General Social and Economic Characteristics, U.S. Summary.

Some of the major occupation groups are sometimes combined as follows:

White collar. Professional, technical, and kindred workers; managers and administrators, except farm; sales workers; and clerical and kindred workers.

Blue collar. Craft and kindred workers; operatives, including transport equipment operatives; and laborers, except farm.

Family income. Family income represents the total income of all members of the family. Income, as defined in this report, represents total money income, or the sum of money from wages or salary before deductions for personal taxes and other purposes, net income from self-employment, and income from other sources received by all family members.

In the June 1976 family income was transcribed from information first obtained at the time a household entered the Current Population Survey and updated when it reentered the survey. For about one-fourth of the sample the data are for the year ending in March 1976, and for other fourths the data are for years ending in April, May, and June 1976, respectively.

Income data in this report are based on the respondent's estimate of total family money income in broad, fixed income levels. Previous research has shown that the use of broad income intervals to record money income tends to reduce the rate of nonreporting while increasing the likelihood that the amounts reported will be significantly understated as compared with results from more detailed questions.

Median. The median is the value which divides a distribution into two equal parts; one-half of the cases falling below this value and one-half of the cases exceeding this value.

Symbols. A dash "-" represents zero or a number which rounds to zero. The symbol "<" means less than. "B" means that the base is too small to show the derived measure; "NA" means not available; and "X" means not applicable. "S" means that the base for a derived number does not meet publication standards because the base is not comparable to CPS estimates.

Rounding of estimates. Individual numbers are rounded to the nearest thousand without being adjusted to group totals, which are independently rounded. Derived measures are based on unrounded numbers when possible; otherwise, they are based on the rounded numbers.

SOURCE AND RELIABILITY OF THE ESTIMATES

Source of data. Most of the estimates in this report are based on data obtained from the Bureau of the Census collected in the Current Population Survey (CPS), the Survey of Economic Opportunity (SEO), and the Decennial Censuses of Population. Other data are from privately conducted in-depth surveys of fertility and related phenomena, such as the National Fertility Study, or from books and journal articles by noted demographers and sociologists. The sources of data in each text table and for each figure can be found at the bottom of that table or figure. The sources of non-Census Bureau data appearing in the text of the report are presented in accompanying footnotes. Brief descriptions of the sources from and procedures by which data of the Bureau of the Census were obtained are presented below. Further information for the data from private sources can be obtained from the individual publications referenced in the report.

Current population survey (CPS). The CPS estimates in this report are based on data obtained in June of 1971 and 1976. The monthly CPS deals mainly with labor force data for the civilian noninstitutional population. Questions relating to labor force participation are asked about each member 14 years old and older in each sample household. In addition, supplementary questions are asked each June about fertility and birth expectations of American women.

The present CPS samples was initially selected from the 1970 census file and is updated continuously to reflect new construction where possible (see section "Nonsampling Variability" below). Samples for previous sample designs were selected from files from the census most recently completed at the time.

The following table provides a description of some aspects of the CPS sample designs in use during the referenced data-collection periods.

Description of the Current Population Survey

Time period	Number of sample areas ¹	Households eligible		Households visited, not eligible ²
		Inter-viewed	Not inter-viewed	
August 1972 to present.....	461	45,000	2,000	8,000
August 1971 to July 1972.....	449	45,000	2,000	8,000
January 1967 to July 1971.....	449	48,000	2,000	8,500

¹These areas were chosen to provide coverage in each State and the District of Columbia.

²These are households which were visited, but were found to be vacant or otherwise not eligible for interview.

The estimation procedure used for the monthly CPS data involves the inflation of the weighted sample results to independent estimates of the civilian noninstitutional population of the United States by age, race, and sex. These independent estimates were based on statistics from decennial censuses; statistics on births, deaths, immigration, and emigration; and statistics on the strength of the Armed Forces. For data collected in the Current Population Surveys between March 1962 and September 1971, the independent estimates used were based on statistics from the 1960 Census of Population. Beginning in October 1971, the independent estimates were based on the 1970 Census of Population.

