ABSTRACT
                One of seven sections of a report that examines the
assessment of occupational competence, this chapter presents
competence assessment as it is defined in practice by selection
techniques currently used by employers. The chapter begins with a
discussion of the major techniques used in employee selection,
focusing on the competencies employers detect and their measurement
properties. The second major portion focuses on the ways in which
selection techniques are used as components of selection systems
within a variety of organizations. Among the questions addressed here
are the following: Do employers actually select on the basis of the
competencies they desire in job applicants? How do selection
practices vary according to the type of job and level of skill
required at entry? What biases enter into selection decisions as a
function of the procedures used? To what extent do employers verify
the importance of certain competencies to job performance or the
effectiveness of their selection procedures? The chapter concludes
with a discussion of how organizational realities and other factors
affect selection practices and what educators can learn from current
trends in these practices. (Other sections of the report are
available separately--see note. The first is an overview; the last is
a synthesis of issues.) (LRA)

THE ASSESSMENT OF

OCCUPATIONAL COMPETENCE

1. COMPETENCE ASSESSMENT IN PERSONNEL SELECTION:
   CURRENT PRACTICES AND TRENDS

I. INTRODUCTION

In a competitive economy where more than one applicant may be found for most jobs or career opportunities that are made available, there exists the need for mechanisms to select the most qualified applicants out of the rest of the competition. From an employer's point of view, a selection procedure should be able to identify people who are right for the job as well as to ensure that selected individuals will choose to remain in the job long enough to justify the employer's investment in training. The degree of success in meeting these aims varies greatly with the selection procedure used and with the requirements of the job to be filled.

Nearly all the selection procedures that are currently used were in use more than 30 years ago. Today, many of these procedures evidence a greater degree of sophistication in their design and application than that which was tolerated in a more naive age. Thirty years ago, subjective judgments on the part of the interviewing employer, a bachelor's degree from a "good school", and test scores on a variety of psychometric measures of general ability all had a life of their own; the relationship between these factors and the merit of applicants for available jobs remained, with few exceptions, largely unquestioned outside of academic circles. Indeed, very few studies

4

-1.1-

of the cost-effectiveness of these dev   were undertaken
because of their appearance of validity and because the costs
of such studies in both dollars and inconve ence outweighed
the costs of administering the selection systems themselves.

Title VII of the Civil Rights Act of 1964 ushered in a new
era and a new consciousness with regard to employee selection.
Title VII is the portion of the Civil ghts Act that deals
with discrimination in employment. I is especially relevant
to employment selection processes bec- e of Section 703(h),
known as the Tower Amendment, which states that it is not "an
unlawful employment practice for an employer to give and to act
upon the results of any professionally developed ability test
provided that such test, its administrathor or action upon the
results is not designed, intended or ed to discriminate be-
cause of race, color, religion, sex   ational origin." This
section was added to the Act as a r   of concern in Congress
that companies would be prevented by   courts from using em-
ployment tests which disqualified me e   of protected classes
(i.e., those identifiable by race,   r, religion, sex, or
national origin). The phrase "prof   onally developed test"
became the impetus for the 1970 ver   of the EEOC selection
guidelines. The guidelines served   efine what a test is,
what constitutes discriminatory use   tests, and what stand-
ards of validity should be used to ine whether a test has
been developed carefully, fairly, and rigorously. These
guidelines, in turn, became the touchstone, implicitly and
explicitly, for professional practice and legal decisions.

Employers were now compelled to demonstrate statistically or rationally the relationship between selection procedures and jobs, to develop procedures which met proposed standards of validity, and to carefully document the fairness of these procedures to previously protected groups. Many organizations began to shy away from testing either out of an inability to deal with the cost and rigor of validation or out of the realization that their procedures did not measure up to the guidelines. In 1972, when an amendment to Title VII gave the EEOC enforcement power, the use of certain selection procedures abated even more swiftly. Ironically, psychometric tests of ability and personality, those selection devices for which statistical data were most readily available, were the first devices to be abandoned, since they were also the first to show discriminatory impact. On the other hand, other devices such as the selection interview, while generally much lower in reliability and validity, have increased in use, since it is more difficult to document the adverse impact of such devices.

At the same time, the last ten years have etched a growing concern in the minds of employers regarding the efficiency and productivity of the work force. Fierce competition from abroad, where labor was less costly and where technology had caught up with the domestic standard in many areas, contributed initially to this concern. In more recent years, the slowing of economic growth due to currency inflation, the increasing cost of energy, and a decline in the availability of resources

6

have placed additional emphasis upon productivity as the key
issue for the American economy. The recent consumer movement
has created its own pressures for assuring the value and qual-
ity of goods and services, and the passage of the Consumer Pro-
tection Act in 1974 placed additional costs on many organiza-
tions which, in the short run, exacerbated the problem of main-
taining costs for goods and services delivered. These sources
of pressure have placed an additional burden on personnel selec-
tion systems to be cost-effective means of selecting competent
and productive individuals, and to screen out those whose lower
productivity and shorter tenure make them poor hiring risks.

The employer of today is faced with a critical dilemma.
Given the state of the art of psychological measurement, is it
possible to use a selection procedure that enhances the ability
of an organization to employ individuals who are both competent
and highly productive, while not excluding disproportionately
individuals on the basis of characteristics such as age, race,
or sex which are, in theory, not correlated with job perform-
ance? Have employers pursued advancing the art and the practice
of selection to make selection both more fair and more predic-
tive of effective performance? Or have they turned away from
selection systems as devices for ensuring competence and toward
on-the-job training and development?

This chapter is devoted to identifying the state of the
practice in competence assessment in employer selection. It

proceeds with a review of selection techniques in current use, with particular emphasis on variations, validities, and problems associated with each. The section that follows shifts focus to the selection practice in more than 200 jobs which represent the spectrum of career opportunity. The concluding section responds to three critical issues for the practice of personnel selection: the discrepancy between actual and ideal practice; some of the factors underlying the discrepancy; and implications of the state of the practice for both educators and employers. These issues are introduced in greater detail below so that they might serve as a conceptual overview to the discussions which follow.

Discrepancy Between Actual and Ideal Practice

Competence assessment for selection can be viewed from two perspectives, that of the personnel researcher, and that of the personnel practitioner in a functioning organization. The ideals of the former perspective might be unlikely to converge with the realities of the latter. In fact, we expected to find considerable discrepancy between the ideal and the actual prac- tice. This disparity is all the more fruitful for our research because it suggests that the selection practices in use today can be more controlled, reliable and valid, and that the exist- ing research on selection practices can be set as a minimum standard for needed improvement.

While the research literature can be used as a base for evaluating the state of the practice, what can serve as a standard for evaluating competence assessment research itself? Although there is no absolute standard for assessing the quality of research, over the years several researchers have written prescriptive documents highlighting the parameters of predictors, measures, samples and criteria which will lead to optimal selection reliability and validity. These prescriptions remain appropriate for evaluating the state of the practice today. In addition, research that neglects these longstanding caveats in the designing of studies is open to criticism. Comparisons between research and practice, with regard to accepted standards of excellence, therefore, will be implicitly and explicitly stated throughout this chapter.

Factors Underlying the Discrepancy

As already noted, competing pressures on employers and the varying efficiency of employee selection procedures are expected to have a telling effect on the practice of competence assessment. Other factors which will later be brought into the picture include the difficulty and practicality of conducting studies on the validity of selection procedures within organizations and characteristics of the organizations themselves that contribute to the likelihood that validity studies will be undertaken. There is always a period of delay between any process innovation and its application, and discussion will be

devoted to an explanation of factors contributing to delay in the use of state-of-the-art employee selection devices.

Indeed, some of the questions that bear on impediments to assimilating new assessment technology are relevant to implementing any new technology. (1) Is the organization ready for the innovation? Can it afford a dramatic change in present practice, and will top decision-makers in the organization support such a change? (2) Is the latest technology really much better than that which is already in use? Do suspicions of change for its own sake create resistance to innovation, or are the benefits of change seen as being too marginal to warrant it? (3) Do the costs of implementing the latest technology outweigh the benefits to be derived? Regarding employee selection, do the costs of validation of a new selection device reduce the likelihood that a well-documented long-used procedure which has wide organizational acceptance will be replaced? These issues flow logically from a discussion of the discrepancy between ideal and actual practices in employee selection, and will be dealt with on the basis of data gathered from the organizations surveyed in the analysis of job selection procedures.

Implications for Educators and Employers

As the present study was undertaken, it soon became evident that exceedingly few employers based their requirements for

employee selection on competency measurements. Whether or not an employer has been able to demonstrate a rational, valid relationship between job performance and specified knowledge, skills, abilities or other personal characteristics of the individual, the majority of employers do not attempt to measure these characteristics directly through an employee selection process. Rather, they rely on their ability to make accurate inferences about the presence or absence of job related competencies from data collected through devices such as the interview, personality inventory, or resume. Employers have rarely been in the practice of making explicit the competencies they seek, except insofar as they are defined by the selection procedures they choose to invoke. With the exception of certain skill tests and job simulations which provide close correspondence to the actual work to be performed, most other sources of information considered in the selection process are open to a great deal of interpretation in establishing a link between, for example, a test score or an event in the employee's background and a competency required for the job.

These observations have certain critical implications for both employers and educators. The employee selection procedures in current use are often the only indicators of the competencies required for jobs to which educators and job applicants have access. It is important, therefore, to examine what, if anything, selection procedures tell us about job requirements that is either true or misleading. Do employers

select applicants on the basis of competencies that are needed for satisfactory job performance, and if so, should educators better prepare students to survive selection assessment proce-dures? Or do employers make selection decisions on the basis of competencies that are largely irrelevant to job performance, and must educators therefore prepare students for both long-term career effectiveness and short-term desirability as a job applicant? The answers to these questions will enable us to examine the emerging role of the employing organization as an educator of adults, and to contrast that role with the one which is currently being played by the approach to education practiced by a number of contemporary "competency-based" educa-tional institutions.

12

-1.9-

II. REVIEW OF EMPLOYEE SELECTION TECHNIQUES

This section is devoted to selection devices, or screening
devices that employers apply to job applicants at entry into
organizations. Promotion and performance appraisal systems,
which are used as the bases for selection from within an organi-
zation, are not considered here, though many of the techniques
described are applicable to this purpose. The interview and
the psychometric test are the two most popular selection tech-
niques, and separate sections will be devoted to discussions of
each. In addition, six other devices--application blanks,
resumes, recommendations, work samples and simulations, thought
samples, and detectors of deception are currently in widespread
use and a single section will be devoted to their description.
Each of the sections will describe different forms of the
devices, the range of competencies and other factors measured,
the reliability and validity of the devices, and issues
associated with their use.

Of particular importance in this review is the considera-
tion of the predictive validity of a selection technique: to be
competency-based, a selection device should measure qualities
of the applicant that are related to effective job performance.
Presently, employers consider four criteria in determining the
validity of a selection technique, which vary in the degree to

which they can be regarded as indicative of employee competence. The reader should keep these criteria in mind as he or she considers the utility of a selection device for competency measurement.

1. "Hard" measures, or direct measure of employee performance such as sales volume, production error rate, and portfolio profitability, are to be preferred as criteria, where available, against which a selection system would be validated.

2. "Soft" measures, including supervisor and peer ratings of performance, are often collected in the absence of direct performance measures. Ratings are susceptible to reliability problems and may, in many cases, bear a low relationship with harder performance measures (Kane and Lawler, 1979).

3. Trainability, defined in practice as how well an employee performs in a training program offered by the employing institution, may be a useful criterion for the employer in keeping costly attrition low. However, whether trainability reflects job competence depends on the to which that the results achieved through training are statistically related to job performance.

4. Attrition, or employee turnover, is a valuable criterion to the employer who desires to select employees who will remain on the job. This criterion is unrelated to competence in the job.

14

The employment interview has proved to be the most widely used technique for employee selection. A survey by Scott, et al. (1961) found that 98.4% of the 852 organizations sampled used the interview in their selection process. Of the companies surveyed 93.9% responded that an applicant would never be hired without first conducting a personal interview. There is no evidence to suggest that widespread use of the selection interview has abated. Campbell, et al., (1970) found that of 146 organizations surveyed, all placed "great importance" on the interview as a selection technique, with only one company attempting to decrease the emphasis placed on it. Perhaps because of such widespread use, the selection interview has evolved into a plethora of forms and styles of which only the most popular will be discussed here.

Variety in Format

Structure

Three primary types of interview structure have been noted in the selection interview: the structured, semi-structured ("guided" or "patterned"), and the unstructured ("laissez-faire") interview. These three approaches differ in the extent to which they rely on a standardized set of questions in conducting the interview.

