ABSTRACT

. Earlier studies of the effect of desegregation on white flight were in conflict, largely because of methodological differences in study design and analysis. More recent studies have used more comparable methodologies and tend to show that under certain conditions desegregation does have a significant effect on white loss, although there is still disagreement on the size and duration of the effect. The present study offers a demographic 🦠 projection method for estimating the size and duration of the white phenomenon and applies the method to school districts experiencing court-ordered mandatory desegregation. Findings indicate that white losses are such that, in many cases, the amount of desegregation (defined as minority exposure to whites) is declining, and for some districts has fallen below the pre-segregation level. As a result, court-ordered desegregation, coupled with normal demographic trends, is producing increasing ethnic and racial isolation in many larger school districts. If this trend is to be stopped or reversed other remedies need to be considered. Given the strong public opposition to mandatory busing as well as the current legal situation, the prospects for metropolitan desegregation appear limited. On the other hand, voluntary methods have worked well in some cases and may offer a more viable alternative in larger cities. (Author/EB)

ABSTRACT

The earlier studies of the effect of desegregation on white flight were in conflict, largely because of methodological differences in study design and data analysis. The most recent studies have used more comparable methodologies and tend to show that under certain conditions desegregation does have a significant effect on white loss, although there is still disagreement on the size and duration of the effect.

The present study offers a demographic projection method for estimating the size and duration of the white phenomenon and applies the method to school districts experiencing court-ordered mandatory desegregation. In most cases the size of the effect is both large and long-term, accounting for 30 to 60 percent of all white losses over extended periods following desegregation. The white losses are such that, in many cases, the amount of desegregation -- defined as minority exposure to whites -- is declining, and for some districts has fallen below the pre-desegregation level.

Court-ordered desegregation, coupled with normal demographic trends, is producing increasing ethnic and racial isolation in many larger school districts. If this trend is to be stopped or reversed other remedies need to be considered. Given the strong public opposition to mandatory busing as well as the current legal situation, the prospects for metropolitan desegregation appear limited. On the other hand, voluntary methods have worked well in some cases and may offer a more viable alternative in larger cities.

INTRODUCTION

Among the many debates that have raged over school busing, few have engaged social scientists with more intensity than the "white flight" debate. Although the white flight phenomenon has a long history in both public and social science discussions, it did not become a truly controversial issue in sociology until James Coleman's well-publicized work on the subject, in which he concluded that school desegregation was a significant cause of declining white enrollments in public schools (1975).

Shortly after Coleman's work appeared, three other major studies were published (or presented) which concluded, quite firmly, that Coleman's analysis was defective and that school desegregation has little or no effect on white flight. The first of these was a study by Reynolds Farley (1975), the second a study by Christine Rossell (1975), and the third a study by Thomas Pettigrew and Robert Green (1976). This latter study relied heavily on the Farley and Rossell data supplemented by some original analyses.

What makes the white flight controversy especially intriguing is that all four of these studies used substantially the same data base; namely, the public school ethnic enrollment reports published since 1967 by the Office of Civil Rights (OCR) of HEW. While social scientists frequently disagree about conclusions from data, one would not think such disagreement could result from analyzing as simple and straightforward a data base as this one. Moreover, while most methodological debates are esoteric and dull, this controversy has generated considerable hear both within and without the profession, Undoubtedly, one of the reasons is that a great deal is at stake in this debate, with major policy decisions hinging upon its outcome. A large number of educational policy makers and social scientists have been supporters of court-ordered desegregation as a means of attaining racial integration. If the white flight thesis is true, then court interventions seeking to eliminate segregation may actually be expanding it. In this event many judges, educators, and social scientists will be in the unfortunate position of promoting the very condition they seek to halt.

All of these earlier studies, were based upon enrollment data through 1972 or 1973 at the latest, prior to implementation of many northern court-ordered desegregation cases (e.g., Denver and Boston). After the initial furor, both Farley and Rossell added enrollment data for subsequent years and refined their analysis techniques. As a result, they modified their original conclusions to some extent, finding more evidence for white flight due to desegregation than they had previously (Farley, 1977; Rossell, 1977a). Interestingly, these newer studies have not been well-publicized as yet, and many social scientists are unaware that there is now less disagreement on the fact of white flight. Disagreement still exists, however, over the size and duration of the effect, and the conditions under which it occurs.

Accordingly, given the importance of the issue for future policial actions, another look at the white flight phenomenon seems justified. This paper reconsiders the white flight issue in several ways. First, the works of Coleman, Farley, and Rossell are reviewed briefly. While some of their latest conclusions differ, due mainly to somewhat different analysis strategies, points of agreement will be emphasized. It is maintained that much of the remaining disagreement stems from a common failure to use demographic methods to establish underlying population trends.

Second, results of a new white flight study will be presented.

The new study attempts to determine both the magnitude and the duration of white flight effects by using demographic projection techniques for the school-aged population. The method is applied to court-ordered cases, which are judged most important for future policy decisions. Although the courts have held that mandatory desegregation or "busing" is more effective than voluntary methods, this claim must be reevaluated in the light of induced white losses and the resultant possibility of resegregation. Changes in desegregation levels for court-ordered cases will be assessed and compared to a voluntary plan underway in San Diego.

Finally, implications for future school desegregation policies will be discussed. The reasons for white flight must be understood in order to improve upon current policies. If white flight is caused by prejudice and opposition to racially integrated schools, then mandatory plans may continue to find support. On the other hand, if white flight

ERĬC

is caused by opposition to mandatory reassignments away from neighborhood schools, voluntary plans may prove more successful than mandatory
plans for intradistrict desegregation, at least for those districts not
yet under court orders. For court-ordered districts experiencing resegregation, of course, metropolitan remedies--mandatory or voluntary--may
be the only solution.

THE COLEMAN AND FARLEY STUDIES

Coleman and Farley used a similar conceptual approach to study white flight, although their initial methods differed considerably. Basically, their approach is to analyze the relationship between changes in white enrollment and changes in a quantitative desegregation index for the same period.

In Coleman's approach the dependent variable is annual change in white enrollment Δw , from 1968 to 1973, while the independent variables are changes in desegregation Δd , proportion black enrollment p_B , log of district size n, a region dummy r (North versus South), and the extent of desegregation within the SMSA d_S . Coleman then examines various linear regression models of the form

$$\Delta w = f(\Delta d; p_R, n, r, d_s)$$
 (1)

applied to the largest 21 central city school districts and the next-46 largest. He also tested various interactions with Δd , including $\Delta d \times p_{\rm R}$, $\Delta d \times r$, and $\Delta d \times d_{\rm S}$.

In Jeman's best model (with an R² of .60 for the 21 largest districts and .40 for the next 46 districts) the strongest and most consistent coefficients occur for changes in desegregation, desegregation within the SMSA, and the interaction between desegregation change and proportion black. If we interpret SMSA desegregation as a surrogate for the existence of white suburbs, then Coleman's major finding is that white loss is accelerated whenever desegregation occurs in large, central city school districts with a substantial proportion

The desegregation measure us d is a relative exposure index which measures the average proportion of white students in schools attended by the average black student (Coleman, 1975).

of black enrollment, and this effect is enhanced whenever predominantly white suburbs exist around the district. He did not find any evidence for substantial long-term effects, although he admitted his analysis was not adequate for this test. Also, he found the effect strong in the South and much weaker in the North; but it must be emphasized that his latest data was for 1973, prior to the start of large-scale desegregation in larger northern cities.

Farley's first analysis (Farley 1) was based on 125 school districts for cities with over 100,000 population (excluding those districts with less than three percent black). Like Coleman, he examined the changes in white enrollment from 1967 to 1972, and related it to change in a desegregation index (a different one than Coleman's 2). But here the similarity ends.

Farley analyzed total change in white enrollment from 1967 to 1972 rather than year-to-year changes. Since Coleman found the largest white losses occurred in the first year following a significant desegregation action, longer time-intervals might obscure the relationship. More important, Farley did not experiment with more complex regression models, and in particular he did not test for the crucial interaction between desegregation and proportion black. His main results showed only the bivariate relationship between white loss and desegregation change, separately for the North and the South; in a footnote he showed a three-variable regression using desegregation change and proportion black. Perhaps not surprisingly, then, he did not find evidence to support Coleman's conclusion:

Farley's second analysis (Farley II) was quite different (1977). Basically the same set of school districts were used as in Farley I, but enrollment data was added for 1973 and 1974. More crucial, however, he applied a regression model much like (1) to annual Changes in white enrollment. He also added several variables not used by Coleman including year, a metropolitan district versus central city district dummy variable (Coleman analyzed only central city districts), and average white enrollment change in the two years preceding desegregation (20).

[.] The index of dissimilarity (Taueber and Taueber, 1965).

With these modifications, Farley II comes to conclusions nor unlike Coleman's. The highest t ratios were found for proportion black, change in desegregation, the metro variable (such that metro districts have less loss than central city districts), and the interaction terms $\Delta d \times \beta_B$, $\Delta d \times n$, and $\Delta d \times \Delta w$. In other words, the effect of desegregation on white loss will be strongest in larger central city school districts that have a substantial proportion of blacks and that show pre-existing white enrollment declines. Coleman found that, for a large central city school district with white suburbs and 25 percent black, a change of 20 points in his desegregation index is associated with an additional white loss of 8 percent; Farley II finds that, for a large central city district with 30 percent black enrollement, the incremental white loss associated with a 20 point change in his desegregation index is 6 percent.

while it is encouraging that the Coleman and Farley II analyses show a convergence in conclusions, there are still many analytic difficulties and several unanswered questions. First, their common conceptual approach makes the assumption that only the amount, and not the type of desegregation makes a difference. If the reasons for white flight are mandatory reassignment to non-neighborhood schools, rather than integrated schools per se, then changes in a desegregation index caused by voluntary transfers of minority students to predominantly. White schools might not cause white losses. Moreover, it is possible that white flight will be diminished or non-existent whenever desegregation — mandatory or voluntary. — is supported by the community rather than being imposed by a court upon a protesting community.