1967 Survey of Economic Opportunity. The 1967 Survey of Economic Opportunity (SEO) sam-

ple was spread over 357 areas comprising 701 counties and independent cities. These areas were chosen to provide coverage in each State and the District of Columbia. Approximately 29,000 occupied households were eligible for interview. Of this number about 2,500 of the occupied units were visited but interviews were not obtained because the occupants were not found at home after repeated calls or were unavailable for some reason. In addition to the 29,000 occupied households, there were also 7,700 sample units which were visited but were found to be vacant or otherwise not to be interviewed.

The SEO sample was selected so that there was a disproportionately large sample from the Black and other races population. The weights applied to each sample case were adjusted to reflect this. This sampling procedure was used to provide more reliable

estimates for Black and other races population although it was known that reliability of estimates not broken down by race and of estimates for Whites would be reduced.

Decennial census of population. Decennial census data in this report are based on complete counts or on the samples associated with the census. The 1960 and 1970 census data are based on 5 percent samples. Descriptions of the samples can be found in the appropriate census publications.

Reliability of the estimates. Since the SEO and CPS estimates in these tables were based on samples, they may differ somewhat from the figures that would have been obtained if a complete census had been taken using the same schedules, instructions, and enumerators. There are two types of errors possible in an estimate based on a sample survey—sampling and nonsampling. For estimates in this report, indications of the magnitude of sampling error are provided, but the extent of the nonsampling error is unknown. Consequently, particular care should be exercised in the interpretation of figures based on a relatively small number of cases or on small differences between estimates.

Nonsampling variability. As in any survey work, the results are subject to errors of response and non-reporting in addition to sampling variability. Nonsampling errors can be attributed to many sources, e.g., inability to obtain information about all cases in the sample, definitional difficulties, differences in the interpretation of questions, inability or unwillingness to provide correct information on the part of respondents, inability to recall information, mistakes made in collection such as in recording or coding the data, mistakes made in processing the data, mistakes made in estimating values for missing data, and failure to represent all units with the sample (undercoverage). The approximate magnitude of two sources of undercoverage in CPS is known and is described next.

Approximately 600,000 conventional new construction units were issued building permits prior to the 1970 census but building was not completed by the time of the census (i.e., April 1970); these units have no representation in the CPS sample. Conventional new construction, for which building permits were issued after the census, is represented. In addition to undercoverage of conventional new construction, CPS misses at least 200,000 new mobile homes. These are missed because there is no systematic sampling procedure to provide representation of mobile homes constructed since the 1970 census. Note that these estimates of missed units are rele-

vant to the present sample only and not to earlier designs where the extent of undercoverage was generally less.

In addition to the above mentioned sources of undercoverage in CPS, several sources of response error with respect to fertility of American women have been identified. Regarding birth expectations, 16 percent of ever-married women and 37 percent of never-married women were counted as "not reporting" (table A-1) in the June 1976 CPS supplement. These percentages include women who were uncertain about additional births expected and did not provide a numerical response as well as women who either were not contacted by the interviewer or who refused to answer the questions. The tables in this report showing birth expectations are restricted to women who supplied a numerical answer. What bias, if any, is introduced by this restriction is not currently known.

Regarding the question on children ever born, 7 percent of the ever-married women and 8 percent of the single women were counted as "not reporting." In these instances, a number of children ever born was imputed, based on a match of these women with other women of similar characteristics who did report children ever born. Tables presenting rates of children ever born are based on all women in the sample, including women with an imputed value for number of children ever born.