1. The most prevalent form of the selection interview according to Hakel (1977), is the semi-structured or patterned approach in which the interviewer covers certain broad areas of questioning, such as education, work experience, and past accomplishments, but maintains discretion over the exact phrasing and order of the questions. This approach assures that certain data will be gathered from all applicants, but does not assure that comparable data will be gathered from all applicants due to differences in phrasings, sequencing of questions, and length of time spent on particular areas. This is true not only among different interviewers, but also with the same interviewer questioning different applicants.

2. The second most popular approach is the "unguided" or "laissez-faire" interview. In this form, interviewers approach each interview as a unique situation in which they are not bound by areas or questions that must be covered, but are free to pursue those areas that seem to be of most interest. Such an approach allows for a high degree of spontaneity and provides a high level of interviewer motivation. This approach, however, suffers from a lack of standardization since the same questions will not necessarily be asked all applicants for the same position.

3. The least popular approach in employee selection is the structured interview in which the interviewer poses a specific set of questions and deviates as little as possible from the list. Such a procedure is described by interviewers as being

repetitive and monotonous, though it does result in a high
degree of standardization, thus increasing validity and relia-
bility of the interview (Schwab & Henneman, 1969; Carlson,
et al., 1971; Bass, 1951).

Administration

In addition to the format, the interview can differ accord-
ing to the number of persons conducting it. It is common for
one interviewer alone to conduct the entire interview with a
given applicant. However, two other approaches are multiple
interviews and group interviews.

1. In multiple interviews, a number of independent inter-
views with the same applicant are conducted by different inter-
viewers. Topics may be divided among interviewers so that
repetition is held to a minimum. Following the entire series
of interviews, the interviewers meet together to pool their
information and opinions and to arrive at a group consensus.
With such an approach interviewer biases or irrelevant data are
less likely to affect the final decision. Additionally, gaps
in information gathered by one interviewer may have been
covered by other interviewers. Thus, a more complete picture,
of the applicant's background and characteristics is more like-
ly to emerge.

2. A group interview requiring two or more interviewers to
jointly question or be present during the interview of a single
applicant is relatively uncommon. Interviewers may take turns
asking questions or one interviewer may question the applicant,

while remaining group members observe. As with the multiple interview procedure, interviewers meet afterward to make a selection decision. This process insures that all members of the group have the same information on which to base a final decision. With this approach, interviewer biases and irrelevant data are less likely to affect the final decision than with the more common approach of one interview per applicant.

Length of Interview

Despite the fact that the interview is used as a selection device by most organizations, there has been little attention paid to the optimal length of the interview. There has been wide variation reported, ranging from less than 15 minutes to two hours or more. Springbett (1958) discovered that the average interview lasted about 15 minutes. The average interviewer was prepared to make a decision about selection after only four minutes, while certainly, the length of time spent in the interview would vary according to level of position vacancy, amount of ancillary data available (e.g., application blanks, psychometric test data, recommendations), number of qualified applicants, and the purpose of the interview (preliminary screen or actual selection tool).

18

Instrument Focus

As might be expected from the wide usage of the interview as a selection instrument, the interview has been used to tap numerous applicant characteristics. A review by Wagner (1949) reported 96 different traits and dimensions that researchers have attempted to evaluate by the interview method. Of these, it appeared that the interview was most often used to evaluate overall ability, physical appearance, manner, intelligence and mental ability, judgment and voice quality. More recent studies by researchers have urged that the interview be used instead to measure interpersonal relations, sociability and likeability (Otis, Campbell & Prien, 1962; Holt, 1958; Loevinger, 1959; Ulrich & Trumbo, 1965), and job motivation (Rimland, 1960; Woodworth, 1957) since the highest validities are reported in these areas. The interview is also a good measure of intelligence, but probably less useful than a psychometric test would be to measure mental ability.

Reliability. There is an abundance of information on the reliability of the selection interview. In general, the majority of information has shown high intrarater reliability. When interviewers evaluate the same applicant by replaying the recorded interview or interviewing the applicant again after a period of time has elapsed, they make approximately the same ratings as they did the first time (Shaw, 1952; Pashalian & Cressy, 1953; Anderson, 1954). These data suggest that an

interviewer will approach the interview situation similarly
from one time to the next. However, when more than one
interviewer evaluates a ʌʌ ʰicant, reliability falters. In a
now classic study, Scot ʰ15) asked six personnel managers to
interview 36 applicants ʰales ability. The interviewers not
only disagreed on the ranking, but for 28 of the applicants,
the interviewers disagreed on whether they should be in the
upper or the lower half of the group. Comparable results have
been found in numerous other studies (Scott, Bingham & Whipple,
1916; Hollingworth, 1922; Uhrbrock, 1933; Wagner, 1949; Raines
& Rohrer, 1955; Plag, 1961; Ulrich & Trumbo, 1965).

One area that has been examined as a source of interviewer
error is the temporal positioning of favorable and unfavorable
information. Some authors have reported heavier weighting for
earlier information, primacy effects, in the evaluation process
(Blakeney & MacNaughton, 1971), while other authors have re-
ported heavier weighting of later information or recency ef-
fects (Farr, 1973). Peters & Terborg (1975) and Tucker & Rowe
(1979) have concluded that a favorable expectancy of the
interviewer at the start of the interview followed by negative
information will result in more favorable ratings than the
negative expectancy followed by positive information. Tucker &
Rowe explain this phenomenon by suggesting that when favorable
expectancies exist in the interviewer's mind, he or she will
give the applicant less credit for personal successes and hold
the applicant more personally responsible for past failures.

20

Contrast effects, resulting from the comparison of job appli-
cants with preceding applicants may also contribute to inter-
viewer error (Carlson, 1969; Hakel, Ohensorge & Dunnette, 1970;
Wexley et al., 1972). However, in other studies, contrast
effects were shown to be minimal (Hakel et al., 1970; Landy &
Bates, 1973).

In recent years, many investigations have focused on how
reliabilities can be increased. One such mechanism for height-
ening interrater reliability is by providing the interviewer
with more information about the job to be filled. Langdale &
Weitz (1973) reported that interviewers who were provided with
job information about the position they were filling, had high
interrater reliability (r=.87) while those provided with only a
job title had low interrater agreement. A second means of im-
proving reliability is interview structure. Schwab & Henemann
(1969) found highest interrater reliability when interviewers
used a structured interview format. When a semi-structured
format was used, reliability dropped (r=.43), and when an
unstructured format was used, the reliability coefficient
dropped even further (r=.36). Similar results were shown by
Carlson, Schwab & Heneman (1970).

The type of rating scale used has been shown to affect in-
terrater reliability. Maas (1965) conducted a study in which
interviewers assessed job applicants for a particular job on
two different rating scales. In the first study, interviewers
rated applicants on a traditional adjectival rating scale. The
reliabilities were low for traits (r=.35), overall rating,

(r=.34) and total ratings (r=.34). When candidates were

ass

inc

for

mea

that

1968;

as five minutes of training was found by Borman (1973) to be

effective in reducing perceptual errors. Shick (1973) likewise

reported fewer errors in perception among raters exposed brief-

ly to training.

The best training pedagogy is still under investigation.

Levine & Butler (1952) found only group discussion to be effec-

tive in reducing "halo" error (a perceptual error in which a

wide variety of positive attributes are ascribed to the appli-

cant on the basis of limited positive data). According to

Levine & Butler, the lecture method and experience had no

effect in reducing the "halo effect." Brown (1968) also ex-

amined a variety of training methods and concluded that all

methods were effective in reducing the halo error. Finally,

Wexley, et al., (1973), and Latham, et al., (1975), found work-

shops with exercises had the most dramatic effect in reducing

rating errors.

22

Validity

The validity of the interview has been assessed against
such criteria as performance ratings, success in training, and
job tenure. The results of most of these studies have been
disappointing. In his review of the studies examining selec-
tion interviewing, Mayfield (1964) stated, "Although the relia-
bilities of interview may be high in given situations, the val-
idities obtained are usually of low magnitude....This indicates
that along with the present emphasis on reliability, there
should be more investigation of just what it is that is being
measured reliably in selection interviews." In Wagner's (1949)
review of 106 studies, the mean validity coefficient reported
for traits and characteristics was only .37 and the validity of
the overall ratings was .35. It must be kept in mind, however,
that the number of studies which assessed validity was quite
small and in those studies a number of different criteria were
used. Nonetheless, they serve to underscore the generally low
validity of the interview as a selection tool. This state of
affairs will probably remain the case as long as the inter-
viewers are permitted to draw their own inferences unsystem-
atically from the data they collect.

Most studies that have examined validity of the selection
interview have used job performance ratings as the criterion
(Raines & Rohrer, 1955; Zaccaria, et al., 1956; Woodworth, et
al., 1957; Trites, 1960; Campbell, et al., 1962; Huse, 1962).
Other criteria have included the successful

completion of training (Plag, 1961; Trankell, 1959) and job

te

th

re

id

on

(196

too fre[illegible]of[illegible]

on the time, information, or both, available to him." An ap-

proach such as Rundquist's might well allow the interviewer to

raise the validity of the interview by focusing on assessment

of one area rather than many. The main area which appears to

be most accurately assessed by the interview is that of socia-

bility or interpersonal relations. Otis, Campbell & Prien

(1962) concluded that the interview yielded valid predictions

only on the personal relations dimension. Other evidence in

support of their conclusion is found in the studies of Holt

(1958) and Loevinger (1959).

A number of other factors also have a bearing on the

validity achieved through the use of the interview. One cause

for low validity may be errors in information processing, an

area which has been exposed to much scrutiny in the last

decade. Springbett (1958) and Bolster & Springbett (1961)

found that the selection interview was used primarily to access

negative information about the candidate. They concluded that

though often unintended, the interviewer comes to weight

negative information too heavily (vis-a-vis its actual job

relevance) when making an employment decision. In later

research Hollman (1972) discovered that negative data are not

more potent because they are given excessive inappropriate

attention by decision-makers, but because positive information

is overlooked or underutilized in the actual decision-making

process. The later research would suggest that interviewers

should be alerted or taught to attend to and use positive

interview data more carefully in order to improve the validity

of their interview decisions.

The effect of training on validity has received some atten-

tion. In research by Borman (1975) it was found that training

programs designed to reduce "halo error" did reduce halo but

left validity unchanged. There was some indication, however,

that relative strengths and weaknesses of the applicants were

recognized somewhat more accurately after training.

Interview structure and the use of biographical information

were examined by Heneman, et al., 1975. It was discovered that

neither the degree of interview structure nor the use of bio-

graphical data influenced validity. The authors speculate that

individual judges may have been making decisions based on their

own unique stereotypes of the characteristics needed to ade-

quately fill the job. This occurred because of the lack of ade-

quate information about desirable characteristics and behaviors

of job incumbents. Indeed, as a study by Wiener & Schneiderman

(1974) demonstrated, when information about the job vacancy was

supplied to the interviewer, more relevant and less irrelevant
information was used in the selection decision.

Sydiaha's (1961) research suggested there is an "ideal" ap-
plicant stereotype against which job applicants are judged. He
further felt this "ideal" stereotype was common to all inter-
viewers. However, in a later study, Hakel, Hollmann & Dunnette
(1970) found that ideal stereotypes do appear to exist, but
they are at least partially unique to the interviewer, rather
than being common to all interviewers.

Various authors have expanded on the stereotype hypothesis
to examine sex stereotypes which affect interviewer decisions
(Cecil, et al., 1973; Shaw, 1972; Heneman, 1977; Cohen &
Bunker, 1975). Mayer & Bell (1975) examined sex stereotypes
and found that different stereotypes of men and women are re-
sponsible for different hiring decisions. Also, the authors
revealed that the sex of the interviewer plays a key role as
well. Female interviewers had more similar and less complex
stereotypes of men and women than did male interviewers.

Table 1 summarizes the reliability and validity of data
obtained in the use of the selection interview and documented
by the studies cited above.

Issues for Users

Perhaps the most crucial problem facing users of the inter-
view as a selection device is its typically low validity.
While studies have indicated that reliability can be raised

through techniques such as interviewer training, structured interview format, use of job information and more sophisticated rating scales, the validity of the interview remains low under most conditions.

The only ways which have been shown effective in increasing the interview's validity were restriction of data collected from the interview to interpersonal relations and the use of greater job information which is behaviorally based. Heneman, et al., (1975) stated the dilemma following a sophisticated study on interview validity. "A strong effort was made to create an interviewing process that would result in valid assessments in the structured interview condition." These efforts included (1) thorough job analysis, resulting in descriptions of basic job elements; (2) use of the job elements in the criterion measures; (3) use of interview rating forms requiring interviewers to make explicit predictions of performance on the job elements; and (4) development of structured interview questions directly from descriptions of the job elements. In spite of these efforts, interviewer validity remained low. It is thus necessary to ask what more could reasonably be done in actual interview settings.

The solution to the dilemma lies in a two-pronged effort that would first minimize interviewer error and bias, thus raising reliability. Heightened reliability increases the possibility that validity could be raised. The second effort should be to obtain job competency analyses of positions to be

filled. This information should be supplied to interviewers who would then interview candidates only for those positions where interpersonal relations were an essential skill to successful job performance.