A second and possibly more serious problem is that no attempt is made to model the basic demographic processes that are the primary causes of white losses in the absence of desegregation; namely, white out-migration to the suburbs and declining white birth rates. If large-scale desegregation causes white loss, and if the mechanism involves conscious choices of white families, then it is possible that some white losses—"anticipatory" white flight—might occur prior to the onset of desegregation. Such a result would be missed in Coleman's model and confounded with an independent variable in the Farley II model (average white loss for the previous two years).

Finally, neither analysis deals adequately with the issue of longer-term effects of desegregation, particularly for large scale court-ordered plans. The main reason, of course, is that the earlier works had data for only 1972 or 1973, and courts did not begin issuing large-scale desegregation orders until 1970 of 1971. Even 1974 is too early to determine long-term effects in the North, since many northern desegregation orders were not implemented until 1973 or 1974. Clearly, the full policy implications of white flight cannot be evaluated without knowing the longer-term effects of desegregation.

THE ROSSELL STUDIES-

The original Rossell study (Rossell I, 1975) took a different conceptual approach for assessing the effects of desegregation on white flight. Observing that Coleman's analysis could not separate the effects of government-imposed desegregation from other types of desegregation, including changes in natural residential patterns, she adopted a quasi-experimental design. Her basic approach is to compare pre-desegregation rates of white loss with post-desegregation losses for school districts that implemented school desegregation plans, and to then compare shifts, if any, to a group of control districts. The districts chosen for study comprised a non-random sample of 86 northern school districts (a subset of the National Opinion Research Corporation's Permanent Community Sample of 200 cities that were in the North and had at least 3,000 black residents). The year of desegregation was established by means of a mail questionnaire sent to school district administrators.

While Rossell I had a distinct advantage over the Coleman and Fatley work by identifying government and court-ordered desegregation, a number of analysis problems hampered this first study, leading to the conclusion of no relationship between desegregation and white flight. First, the dependent variable used was not change in white enrollment but, rather, change in the percent white. This measure confounds the possibly different movements of two independent populations, whites and blacks. For example, the percent white will decline if black enrollment is increasing while white enrollment is stable.

After a desegregation action, if black enrollment levels off and white enrollment starts declining, the percent white will continue to drop, thereby masking a significant shift in population movements. This phenomenon has actually occurred in a number of desegregation cases, including Boston.

Like Farley I, Rossell I enrollment data stopped in 1972, and no attempt, was made to control for most of the significant factors identified by Coleman as intervening in the relationship between, desegregation and white losses, such as proportion black, existence of white suburbs, and so forth. Finally, the effect of desegregation was evaluated by fitting a regression line to pre-desegregation white loss rates and comparing this slope to a post-desegregation regression slope. Since the year of desegregation is simply the year of the most significant government action, the slope of the pre-desegregation regression might be influenced by other desegregation events -- or several events -- prior to the year chosen. For example, the year of desegregation chosen for San Francisco is 1971, when court-ordered busing began, but a major school-board busing plan was adopted in 1969 and implemented in 1970, during which time substantial white losses occurred. As a result San Francisco does not have significant white flight in Rossell's studies.

Rossell II (1977) represents a major updating with more data and more extensive analyses. She added southern school districts as well as ehrollment data through 1975. She also grouped the districts according to type of desegregation plan (government-ordered or school board-initiated), extent of desegregation, and region. In this new analysis she finds more districts with significant white losses associated with desegregation changes. The strongest effects are found for those districts with court-ordered desegregation that have substantial portions of white students reassigned by the plan.

This improved analysis still has several difficulties. Districts are not grouped adequately by size, by percent black enrollment and ... by availability of white suburbs. Moreover, like Farley and Coleman, there is no demographic analysis against which to establish white loss rates in the absence of desegregation. This is an even more

A more recent paper by Rossell was received too late for full consideration here (Rossell, 1978). In brief, multiple regressions show that first-year losses are most strongly related to percent black, percent whites reassigned, their interaction, and district/SMSA segregation ratio. No long-term effects are found.

critical problem in Rossell's analysis, since the use of pre-desegregation enrollment trends assumes that no white loss is occurring due to anticipatory effects or to the effects of less major desegregation actions. If such effects occur, then the pre-desegregation trend being used to compare against post-desegregation trends may be steeper than they would have been with no desegregation at all. Clearly, other types of analysis must be adopted to investigate this possibility.

There have been other white flight studies besides the ones reviewed so far. For the most part, however, they provide little additional information over and above the combined Coleman, Farley, and Rossell findings. The Pettigrew and Green study (1976) does present some new analyses for the 21 largest cities, but their approach is basically the same as Farley I: they do not analyze year-to-year changes; they do not include critical interaction terms in their models (especially $\Delta d \times p_B$); their data stops in 1973; and they do not identify court-ordered desegregation. A study by Fitzgerald and Morgan (1977) attempts to offer a broader model of white out-migration from larger cities (over 50,000) using such variables as crowded housing, crime, and poverty. But these variables are not studied on a yearly basis in association with desegregation changes, and no demographic analysis is conducted to establish changes in white birth rates.

A NEW STŪDY

Given the latest works of Farley and Rossell, there seems to be substantial agreement on several critical points. First, the <u>fact</u> that white loss is associated with desegregation in some instances is not in dispute. Second, it is a conditional relationship: it occurs under some conditions but not others. Third, the effect is seen most clearly in the year that desegregation takes place, which in most cases is the first year of a plan's implementation except when a plan is implemented in several phases (as for Boston or Oklahoma City).

Although there is variation in the nature of the conditions cited by each investigation, some convergence is apparent when all three studies are compared. First, the effect appears to depend upon a substantial proportion of black (or minority) students, perhaps on the order of 20 to 25 percent. Second, the effect appears strongest for central city districts surrounded by accessible white suburbs (e.g., Boston) and weakest for large metropolitan school districts surrounded by minimally developed rural areas (e.g., Charlotte, N.C.).

Finally, the effect appears strongest when there is a significant shift in the racial balance of schools, and especially when white students are included in the shift. In the Coleman and Farley studies this shows up as a desegregation index change of 20 points or so, while in the Rossell study this corresponds to reassignment of at least 20 percent or so of black students or at least 5 percent or so of the white students.

In the vast majority of cases, however, shifts on this order of magnitude rarely occur outside of court-ordered desegregation plans. In Coleman's list of the 70 largest central city districts, 16 showed an annual change of 20 percentage points or more on his desegregation index, and only one was not involved in a court-ordered desegregation case (Wichita, Kansas, which was involved in a HEW mandate). Of the 86 Rossell II school districts, 22 showed a change in the index of dissimilarity of 20 points or more, but only 6 were not brought about by court order (Wichita and Tyler and Amarillo, Texas, which were involved in HEW mandates; and Berkeley and Riverside, California, and Ann Arbor, Michigan, which had School-board initiated plans). Perhaps more important, of the 16 Rossell II districts that showed at least 5 percent of white Students reassigned — which may offer the greatest potential for white flight — only Berkeley was not by court order.

It seems fairly clear, then, that while changes in desegregation indices are the empirical correlates of white losses, large changes are generally brought about only through court-orders.

Given this state of knowledge, the new study was designed to focus specifically on court-ordered desegregation cases in which mandatory reassignment (as opposed to voluntary transferring) takes

The percentage of students reassigned is actually based on those students who show up at schools to which they are reassigned. Thus when white flight occurs, the percent of white students actually reassigned is probably considerably higher.

place. Furthermore, the emphasis of the study is on certain questions not adequately answered by the existing research; namely, the magnitude and duration of the effect of court-ordered mandatory desegregation. In order to answer these questions with greater precision, we have employed demographic techniques to project school enrollments in the absence of desegregation.

Methods

The potential universe for the study consisted of all school districts undergoing court-ordered mandatory desegregation (COMD), by which is meant a desegregation plan involving mandatory reassignment of students arising from a court order. Mandatory reassignment plans not due to court order and court-ordered voluntary plans will not be analyzed in detail. (This is not a serious restriction since there are relatively few such cases.) Given the Coleman and Farley findings, the universe was further restricted to school districts enrolling over 20,000 students and having at least 10 percent minority enrollment in 1968, which is prior to the start of COMD cases.

Searches of published studies, legal references, and telephone interviews with school district officials yielded 54 school districts meeting the selection criteria. Excluded from the present study are Stockton, California, Payton, Ohio, Milwaukee, Wisconsin, and Omaha, Nebraska whose court-ordered plans did not begin until 1976, and Charleston, South Carolina, for which complete data could not be obtained.

In addition to the OCR enrollment data, extensive telephone interviews were conducted with school district officials to determine critical dates of court orders and plan implementation; characteristics of plans, including number of schools affected by pairing, clustering, or other reassignment mechanisms; and the existence and accessibility of developed suburbs. Written court orders and plans were obtained wherever possible, and additional information about suburbs was obtained by examining maps and OCR enrollment data for surrounding school districts. Two different types of analyses have been conducted with the data.

Rossell lists 8 board-initiated, city-wide, mandatory plans all but one of which (Berkeley) had no white reassignment; none but Berkeley had significantly accelerated white losses. The author knows of only two court-ordered voluntary plans meeting the inclusion criteria after 1971: Dayton, Ohio, which was recently ordered to implement a mandatory plan in 1976, and San Diego which started a court-ordered voluntary plan in 1977.