The June 1976 CPS included single women 18 to 59 years old among those asked about previous childbearing. Consequently, there is the likelihood of some deliberate misreporting of the facts, especially among women who perceive out-of-wedlock childbearing as bearing a social, moral, or legal stigma. It is also quite possible that the level of misreporting may differ systematically according to various demographic and social characteristics.¹

Sampling variability. The standard errors given in the following tables are primarily measures of sampling variability, that is, of the variations that occurred by chance because a sample rather than the whole of the population was surveyed. As calculated, the standard error also partially measures the effect of certain response and enumeration errors, but it does not measure any systematic biases in the data. The chances are about 68 out of 100 that an

¹For an assessment of the reliability of these data see Maurice J. Moore, "Asking Single Women About Their Children: The Census Bureau's Experience," Proceedings of the Social Statistics Section 1976, American Statistical Association (Washington, D.C., 1976): 618-23.

estimate from the survey differs from a complete census figure by less than the standard error. The chances are about 90 out of 100 that this difference would be less than 1.6 times the standard error and about 95 out of 100 that the difference would be less than twice the standard error.

All the statements of comparison appearing in the text are significant at a 1.6 standard error level or better, and most are significant at a level of more than 2.0 standard errors. This means that for most differences cited in the text, the estimated difference is greater than twice the standard error of the difference. Statements of comparison qualified in some way (e.g., by use of the phrase, "some evidence") have a level of significance between 1.6 and 2.0 standard errors. Comparisons involving data or statements from journal articles or publications not written at the Bureau of the Census do not necessarily meet these statistical standards.

Note when using small estimates. Percent distributions are shown in this report only when the base of the percentage is greater than 75,000 for any data collected in the June 1976 or June 1971 CPS and for data on Black women collected in the February-March 1967 SEO, or when the base of the percentage is greater than 125,000 for data on all races and on White women collected in the February-March 1967 SEO. Because of the large standard errors involved, there is little chance that percentages would reveal useful information when computed on smaller bases. Estimated numbers are shown, however, even though the relative standard errors of these numbers are larger than those for the corresponding percentages. These smaller estimates are provided primarily to permit such combinations of the categories as serve each user's needs. Similarly, estimated numbers of children ever born per 1,000 women and birth expectation data are shown in the report only when the associated number of women is greater than 75,000 or 125,000 as specified above.

Comparability with other data. Data from sources other than the Census Bureau may be subject to both higher sampling and nonsampling variability. In addition, data obtained from the CPS are not entirely comparable with data obtained from SEO or other sources. This is due in large part to differences in interviewer training and experience and in differing survey processes. This is an additional component of error not reflected in the standard error tables. Therefore, caution should be used in comparing results between these different sources.

Standard errors for data based on the decennial censuses. Sampling errors of all data from 5 percent samples of the 1960 and 1970 decennial censuses

shown in this report are small enough to be disregarded. However, the standard errors may be found in the appropriate census volumes.

Standard errors for data based on the CPS or SEO. Standard error tables, formulas and their use. Instead of providing individual standard errors for each characteristic of interest, generalized standard errors are provided for each set of characteristics which have nearly equal standard errors. As a result, an indication of the order of magnitude of the standard errors is provided rather than the precise standard error for any specific item.

The figures presented in tables B-1 and B-2 are approximations to standard errors of estimated numbers and estimated percentages. The figures presented in table B-3 are approximations to standard errors of estimated fertility ratios. Estimated standard errors for specific characteristics cannot be obtained from tables B-1, B-2, and B-3 without the use of the factors in table B-4. These factors must be applied to the standard errors in order to adjust for the combined effect of sample design and estimating procedure on the value of the characteristic. Standard errors for intermediate values not shown in the tables may be approximated by interpolation.

If one chooses, instead of using the standard error and factors tables, standard errors can be computed directly using the formulas that follow and the parameters from table B-5. Direct computation of the standard errors will give more accurate results. Methods for direct computation are given in the following sections.

Standard errors of estimated numbers. The approximate standard error, σ_x , of an estimated number shown in this report can be obtained in two ways. It may be obtained by use of the formula

$$\sigma_x = f\sigma \quad (1)$$

where f is the appropriate factor from table B-4 and σ is the standard error on the estimate obtained by interpolation from table B-1. Alternately, standard errors may be approximated by the following formula, (2), from which the standard errors were calculated in table B-1. Use of this formula will provide more accurate results than the use of formula (1) above.

$$\sigma_x = \sqrt{ax^2 + bx} \quad (2)$$

Here x is the size of the estimate and a and b are the parameters in table B-5 associated with the particular type of characteristic.