A related question is that of functional utility. Though the validity of the interview is low, it may still be an acceptable component of the selection process, provided it makes a unique contribution to the data needed for a selection decision. However, it appears that the data most easily and validly assessed by the interview may also be assessed, perhaps more effectively, by other methods such as psychometric testing or thought samples. Some researchers (Huse, 1962; Plag, 1961; Ulrich & Trumbo, 1965; Grant & Bray, 1971; Wright, 1969; Schmitt, 1976) have already raised this issue, but relatively little work in this area has been conducted.

An auxiliary question to that of relative utility is the issue of cost-effectiveness. Even if the interview can be shown to make a unique contribution to prediction of job success, tenure or training success, is the gain in predictive ability worth the cost involved?

A third issue which must be addressed is the legal position of the interview as a selection device. The interview has not come under attack to the same extent as other selection devices under Title VII, such as psychometric tests. However, employers who use selection interviews may be called upon to give evidence not only for the validity of the instrument, but also for its

fairness to minority groups and women. As mentioned earlier, it is clear that sex and race do impact interview decisions in quite complex ways. This evidence combined with the typical low validities and reliabilities associated with the selection interview are likely to make defense of the interview quite difficult.

Psychometric Tests

Testing as a tool for personnel selection has been in existence for more than 50 years, receiving its first widespread use during World War I as a selection device for the U.S. military. The development of tests for selection expanded during the following decades, reaching a high degree of sophistication in the post-World War II period. Acceptance has not been as widespread as one might assume. Ward (1960) surveyed 1610 managers on the use of tests in their companies. Of these, 42% reported tests were used for hourly employees while 53% said tests were used for exempt employees. Campbell, et al., (1970) estimated that 60-70% of the companies in the U.S. use ability or aptitude tests, with many fewer firms using personality tests.

There appears to be wider use of tests for selection decisions involving hiring persons from outside the firm. Ward (1960) found about 53% of companies surveyed used testing for external selection, while 36% used testing for internal selection. This differential testing emphasis was supported by

-1.27-

Campbell, et al., (1970) who reported that approximately 90% of companies sampled used tests with external hires; only 40% tested for internal decisions. The rationale given for this difference was that testing is really helpful "only when little is known about the individual."

Construction of Tests

Dunnette (1966) has noted three basic methods for construction of tests: (1) armchair theoretic, (2) factor analytic, and (3) empirical.

1. The "armchair theoretic approach" involves devising a set of materials or questions that will be used to elicit responses from persons, deciding what the responses mean, and then either confirming or disconfirming the actual behavior of those persons tested. This approach is used quite commonly, but has little to recommend it since validities with job performance tend to be low.

2. The factor-analytic approach involves describing and rating actual behaviors shown by persons. These descriptions are then correlated and factor analyzed in order to yield basic dimensions of behavior. Tests are then constructed to measure these various factors.

3. Finally, the empirical approach involves observation of differences in a particular behavior, rating or categorizing individuals according to the amount of the behavior they show,

constructing stimuli which appear to be related to the behavior under study, and then testing the stimuli to see which measures actually differentiate groups of persons having differing amounts of the behavior studied.

Of these three methods, the most desirable is the empirical method because it is so strongly behaviorally based and tends to demonstrate the greatest validity.

Administration and Content

Tests differ substantially in their administration and content areas. For example, tests may be closely timed (speed test) or untimed (power test); they may involve "hands-on" manipulation (performance test), oral questions, or paper and pencil measures; they may have correct answers (objective tests) or no correct answers (subjective tests).

The most important dimension on which tests differ is the content they are designed to measure. Accordingly, the hundreds of tests in use in selection decisions may be grouped under two major headings: ability and skill tests and personality tests.

Ability and Skill Tests

Ability and skill tests are theoretically different, the ability test purporting to measure potential as opposed to level of acquired skill. In practice, the main difference between the two tests is the purpose of the testing: the same test is frequently used to assess potential or actual skill.

Ability and skill tests differ according to the content they measure as well as the specificity of the dimensions tapped. General ability tests usually measure general intellectual ability, while specific ability and skill tests measure particular facets of intellectual, perceptual, psychomotor or other abilities.

General Intellectual Ability Tests

Variety in Format

There has been an evolution of general intellectual ability tests, beginning with the early, "spiral omnibus" tests. These tests assumed a general aptitude which would be measured to some extent by all questions. The result of this type of measure was the single score derived from a number of different types of items. The spiral omnibus variety gave way to a different type of test which assumed a certain number of factors or dimensions comprising intelligence, rather than a single factor. In some cases, an overall score was given as well. Doppelt (1954) reported a growing trend for the factorial concept and a decline among single score tests.

Usually, for personnel selection, intellectual ability tests are administered to groups of persons rather than to one individual at a time. This allows the cost of testing to be kept substantially lower per applicant than would otherwise be the case. In addition, the time required for such tests is shorter than in other settings, again allowing a lowered cost

per person. This need for group administered, short tests of
intellectual ability has produced a wide variety of occupational
tests designed to measure general intellectual ability. Notice-
ably absent from the test used in industry is the Wechsler Adult
Intelligence Scale, widely used in other settings, but which
requires individual administration combined with a rather long
completion time of approximately one hour. In contrast, meas-
ures commonly used in industry average only 20-30 minutes for a
complete administration and may be given to large groups if
needed. They tend to be multiple choice speed tests which
increase in difficulty. General intellectual ability tests are
usually used as a preliminary screening device to be followed
by performance or skill tests.

Instrument Focus

Some of the more popular tests designed to measure general
intellectual ability are listed in Table 2. As seen in that
table, there is a pronounced emphasis on cognitive abilities
with some attention to problem-solving ability. In particular,
such dimensions measured as fluency with numbers and words, dis-
covering relationships among words and general reasoning are
tapped by most of the tests commonly used. However, dimensions
such as flexibility, creativity, and problem diagnosis, also
part of general intellectual level, are not measured by the
tests. Guion (1965) stated, "...the general intelligence tests
have been conducted less than general because they do not

34

measure the important intellectual powers involved in creative thought, planning and judgment. They do not even tap some of the lower level intellectual skills measured in tests of clerical or mechanical aptitude."

Psychometric Properties

Nonetheless, some of the general intelligence tests have proven to be useful additions to testing batteries for some jobs. Ghiselli (1973) examined all the validity studies (1921-1971) using occupational samples. From these data, he completed the average validity coefficients for the criteria of training and job proficiency. Unfortunately, in computing these coefficients, concurrent and predictive validity studies using all general intellectual ability measures were combined, as were both well constructed and poorly designed studies. The validity figures attained, therefore, are likely to be underestimates of true validity. These validity coefficients which may be seen in Table 3 reveal some interesting trends. (1) General intelligence tests appear to be much better predictors of success in training than of job performance. This is to be expected given the scholastic nature of most intelligence tests. (2) The utility of general intelligence tests is most apparent in clerical and managerial occupations. Overall, validities of general intelligence tests are low (between .15 and .30) for all occupations.

Specific Aptitude Tests

Specific aptitude tests attempt to measure an applicant's potential on a specified set of traits and abilities. Of course, in reality, true tests of potential do not exist, but are always influenced to some degree by such factors as previous experience and learning or motivation. Specific aptitude tests may be combined to form a multiaptitude battery with each subtest designed to measure different dimensions of potential for a given job.

Instrument Focus

Specific aptitude and skill tests exist for a variety of dimensions, but in personnel selection the most prominent areas are:

- Specific intellectual abilities including the ability to deal with verbal and numerical materials and geometric forms. Perceptual abilities and memory are often important aspects as well. Specific intellectual ability tests have been most often used to assess clerical aptitude.

- Mechanical aptitude measuring spatial orientations or visualization. These tests may be paper and pencil measures or require actual object manipulation. These skills are most often measured for trades and crafts-people, such as electrical or structural workers, or some machine operators.

- <u>Creativity and judgment</u> which explores some of the higher intellectual processes omitted in general intelligence tests. The traits tapped by creativity and judgment tests include the ability to make inferences, recognize assumptions, deduce logical conclusions, and evaluate arguments. They have been most used in managerial and scientific professions.

- <u>Sensory and perceptual capabilities</u> including such aspects as vision acuity, depth perception, and auditory acuity. Such traits are especially important to clerical workers, inspection workers, vehicle operators, machine operators, some laborers, and mechanic and skilled tradespeople.

- <u>Psychomotor ability</u> including dexterity, eye-hand coordination and object manipulation. These abilities are most needed in work requiring speed and object manipulation, such as assembly of small components or electrical wiring.

Table 4 lists some of the more common tests in each of these categories as well as the dimensions of facets of behavior measured by each.

ement

(1973). These may be seen in Table 5. As with general intelli-gence tests, it appears as if training success is more accu-rately predicted by aptitude tests than job proficiency. Unfortunately, in Ghiselli's work, he did not report validities of measures of creativity with training or job performance. However, what data there are tend to be concurrent studies which show reasonably good discrimination among creative and non-creative engineers and programmers (Owens, et al., 1957; Langmuir & Kendall, 1961; McNamara & Hughes, 1961).

Multiaptitude Test Batteries. Test batteries which assess aptitude in a number of areas have increased in popularity in recent years. The advantages of such batteries are greater efficiency in the use of testing time, and a greater amount of data obtained about the applicant. Such batteries may be used to assess the wide variety of skills which may be needed to successfully perform the various facets and tasks of a particular job. The use of multiaptitude test batteries has been most prevalent in the military though recently private industry has begun to accept and use some batteries. Table 6 summarizes data from four major multiaptitude tests in current use.

Personality Tests

Variety in Format

Personality tests are designed to measure the emotional, interpersonal, attitudinal and motivational facets of an appli-cant. Personality measures originated in guidance centers and

mental hospitals, then moved into industrial personnel selection on the assumption that personality is an important determinant of job performance, job tenure and absenteeism, and general quality of life. The number of personality tests is now in the thousands, making test selection frequently difficult.

There are two basic forms of personality measures: the self-report inventory and projective techniques. The self-report inventory requires the applicant to indicate how descriptive statements or adjectives relate to himself or herself. The primary difficulty inherent in this approach is the opportunity for "faking" or giving only socially desirable answers. Particularly in personnel selection, there may be a strong desire on the part of the applicant to "look as good as possible" in order to be selected for the position.

Several procedures have been tried to decrease or eliminate the effect of the social desirability bias in the use of self-report measures. One solution is the use of "forced-choice" measures in which the applicant chooses between two or three possible descriptors, all keyed to have the same desirability. There is some evidence to suggest this minimizes the effect of the "faking", but still does not eliminate it as a source of bias (Wiggins, 1966). A second way to counter the problem of "faking" is the construction of special keys which assess the degree to which responses appear to be heavily influenced by wanting to appear in a more favorable light. These keys also appear to reduce the effect of the bias, but do not eliminate it (Cofer, et al., 1949).

Other difficulties which beset the use of self-report inventories is that of response sets of styles. Inventories lend themselves to such biasing response patterns as acquiescence (the tendency of the applicant to agree with statements) or deviance (the tendency to give unusual or uncommon responses).

A second form of personality measure is that of projective tests. The primary characteristic of projective technique is the use of ambiguous or unstructured stimuli. It is assumed that by using ambiguous stimuli, the applicant is free to project his or her own desires, emotions, needs onto the stimuli, and structure the situation according to fundamental aspects of personal psychological functioning.

Projective techniques are disguised in that the applicant seldom is aware of the interpretation that will be made of particular responses. Thus, faking and response sets are not a problem with this type of technique. Unfortunately, most projective techniques, with the exception of those utilized to collect thought samples, lack standardization of administration and scoring. This makes results obtained suspect, due to lower inter- and intrarater reliabilities. Additionally, many of the projective measures use subjective rather than objective scoring techniques. Normative data, as well, are frequently not available, especially on industrial samples.

Interest Measures

Interest measures were devised originally for clinical use in guidance counseling rather than employee selection. These measures are typically self-report instruments requiring a rating of a particular activity, or a preference among several activities.

The two most commonly used interest measures are the Strong-Campbell Interest Inventory (an earlier version being the Strong Vocational Interest Blank), and the Kuder Preference Record. In the SCII, applicant responses are compared with responses of people in various jobs. These interest similarities and dissimilarities are charted for a number of occupations allowing the applicant to gauge how closely his or her interests match interests of people in those occupations. The Kuder Preference Record requires the applicant to indicate preferred activities in a forced-choice format. The results are given in strength of interest traits, such as mechanical, scientific, artistic, etc., rather than in terms of occupations. In both interest measures there are verification scores to detect faking or carelessness. Other interest measures exist, but are seldom used in industrial settings.

53

Instrument Focus

Personality tests also vary according to the content and purpose of the test.. The two dominant forms of content of personality tests are (1) Motives and Traits, and (2) Interests.