Most COMD cases occurred after the Swan v. Board of Education (402 U.S. 1), decided in 1971:

Analysis I: Again, one difficulty of the Coleman, Farley, and Rossell analyses is the presumption that white flight will occur only in the year when there is a change in a desegregation index or during the years following the largest desegregation action. But if the white flight phenomenon is real, it is reasonable to expect that some "anticipatory" flight will take place when the community becomes aware that mandatory desegregation is about to take place. This hight occur after a court order but prior to implementation, while appeals are being exhausted, as in cases like Denver and Detroit. It also could occur during an intense community controversy when a lawsuit is brought but before a court order is issued, as in cases like Boston, Pasadena, and Pontiac. Such possibilities cannot be investigated with the methods used in these other studies.

In an attempt to solve this problem, the first analysis was a modified quasi-experimental design with pre- and post-desegregation enrollment changes compared to a control group (Armor, 1976). The major differences between this analysis and Rossell's are (a) following the Coleman and Farley II findings, districts are grouped according to proportion of minority enrollment and the availability of suburbs and (b) pre-desegregation enrollment changes are measured prior to any significant court orders or partial implementations. A revised summary of this analysis, which encompasses all 54 districts, will be presented.

This first attempt to establish a loss rate prior to the first significant court order was not wholly satisfactory. First, in some cases the time of the court order and the time of the actual start of busing are separated by several years, raising the possibility that demographic changes alone -- such as declining births -- might explain some of the difference in loss rates. That is, post-desegregation loss rates might have been higher than pre-desegregation loss rates even if the court case had not occurred. The second problem is that many desegregation cases are long and complex, with many orders and controversies covering an extended period of years. Locating a single year to divide the pre- and post-desegregation period is liable to generate much argument and disagreement.

Analysis II. A more adequate solution for these problems requires some sort of demographic method similar to those used by many school districts to project future school enrollments. The unique advantage of projecting a school age population is that at any one point in time the cohorts who will be entering school during the next five years actually exist in the population at large (i.e., children born in the previous five years). Thus birth data, adjusted for net migration rates, permit projection of a future school population five years from any given year. This in turn offers a test for both anticipatory and long-term white flight.

The demographic projection method used here relies on birth data from 1950 to 1972 and census data for 1950, 1960, and 1970. Persons born from 1950 to 1962 represent the potential school age population in 1967, with most 12th graders having been born in 1950 and most

kindergarteners in 1962. If all births survive and there is no net migration, them the sum of births from 1950 to 1962 would be the projected school age population for 1967. The projected population for 1968 would be obtained by subtracting the graduating seniors (1950 cohort) and adding the incoming kindergazten (1963 cohort), and so forth for succeeding years, with 1972 births being used to project the 1977 pop-Thus year-to-year charges in the potential population, can be calculated and projected for 1968 to 1977 using birth data that is at least five years prior to any given year. The crucial advantage of this approach for school desegrégation cases is that a given event, such as filing a lawsuit or a court order, cannot affect birth rates that preceded it by several years. This is especially useful for extended litigation; cases, where an initial order might occur in 1971 but not be implemented until 1974. Projecting the potential change between 1971 and 1974 depends upon 1969 births at the latest, two \cdot years prior to the court order.

Of course, not all births survive, and net migration can occur which reduces (or increases) a potential cohort by the time it reaches any given grade level. Hence birth rates must be adjusted to reflect both survival and net out-migration. This can be done using 1950 to 1970 census data to establish cohort tetention rates. For a number of reasons, including statistical reliability and coverage, the 0-4 cohort is used for estimating migration. The 1950 to 1960 retention rate is simply the ratio of white children aged 10 to 14 in 1960 to white children under 5.in 1950. Since this ratio is actually a 10-year rate, we can convert it to an ll-year rate by using an exponential law; for a given birth cohort this gives us the retention rate when that cohort reaches sixth grade, which is midway in the school career. Rates would of course be lower in éarlier grades and higher in later grades, but 🤟 we assume that the midpoint is very close to the average. For instance, if the 11-year retention rate is .70, then 1950 births can be reduced by .70 to estimate that proportion who would be in the school population 11 years later. A similar rate can be calculated for 1960 to 1970; in most cases it is lower than the 1950-1960 rate reflecting the fact that net out-migration for Whites is higher in the 1960's than in the 1950's. This rate is applied to births in 1960. Since annual census data is not available, our method interpolates retention rates between 1950 to 1960, assuming that the annual change occurs in equal increments. Given the relatively steady growths/ declines in most school populations, once birth cohort changes are taken into account, this is not an unreasonable assumption for our purposes.

The critical question is how to adjust 1960's births for net migration during the 1970's this requires a metention rate for 1970 to 1980. We have used two approaches: Method A assumes that net white out migration is the same in the 1970's as in the 1960's; and Method B assumes that whatever change occurs between 1950-1960 and 1960-1970 (which is nearly always a decrease) also occurs between 1960-1970 and 1970-1980. Hence if the retention rate drops from .7 to .6, the estimated 1970-1980 retention rate under Method B would be .5.

An important feature of the demographic method is that its validity can be tested by examining projected and actual loss in years prior to a desegregation controversy. In applying the method to numerous cities in our sample. Method A usually produces a better fit to enrollment losses prior to desegregation events, particularly when a significant desegregation event occurred by 1970. Method B may overstate out-migration in the 1970's, particularly since out-migration did not get underway in most cities until the late 1950's. Also, if desegregation actually began in 1970 and some white flight has occurred, the 1970 census will reflect accelerated out-migration. Accordingly, the projections in this report are based on the method that gives a better fit to actual losses prior to the start of any significant court action.

For the purpose of comparing projected and actual school enrollments, annual rates of change are used rather than absolute numbers. The reason is that even correcting for net out-migration, projected school populations usually differ from the actual school enrollments because (1) not all 5 year olds go to kindergarten, (2) some students drop out before age 17, (3) some children attend private schools and (4), in a few cases school districts are slightly larger (or smaller) than civil divisions used for birth and census counts. Thus the projected school enrollment starts with the actual school enrollment as of a certain year (usually 1967 or 1968) and is reduced by the rates of change derived from the projected school-age population.

To put all this more formally, the 10-year retention rate for year i, R_i ; is found by

$$R_{50} = \frac{10^{-14}}{60} \times \frac{10^{-14}}{10^{-14}} \times \frac{5}{10^{-14}} \times \frac{5}$$

The ll-year rate/R is found by applying the compound interest law to R, to obtain a yearly rate, and then converting this back to an 11-year rate; thus

 $R_{i} = (R_{i})^{11/10}$

(3

ERIC

Rates for intermediate years are found by interpolation (and for 1971 and 1972 by extrapolation of the 1960-1970 trend). Then the initial projected white population in 1967 is given by

$$W_{67} = \sum_{i=1}^{62} \sum_{50}^{(R_i B_i)} (R_i B_i)$$
 (4)

where B_1 are white births in year i. To get the projected population in 1968 we subtract $R_{50}B_{50}$ (1967 graduates) and add $R_{63}B_{63}$ (1968 kindergarten), to W_{67} , and similarly for successive years. The projected loss rates are then $1-W_{\rm t}+1/W_{\rm t}$, and these are applied to the 1967 or 1968 actual school enrollment to obtain the projected enrollments.

In most cases the projection method is fairly close to a linear projection of pre-desegregation losses, provided that no years with significant desegregation activity are included, although generally the demographic method yields somewhat steeper rates of loss. The reason is that the declining birth rates in the sixties are coupled with very high birth rates in the fifties. It can be shown that linear increases in births coupled with subsequent linear decreases in births can combine to yield non-linear increases and decreases in school age populations.

Another refinement is required for certain districts. White birth data includes Mexican-American births, and in western school districts where this population is substantial white births must be reduced accordingly. This is accomplished by using school ethnic encollments responsect relative proportions of Mexican and Anglo back to 1960 and 1950 and applying an estimated Anglo fraction to the White birth rate.

It is emphasized that the method used here does not attempt to model the out-migration process itself, but rather takes out-migration as a given and (by our model) assumes that those forces operating to cause (or accelerate) out-migration between the fifties and sixties operate to cause it (or increase it) in 1970's. The central question in our approach is not whether court-ordered desegregation causes white loss, but rather whether desegregation causes an increase in white loss rates over and above what would have happened without it, assuming — conservatively — that out-migration would continue in the 1970's. It is possible that changes in other unmeasured events in the 1970's including crime, higher taxes, and other urban problems might have accelerated white loss rates in these cities, but the out-migration rate used for the 1970's, mased on known trends, probably incorporates most of their effects.

Raw data, and calculations are provided in the Appendix.

.15

A final point on methods deserves comment. Although we are using the term "white flight," in keeping with customary usage among researchers in this field, it must be emphasized that we are not studying only residential relocation. As applied to the school desegregation field, white flight means white losses in school enrollments in excess of what would have been observed without desegregation. Given this meaning, there are three major processes which can give rise to white flight from public schools: (1) residential relocation outside the district; (2) transfer of children from public to private schools; and (3) failure of hew area residents to replace regular outmigrants who are leaving the area for reasons unrelated to desegregation. The third source is frequently overlooked. Although our methods do not enable systemmatic apportionment of white flight according to these three sources, special data from one school district will enable a preliminary look at this issue.

Results

Analysis I. The can get a broad picture of the white flight phenomenon through the crude "quasi-experimental" analysis applied to all 54 districts. First, the districts are grouped according to characteristics already known to be related to white losses; namely, the proportion of minority students, the availability of suburbs, and region. To determine whether white flight exists, post-desegregation loss rates are compared to predesegregation loss rates for a control group.