Table B-1. Standard Errors of Estimated Numbers

(68 chances out of 100. Numbers in thousands)

Size of estimate	Standard error	Size of estimate	Standard error
20.....	6	2,500.....	61
50.....	9	5,000.....	82
100.....	12	10,000.....	115
250.....	20	25,000.....	160
500.....	28	50,000.....	189
1,000.....	39		

Table B-2. Standard Errors of Estimated Percentages

(68 chances out of 100)

Base of estimated percentage (thousands)	Estimated percentage					
	1 or 99	2 or 98	5 or 95	10 or 90	25 or 75	50
100.....	1.2	1.7	2.7	3.7	5.4	6.2
250.....	0.8	1.1	1.7	2.4	3.4	3.9
500.....	0.6	0.8	1.2	1.7	2.4	2.8
1,000.....	0.4	0.6	0.9	1.2	1.7	2.0
2,500.....	0.2	0.3	0.5	0.7	1.1	1.2
5,000.....	0.2	0.3	0.4	0.5	0.8	0.9
10,000.....	0.1	0.2	0.3	0.4	0.5	0.6
25,000.....	0.06	0.12	0.2	0.2	0.3	0.4
50,000.....	0.03	0.06	0.15	0.2	0.2	0.3

Table B-3. Standard Errors of Estimated Fertility Ratios

(68 chances out of 100)

Number of women thousands	Children ever born or expected per 1,000 women							
	500	1,000	1,500	2,000	2,500	3,000	3,500	4,000
250.....	51	93	129	164	198	234	274	315
500.....	36	66	92	116	140	166	194	222
750.....	30	54	74	95	114	135	158	181
1,000.....	26	47	65	82	99	117	137	158
2,000.....	18	33	45	58	70	83	97	112
5,000.....	11	20	29	37	44	52	61	70
10,000.....	9	15	20	26	31	38	44	50
15,000.....	7	12	16	21	26	29	35	41
20,000.....	6	11	15	19	23	27	31	35
25,000.....	5	9	12	16	20	24	28	32

Table B-4. "f" Factors to be Applied to Generalized Standard Errors in Tables B-1, B-2, and B-3

Type of characteristic	"f" factors for persons
CPS, total, White or Black women ¹	1.00
CPS, Spanish origin women ¹	1.24
SEO, total or White women.....	1.44
SEO, Black women.....	1.35
CPS, Farm women.....	1.38

¹Apply a factor of 1.41 to these factors for metropolitan only-nonmetropolitan only characteristics.

Table B-5. "a" and "b" Parameters for Estimated Numbers and Percentages of Women

Characteristic	Parameter	
	a	b
CPS, number of women ¹	-0.000018	1567.0337
CPS, Spanish origin women ¹	-0.000033	2396.7828
SEO, total or White women.....	-0.000036	3229.6219
SEO, Black women.....	-0.000041	2861.4979
CPS, Farm women.....	0.000322	2993.0344

¹Apply a factor of 2 to these parameters for metropolitan only-nonmetropolitan only characteristics.

Standard errors of estimated percentages. The reliability of an estimated percentage, computed using sample data for both numerator and denominator, depends on both the size of the percentage and the size of the total upon which this percentage is based. Estimated percentages are relatively more reliable than the corresponding estimates of the numerators of the percentages, particularly if the percentages are 50 percent or more. When the numerator and denominator of the percentage are in different categories, use the factor or parameters indicated by the numerator. The approximate standard error, $\sigma_{(x,p)}$, of an estimated percentage, p , on a base of size x can be obtained by use of the formula

$$\sigma_{(x,p)} = f\sigma \quad (3)$$

In this formula f is the appropriate factor from table B-4 and σ is the standard error on the percentage from table B-2. Alternately, the standard errors may be approximated by the following formula, (4), from which the standard errors in table B-2 were calculated; direct computation will give more accurate results than use of the standard error table and the factors.

$$\sigma_{(x,p)} = \sqrt{\frac{b}{x} (p) (100-p)} \quad (4)$$

Here x is the size of the subclass of the number of women which is the base of the percentage, p is the percentage ($0 \leq p \leq 100$), and b is the parameter in table B-5 associated with the particular type of characteristic in the numerator of the percentage.