Measures of Motives and Traits

A sampling of the many motivational and trait measures used for selection purposes are shown in Table 6. No one test seems to be used most frequently, though projective tests are used less frequently than self-report measures, probably due to the difficult scoring procedures typical of these measures and the low interrater reliabilities. Most of the measures of motives. and traits tap rather ambiguous personality dimensions such as dominance, extroversion, stability or masculinity, which may or may not be reflected in behavior on the job. Cronbach (1960) criticized trait measures by challenging the assumptions on which the tests are based. The assumptions according to him are:

- Personalities possess considerable consistency; a person shows the same habitual reactions over a wide range of similar situations.

- For any habit we can find, among people, there is a variation of degrees or amounts of this behavior.

- Personalities have some stability; since the person earning a certain score this year usually has a somewhat similar score next year.

Each of these assumptions is highly questionable. It seems unrealistic to assume persons will react similarly in diverse situations. Rather, traits should be measured in "terms of behavioral tendencies with a defined class of stimulus situations" (Guion, 1965) that most approach the work situation. Secondly, the assumption that variations of traits are great enough among average people to allow such traits to be used as predictors is questionable. Such measures are likely to pick up the highly unusual cases, but in fact, the majority of persons likely to be tested for positions in industry are unlikely to be situated at the extremes on a measure of a particular trait. Finally, personalities show some change over time which is reflected in low test-retest reliabilities on personality trait measures (McClelland, 1980).

Psychometric Properties. Reliabilities and validities for particular motive and trait measures may be seen in Table 7. Further, the validities of these tests for various occupational groups may be seen in Table 8. The results of this table show good validity of these measures for predicting training success of managers and moderate validity for job performance of sales personnel. For other groups, however, validities are quite low.

Reliabilities of measures of motives and traits have long been a problem. Not only have these tests shown lower reliability over time, but with projective techniques in particular, interrater reliability is frequently low (Anastasi, 1968).

*Adapted from Ghiselli (1973)

Psychometric Properties. As with motive and trait measures, predictive validities of interest measures for performance of various occupational groups have been shown to be generally low. However, the validity of interest measures to predict success in training for managers is quite high. One way which has been shown to be a particularly effective means of boosting the validity of interest measures is through the use of empirically derived scoring keys (Boyd, 1961; Knauft, 1951; Tiffin & Phelan, 1953).

In contrast to motive and trait measures, interest tests show remarkably good reliability over time. In a study of the SVIB, Strong (1951) conducted follow-up testing with time intervals of 5 to 22 years. He found reliability of interests were .84 after five years, .82 after 10 years, and .75 after a 22-year interval.

Issues For Users

The use of tests in industrial selection appears to have come under a great deal of attack in recent years. Ebel (1977) states that while the attackers are varied, the target of attack is always the same: the alleged lack of validity of the tests. As we have seen earlier, validities of personality tests and general intelligence tests on job performance tend to be especially low for all occupational subgroups. Reasons for this lack of validity have been postulated by a number of researchers and include poor test construction, poor test selection, and differential validity.

59

Test Construction

Dunnette (1966) has urged a move away from "armchair theorizing" as the basis of test construction to more sophisticated, behaviorally-based approaches. Yet, a number of tests are constructed on the basis of "pet theories" without adequate attention being paid to the actual behaviors indicative of success on the job. Dunnette states, "Most existing behavioral theories have at best doubtful validity, and it is unlikely that any test developer is so omniscient that he or she can accurately intuit what a person's responses to a set of stimuli may mean in terms of later observed behavior."

In addition, most tests have been constructed to be adapted to the widest variety of industrial situations. This feature lowers the ability of a test to predict the unique behaviors necessary for success in a specific job. Instead, tests should be made much more "situationally specific", i.e., constructed on the basis of behaviors which differentiate successful from unsuccessful performance for a particular job.

Test Selection

Some rationale is always needed for the inclusion of particular tests into a selection battery. Unfortunately, according to Bray & Moses (1972), such rationale is frequently based on test availability or on intuition. A study by Parry (1968) illustrates this point. She asked 10 industrial psychologists to estimate the validities of a number of tests widely used in

personnel selection. Her results showed only one person was able to achieve an accurate estimate of validity, with the other psychologists showing a marked tendency to overestimate the validities. This overestimate would encourage the use of widely known tests without assessing the utility of the instrument for the particular job.

As shown earlier, tests predict better for some groups of individuals than others. Thus, inclusion of a personality test in a managerial battery to predict success in a management training program may be a useful addition. However, use of the same test to select police recruits who would successfully complete training at the Police Academy would likely be inappropriate. Therefore, tests must be examined for their utility in predicting a certain outcome for a given occupational group.

Differential Validity

An additional factor in the attack on test validities is the possiblity that tests may be more valid for some groups than others, i.e., differentially valid. A number of studies have claimed such differential validity exists (Bass & Turner, 1973; Kirkpatrick, et al., 1968; Tenopyr, 1967; Bartlett & O'Leary, 1969; Boehm, 1972) while other studies have claimed differential validity is merely an artifact of poor criterion design (Campbell, 1943; Crooks, 1972) or other methodological problems (Schmidt, et al., 1974). A later section of this chapter deals with this issue in greater depth.

61

In light of the questionable validity of many tests, as well as the recent attention testing has received in court cases, many companies are re-evaluating the utility of maintaining a testing program as part of personnel selection. Where tests are being retained, they appear to be much more behaviorally focused with less attention being given to person ability or general intelligence measures.

Other Selection Devices

This section is devoted to a discussion of the use of application blanks, resumes, recommendations, work samples and simulations, thought samples and detectors of deception. These devices are dealt with as a group due to their less frequent use and the fact that relatively few studies exist that attempt to describe the reliability and validity of these data sources.

Application Blanks

Many organizations judge a job candidate's potential on the basis of background information about that candidate. They reportedly consider biographical data, educational background, work experience and/or performance on a previous job. One of the "easiest" ways to access some of this information is through the use of an application blank. It is easy because the blank can be designed to include questions on exactly those background areas in which an employer is interested. The form, which can

be reproduced cheaply, provides a standard set of questions that can be given to all candidates. Using an application blank, the prospective employer can gather comparable data from a number of candidates without investing a significant amount of time in gathering that information such as would be required in preliminary interviews; a receptionist or secretary can simply ask all applicants to fill one out. Later, candidates can be compared and those most qualified on the basis of the self-report application forms may then be interviewed or hired.

Variety in Format

Most application forms look somewhat alike, though they may vary significantly in the amount of thought that was applied to designing them and the amount of information that they provide. Most include spaces for indicating name, address, age, weight, schools attended and dates of attendance, period of military service, previous jobs held, and names of personal references. More detailed applications may probe these areas for additional job-related information such as college grades, area of academic concentration, favorite subjects, type of military discharge, responsibilities in previous jobs, the number of people supervised and reasons for leaving a job. Still other application blanks ask specifically if the candidate has held a job similar to the one presently applied for, or ask for the candidate's career plans. The more general forms of the application blank are less expensive, and are usually bought in large quantities

63

from a business form supplier who imprints the organization's name at the top. The custom-made application blank which asks numerous detailed questions gives much more specific job related information at the greater cost incurred by analyzing the specific job to generate questions related to important areas of job functioning. The general form can be used for a variety of jobs; the specific form is only appropriate for jobs that require a particular kind of background and preparation.

While the majority of organizations have all applicants complete application blanks, many of those organizations would be surprised to hear the application blank called a selection device. Most firms use a general form for entry into all areas of the organization. While such forms help the organization to gather data, these data are used in an idiosyncratic manner, unspecified weight being given to that information which may be combined with interview test or reference data. A small minority of organizations use "weighted" application blanks, which are empirically keyed to and validated against job performance. Weighted application blanks are also used as selection devices, either by themselves or in combination with other data.

Instrument Focus

What information do application blanks provide to an employer? At the most basic level, the devices can give basic indications of literacy, spelling, grammar and usage, as well as neatness and the ability to follow simple directions, and they

provide verifiable age, education, military service and employment histories. If accurately recorded, these data provide an uncomplicated profile of applicant skills and job related experience. Questions about one's reasons for leaving a job, or one's career goals, on the other hand, may provide a crude reading on the motivation of the applicant. This information may be helpful in deciding if an applicant would "fit in" on the new job. However, as the self-report information on the application becomes less objective, and therefore less verifiable, it also can be less detectably faked. All self-report knowledge, skills and abilities should probably be verified, using the application blank only as a preliminary screen to identify potential employees rather than for making hiring decisions about jobs that require those knowledges, skills and abilities.

Psychometric Properties

Reliability. The reliability of an application blank, generally speaking, is not at issue. One's education, job history, and the opinions of one's references would not be expected to change very much over short intervals, to vary with changes in the format of an application blank, or to contradict other pieces of information on the same form. There is, nonetheless, the potential problem of candidates faking information in order to present the image they think will get them jobs. Early researchers found self-report data on work history, and

65

related information to be highly reliable, correlating approximately .94 with verified data (Keating, et al., 1950; Mosel & Cozen, 1952). More recent research suggests that applicant information may disagree with verified information as much as 57% of the time (Goldstein, 1971). However, among incumbents who need not sell themselves for the job (Cascio, 1975), and among applicants led to believe that a faking scale is included in the application blank (Schrader & Osburn, 1977), verified responses indicate that application blank data are highly reliable.

Validity. The validity of biographical items on application blanks, as compared to personality measures and other predictors, has been good for the prediction of job performance (Asher, 1972); biographical items have outperformed intelligence, aptitude, psychomotor, perception and personality scores as predictors of job proficiency. It is important to note, however, that it is a rigorously defined subset of the universe of all types of biographical data which has fared so well in such comparisons. Asher reported and compared only uses of "hard" biographical items, items which have been cross-validated, and which have been combined as a predictor based on a set of biographical questions rather than used as single items. Of 11 studies and 31 validity coefficients meeting this set of criteria, all but 3% achieved validities greater than .30, and 35% of the reported validity coefficients were in

excess of .60. Many employers, however, use data from application blanks which may include "soft" unverifiable items which can be faked easily. Also, many users simply apply a scoring key to an application blank and use the key for selection without ever cross-validating it on another applicant sample to identify the dependence of predictiveness on chance sample variability. Still other users attend to individual items on the application blank, ultimately using one or a few of them as predictors instead of using the combined biographical profile which will, by definition, be able to explain more of the variance in job performance. Asher drew his conclusion about the utility of biographical items from a sample of methodologically sound uses. Users of biographical data (Thayer, 1977; Roach, 1971) reporting validities between .30 and .40 have also argued forcefully for use of application blanks which are continually cross validated and updated to match the job-relatedness of background items for new applicant populations.

igor is required to maintain validities even at a moderate level (r=.35). Economic and organizational climate, as well as changing personnel practices, have a continual influence on the predictive validity of information gathered on an application blank. If it is acknowledged that none of these factors is static, then the good predictive validity of biographical data (e.g., personal, education and job history information) from application blanks is something that must be constantly monitored, and changes should be made when necessary to preserve validity.

Utility and validity of the application blank for gathering
predictive biographical data has been demonstrated for a variety
of jobs types and job environments. Keyed application blanks
have been used in the insurance industry since 1922, yielding
cross-validated validity coefficients around .45 (Roach, 1971).
Typical of the validities obtained for different jobs are .58
referenced to performance in training and on the job for Navy
divers (Helmreich, et al., 1973), .36 for men in the Israeli
Army (Nevo, 1976), and .67 referenced to quality of performance
among dance, theater, music, and visual arts students (James,
et al., 1974).

One study of the application blank examined both its reli-
ability and its validity for prediction of job performance. In
a crosscultural study of American and Western European salesmen,
a biographical inventory demonstrated good median internal con-
sistency, or reliabilities, of .75 and a median validity coef-
ficient of .42 (Hinrichs, et al., 1976). The 48-point range of
validities, however, reinforced the author's point that sample
variations and variations in personnel practices necessitate
validation of the keyed applications from each company and work
group despite perceived similarity of job titles and job
descriptions between groups. Similarly, the variation in reli-
ability estimates between groups (a 29 point spread) raises
questions about whether experienced job applicants are less
reliable in their responses, and whether that lower reliability
suggests an effort at self-presentation which decreases relia-
bility and thence, validity.

Issues For Users

At this point it should be clear that beyond the basic con-
cerns of reliability and validity, there are several other seri-
ous issues to be considered when using an application blank as
a selection tool. The issue of fakeability is a serious one;
faked responses may reduce both reliability and validity of the
method. Cross-validation is also important: a validity coef-
ficient for a sample on which the device is keyed will often be
reduced to insignificance when the key is applied to a sample
which doesn't have the unique pattern of variance the original
sample had. A third issue is one that was passed over earlier;
biodata validity may be different for different applicant sub-
groups divided on the basis of age, sex, race, education, and
other background variables. One large trade organization has
developed close to 50 different keys to scoring its biodata
blank due to changes in applicant populations over time and to
differences among subsamples of the population (Thayer, 1977).
A fourth issue concerns the nature of published studies. It
has been argued (Schwab & Oliver, 1974) that few studies have
been published on the validity of applications' biographical
data because they are seldom valid predictors of performance.
Studies finding no validity, or lost validity upon cross-
validation, tend not to be published, but this is difficult to
verify.