A summary of this analysis is shown in Table 1. It is readily apparent that, if there is a white flight effect, it appears most prominent among school districts that have over 20° percent minority and accessible suburbs. In these cases the northern post-desegregation white loss rate is three times the pre-rate, and double the rate in the control districts for the first two years after the start of desegregation. Moreover, the loss rates remain high, compared to both the pre-rate and the control district rate, 3 and 4 years after desegregation. No appreciable difference is found for northern and southern districts within this category; this differs from Coleman's results, which showed a stronger effect for southern districts. However, Coleman's data stopped prior to the start of court-ordered desegregation in many northern cities.

Size of district is controlled by confining the analysis to districts with over 20,000 enrollment. The amount of desegregation is not controlled, but since all are court-ordered plans the amount of mandatory reassignment is substantial in all but a few cases.

Dallas, Houston, Ft. Worth, Texas; Atlanta, Georgia; Oklahoma City; Birmingham, Alabama; Little Rock, Arkansas; Memphis, Nashville, and Chattanooga, Tennessee; Norfolk, Richmond, and Roanoke, Virginia; Greensboro and Raleigh, North Carolina; Jackson, Mississippi.

CMobile and Montgomery Counties, Alabama; Bibb, Chatham, Muscogee, and Richmond Counties, Georgia; Louisville-Jefferson County, Kentucky; Baton Rouge, Shreveport, Louisiana; Winston-Salem, Charlotte, North Carolina; Greenville, South Carolina (data for Charleston incomplete); Austin, Texas; Portsmouth, Newport News, Virginia.

^dMinneapolis; Las Vegas; Tulsa; Lexington, Kentucky; Pulton County, Georgia.

All are counties; Palm Beach, St. Petersburg, Pensacola, Daytona, Gainesville, Ft. Lauderdale, Miama, Jacksonville, Tampa are the main cities in their respective county school districts.

Rossell northern "control" and "token plan" districts which reassigned no white students and less than three percent black students and which had total enrollments over 20,000 with 20-60 percent minority in 1968. Pre-order is the average annual loss rates for 1969 and 1970 (prior to the starr of most court-ordered mandatory desegregation); 1-2 years post-start is average loss for 1972 and 1973; 3-4 years post-start in average loss for 1974 and 1975. See Appendix for list of districts.

Districts that have substantial minority enrollments but less (or no) access to suburbs, all of which are southern county-wide school districts, also appear to show an effect, but it is smaller in absolute terms and drops off rapidly in the 3rd and 4th years. Actually, the rate of acceleration of white loss (from -0.8 to -6.0) is greater than for the districts with suburbs, due mainly to the existence of several districts which were growing prior to the court order (e.g., Charlotte, North Carolina and Newport News, Virginia) and which stopped growing after desegregation. This raises the possibility that some white flight effects are manifested by the slowing down of white growth rather than the acceleration of white decline. In any event, from the point of view of providing desegregated education such an effect has less policy relevance, since a relatively stable white population is all that is needed to maintain racially balanced schools.

School districts with 10 to 20 percent minority have no significant white losses associated with COMD. The underlying reason undoubtedly. has to do with the fact that relatively little reassignment of students — especially white students — is necessary in such cases, thereby minimizing the opposition by white parents. For example, before Minneapolis desegregated in 1973 no school was predominantly minority, and according to Rossell, only 7 percent of black students and 1 percent of white students had to be reassigned to accomplish desegregation.

Finally, I have grouped the Florida districts together because they represent a distinctly different situation. All Florida districts were desegregated by a state court order between 1969 and 1971, and all are very large county-wide school districts. Thus the white flight phenomenon can occur in Florida only if whites leave (or do not move into) the state or if they enroll in private schools. This apparently has not happened to any great extent, and therefore the Florida group represents the only group where a majority of the school districts are still showing white enrollment gains well into the 1970's. These districts clearly show that the white flight phenomenon is conditional, with crucial dependence upon the environment surrounding the desegregating district.

In summary, the quasi-experimental analysis shows that the most serious white flight effects may occur in districts having substantial propertions of minorities, which require more extensive mandatory reassignment to accomplish desegregation, and in central-city districts with available suburbs, which offer the opportunity for convedient residential relocation. Districts with substantial minority populations but without developed suburbs — all of which are county-wide or "metropolitan districts"— may have less white flight due to the inconvenience of relocation. The fact that there is some apparent white flight in those districts, especially in the first year or two, raises the possibility that private school transfers may well comprise a significant portion of white losses in metropolitan desegregation cases.

Analysis II: Demographic Method. While the quasi-experimental method is suggestive, it is not definitive. The pre-court order loss rates may be affected by anticipatory white flight, leading to an underestimate of the true magnitude of the effect. Conversely, demographic trends may be such that loss rates in the desegregating districts would be increasing even in the absence of desegregation; if so, the pre-post comparison would overstate the size of the effects, especially the long-term effects.

The demographic analysis can help alleviate these problems. We have applied demographic projections to those districts in the first group in Table 1, which are the most likely candidates for white flight. These districts include all of the important busing cases in larger cities, including Dallas, Memphis, Denver, Boston, and San Francisco. The critical questions at issue here are the magnitude and duration of the effect, given a demographic projection of what school enrollments would have been without the desegregation activity.

The average actual and projected white loss fates are shown for the nine northern districts in Figure 1. Prior to the filing of lawsuits in these districts, the average projected loss rate is nearly identical to the actual loss rate. But after the lawsuits were filed, prior to the start of desegregation, the actual loss rates are over one and one-half the projected loss rates, thereby offering evidence that anticipatory effects do occur.

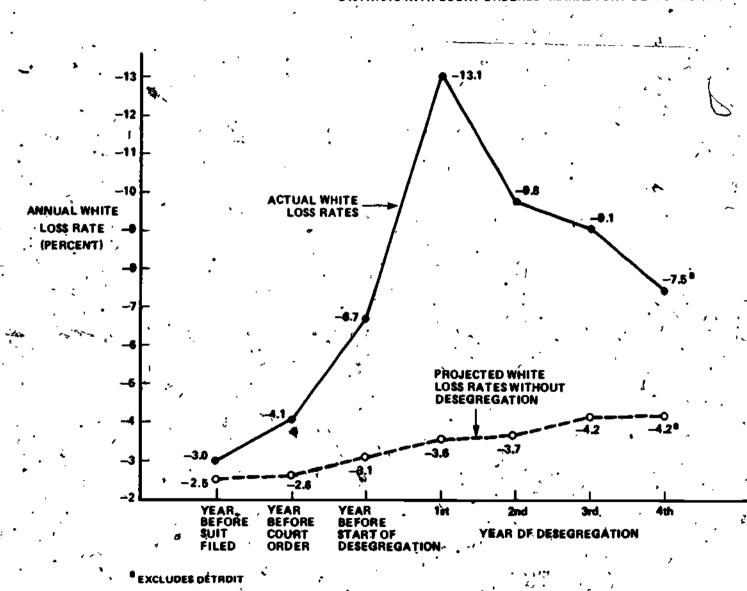

The most substantial acceleration of white loss for these districts occurred in the first year of desegregation implementation, when the actual rate is nearly four times the projected rate. The actual rates of loss drop somewhat after the first year, but they remain between 1-1/2 to 2-1/2 times greater than projected loss rates up to four years after the start of busing. It would appear, then, that the magnitude and duration of the effect of court ordered desegregation may have been underestimated by previous studies.

In order to demonstrate the impact of these accelerated loss rates, it might be helpful to give a hypothetical example. Consider a school district with 50,000 white students prior to the lawsuit, and assume that the loss rates in Figure 1 apply to six consecutive years following the filing year. At the end of the six-year period the projected white loss would be about 10,000 students, while the actual white loss would be about 20,000. Therefore, the average long-term effect of the court intervention is to double the number of white students lost, over and above the losses due to demographic factors alone.

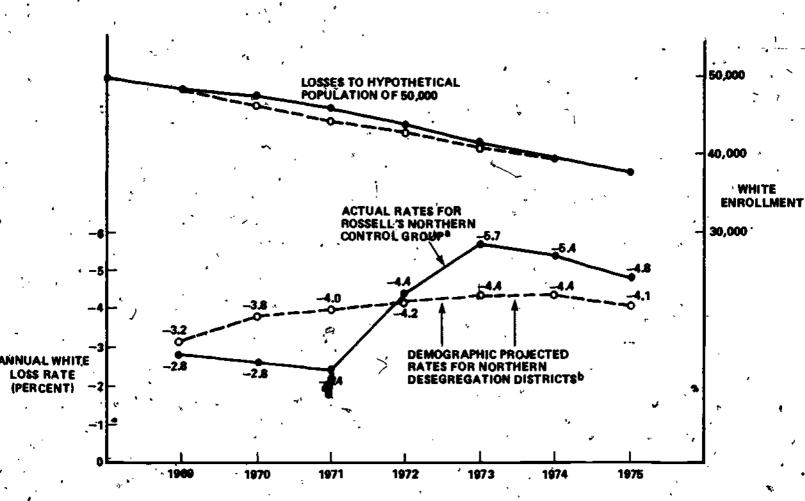

It is important to note that the projected loss rates do in fact rise in these districts, on the average, from 2.5 to 4.2 percent over the six to seven years spanning their desegregation periods. This reflects a combination of long-term declines in births and continuing white out-migration during the 1970's. Thus a comparison of post- to pre-desegregation loss rates will probably overstate white flight effects, especially over the long run. However, neither the magnitude nor the pattern of these moderate demographic changes can begin to explain the dramatic increase in white loss rates during a desegregation controversy and after its implementation.

Another way to test the validity of these demographic projections is to compare them to other similar districts not experiencing desegregation. Figure 2 shows the projected rates for the narthern desegregation cases compared to the actual loss rates of the 18 school districts

FIGURE 1 - ACTUAL AND PROJECTED WHITE LOSS RATES FOR NORTHERN SCHOOL DISTRICTS WITH COURT-ORDERED MANADTORY DESEGREGATION

· WHITE

OISTRICTS HAVING BETWEEN 20 AND 80 PERCENT MINORITY, AND OVER 20,000 ENROLLMENT IN 1986. DEXCLUDES PRINCE GEORGES COUNTY.