Illustration of use of standard error tables. Table 11 of this report shows that in 1976 there were 893,000 wives reporting on birth expectations who had one or more births to date and who were of Spanish origin. Table B-1 shows the standard error on an estimate of this size to be approximately 37,000. Applying the appropriate factor from table B-4 and using formula (1) the approximate standard error is $1.24 \times 37,000 = 46,000$.² The chances are 68 out of 100 that the estimate would have been a figure differing from a complete census figure by less than 46,000. The chances are 95 out of 100 that the estimate would have differed from a complete census figure by less than 92,000 (twice the standard error).

Of these 893,000 wives of Spanish origin with one or more children born to date 291,000, or 32.6 percent, gave birth to a child less than 2 years ago.

² Formula (2) gives a standard error of 46,000.

Since the numerator of this percentage is the number of Spanish origin women given birth to a child less than 2 years ago, the b parameter from table B-5 is 2396.7828. Using formula (4) the standard error on an estimate of 32.6 percent is approximately

$$2.4 \pm \sqrt{\frac{2396.7828}{893,000}} \quad (32.6) \quad (67.4)$$

Consequently, chances are 68 out of 100 that the estimated 32.6 percent would be within 2.4 percentage points of a complete census figure. Chances are 95 out of 100 that the estimate would be within 4.8 percentage points of a complete census figure, i.e., the 95 percent confidence interval would be from 27.8 to 37.4 percent.

Standard error of a difference. For a difference between two sample estimates, the standard error is approximately equal to

$$\sigma_{(x-y)} = \sqrt{\sigma_x^2 + \sigma_y^2} \quad (5)$$

where σ_x and σ_y are the standard errors of the estimates x and y ; the estimates can be of numbers, percents, ratios, etc. This will represent the actual standard error quite accurately for the difference between two estimates of the same characteristic in two different areas, or for the difference between separate and uncorrelated characteristics in the same area. If, however, there is a high positive correlation between the two characteristics, the formula will overestimate the true standard error.

Illustration of the computation of the standard error of a difference between estimated percentages. Table 11 also shows that of the 893,000 wives of Spanish origin who reported on birth expectations and had one or more births to date 205,000, or 23.0 percent, last gave birth to a child 5 to 9 years ago while, as shown above, 32.6 of these wives last gave birth less than 2 years ago. The standard error (σ_x) on 32.6 percent is 2.4 percentage points, as shown above. Using formula (4) and the b parameter for Spanish origin women from table B-5, the standard error (σ_y) on 23.0 percent is approximately 2.2 percent. Therefore, using formula (5), the standard error of the estimated difference of 9.6 percent is about

$$3.3 \pm \sqrt{(2.4)^2 + (2.2)^2}$$

This means the chances are 68 out of 100 that the estimated differences based on the sample estimates would vary from the difference derived using complete census figures by less than 3.3 percent. The 68 percent confidence interval about the 9.6 percent difference is from 6.3 to 12.9, i.e., 9.6 ± 3.3 . A

conclusion that the average estimate of the difference derived from all possible samples of the same size and design lies within a range computed in this way would be correct for roughly 68 percent of all possible samples. The 95 percent confidence interval of the difference is 3.0 to 16.2. Since this confidence interval does not include a difference of 0.0, we can conclude with 95 percent confidence that there is a difference between the 1976 percentage of Spanish women who last gave birth less than 2 years ago and the percentage who last gave birth 5 to 9 years ago.

Standard error of a fertility ratio. A separate standard error table, table B-3, provides standard errors for both number of children ever born and number of expected lifetime births per 1,000 women. The sampling variability on the ratio of children born per 1,000 women depends on the shape of the distribution on which the ratio is based, the size of the sample, the sample design and the use of ratio estimates. Table B-3 was formed by using the following equation:

$$\sigma(1,000\bar{x}) = \frac{FR}{N} \sqrt{\sum n^2 x_n - \frac{(\sum n x_n)^2}{N}}$$

where $\sigma(1,000\bar{x})$ is the standard error of a fertility ratio per 1,000 women (1,000 \bar{x}),

R^2 is a constant which depends upon the size of the sample.