69

Lastly, a most serious concern for practitioners today is the legal defensibility of a selection technique as "job related". It has been suggested that data from the application blank be weighted according to their job-relatedness (Pace and Schoenfeldt, 1977) in order for the application to be a job related selection device. This complicates what was originally an empirically simple method. Nevertheless, employers who are committed to using biographical data of the types included in an application blank may be able to meet legal requirements and develop a valid scoring key in this way (Cascio, 1976).

Resumes

Many organizations screen, or even select, applicants on the basis of resumes they submit. A resume is similar to an application blank in terms of the information it supplies to the potential employer. The resume, however, presents a less objective, less standardized self-portrait by a job candidate. Like the application blank it suffers from the typical weak-nesses of self-report measures. Applicants present themselves as they wish to be seen, including only what they want and elaborating on information expected to cast them in a positive light. A resume often may not include specific job related information, such as reasons for leaving the previous job and school grades, that the employer might desire.

A resume is prepared by the applicant and given to the pro-spective employer. It typically includes a personal section, including information on age, marital status, and number of

dependents, memberships and offices held in social and profes-
sional organizations. An education section will list the
schools attended, years in attendance, and degrees obtained,
and may also include grade-point average, academic honors, con-
centration of study or areas of special interest. A section on
job history may simply list organizations and job titles or may
be expanded to give varying amounts of detail on responsibili-
ties, descriptions of projects and salary history, and profes-
sional applicants may also list job-related publications or
public presentations. Clearly, considerable variety in content
and specificity may exist among even a small sample of resumes
for the same job.

Resumes do provide the employer with biographical informa-
tion about the job candidate which includes some indication of
personal interests, information on the candidate's education,
and related job experience. Any self-report information on
knowledge, skills and abilities, however, does not necessarily
constitute definitive evidence of them. These self-reports may
be more or less accurate depending upon the distortions (inten-
tional or unintentional) inevitable in self-presentation. To
the best of our knowledge, no evidence of the reliability or
validity of resumes exists. However, all those who have writ-
ten resumes recognize that they are written to specific audi-
ences, for specific jobs and are often rewritten for new audi-
ences and opportunities. This would tend to reduce slightly
both reliability and validity of the resume as a data source.

71

In addition to applicant biases, there are situational and personal biases introduced by the decision maker which will affect the use of resume data. For example, it has been shown that a resume will be evaluated differently depending upon the quality of the preceding resume which serves as an unwitting standard for comparisons (Hakel, et al., 1970). While these contrast effects on resume evaluation are real, they account for a very small portion of the variance (about two percent) in the ultimate interviewer decision. If a candidate is only mediocre in qualifications on a resume, however, being preceded by a terrible candidate may make him or her look good by contrast, and result in an offer of a follow-up interview. Resume evaluations also tend to be more positive for attractive and qualified male candidates (Diploye, et al., 1975, 1977). Content areas, scholastic history, interest, and experience are all important inputs into resume ratings, which tend to be a function of the importance of the particular content area for job performance and the favorability of the information (Hakel, et al., 1970). A systematic review of the biases involved in resume evaluation may be found in Arvey (1979). In sum, there are both job-related and unrelated influences which affect the validity of employment decisions based ostensibly on resumes.

In conclusion, the resume is widely used because of the potential wealth of information it can provide about a candidate's personal, educational and job histories. It is, however, a biased form of data, but one which is used for a first

cut at whom to invite for a later interview. If used as a
prescreen for standard selection procedures, the basis for
choosing resumes should be demonstrably job-related or else it
may be vulnerable to legal contest. Those who use resumes as
the basis of selection, or as a prescreen should also be aware
of non job-related biases which may affect and invalidate those
judgments.

Recommendations

Employers or personnel directors may consider recommenda-
tions from acquaintances, other employers or colleagues, or
individuals suggested by the applicant, when making decisions
about a job candidate. As with application blanks and resumes,
recommendations may be used directly to make hiring decisions,
but are more likely to be used as the criterion for inviting a
candidate to an interview. While some employers say they value
a phone call to a past employer or the verbal opinion of a col-
league, only recommendations submitted in writing may be studied
in any systematic way. Therefore, the present discussion is re-
stricted to written recommendations requested by the employer.

A written recommendation may take a variety of forms. The
prospective employer may simply request a certain number of
reference letters of the applicants or a form letter may be
sent to persons named by the candidate. This letter may vary
in structure ranging from a space for candidate and reference
names, some simple directions and perhaps guiding questions

specifying length and content of response, followed by a blank space for writing, to a detailed questionnaire including free response, multiple choice, ranking, and forced-choice questions tapping information pertaining to work habits, personality, employment history, and whether the reference person would hire the candidate. Both the more and less structured forms have the advantage of letting the referring person communicate those things about the candidate that he or she knows uniquely and which can't be obtained from an application blank or interview. At the same time, multiple unstructured references for candidates for a single job may vary in content, quality and specificity. Comparison of unequal data and reconciliation of contradictions is difficult under these circumstances. On the other hand, structured recommendation forms provide comparable data, from multiple sources or for multiple candidates, but may not be flexible enough to access the unique data the reference person may have about the candidate.

The exact reason for using recommendations varies by job, company and particular user. In general, recommendations are intended to obtain information on job-related skills, employee character, work habits and employment history. It is the most conventional way to check on what an applicant says he or she has accomplished. A candidate will tell you what jobs he or she held, and what responsibilities he or she had. An employer will tell you how well the candidate fulfilled those job requirements.

Unfortunately, since most recommendations are relatively unstructured, they are consequently somewhat unreliable. Different supervisors and acquaintances have different levels of writing skill, their vocabularies differ, and their skill at person perception and understanding of the new job are highly variable. As a consequence, the data they contribute are also variable, resulting in interrater unreliability. In addition, employers react favorably to well-written recommendations, regardless of the quality of the candidate described. While writing skill may reflect something about the basic intelligence of the author-observer, an employer will have difficulty operating the erudition of the reference from the important qualities possessed by the job applicant. As a consequence, judgments based on reference quality rather than content may be invalid, reflecting more on the writer than the subject of the letter of reference (Mosel and Gohen, 1959). There is also some evidence that employers stereotype authors of recommendations by their sex, and judge recommendations accordingly (Kryger & Shikiar, 1979). Nevertheless, recommendations may include valid, useful information on the applicant's character: the validity of such information is best determined for the population and job of interest (Mosel, 1958).

In sum, when recommendations are used as part of an employment process, three issues need to be considered. (1) The employer should recognize that unstructured formats are unreliable. The user should determine whether to structure content

or prescribe reference sources in order to reduce that unrelia-

bility. (2) Those who actually use the recommendation in a

decision process should be forewarned or trained to attend to

content rather than style of the reference, and to consider the

related validity issue. (3) With the advent of the 1974

Family Educational Rights of Privacy Act, applicants who submit

letters of reference from teachers and professors may request

that those letters be placed in a file open to candidate in-

spection or a confidential file to which the candidate has no

access. While it is unclear exactly what the difference would

be between two letters by the same author for the two different

files, it appears that employers react more favorably to con-

fidential files, regardless of the enclosed recommendations on

candidate competence (Shaffer, et al., 1976).

Work Samples/Simulations

One method of determining a candidate's suitability for a

job is to have the candidate try his or her hand at a simula-

tion or sample of job tasks. While we may refer to all such

tests as work samples, it is important to remember that there

are potentially as many different forms of work samples as

there are different jobs to be filled. They can be roughly

classified into two groups: motor, involving the manipulation

of things, and verbal, usually language-oriented or people

oriented (Asher & Sciarrino, 1974).* These work sample
assessments are usually conducted outside the personnel office
and away from the actual job situation in a place where there
will be no interference from factors unrelated to the test
and where standardized observation of performance is possible.

Work sample assessments are generally intended to ascer-
tain the level of specific job related skills that the can-
didate possesses. Self-report of skills, from interviews,
resumes or application blanks, can be verified in work
samples. Coordination, planning and other cognitive skills,
as well as interpersonal and motor skills which may be very
important for good job performance can be evaluated by
observation of work samples, although they cannot be assessed
from most paper and pencil tests. While an applicant may
demonstrate that he or she possesses some knowledge by taking
a paper and pencil test, a simulation is more appropriate for
demonstrating an ability to apply that knowledge.

The reliabilities for work sample tests generally are not
reported. It is not unreasonable, however, to conclude that

---

* The verbal category would include most cognitive tasks, for
  even if the cognitive process involved neither language nor
  people, the output would have to be verbal to be evaluated.

they must be fairly high on the average on the basis of the similarity between work samples and skill tests. Validities are fairly high for work sample tests, an impossibility without good reliability. Also, work samples are by definition highly structured situations where specific tasks are observed and prescribed actions are credited as appropriate. However, to our knowledge, no useful reliability data exists to support these inferences. Nevertheless, as already suggested, the validity evidence for the work sample is strong in a review of over 60 validity studies for both motor and verbal work sample tests (Asher & Sciarrino, 1974). Two-thirds or more of all the validity studies reviewed exceeded a validity coefficient of .30, regardless of whether the work samples were verbal or motor, or whether the criterion was job proficiency or training success. More specifically, the literature suggests that verbal work samples outperform motor work samples in predicting training success, and motor work samples likewise outperform verbal work samples for prediction of job proficiency. However, Asher & Sciarrino (1974) found that work samples of both kinds consistently finish behind biographical data in validity, referenced to the criterion of job proficiency.

These findings raise some issues, as yet unresolved, about the nature and use of work samples. First, if, as has traditionally been argued, a work sample tends to be a valid

predictor because of its point-to-point relationship to the job performance criterion, then why do biographical data items tend to be more valid? Perhaps the focus on behavioral matching overlooks the facilitating motivational set which can be conveyed in biographical data. Second, Weitz & Adler (1973) suggest that simulations should be short or of moderate duration. In long simulations, subjects may start to adopt simulation-specific skills which are not job-related, and in fact interfere with transference of the basic work skills to the real work situation. To the best of our knowledge, no one currently using work samples for selection considers this caveat from the history of simulation training. Third, while different racial groups may perform equally well on the work sample, they may have differential attrition rates on the job (Farr, et al., 1973). If turnover is a criterion of interest, then a user should do careful subgroup analyses of work sample performance and subsequent nontask behavior in the work setting.

The last, and most basic issue is, how does one construct and score a work sample? Clearly some kind of job analysis is necessary to build a simulation with content and face validity (Campion, 1972), but a job analysis that simply lists tasks or outcomes is insufficient without a component that ranks or rates their importance for job functioning. It has been shown that a content-valid simulation, the "in-basket" exercise, may

79

not be predictively valid unless it is scored on the basis of those skills which are most important for the job (Brass & Oldham, 1976).

Thought Samples

A special technique somewhat similar to work sampling has been developed to assess, in particular, motive dispositions related to various jobs. It involves objectively coding samples of a person's thoughts in imaginative stories written in response to pictures. The codes were originally derived (see McClelland, et al., 1953; Atkinson, 1961; Winter, 1973) by identifying what characteristics of thought regularly appeared when a given motive was aroused. Then, if those thoughts occurred in stories written by subjects not under conditions of motive arousal, it was assumed that they were generally under the influence of the motive which uniquely produced such thoughts. In this way, measures have been developed for the need for Achievement (McClelland, et al., 1953), the need for Affiliation (Atkinson, 1958) and the need for Power (Winter, 1973).

The general logic of this approach assumes that being concerned about certain issues, or thinking a lot in terms of certain goals, means that a person will act in ways that are especially appropriate for success in particular jobs. The logic is not unlike that for work samples: what a person does

(thinks) in a sample situation predicts what he will spend his time doing on the job. Two motivational thought patterns in particular have been associated with successful vocational outcomes. The first involves the need for Achievement, or the tendency to think a lot about doing things well or in a more efficient way. Such a thought pattern has been regularly found to be associated with success as a small businessperson or entrepreneur (McClelland, 1961, 1966; McClelland & Winter, 1971; Mum & McClelland, 1979). The relationship has good theoretical validity because it makes sens· that a person who thinks a lot about doing better, e.g., getting more output for less input, should be just the kind of person who will succeed in a small business which requires constant attention to input/output ratios.