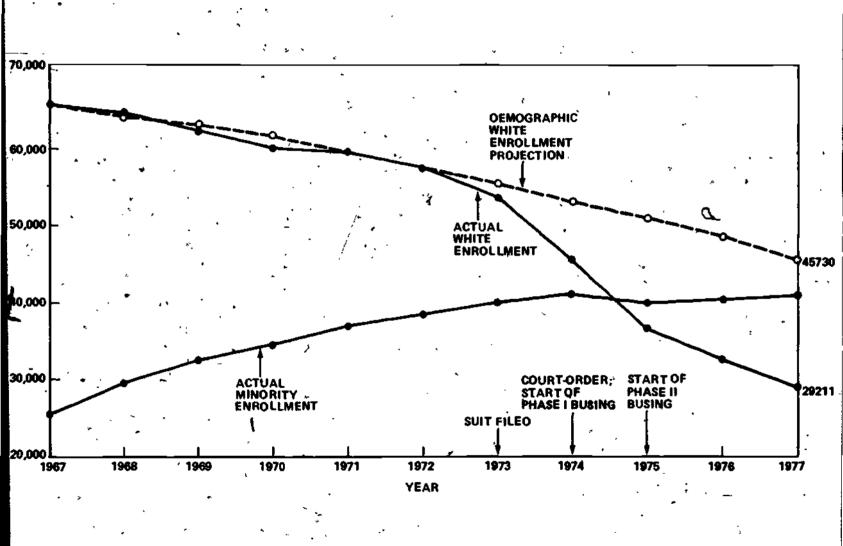

from Rossell's northern non-desegregation group matched in size and percent minority. The fit is fairly good, although the control districts show somewhat more variability with a decrease in loss rates followed by a steeper increase from 1971 to 1973 than the projected rates. However, the total losses explained by these two sets of rates, shown in the upper portion of Figure 2 for a hypothetical population, are nearly exact. Therefore, we conclude that the demographic projection method being used here yields realistic loss rates when compared to similar non-desegregating districts.

It might be worthwhile to examine the detailed results for one of these districts. Figure 3 shows the projected and actual white enrollment in Boston, which has been one of the most celebrated courtordered cases. First of all, it is observed that the projected and actual loss rates for Boston are very close for the five-year period between 1967 and 1972. This is evidence that, for Boston, a projection method based on birth rates and net out-migration (R, is .67 for the fifties and the sixties) can account virtually for all of the white losses during this period. But in 1973, after a lawsuit was filed and after considerable controversy over actions by the State Board of Education, the actual loss rate is -6.6 compared to a projected rate of -3.8. While this is not a large difference, it does reflect some anticipatory behavior; any, linear projection that includes the 1973 white enrollment for the pre-desegregation trend (such as Rossell's) would clearly overestimate the white losses in the absence of desegregation. The Boston plan was implemented in two phases, with Phase II involving more students than Phase I. When Phase I was implemented in 1974, > the actual loss rate was nearly four times the projected rate; when Phase II was implemented in 1975, the actual rate of loss jumped to over five times the projected rate. In the third year of implementation the loss rate was 10 percent, which is still more than twice the projected rate.

Prince Georges County is excluded from the desegregating districts because none of Rossell's districts had comparable growth rates during the late 1960's. It should also be noted that some of Rossell's districts, including Grand Rapids, Cleveland, Cincinnati, and Omaha were involved in court actions in the early 1970's, so that anticipatory white flight might be a partial cause of the rise from 1971 to 1973. In fact, it is hard to find any large school district with a substantial minority enrollment that has not been involved in some type of desegregation lawsuit.

FIGURE 3 - PROJECTEO AND ACTUAL ENROLLMENT FOR BOSTON

93

Before the desegregation action in Boston (1972) there were 57,000 white students, but by 1977 there were only 29,000. Of this total decline of 28,000, about 16,000 (or three-fifths) is attributable to desegregation activities. As a direct result of court-ordered busing, Boston became a majority black school district in 1975. It is interesting to note, also, that minority enrollment stopped growing rather suddenly in 1975; while not shown on the graph, projected black enrollment should have continued to grow slightly during this period. This suggests that black flight — which has not been studied — may also be a phenomenon in court-ordered desegregation, although its magnitude is very small compared to white flight.

Southern Districts. The demographic projection method has also been applied to southern districts with over 20 percent minority and available suburbs. The results are quite similar to those for the north, although the average effects are somewhat larger.

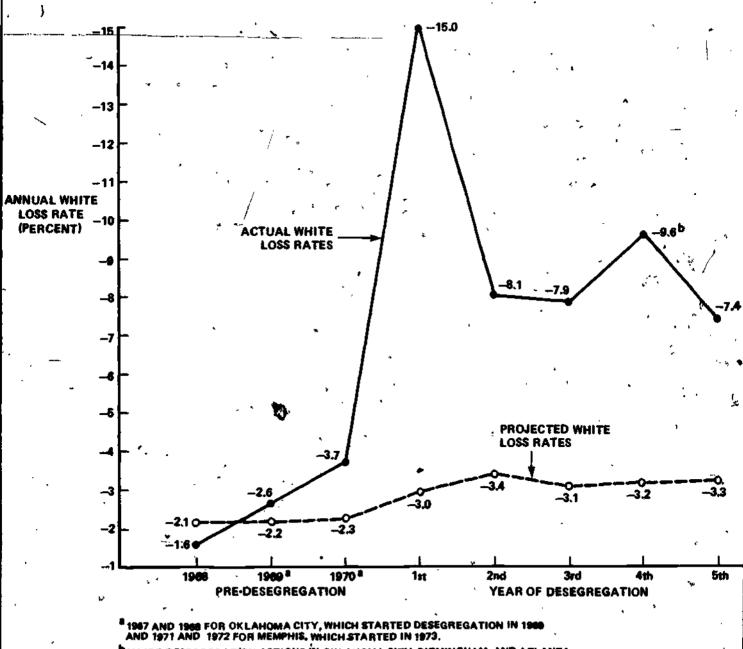

Figure 4 summarizes the actual and projected toss rates for 14 southern districts. Since nearly all these districts began desegregation in 1970 or 1971, the before-desegregation rates are given by year, with those districts which began desegregation in 1970 excluded from the 1970 averages. Interestingly,—anticipatory effects seem weaker in the south; this may be due in part to the fact that these were the earliest cases, when the concept of mandatory busing was in its infancy; persons may have been less aware of what to expect.

The effects after busing started, however, are stronger than in the north, with the actual loss rates rising to over five times the projected rate in the first year of busing. In the second to fifth years of busing the actual rate ranges from two to three times, the projected rate. The elevation of the actual loss rate in the fourth year of desegregation is caused by major second-stage desegregation actions in three cities (Atlahta, Chattanooga, and Oklahoma City) which occurred coincidentally at this time.

¹⁰ Richmond and Norfolk, Virginia could not be analyzed due to annexations which could not be disentangled from enrollment changes.

22

b_{MAI}OR DESEGREGATION ACTIONS IN OKLAHOMA CITY, BIRMINGHAM, AND ATLANTA.

It is noteworthy that, like the north, the projected loss rates do rise from the pre- to post-desegregation periods. The rates of white loss for the south are, however, smaller than for the north. This reflects the fact that most of these districts were gaining in school-age population in the 1950's, and out-migration levels in the 1960's were lower than in most northern cities.

<u>District Variations.</u> The previous discussion has presented average white flight effects for groups of school districts. The extent of variation in effects from one district to another can be examined in Table 2, which provides the actual and projected rates of white loss for each of the northern court-ordered cases.

First, it is noted that in the years prior to filing of lawsuits, all but two cases (San Francisco and Prince Georges County) have projected rates of changes that closely match the actual rate, thereby giving substantial evidence for the validity of the demographic technique being used here. San Francisco's projected losses exceed the actual, leading to the possibility that white flight in San Francisco is underestimated by the method. This is balanced to some extent by a possible overestimate in white flight for Prince Georges County, whose projected gain exceeds the actual gain prior to the lawsuit. As a conservative test of white flight effects, the last row in Table 2 shows average loss rates excluding Prince Georges County; the results are not substantially different.

Second, during the first year of desegregation all but one district—Springfield, Mass.— show a white loss rate at least two and one-half times the projected rate, and five show accelerated losses on the order of 3 to 5 times the projected rates. In other words, the first year effects are both massive and consistent. Moreover, with the same exception, the long-term effects are also consistent, with actual 4th year losses ranging from 1-1/2 to 2 times the projected rates.

The sole exception to these strong white flight effects requires some explanation. One reason may be that in 1974 Springfield desegregated only five predominantly black elementary schools (out of 35) under court order, with a corresponding small involvement of the white student population. The secondary schools were already desegregated by 1970,

dyears before board order of mandatory busing (1967 and 1968).

largely due to school board actions under pressure from the Massachusetts State Board of Education. It is pre-court order white losses might have been accelerated by secondary school desegregation, and post-order losses might be smaller than expected because of the small proportion of elementary schools affected by the plan. Of course, it is also possible that white flight has not occurred in Springfield, for reasons not fully understood at present.

Table 3 offers similar data for each of the southern districts.

Again, the actual pre-desegregation loss rates in 1968 and 1969 either match or are exceeded by the projected rates in all but three cases.

Oklahoma City, Little Rock and Birmingham have less projected than actual white losses during the 1967-69 period and thus may have somewhat overstated white flight effects. At the same time the method may be understating the white flight effects for Dallas; Forth Worth, and Greensboro.