For 1976

$$R = 1,000 \sqrt{1.170} = 34,200,$$

n is the specific number of children ever born or expected ($n = 0, 1, 2, 3, 4, 5, 6, 7 +$),

x_n is the estimated number of women who have n children ever born or expected,

N is the total number of women = 7+

$\sum_{n=0}^{\infty} x_n$, and

F is dependent on the particular sample design used for this survey and is also a function of the magnitude of the ratio of children ever born or expected per 1,000 women. The values of F used in compiling table B-3 are follows:

F for Children Ever Born or Expected Per 1,000 Women

Number of Children per 1,000 Women	F
500.....	1.05
1,000.....	1.14
1,500.....	1.18
2,000.....	1.22
2,500.....	1.26
3,000.....	1.30
3,500.....	1.34
4,000.....	1.38

It should be noted that for data involving only one kind of event per woman, e.g., one additional birth expected, table B-2, the table of standard errors of percentages, should be used (with the ratio adjusted to a per-100 basis when ratios are on a per-1,000 basis). For data involving two or more possible events per woman, table B-3, the table of standard errors of estimated fertility ratios, should be used.

Illustration of the computation of the standard error of a fertility ratio. Table 6 of this report shows that in 1967 wives 25 to 29 years old expected 3,037 lifetime births per 1,000 wives. Table 6 also shows that there were 3,773,000 wives in this group.³ Table B-3 shows the standard error of a ratio of 3,037 births on a base of 3,773,000 women to be approximately⁴ 66. Multiplying the standard error of 66 by 1.44 (the factor for total or White population data based on the 1967 Survey of Economic Opportunity), the standard error becomes 95 per 1,000. Consequently, the chances are 68 out of 100 that the estimate would have been a fertility ratio differing from a complete census figure by less than 95 per 1,000. The chances are 95 out of 100 that the estimate would have been a fertility ratio differing from a complete census figure by less than 190 per 1,000 (twice the standard error), i.e., this 95 percent confidence interval would be between 2,847 and 3,227 lifetime births expected per 1,000 wives 25 to 29 years old in 1967.

³Some tables in this report do not show the basis of the fertility ratios. The bases may be obtained by referring to the source of the data indicated at the bottom of each table.

⁴Determined by interpolation and rounding to the same accuracy as in the table.

The standard errors of estimated numbers as calculated for this report are not applicable to estimates of total women by age or race. As estimates by age, sex, and race are independently derived totals, they are not subject to any sampling error. Because of the use of ratio estimation, any published number which is a large subset of a given age-sex-race group (i.e., 50 percent or more) will have a sampling error smaller than shown in table B-1. For such items, a closer approximation to the standard errors can be obtained by using the population of the age-sex-race group (1976 figures are available in table 18) as the base of the percentage and converting the standard errors in table B-2 from percentages to numbers by multiplying them by the bases. For example, table 1 of this report shows that in June 1976 there were 4,880,000 currently married White women 25 to 29 years old reporting on birth expectations. If this figure were a subset of a considerably larger independent age-race group, the standard error on this estimate should be taken from table B-1. However, since the figure of 4,880,000 currently married White women reporting on birth expectations represents approximately 63.8 percent of the 7,650,000 White women in the 25 to 29 year age group, a closer approximation to the sampling error of the figure can be obtained using table B-2. The standard error of 63.8 percent on a base of 7,650,000 is approximately 0.7 percent. Thus, the standard error of 4,880,000 would be 7,650,000 multiplied by 0.007, or about 54,000. Consequently, the chances are 68 out of 100 that the estimate would have been a figure differing from a complete census figure by less than 54,000. The chances are 95 out of 100 that the estimate would have been a figure differing from a complete census figure by less than 108,000 (twice the standard error).