The second motivational or thought pattern is associated with managerial success in larger businesses. It is called the leadership motive pattern and involves a relatively high need for Power which is higher than the need for Affiliation, and a high sense of self-control. This motive pattern has been found to be related to success as a sales manager (McClelland, 1975), to rated performance as a Naval Commanding and Executive Officer (Winter, 1979) to promotion to higher levels of management within the American Telephone and Telegraph Company over a 16-year period (McClelland, et al., 1980) and generally to success in top management jobs in

81

American companies (Boyatzis, 1979). Again the relationship has good face validity, for it means people who make good managers tend to think a lot about influencing others, carefully control their influence attempts, and are not excessively concerned whether they are liked or disliked (need for Affiliation).

The reliabilities for measures obtained from objective coding of thought samples have generally been reported to be low (Entwisle, 1972). However, there are important reasons for believing that the coefficients reported may be serious underestimates of the true stability of the measures. As McClelland has pointed out (1971), the instructions for the test tell the subject to "be creative," which is interpreted by them to mean that they should tell different stories each time. It is well known that in all organisms there is a built-in tendency to vary spontaneous responses, which has been called "associative refractory phase." Winter and Stewart (1977) have demonstrated that if the variability set is broken by telling subjects on the second administration of the picture-story test that they are free to tell the same or different stories, then test-retest coefficients rise to the more respectable level of .60. More importantly, the validity studies mentioned above indicate that the measures must have a higher reliability than what has typically been reported, if we assume that validity cannot be higher than reliability.

82
-1.73-

Finally, Atkinson and Birch (1979) have argued that for measures of spontaneous behavior like these, the traditional psychometric model of reliability does not apply.

These measures have an important but limited utility. They are objective in the sense that the coding schemes for them are precise enough for two different judges to obtain a high degree of agreement (r=.85-.90) in coding the same protocol. For types of positions in entrepreneurship and management for which the most research using them has been carried out, they have good face validity, and they do provide information on the motives needed for these two types of jobs which is not obtainable in any other way. On the other hand, their limitations are: (1) that the testing conditions must be carefully controlled since stories written can easily be influenced by situational factors; (2) that they are more costly to score than tests involving machine scoreable choices; (3) that their coverage of competencies and types of jobs is so far quite limited; and (4) that the method is often viewed with some suspicion because it appears to be getting at some unconscious aspect of the self.

Nevertheless, the principles behind thought sampling--objectively coding thought patterns--can be extended to selection techniques such as the interview to determine the response of a wider range of skills. McClelland (1973) and Boyatzis (1979) have reported success in isolating and

83

reliably coding evidence for intellectual and interpersonal competencies in top performers through unstructured self-report. These competencies were then made the focus of specific psychometric tests which successfully validated their presence in better performing job incumbents.

Detectors of Deception

One group of employment prescreens seldom studied by psychologists are the detectors of deception. These include the polygraph, voice stress analyzer, and paper and pencil methods of detecting deception. Each of these methods is used occasionally as an employment prescreen by organizations concerned with employee theft or confidentiality of corporate information. The polygraph is designed to measure physiological indicators of stress such as pulse rate, relative blood pressure, rate and depth of respiration and galvanic skin response (GSR). Voice stress analyzers presumably measure inaudible stress-related frequency modulations in the voice. Stress is assumed to increase when the applicant is trying to deceive the tester. The paper and pencil instruments are designed to access information about applicant attitudes toward theft, admissions of theft, and biographical correlates of deception. The actual questions included, equipment involved, and time spent on detecting deception may vary between different organizations but all of these employment screening

processes are administered in the employment office or testing center. Administration would appear to be under constant conditions within an organization.

Strictly speaking, detectors of deception do not try to identify any job related knowledge, abilities or skills. If an applicant should try to deceive the employer about his or her background or experience, this would presumably be detected as physiological or vocal stress. The employer, however, appears to focus the examination on issues related to honesty, theft, and lying behavior rather than on issues related to job-related skills.

Psychometric evidence of reliability and validity is tenuous for these employment prescreen methods. Reliabilities in the .80s and .90s have been reported for the polygraph between graduates of the same training program, but reliability drops significantly for more heterogeneous groups of polygraph operators. Likewise, the percentage of accurate response (validity) reported for polygraph use is presentable but the research designs do not correspond to the realities of employment situations (i.e., accuracy is assessed in circumstances when all subjects have some piece of information to hide and accuracy is equal to the hit rate for an operator in identifying the deception). In most employment situations, the operator doesn't even know what areas of the individual's history include deceptions, and very few applicants in the

85

total applicant population may have some employment-related
problem to hide. Demonstrated validity for voice stress
analyzers is even lower, and again, is determined in situ-
ations not analagous to employment settings. Sackett & Decker
(1979) review the reliability and validity data on all three
techniques in some detail, and conclude that the techniques
are fairly widely used in criminal investigations and employ-
ment selection decisions, but the validity data that exist
are inadequate to support the use of these methods for
selection.

In sum, most of the comments that can be made about the
use of detectors of deception are in the form of cautions.
Before implementing polygraph tests as employment prescreens,
one should be sure to check state law. Use of the polygraph
is currently restricted in 15 states, with 19 states requiring
licensing for all polygraph operators. There are also ethical
considerations in the use of such devices. Is the polygraph
an invasion of privacy, as is argued about personality tests?
Can one decide that someone is lying on the basis of a test
of unknown validity in the employment setting? These two
questions bring us to an issue at the heart of any application
of detectors of deception: Are these methods valid in an
employment setting where base rates of deception are low?
Virtually all research on the reliability and validity of
detectors of deception has been conducted in actual or simu-
lated criminal investigations. The ability of these data to

be generalized to low base rate employment situations is, as yet, unproven.

Table 9 summarizes reliability and validity data on application blanks, resumes, recommendations, work samples and simulations, thought samples, and detectors of deception. These data are less voluminous than those for the interview and the psychometric test, and are presented together for ease of comparison.

Differential Validity and Test Bias

When considering the merits of using any one of the preceding selection methods, whether from the compliance perspective of a government agency or the pragmatic perspective of an employer, a primary concern is whether their use will result in adverse impact on protected classes of applicants (i.e., .. subgroups identifiable by race, creed, color, sex, religion, national origin, age, marital status or handicap). We define adverse impact as disproportionate hiring of individuals on the basis of their potential job performance. For example, when a hospital accepts applications and selects chaplains who are male and Catholic only, this does not constitute adverse impact on members of other groups, because being male and being Catholic are bona fide occupational qualifications for a position which requires a person to give the last rites to Catholic patient. Other individuals are excluded on the

basis of their sex and religion but that exclusion is job-related. If, however, a hospital refused to consider or hire female applicants for the position of Protestant chaplain, their actions would have adverse impact on women since both men and women can be ordained ministers in most Protestant sects. The exclusion on the basis of sex would not be job-related.

Adverse impact is the visible consequence of what psychometricians and industrial psychologists call test bias. In this phrase the word is used in the very generic sense adopted by the EEOC and other federal agencies charged with assuring use of fair employment practices; a test is any paper and pencil or other measure used as the basis of an employment decision. In the preceding examples the implicit question, "what sex are you?" is the test used as a basis of the employment decision. The phrase test bias is used to refer to unfair consequences of using tests (predictors) as the basis of selection decisions in a real life situation. A test which is used to disproportionately eliminate applicants on a non-job related basis shows test bias. The most visible and socially unacceptable examples of test bias disqualify minorities, the handicapped, etc., from jobs on the basis of predictors (tests) that are not in fact job-related. Test bias may also occur but result in no adverse impact. For example, as an employer, one might arbitrarily decide to hire

only receptionists who indicate on their applications that they are left-handed. This would consititute test bias since being left handed is not job related. It would not, however, constitute adverse impact since no protected classes would be disproportionately eliminated from consideration; all right handed people regardless of subgroup membership would be disqualified. This kind of test bias is not illegal under Title VII of the Civil Rights Act of 1964.

For the purposes of federal agencies, employers and the law, test bias resulting in adverse impact is a serious problem and the driving issue behind compliance reviews, careful choice of selection procedures, and court cases. Therefore, given the preceding definitions and the concerns of our readers, we will focus now on the potential for illegal test bias (i.e., adverse impact) from use of selection predictor measures.

Since test bias refers to unfair consequences of test use it is not surprising that several different authors have attempted to define what is an unfair consequence. As a result there are now nearly as many different models of test bias, defining unfair consequences in different ways, as these are authors who write about test bias. For example, there are 11 models of test bias included in Peterson & Novick (1976), each of which defines fair use of a test differently. Basically what these models do is define what kinds of

selection errors must be minimized for a test to be fair to all applicants. Some authors say that a test must be used to maximize choice of individuals who will succeed; this is a fair use of a test. Others say a test should be used to minimize the likelihood of either rejecting someone who would have succeeded, or accepting someone who would have failed. Still others try to maximize the chances of rejecting a person who would have failed. Even though these do not sound like contradictory goals, each definition of what constitutes fair use of a test implies different statistical corrections should subgroup performance differ on the predictor. Measures taken to prevent test bias vary greatly depending on the model accepted by an organization. To use a test fairly an organization may choose appropriate cut-off scores and select proportions of individuals from subgroups so as to maximize its goal in terms of fair consequences while minimizing nonjob-related disadvantages to members of subgroups.

The Uniform Guidelines on selection practices, as well as their predecessors, have focused on adverse impact and in particular on differential validity leading to adverse impact. The term differential validity refers to a situation where the correlation coefficient between a selection procedure (e.g., test score or information used as a predictor) and job performance is significantly different for different applicant subgroups. In cases where a difference in these

93

validity coefficients exists between subgroups identifiable by race, sex, etc., but the test score or predictor information is used in the same way to select applicants without regard to subgroup differences, test bias and adverse impact results. An organization that does not closely examine its selection procedures for differential validity may end up using its selection procedures in ways which have unfair consequences. However, once a model of test bias has been chosen which targets unfair consequences of test use, statistical corrections can be made and selection cut-off scores set to reduce or eliminate adverse impact from use of the predictor test. Therefore, though differential validity can obviously lead to adverse impact, it need not do so. The potential unfair consequences of differential validity can be statistically eliminated while still allowing for use of the test.

The explicit attention given to differential validity as a cause of adverse impact has blinded many users to the broader issue of unfair test use.(i.e., test bias resulting in adverse impact). It is very important to note that an absence of differential validity does not preclude adverse impact. Consequently, an organization which assumes it is using a test fairly because correlations between tests (or predictors) and performance are equal across subgroups may be in error. If the range or means of predictor scores for

those subgroups differ, setting predictor score cutoffs to select applicants as if the groups were identical will result in test bias; selection without attention to characteristics of the subsample scores (including mean, range or validity coefficient) may also result in adverse impact.

Adverse impact, therefore, results from test bias and may be the consequence of any number of factors, of which differential validity is but one. Thus, as suggested by Fincher (1975) and Schmidt, Berner and Hunter (1973), differential validity may be a pseudo problem that overshadows the problem of test fairness.

Early court cases concerned with discrimination resulting from use of employment tests focused on test bias and differential validity without clearly distinguishing between the two. In the classic Griggs case the courts disallowed the Duke Power Company's test because they were not demonstrably job-related for the blacks who were required to take them to advance, and because they were used in a way that had clearly negative consequences for the black workers. The impression gathered from our sample of employers is that organizations have interpreted the ensuing court cases and public policy as being solely concerned with identifying cases of differential validity even though, as indicated above, differential validity is not necessary for test bias or adverse impact. Nonetheless, policy-makers in business and government have

been rightly concerned with the need to conduct subgroup

analyses and be wary of the adverse impact that may result

if a generalized decision rule for hiring is used to select

applicants from sub-groups whose validity coefficients differ.

Corporate experience and academic research have demonstrated

that differential validity sometimes occurs.* More important

issues are: when and why differential validity occurs; how

the controversy over the existence of differential validity

relates to the central issue of test bias; and what steps are

possible to prevent adverse impact of test use.

We refer to recent writings and opinion on differential

validity as a controversy because the current trend among

researchers is to aggregate individual studies of differential

validity and draw conclusions about whether differential

validity in fact exists at all! Researchers and practitioners

who have calculated subgroup validities and found signifi-

cantly different validity coefficients may be very skeptical

of any research which questions the existence of differential

validity. Nonetheless, a few researchers have examined large

numbers of studies in an attempt to determine if findings of

---

*   For a compete review and bibliography of all such published
    studies of differential validity, see reviews by: Boehm,
    1977; Katzell & Dyer, 1977; Dunnette & Borman, 1979; Hunter,
    Schmidt & Hunter, 1979; Arvey, 1979.)

differential validity are chance occurrences or are indicative of true differences in subgroup test performances. In one such investigation Boehm (1977) examined 31 studies involving 297 comparisons of employment and training selection procedures administered to blacks and whites. Of those 297 comparisons only 8% showed differential validity. A closer look at those studies revealed that reports of differential validity were likely to come from methodological weak studies, i.e., those characterized by small sample sizes, criteria which were not performance measures and/or a weak rationale for hypothesizing that the predictor(s) would have any relationship to the criterion. In sum, she concluded that findings of differential validity were methodological artifacts, and did not reflect any relationships across subgroups. In another study Katzell and Dyer (1977) reviewed 31 studies and concluded that differential validity did occur at above chance levels in those studies but that differential validity did not favor one subgroup over another (i.e., validity coefficients were lower for whites as often as for blacks). Finally, in an extensive study aggregating 866 validity comparisons of blacks and whites from 39 studies, Hunter, Schmidt and Hunter (1979) identified and controlled for methodological biases. They concluded that findings of differential validity were produced by chance and statistical artifacts, and that therefore differential validity probably did not exist in the population.