It is quite apparent that, even though the average first-year effect in the South is larger than in the North, the South also has more variability. Dallas. Fort Worth, Houston, and Roanoke. Virginia. experienced only a doubling of the expected loss rates, while Jackson, Mississippi and Memphis, Tennessee experienced enormous loss rates of 40 percent during the first year of busing. One reason for the lower rates for the Texas and Virginia districts may be that they had very little white reassignment during their first year of desegregation. For example, in the first year of Dallas's court-ordered plan, only black students were bused; a reassignment order for majority-white ' schools was stayed. During this first year, Dallas's white loss was 9 percent compared to a projected loss of 4 percent. But when a grade 4 to 8 plan was implemented in 1976, which bused both black and white students, Dallas's white loss, was, nearly 13 percent compared to an expected loss of 3 percent. Po contrast Roamoke, Virginia, implemented only satelliting and attendance zone revisions in 1971. Its loss rate was 6.6 percent compared to an expected 3.5 percent during the first year, but within three years the projected and actual rates

Massachusetts passed a racial balance act in 1965, which required all public schools to have no more than 50 percent minority enrollment. There was considerable controversy over confrontations between the Spring field School Committee and the State Board between 1966 and 1971, which included two threats by the State to withhold state funds for non-compliance with the law.

almidicates that a major mandatory reassignment took place that year, either equaling or surpassing the initial reassignment.

ERIC

because of pre-1970 annexations demographic projection cannot be used; projected rates are based on a linear projection of 1965 to 1968 enrollments (major annexations occurred in 1969 and 1970). Actual rates in 1973 to 1975 exclude additional annexations of the Raleigh area.

were nearly identical; no additional reassignments took place. It would appear, then, that the white flight effect is more heavily influenced by the amount of white student reassignment than by the amount of black student reassignment. This conclusion is amply supported by data from the Rossell II study (1977).

The long-term effects four or five years after the start of desegregation are also substantial in most cases, exceeding a factor of 1-1/2 for all districts except Roanoke and Nashville. Considering all 22 districts, then, all but three show substantial short- and long-term acceleration of white losses as a result of court-ordered mandatory desegregation.

Effects of Court Orders on Resegregation

The primary purpose of desegregation orders by courts has been to remedy illegal segregation existing within a school district. It has long been assumed by the courts that voluntary plans will not "work," in the sense of providing a sufficient degree of desegregation. Mandatory plans desired, provide a greater amount of desegregation, at least initially. However, given the substantial accelerated white losses over a prolonged period, the possibility arises that mandatory plans ultimately fail because of resegregation. If so, the question arises whether voluntary plans might be more successful for intradistrict desegregation.

One of the difficulties in evaluating the extent of resegregation involves the definition of desegregation. If it means no more than ethnic or racial balance, then mandatory plans can always be successful, even if white flight causes a district's proportion white to drop to very low levels. As long as each school reflects the district ratio, even if the district is only 10 percent white, then a strict balance criteria would mean successful desegregation. However, neither the courts nor social scientists have ever held to such a standard of desegregation; rather, most definitions embody the concept of substantial opportunities for contact between minority and majority students. Therefore, if the proportion of white students in a district drops too low, then the district as a whole becomes either segregated or imbalanced compared to the ethnic composition of a region as a whole. If this condition is undesirable for individual schools, then it is certainly undesirable for

an entire school district. Accordingly, to study resegregation we adopt measures of desegregation that reflect the absolute proportion of white students within each school in a district.

Before turning to such desegregation indices, Table 4 shows the total losses of white students attributable to court orders, along with the effect this has had on the overall percent white. The long-term impact of court orders is massive in 15 out of 23 districts, accounting for over half of all white losses over priods of at least seven years. In larger districts this translates into tens of thousands of students. In six other cases the effects have been substantial, accounting for nearly a third of all white losses. Only Springfield, Massachusetts and Fort Worth, Texas, have experienced insignificant losses attributable to court orders.

Of those districts that were majority white prior to the start of mandatory busing, most are now predominantly minority or fast approaching that status. Of these cases, the projected percent white shows that many would still be majority white or close to 50-50 including Boston, Denver, Pasadena, Pontiac, Dallas, Houston, Little Rock, Jackson, and Chattanooga, if the court order had not occurred. Of those districts that were predominantly minority prior to the start of the court case, the accelerated white loss has contributed to transforming most of them into virtually minority isolated school districts, including Detroit, San Francisco, Memphis, and Atlanta.

Another way to evaluate the effect of court orders on resegregation is by means of a desegregation index. The index chosen for use here is called an "exposure" index, which is the average percent white in schools attended by minority students (Coleman, et al., 1975). If all minority students were distributed in a completely random fashion throughout most regions of the United States, and all schools

¹² The index of dissimilarity and Coleman's relative exposure indices are not appropriate for measuring desegregation as defined here, since they can attain "perfect" scores of 0 when all schools are racially balanced, regardless of the actual exposure of minority to majority students.

alm order to include anticipatory effects, "before start" means losses two years before actual implementation; "present" ranges from 1975 to 1977; depending on the districts (see Appendix for detailed data).

bPrince Georges County's projected enrollment is larger than the initial enrollment.

In 1967, prior to annexations.

were desegregated, each school would be between 70 and 80 percent white, and thus each district would have an exposure index between 70 and 80.

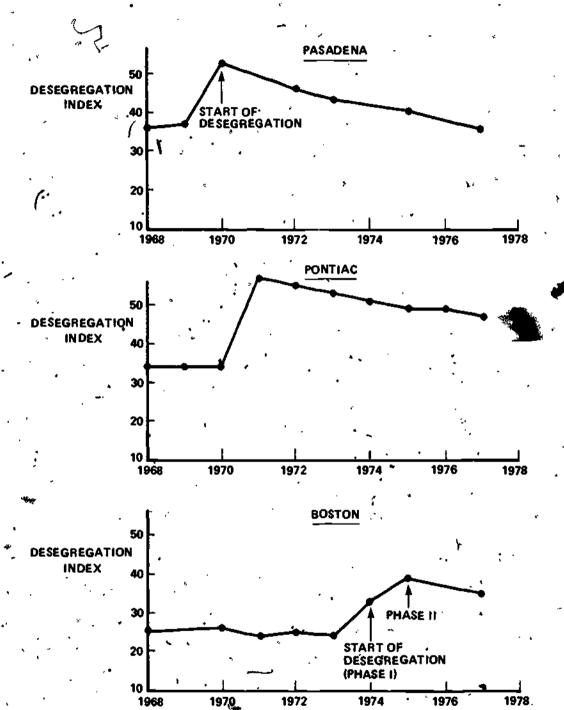

Figure 5 shows the trends in the amount of desegregation in those four northern school districts that have "tipped" as a result of court orders. The most interesting case is Pasadena, which had an index value of 37 the year before court-ordered desegregation. The success of the court's mandatory plan is seen in the first year of busing, when the index rose to 53. But because of white flight the index dropped to 35 by 1977, two points less than it was before desegregation. Although there was considerable ethnic imbalance in Pasadena in 1969, on the average the amount of minority exposure to white students was higher then than today in spite of a massive busing program.

The other three districts have not yet reached that point, but it is noteworthy that none of them have been able to maintain an index level over 50. In Boston the white flight has been so massive that even when Phase II was implemented the index reached only 39, and it has dropped sharply to 35 during the past two years. In spite of the strong court actions in Boston, this low degree of minority and white contact makes it hard to claim that its schools are desegregated today. The major social and political upheaval experienced by Boston seems a high price to pay for raising the percent white in the average black student's school by 10 points.

The trends in these four cities can be contrasted to San Diego which has pursued a strictly voluntary plan. Although the percent white declined from 76 percent in 1968 to 64 in 1977, the demographic projections shown in the Appendix reveal that there has been no accelerated white flight. During this time the desegregation index has actually increased slightly to a high of 46 due to a vigorous voluntary program. Under court orders this plan will be expanded over the next four years, and the index is projected to increase by several points by the early 1980s. Of course, some minority students are relatively isolated while others are in schools ranging from 60 to 80 percent white. But by avoiding white flight (so far), San Diego has managed to offer desegregated education to about half of its minority students.

It is frequently overlooked that mandatory busing increases the desegregation experience, of the isolated minority student only by

FIGURE 5 - CHANGES IN DESEGREGATION, INDEX FOR SELECTED CITIES .

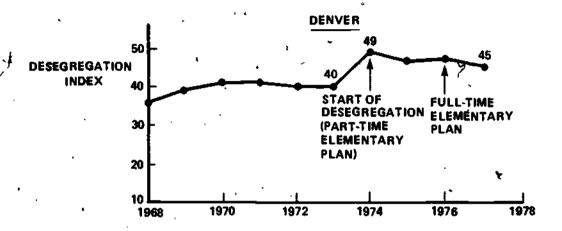

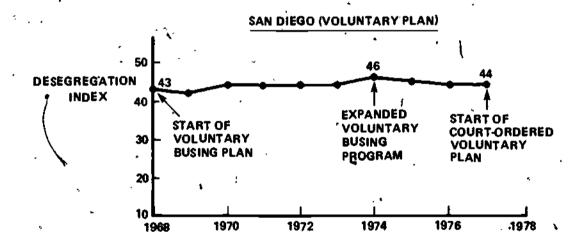

^{*} DESEGREGATION INDEX IS THE AVERAGE PERCENT WHITE IN SCHOOLS ATTENDED BY MINDRITY STUDENTS.

1976

1968

FIGURE 5 - (con't)

decreasing the desegregation of other minorities. Then, after ethnic balance is attained, desegregation is decreased for all minority students by white losses, which are accelerated by white flight. When the percent white drops below 50 for the district as a whole, none of the minority students are truly desegregated. By contrast a voluntary plan can avoid white flight, thereby allowing a district to maintain its majority—white schools and offer desegregation to both resident minority students as well as to isolated minority students who transfer into these majority—white schools. Under such conditions, a voluntary plan like San Diego which desegregates a significant proportion of its minority students may well be considered more successful than a mandatory plan like Boston in which no minority students are desegregated.

Although not all the districts studied here have experienced the same degree of white flight as Boston, it is noteworthy that only four districts are now over 60 percent white, thereby providing for a substantial degree of desegregation. Five others are between 50 and 60 percent white, but the rate of white loss in these districts is such that most will probably "tip" within a few years. Even now some of these districts (e.g., Fort Worth, Springfield, and Indianapolis) have desegregation indices below 50. It seems clear; then, that nearly all school districts meeting the percent minority and suburban access criteria have experienced sufficient court-induced white flight to be in clear danger of resegregating.

Metropolitan Plans: Jefferson County

The existence of white flight in central city school districts has led some policy analysts to conclude that desegregation should be carried out on a metropolitan basis. A metropolitan plan combines central-city and suburban school districts and, if mandatory, exchanges inner-city minority students with suburban white students. Many advocates of mandatory metropolitan plans believe that eliminating the possibility of suburban relocation largely solves the white flight problem. Moreover, for those school districts that already have predominately minority enrollments, a metropolitan plan of some type — either mandatory or voluntary — may be the only recourse for desegregation.

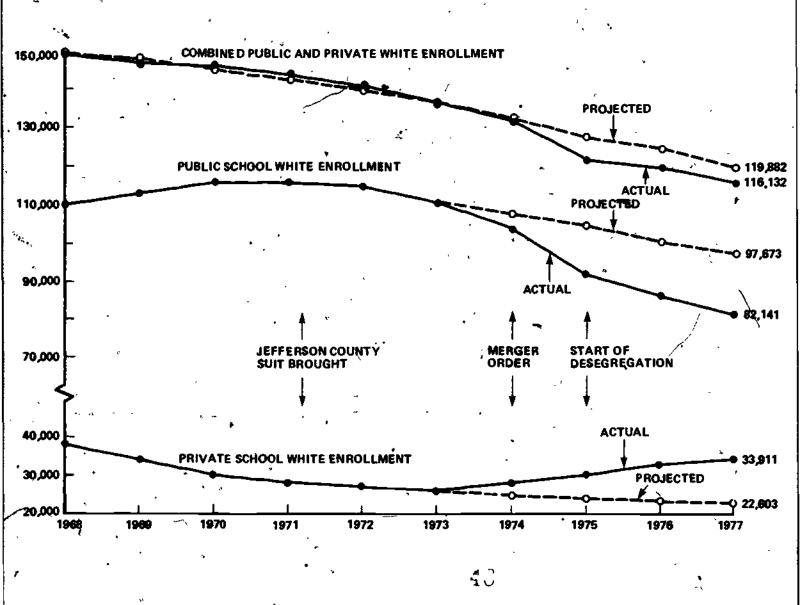

white flight in mandatory metropolitan plans. It might be argued that the county-wide school districts without suburbs shown in Table 1 can be used for this purpose. However, generalization from these districts to true metropolitan plans -- such as those proposed for Detroit or Atlanta -- presents several hazards. First, the Florida districts, which do show very little white flight, are unique because all counties came under court orders, so that white flight could occur only if persons left the state or enrolled in private schools. Second, all of the other cases (except Louisville) involve a single county-wide school district and all are in relatively rural regions of the South, where mobility may be constrained. Even so, the quasi-experimental analysis shows that some of these districts appear to have experienced white flight.

The fact is that the Supreme Court has imposed stringent requirements for metropolitan remedies, and as a result only two large-scale plans have been approved to date. One is Wilmington, Delaware and the other is Louisville, Kentucky, but only the latter has been implemented. Furthermore the Louisville plan, involving a merger of Louisville with the surrounding Jefferson County school district, might be debatable as a metropolitan wase since it excludes several suburban school districts in Indiana located immediately across the Ohio River from Louisville. Nonetheless, the Jefferson County-Louisville desegregation plan comes closest to a true mandatory metropolitan plan of any implemented so far, and therefore its outcome is of considerable interest for clues about metropolitan white flight.

The existence of a comprehensive study of enrollment trends in Jefferson County (Johnson, et al. 1977), which documents both public and private white enrollment data from 1968 to 1977, can improve the projection analysis. The private school data enables a unique examination of the relationship between public and private school enrollments during court-ordered desegregation, an issue that may be especially important for metropolitan plans.

Actual and projected white enrollments for Jefferson County are shown in Figure 6 (see Appendix for detailed data). The uppermost solid line is the actual combined public and private enrollment for grades 1-12. Since our demographic technique projects the total

FIGURE 6 - PROJECTED AND ACTUAL WHITE SCHOOL ENROLLMENTS FOR THE LOUISVILLE-JEFFERSON COUNTY DISTRICT, 1968-1977

school-age population, it is most appropriately applied to this combined enrollment; the projected enrollment is shown by the uppermost dashed line. It is clear that the actual and projected enrollments are extremely close between 1969 and 1974, the year before desegregation began, thereby again supporting the validity of the projection method. In 1975, the first year of desegregation, the actual loss rate jumps to 7.1 percent while the projected rate is 3 percent, yielding an excess loss of nearly 6,000 white students. Not all of this loss appears to be due to relocation, however, since during the next two years the actual loss rate is smaller than the projected rate. By 1977 the excess loss is reduced to about 3,000 students; this suggests that during the first year of desegregation several thousand students were kept out of school.

The actual and projected public and private school enrollments are shown by the two lower sets of lines. Between 1968 and 1971 there appears to have been a general transfer taking place from private to public schools, so that the public schools were actually gaining white enrollment even though the school-age population was declining. gain clearly came from private schools, since they were declining more rapidly than the school-age population. For this reason the separate demographic projections for private and public schools have been applied starting in 1973 when both public and private enrollments' begin to match the total school-age trend. The projected loss rates used are those for the total school-age population, which of course assumes that both private and public schools would have continued to lose students at the same rate. This is a refinement of the projection method which can be applied only when private school enrollments are available. Similar transfer patterns between public and private schools in the late 1960's could explain why the projected losses are higher than actual losses for several cities described in previous tables.

After some anticipatory white loss in 1974, there is a very substantial public school loss of 11.3 percent in 1975 when busing began, which is more than 3-1/2 times the projected rate of 3 percent. The next two years the actual loss rate is between 1-1/2 to 2 times higher than the

projected rate. Thus the first-year white flight effect in Jefferson — County is comparable to what we have found for central-city districts, but the longer-term effect is not quite as strong. This demonstrates that mandatory metropolitan plans can indeed have white flight, but perhaps with somewhat weaker long-term effects.

What is equally interesting about these results is the amount of flight due to relocation (or failure to move in) versus the amount due to transfers to private schools. By 1977, the excess white loss in Jefferson County public schools due to the court order was about 15,500 students. The excess increase in private schools, over and above their projected white enrollment, is about 11,000. Therefore, it appears that most of the white flight in Jefferson County is in the form of private school transfers; only about one-third of the loss is attributable to relocation.

These results reveal that significant white flight is possible in metropolitan plans, although, if Jefferson County is any indication, it may take the form of transfers to private schools. However, perhaps because of the expense and availability of private schools, the long-term white flight effects in metropolitan plans may be smaller than for central-city districts.

DISCUSSION

Summary of Findings

The findings of Coleman, the latest Farley and Rossell studies, and the present study all agree on one important fact. Desegregation can cause accelerated white flight, particularly in larger school districts with substantial minority enrollments (over 20 percent or so) and in districts with accessible white suburbs. This conclusion is robust, based on a concensus from four different studies employing different conceptual and analytic strategies.

Rossell's latest study and the present study clarify certain aspects of the white flight effect. The effect tends to happen only when significant numbers of students are mandatorily reassigned (or "bused"), and especially when white students are reassigned to formerly minority schools. This situation develops mostly in courtordered cases, although there are several mandatory HEW-ordered plans

and at least one case of a community-initiated mandatory plan. ¹³
Therefore court-ordered mandatory plans, rather than desegregation per se, have been the primary causes of accelerated white flight in desegregating school districts. Voluntary busing plans such as that adopted by San Diego do not appear to have any significant effect on white flight.

Using demographic projection methods, the present study offers further information about white flight induced by court-ordered desegregation. The effect is strongest in the first year of desegregation, with average white losses accelerating by factors of 2 to 4 in most cases. But the projections also show that many districts suffer anticipatory white losses, usually between the initial legal activities and the actual start of desegregation. More important, the method also shows that in most districts the accelerated white losses last for prolonged periods up to four or five years or more. Sometimes these longer-term effects are boosted by subsequent court actions taken to broaden desegregation.

The longer-term effects are stronger in large central-city school districts that have ample two-way busing, available suburbs, and higher minority concentrations. In some of these cases the court action seems to have permanently altered the rate of white decline in the public schools.

It is important to stress that not all white losses are attributable to the court actions. Many districts, especially those in the larger urban areas, would have experienced substantial white declines during the 1970's without the court orders. Most of these "natural" declines are due to a demographic transition characterized by declining white births combined with increasing central-city white outmigration rates. None theless, the extra white losses caused by court-ordered mandatory desegregation are very substantial, in most cases amounting to over half of all white losses over periods of six to eight years.