97

If testing practitioners find differential validity when examining their selection procedures but researchers argue that differential validity doesn't really exist, what can we conclude about differential validity and the potential for adverse impact in employment selection? The recent research suggests that careful design of validation studies may prevent differential validity from occurring. Accordingly careful validation, control, and design may eliminate differential validity as a source of adverse impact. However, we must also remember that elimination of differential validity is not a panacea because many other characteristics of the distribution of subsample predictor scores may contribute to test bias and adverse impact. Nonetheless, if carefully designed validation studies are conducted to reduce the possibility of finding differential validity, then these studies will also provide means, standards deviations and score ranges which can be examined to determine their potential for adverse impact.

The difference models which identify unfair use of a test, and provide a rationale and method for setting cutting scores and selecting individuals fairly from differing subgroups, can be used in combination with a good validity study to guide an organization toward more job-related and equitable selection. Models of test bias reflect selection goals of sufficient diversity to accommodate almost any organizational choice about the kinds of selection errors that constitute test bias. One model (Darlington, cited in Peterson & Novick, 1976) even

exists which allows organizations that wish to consider not only performance criteria, but also employment parity or compensatory hiring of minorities in their definitions of test fairness. This model permits explicit inclusion of such factors in setting cutoffs and making selection decisions which are fair in accordance with the organization's values. Regardless of intentions and choice of policy regarding test fairness, an organization's resources may be inadequate for a good validation study because sample sizes (i.e., job openings) are limited. For this reason, cooperative validity generalization studies make the validation process an even more palatable strategy because they can provide data to reduce adverse impact and enable greater work force productivity at reduced costs.

Comparison of Selection Devices

After a variety of techniques have been described and their research reviewed, it is important to step back and put them into perspective. Recommendations can be made, endorsing certain methods for certain purposes. Table 10 is a tool for doing just that. The techniques are compared on the basis of eight important issues for someone choosing a method for personnel selection: (1) reliability, (2) validity, (3) research support, (4) objectivity, (5) face validity, (6) unique data, (7) cost, and (8) skill coverage. Despite the wide variance in the amount and depth of research on each technique, objectivity, cost, skills covered, and psychometric properties, each of the data collection methods is appropriate to use for certain purposes.

The application blank is commonly used by most companies as it is an inexpensive means of gathering background data, including experience and education. Applicants expect to fill out an application blank, thus face validity is good. Additionally, reliability and validity of certain items can be quite high. The disadvantage of the application blank is that it does not directly measure skills. Therefore, where assurance of skill is critical, the application blank would be deficient by itself as a data base for an employment decision. When the employer has little doubt about applicant abilities (e.g., applicant has a license or degree indicating skill level)

TABLE 1(

Comparison of S⋯⋯ on Techniques

METHOD	RELIABILITY	VALIDITY	RESEARCH	SCOR⋯ CRITERIA	FACE VALIDITY	UNIQUE DATA	COST	SKILL COVERAGE
Inter-views	very specific to situation and inter-viewer; Median Range=.55-.⋯	very specific to situation & inter-viewer; Median Range =.20-.25 for JOB PROFICIENCY; somewhat higher for training	extensive, primarily focused on interper-sonal per-ception and decision formulation	subjective judgement of employer	usually good, de-pending on interview content	provides opportunity to interact with appli-cant and observe in-terpersonal dynamics	moderate to high, depending on amount interview-er time, number of interviews and training	intellectual ability, mo-tivation inter-personal relations
General Intelli-gence Tests	Good; Median Range=.80-.90	Higher va-lidity for managerial and clerical occupations. Median Range =.20-.30 for JOB PROFI-CIENCY; some-what higher for training	extensive	reliable scoring keys	fair depen-ding on job	provides overall ability measure-ment	usually low with stan-dardized tests. In-crease in costs with adminis-tration and scoring time	General Reasoning & Logic; Verbal comprehension & fluency; numerical comprehension & fluency; Spatial Relations
Specific Skills and Abilitys	Specific to instru-ment; Median Range=.65-.80	Higher va-lidity for managerial and cleri-cal occupa-tions; Me-dian Range =.25-.35 for JOB PROFICIENCY somewhat higher for training	extensive for most ability tests. Very little on measures of creativity and judg-ment	rel scc key	usually good depen-ding on job	provides independent measure of skills and aptitudes.	low admin-istration cost; mod-erate to high equipment costs	Separate measures of Verbal ability, Numerical ability, Spatial Ability, Creativity, Psycho-motor Ability

102

(Table 10. continued)

METHOD	RELIABILITY	VALIDITY	RESEARCH	SCORING CRITERIA	FACE VALIDITY	UNIQUE DATA	COST	SKILL COVERAGE
Personality Tests	Specific to instrument. Highest for Interest tests; Lowest for Projective tests; Median Range=.60-.70	Higher validity for sales occupations. Median Range=.20-.25 for JOB PROFICIENCY. Usually lower for training	Extensive research in clinical settings. Much less in industrial settings.	General rules provided for scoring; raters may disagree on ratings	poor	provides standardized information on personality characteristics and interests	low to moderate, depending on test administration time and scoring procedures	Interests, Psychological Traits, Psychological Adjustment
Application Blanks	good; median range .87<r<.97	median range .40<r<.50	quite a bit on items, discrimination, bias	usually objectively coded; depends on how structured questions are	good	not usually, but can ask for goals and self-perceptions (e.g., weaknesses and strengths)	low cost; costs increase with job analysis, keying, continued validating	bio data, job experience, education level
Resumes	not available	not available	none evident	Subjective judgement of employer	good	provides data on style, organization, self-perception	no cost to organization	bio data, job experience, education level, communication ability
Recommendations	not available	standard questions may be valid for some, but not all jobs; when valid .21<r<.29*	very limited	subjective judgement of employer	good	data from ex-boss and friends	very low cost (phone call or request letter)	job proficiency, interpersonal skill

METHOD	RELIABILITY	VALIDITY	RESEARCH	SCORING CRITERIA	FACE VALIDITY	UNIQUE DATA	COST.	COVERAGE
Work Samples and Simula- tions	generally not available, but design suggests good consistency of application and measurement	median range, ver- bal work sample: r= .30-.40, job proficiency r=.40-.50, training; motor work sample: r= .40-.50, job r=.30-.40 training	extensive on validity	criteria are explicit; raters tend to agree on ratings	very good	job per- formance shows com- bination of desire and skill to do job proficiency,	expensive to design, large amounts time, $ to adminis- ter	intellectual ability, inter- personal skills, psychomotor skills (dependir on job sampled)
Thought samples	Not known, but validity coef- ficients sug- gest at least .60	high for management entrepre- neurial jobs: r=.40-.80	extensive on manage- ment and entrepre- neurial jobs	scoring categories are well- defined; scorer agree- ment exceeds .85	good for scoring criteria poor for test instru- ment	motivational competencies	moderate to high cost: protocols must be hand- scored	interpersonal skills (motive dispositions and ego matur- ity)
Detec- tors of Decep- tion	high, but data based on settings not comparable to employment	measured in accura- cy terms which are inappropriate for employ- ment appli- cation	not relat- ed to em- ployment realities	scoring criteria in laboratory settings	poor	data on stress and and atti- tudes	high to mod- erate cost to buy equip- ment and hire trained oper- ator-inter- preter	doesen't cover skills

104

105

and where cost is an issue, the application blank can be a
fairly inexpensive and effective selection tool.*

If an applicant's goals and self-image are important, the
resume is a less structured way to access and expand on this
information. The cost to the organization is minimal and a
resume provides more detail in these areas than does an appli-
cation blank. Little research evidence is available on the
reliability and validity of the resume. Like the application
blank, the resume will seldom be sufficient for making selec-
tion decisions as skills are not directly measured.

In those cases where interpersonal skills or task related
skills are important on the job, recommendations may be a
useful addition to the selection process. These are inexpen-
sive and provide a subjective measure of skills which are meas-
ured more objectively, but also at greater cost, by other
methods. There has, however, been little research on the
psychometric properties of recommendations.

The work sample appears to be an especially useful data
collection method as it can directly assess intellectual,
interpersonal, or psychomotor skills. Psychometric data show
work samples to have high validity and good consistency rela-
tive to other techniques. The cost may be prohibitive,

---

* Though employers often worry credentials such as licenses
  and degrees say something about an applicant's competence,
  Chapter 3 examines this questionable assumption in great
  detail.

however, as work samples generally require large capital expenditures and may be expensive to administer.

Thought samples provide some of the most useful data available in assessing these institutional components of interpersonal competence. This technique, indeed, is the only way in which motives can be measured. In complex jobs in areas such as management that rely on interpersonal skills, thought samples have shown the greatest consistency in predictive validity over time. They are expensive to score properly, but return a long-term selection benefit far out of proportion to the initial scoring investment.

Detectors of deception such as polygraphs have little to recommend them. Their reliability and validity are tenuous; they tend to antagonize the subject. Nonetheless, in situations where the good will of applicants is not a consideration, where false negative decisions (i.e., identifying an honest response as a lie) are unimportant because of the tremendous cost of false positives (i.e., hiring a dishonest worker), then polygraphs (and such) may provide some unique data of utility for that specific decision situation.

Interviews have high face validity in employment situations and may be particularly useful in assessing interpersonal skills. Though reliability is typically lower than many other measures, with only moderate expenditure it can be raised quite substantially. Validity is low when the interview is used to assess skills other than interpersonal. Therefore, when other

skills are required, the interview will be an inadequate measure. The objective coding of interview data as discussed under Thought Samples provides the best potential solution to problems of reliability and validity. Because of the time required to administer an interview properly, its cost may be prohibitive for its utility as a selection device for many jobs. However, if it is used for other purposes as well, such as public relations, the cost may be more easily justified.

General intelligence tests may be appropriate as measures of overall intellectual ability for lower level clerical or managerial jobs. However, specific tests of intellectual ability show approximately the same cost with higher validity. Cost for both measures will be low if a standardized commercially available test is used.

Specific skill and ability tests are available for assessing intellectual or psychomotor skills. These tests usually appear face valid to the applicant and show good psychometric properties. If tests are constructed by the organization for particular jobs, costs will increase substantially. Tests may also show higher validity for particular jobs if the test uses actual job equipment, but, of course, this will also increase the cost to the organization.

Finally, personality tests show relatively low reliability, predictive validity and face validity but may be especially useful in assessing interests. Also, if psychological adjustment is an issue, these tests may be quite appropriate. The

cost of commercially available tests is usually low, but administration time varies quite widely, and may serve as a source of hidden cost. Scoring keys for particular companies can be constructed for many tests. This will increase the cost but will usually raise the validity of the test as well.

In sum, all the selection techniques discussed, even the most questionable ones, have some advantages. Their unique strengths and weaknesses (in terms of the 8 criteria identified above) should all be considered before making a choice of selection method(s).

109

III. THE PRACTICE OF PERSONNEL SELECTION

The previous section has described and compared the major employee selection techniques currently in use. The present section is devoted to the application of these techniques in job situations. Nearly all the literature on employee selection deals with the selection instrument as the unit of analysis, rather than with the job or type of job in regard to which a selection decision is made. The intent of shifting attention to the job as the unit of analysis is to examine the appropriateness of a selection system in which multiple sources of data are considered to identify the most appropriate job candidates. Given what is known of the strengths and weaknesses of individual selection techniques, an account of how these techniques are used as the basis for job selection enables the analysis of how organizations carry out matching applicants to jobs.

This section summarizes an empirical study of employee selection practices in the field. The present study was intended to involve a representative sample of jobs to which selection devices are routinely applied, so that the state of the practice in entry level employee assessment could be ascertained for a wide variety of competencies. This study was initiated by defining a sampling strategy based on a comprehensive but simple job taxonomy which would yield to quantitative analysis. Using the taxonomy as a guide, direct contact was initiated with more

than 100 organizations which were expected to represent the most comprehensive employee selection practices, and to elicit from them as much information as they were willing to share regarding their current and past procedures. Following the description of these procedures, this section presents an account of the state of the practice with regard to key issues in employment selection and a statistical analysis of data gathered on 239 jobs that documents current trends in employee selection.