¹³ Berkeley, California is the only city meeting our size and percent minority criteria which has voluntarily implemented a comprehensive two-way busing plan, although Seattle, Washington, has proposed to do so in the Fall of 1978.

white flight appears to be insignificant in most Florida districts and in districts with small concentrations of minority students. The latter cases are apparently explained by the relatively minor dislocation necessary for desegregating relatively small numbers of minority students. In other county-wide districts without suburbs — which might be considered "metropolitan" — court orders have induced white flight, but the effect may not be long-term like that in central city districts. According to the Louisville-Jefferson County experience, the reason may have to do with cost and availability of private schools, which logically forms the primary avenue for white flight in metropolitan plans. Of course, should the supply of private schools be increased, as it might with tuition tax credits or with property tax cuts such as those occurring in California, metropolitan plans could rival intradistrict plans in white flight.

The Future of School Desegregation

Having provided further evidence that court-ordered desegregation does cause white flight, and that under certain conditions the effect is very substantial, it must be conceded that the present study will probably not end the debate. All projection studies must make assumptions, and while the assumptions adopted here seem reasonable, they can be challenged. Moreover, at least one other recent study using different methods has argued that long-term effects are rare (Rossell, 1978). As a result, it is likely that there will be continuing argument, not over the existence of court-induced white flight, but over its full magnitude.

Nonetheless, this argument should not be allowed to obscure the central policy issue. Most of the school districts studied here are losing whites at a rapid rate. While part of the cause may be demographic, the court action only increases the rate of loss and increases the risk of resegregation. For persons who sincerely desire to increase the total amount of integration, this risk has to be disturbing. At precisely a time when policies are needed to halt or reverse the normal white declines in urban areas, we have instead court actions which are exacerbating the condition. Although the effects may be relatively

small in some cases, in other cases they are large. In either case they seem inappropriate during an era when most urban experts are urgently seeking ways to attract whites back into cities. Clearly, other remedies for school desegregation should be considered.

One alternative, of course, is to abandon "induced" school desegregation policies entirely, and let school desegregation take place "naturally" by housing choices of white and minority families. Given the failure to document definitive and meaningful educational and social benefits from induced school desegregation policies (Armor, 1972; St. John, 1975), we may eventually discover that natural desegregation is the wisest policy.

However, given current knowledge about housing segregation, which appears to be increasing in many metropolitan areas, many educational policy makers will not be content with the amount of desegregation arising naturally from neighborhood school assignments. Accordingly, for many policy makers there are only two meaningful alternatives: expanded voluntary plans, either on an intradistrict or metropolitan basis, or mandatory metropolitan plans.

In evaluating the relative merits of these two options, it is essential to gain some understanding of the reasons for white flight. If we are to improve upon present policies, so that the participants do not undermine and ultimately defeat the goal of desegregation, we must learn more about why whites oppose mandatory desegregation and how strong these feelings are. Obviously, it is beyond the scope of this paper to present an in-depth study of this issue. But it is possible to offer some helpful insights from attitudinal studies of busing which complement the behavioral findings already presented.

Most national public opinion polls have shown that whites are strongly opposed to busing for the purpose of desegregation (on the order of 75 to 85 percent), a stance that has changed little in spite of the increasingly commonplace status of busing during this decade (Weidman, 1975). Similar results have been found in recent special surveys in Log Angeles, San Diego, and Wilmington, Delaware, all of

which are involved in court desegregation cases (Armor, 1977; Kaplan, 1977). Thus attitudinal opposition to busing is consistent, in the aggregate, with the behavioral white flight phenomenon.

Yet these same surveys document substantial white support for the concept of integrated schools, and there is little opposition among whites to the prospect of minority children coming into their children's present schools. In the Los Angeles survey, 87 percent of white parents said they would not object if their child attended a school that was one-third black and two-thirds white, and 74 percent would not object if minority students were bused into their child's present school "in large numbers" (18 percent objected). Again, the behavioral evidence in white flight studies validates these attitudinal findings. Many school districts, including Los Angeles and San Diego, have promoted voluntary busing programs that have brought large numbers of minority students into schools that were formerly nearly all white. Yet little or no white flight has been observed as a result of these voluntary programs.

Contrary to the suggestions of some policy commentators, these results are not consistent with the thesis that opposition to busing and white flight are latent forms of prejudice and racism. Of course, prejudice and racism do exist, and undoubtedly persons with such attitudes are among the first to flee a desegregation program. But racism as an explanatory factor is not alone sufficient to account for the fact that the vast majority of whites accept desegregated schools when brought about by voluntary methods but reject them when their children are mandatarily bused or reassigned to schools outside their neighborhoods. The conclusion that racism is not the explanation is also supported by special analyses of the NORC 1974 survey, which found that whites with low racial prejudice scores were nearly as opposed to busing as persons with high prejudice (82 percent and 88 percent, respectively; Weidman, 1975).

If racism does not explain white flight, what does? The Los Angeles survey offers two further clues which support a different explanation. First, when asked about their reasons for opposing busing, the majority of whites mentioned a belief in the neighborhood school or related

issues such as distance, loss of choice, lost time, and lost friends. Second, when asked about the benefits and harms of desegregation, a large majority of white parents believed it would improve neither minority education nor race relations, while it would increase discipline problems and racial tensions. A majority of black parents believed the opposite, while Mexican-American parents were in between. Thus most white parents believe they are being forced to give up something they value — the neighborhood school — in return for a policy that benefits no one and may even be harmful. Given the strength of these feelings, and their persistence over time, it is quite possible that we have, underestimated the depth of belief in and commitment to the neighborhood school.

This substantial public opposition to mandatory busing makes it unlikely that legislative bodies, whether state or federal, will enact mandatory metropolitan desegregation. Realistically, the only hope for mandatory metropolitan plans rests upon further court action. Before federal courts can order metropolitan remedies, however, they must show that suburban school districts have had a direct and substantial effect on the central-city's school segregation. At present, this has been found for Wilmington, Delaware and may yet be found for Indianapolis, both for quite special reasons. As was true for Detroit, however, it will be difficult to show such connections in most cities. The NAACP and the ACLU are pursuing metropolitan remedies in Cincinnati and Atlanta on the grounds of government-caused housing segregation, but it is an open question whether federal courts will agree with this allegation.

An important exception may be California, whose school desegregation cases are being handled in state courts under the State Supreme Court edict that all school segregation is unconstitutional regardless of its

ERIC*

¹⁴ Wilmington's metropolitan remedy was imposed because of a state law which specifically prevented the largely black Wilmington School. District from annexing suburban districts. Indianapolis may get a metropolitan remedy because of state actions that created a metropolitan local government but which kept the school district intact. The Louis-ville-Jefferson County merger'was first ordered by an Appellate Court but was actually implemented by the State Board of Education after the Supreme Court disapproved the appellate order.

causes. There is nothing in the logic of the state court's holdings that would preclude a judge from ordering a metropolitan remedy.

Given the strong majority opposition to busing, however, and the inevitable legal and political bettles that will ensue, it is unclear whether any court will try to do so. For example, if any school district needs a metropolitan remedy it is Los Angeles, where the Anglo enrollment is already down to 35 percent. The projected Anglo losses under busing are likely to turn Los Angeles into a minority-isolated district by 1980 or so, where few minority children will attend desegregated schools (Armor, 1977). Yet, the court is allowing an intradistrict plan to start and has given no indication it will expand it into a metropolitan plan.

Even if the courts were to order metropolitan mandatory desegregation, there is no guarantee of success. The experience of Jefferson County, Kentucky, shows that white flight can occur in a metropolitan plan, albeit via transfers to private schools. The current dissatisfactions with public education coupled with growing pressure for California-style property tax cuts could lead to an upturn in private school resources. Property tax cuts can accelerate the trend with a two-pronged affect: they make it harder for public schools to deliver services, while at the same time increasing a family's ability to pay for private schooling. Tuition tax credits now being considered by Congress will have a similar affect. In this context, a court order of metropolitan busing could deliver a devastating blow to public education.

If the courts fail to order metropolitan desegregation, then voluntary plans will be the only remaining alternative, possibly on a metropolitan basis if state or federal funds become available. Although voluntary plans are widely believed to be ineffective, we have shown that San Diego's voluntary plan has maintained a substantial degree of desegregation, surpassing the amount of desegregation offered by the celebrated mandatory plans in Pasadena, Denver and Boston. Although we cannot generalize from the success of a single city, the fact remains that in recent times the voluntary approach has not led to the intense controversy observed in mandatory busing cases. Perhaps we have not given voluntary methods a fair trial. If other school districts can duplicate San Diego's experience, voluntary plans would provide desegregation for a large fraction of minority students, perhaps for those who could benefit most.

Most important, a voluntary program eliminates the inevitable social costs of programs which are forced upon an unwilling and protesting public. Aside from the direct costs in the form of white flight, it is quite possible that mandatory busing has already added to the erosion of confidence in public education. Indeed, regent Gallup polls show that integration/busing is named as the number two problem facing public education (AIPO, 1978). Given this climate of opinion, voluntary desegregation programs not only offer more enrollment stability; they may also help to stop this unfortunate decline in support for the public schools.

APPENDIX

The tables in the following pages present raw data and calculations for the demographic projections of the school-age population in each school district in the study. All birth data, except as otherwise noted, are live births by place of residence from Vital Statistics of the United States, National Center for Health Statistics. School data are fall enrollments from the Office of Civil Rights, HEW, racial and ethnic census reports, unless otherwise noted. The court actions are taken from written decisions and school district interviews.

The last table in the appendix is adapted from the Rossell Study (Rossell, 1977).

aProvided by school district.

1960

Suit brought.
First order of general desegregation.
Start of partial desegregation. 1969

1970

1971-72 Minor expansions.

Final order and major expansion of plan.

bEstimate: 1950 births of 6244 invalid due to major annexation in 1952.

COURT ACTIONS (Calhoun v. Cook)

PROJECTED WHITE ENROLLMENT FOR THE LOUISVILLE-JEFFERSON COUNTY SCHOOL DISTRICT, 1967-1977