The Scope of the Study

A prime requisite of this research was a job sampling strategy which would be representative of a cross-section of job functions, since it was expected that the majority of formal competency-based selecton systems would be founded on a rational analysis (e.g., Fine & Wiley, 1971) of the tasks and functions performed by individual jobs. The functional taxonomy developed by Katz and Kahn (1978) was particularly appropriate for the present purpose. These authors described their formal taxonomy in terms of five sub-systems which identify formal operations within organizations, and which may also be applied to describe dominant job functions:

1. Production jobs are based on task accomplishment through technical proficiency. These are jobs in which energy is transformed into output and value is added for the organization.

2. Maintenance jobs are oriented toward maintaining stability and predictability within an organization. This may take

111

the form of preserving existing relationships among other indi-
viduals in the organization, or toward the preservation of the
status quo.

3. <u>Managerial jobs</u> contain the controlling or decision
making aspect of work. People in these jobs coordinate exter-
nal requirements with internal resources and resolve conflicts
among other job functions.

4. <u>Boundary jobs</u> are characterized by their function as
linking the parent organization with their counterparts in
other organizations. Individuals in these jobs carry out the
transactions leading to the procurement and disposal of goods
and services.

5. <u>Adaptive jobs</u> are characterized by their roles in or-
ganization change, including intelligence gathering, research
and development and planning functions. Though these jobs are
concerned with innovation, their primary task is helping an
organization adjust to a changing environment.

The translation of this functional taxonomy of organiza-
tions into a taxonomy of jobs, however, involves adding the
<u>level of skill</u> with which a function is required to be per-
formed as an independent dimension. Accordingly, jobs were
also classified according to whether applicants were relatively
<u>unskilled</u> with regard to the function they would perform in the
job; were <u>skilled</u> or moderately proficient in technical and
procedural aspects of the job, or were <u>professional</u> in their
skill level, meaning that extensive specialized training or
experience was acquired prior to selection. Classification of

each job in the taxonomy by skill level was made on the basis of skill level required of the applicant at point of entry into an organization, rather than on the basis of a skill acquired on the job following a suitable period of on-the-job experience or training provided by the hiring organization.

The next task was to identify employers which had documented their selection systems sufficiently well to be helpful in the present study. It was expected that many employers would resist sharing recent documentation of employee selection procedures for reasons bearing on the proprietary nature of selection procedures, the maintenance of confidentiality of the information source, and questions of compliance with EEOC guidelines. To minimize this problem, the first approach taken was to identify specific individuals within target organizations which had conducted selection research and had presented it in both published and unpublished literature, and other individuals who were otherwise known to the authors through personal or professional contact.*

---

* The identification of contacts through the literature review produced mixed results. A significant number of organizations who are pursuing research on their own selection systems could be traced through articles published in academic journals. However, surprisingly little of value regarding the state of the practice was gleaned from a survey of periodicals devoted to personnel practices in specific trades, careers or professional associations. From a random sample of over 100 such periodicals, not a single article within the last five years could be found in which either a rigorous statistical analysis of selection system practices was undertaken or in which data-based research regarding a particular selection device was attempted. Of those articles which dealt with personnel selection practices, the only data available were anecdotal in nature and not useful to the present study.

113

This procedure obtained access to selection system data on 154 different jobs, from 79 organizations. An additional 85 jobs from 38 organizations were identified through less personal means, including "cold call" contacts with the personnel directors of selected Fortune 500 industrial organizations, and with organizations who had recently advertised employment opportunities in a number of major newspapers, although it was not possible to obtain the same degree of selection system documentation for this additional job sample.

Next, open-ended interviews were conducted with the contact persons within the target organizations. Interviewees were encouraged to provide information about specific jobs for which selection procedures had been documented and to supply that documentation in writing wherever possible. Included in the information sought during this process was a specification of the kinds of knowledge, skills, abilities and other characteristics sought, the types of selection devices that were used to identify them, factors relating to the development and implementation of the selection system, validity and reliability of the system in use, and the number of jobs affected by the process. Data were sought with special emphasis regarding the application of the various sources of selection data discussed earlier, including interviews, objective tests, work samples, simulations and recommendations. As application blanks and resumes are used to gather a qualitatively wider variety of selection data, respondents were asked to indicate whether
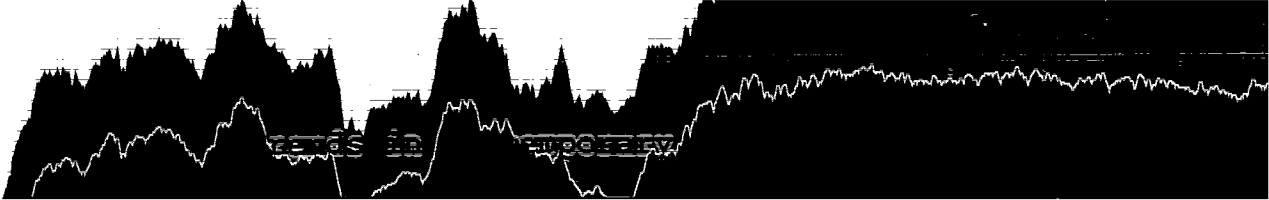

biog[...] [...] [...] [...] r

jobs or education requirements were the important considera-
tions. Additionally, resp[...]dents were asked whether or not a
license was required for [...]   [...] a particular job. No data
were available regarding   [...]e of thought samples or detectors
of deception in the preser   [...]mple.

Table 11 provides a summarized classification of the 239
jobs for which selection system data were available. Approxi-
mately 25% of the jobs in this table were drawn from "Fortune
500" companies, 30% from other sizable businesses in the pri-
vate sector, 25% from the federal and state service, education,
and other public sector sources, and the remainder from miscel-
laneous sources. Note that production jobs comprise the largest
number of jobs classified according to the taxonomy. It appears
reasonable that the majority of jobs that exist are those in
which some amount of value is added directly by the employee to
the product or service. It is also reasonable that the greatest
number of jobs on which selection systems have been documented
are production jobs, since value added provides a more access-
ible validation criterion than do other measures of performance
effectiveness. By contrast, the fewest number of selection
situations involved jobs classified as adaptive, since most
jobs in this category are filled from within the organization
through promotion, or from without through highly individual-
ized means of selection which are beyond the scope of the
present study.

115

TABLE 11

Taxonomy of Jobs Surveyed by
Level and Function: A Representative Summary

Job Function

Skill Level	Production	Maintenance	Managerial	Boundary	Adaptive
Unskilled	assembly line worker cashier nonskilled clerical transportation worker waiter stock checker refinery worker miner cook	file clerk employment rep. aide/orderly inspection worker mechanical worker administrative psychiatric attendant	management trainee store manager statistical manager administrative trainee	duty collector checkout computer checkout salesperson human service worker toll collector library clerk revenue officer truck driver

	109	38	40	116 46	6

Many of these organizations in our sample, particularly those with a long history of selection system documentation provided us with much information about selection practices that would not be reduced to statistical analysis. This section is therefore devoted to some of the more qualitative aspects of employee selection which may serve as an introduction to the qualitative presentation that follows. The concern of this section include the underlying motivation for choosing a given device, the issues and problems that arise with particular selection procedures, and the changes organizations anticipate over the next several years.

First, it should be noted that employing organizations are highly reluctant to share data about their use of employee selection systems. This was not unanticipated, due to the sensitivity and proprietary nature of the information we were selling. However, even after establishing our research credentials through references and correspondence and guaranteeing confidentiality of the data and their sources, nearly 25% of the organization contacted did not wish to contribute to the present study. During our study, we found companies particularly reluctant to share demographic data with us about the applicants. Those who did seem to have data, and were willing to share it, fell into two basic classes: (1) a group of large organizations who were using biographical data explicitly as validated predictors, and therefore were willing to share

applicant characteristics with us; and (2) a group of people who were keeping applicant flow figures, and were in reasonably good positions with the EEOC. Otherwise, companies were particularly defensive and reluctant to give out information about the characteristics of people who went through the process. Their reticence was rooted in a fear that this data could be used against them.

One of the emergent patterns in selection was the use of industrywide selection devices as in the petroleum and insurance industries. In both of these industries, several firms have pooled resources and looked at common needs and selection issues. As part of their cooperative study, these groups examined job analysis, test design and validation. In addition, the petroleum industry has been involved in cooperative studies on validity generalization in hopes of identifying job-related skills and appropriate tests which can be used by the companies within the industry.

When companies described the process of selection in which they were engaged it was revealed that everyone uses interviews. There is, however, great variability as to whether interviews are used as the first screen for an applicant, or whether they are used for a final decision after consideration of other kinds of data such as applications or resumes.

While all organizations reported using interviews, and most organizations reported using skill tests for clerical people, there are other consistencies which emerge in the use of methods

by ind[...] [...]

biogr[...]

insurance industry while public broadcasting companies rely
heavily on resumes and trade publications which post job open-
ings. These trends may be reflective of similarities between
jobs within a given industry and/or may reflect an industry
tradition in terms of selection methodology.

Another trend that emerges in the use of testing as a
selection tool is the reduction in the use of personality and
intelligence tests by most companies, usually for equal employ-
ment considerations. In one case where EEO legislation has had
a visible impact on the company's testing process, the firm has
dropped testing from its selection procedures, instituting post-
hire testing instead. After selection, a person is tested to
see where he or she should be placed within the company. Those
tests that continue to be used for selection purposes are skill
tests which generally have high face validity for the job.
These tests are given at lower levels for skilled and unskilled
jobs, clerical jobs, and hourly workers.

The extent of structure given to the interview process
varies across interviewers, departments and organizations. In
our sample, two interviewers are seldom required to use the same
structure. While great variability exists between interviews
for a single job, variability is even greater across jobs. The
finance department might interview people differently from the
sales department. Another general finding in the use of

119

interviews is that more interviews are required for higher level jobs. A professional level applicant will probably be interviewed by many people whereas for lower level positions, the interview process consists of one interview with someone in personnel.

When we asked companies why they had instituted particular selection processes, it was found that the motive behind the selection process was seldom a desire to understand or identify competence for the job. Usually, the selection procedure had been instituted because of a particular problem, such as turn-over, or because of equal employment issues. The companies seemed concerned about the need to protect themselves from any suit that might be brought against them, as well as wanting to show affirmative action.

One set of issues of particular interest to us was how the organizations identified the criteria for their selection process, and what these criteria were (i.e., specific knowl-edge, skills, abilities, or other characteristics). We found two trends along this line, the first being that, in our sample, rigorous job analysis was clearly the exception rather than the rule. Very few companies had actually conducted job analyses. The second trend was that the domain of job requirements tended to be identified by talking to the hiring supervisor and gener-ating a list of characteristics the supervisor felt to be neces-sary for the open job. One reason infrequent use of formal job analysis could be that organizations tend to think of job

analysis as appropriate for the development of paper and pencil tests, but not as an important step in developing a method to evaluate resumes, application blanks, or as a prerequisite to the interview. Since these latter techniques are more often used than paper and pencil tests, job analysis is less common. The sample was asked how the selection process was originally developed. The practitioners, however, seldom had knowledge of the process development. Typically the process was described as evolving over a long period of time or else it was empirical, not based on a concept of what was important to the job, but rather, on finding items which would empirically predict performance. Organizations with empirically keyed selection tests (such as scored biographical data forms) must continually revalidate them and therefore are more in touch with the development of the process. Trait or skill measures are more likely to be considered logically related to job performance and therefore receive less questioning of the rationale for their use.

The organizations mentioned three other ways their selection procedures were developed. By far the most typical was using published tests that already had established norms as well as documented reliability and validity data for similar jobs. In addition some companies spoke of developing their own inhouse tests. The fewest number of organizations mentioned hiring outside consultants to develop some of the more sophisticated kinds of selection techniques, such as assessment centers for selection or coded interviews.

121

When organizations were queried about the validity of their selection process, it was revealed that few organizations had conducted actual validity studies. Those that had done validation primarily examined the validity of psychometric tests, especially those used for selection into high-level positions. Also tests were more likely to be validated by the company if their relatedness to the job wasn't immediately clear. Personality tests with their low face validity frequently fell into this category. For lower level positions, tests in use were seldom validated. Instead the organizations relied on published validity statistics.

Interviews were also very seldom validated. Only a few companies were concerned with the validity of their interviews because they didn't think of them as selection tests. The only other selection device which has been examined for validity is biographical data. These data were usually validated for particular jobs through keyed application blanks. Other methods, such as recommendations, standard non-keyed application blanks and resumes, tend not to be validated forms for collecting biodata.

When representatives of organizations were asked how their selection process had worked, they relied on anecdotes, face or content validity, as evidence that their ongoing selection process was selecting the right people. They did not rely on more empirically rigorous methods for demonstrating the utility of their selection process. Where there was empirical evidence,

that evidence tended to be gathered for the more complex, or less face valid procedures such as biographical data, personality tests, or assessment centers.

A few organizations reported that the problems they had encountered in the use of various selection processes were that an instrument was not seen as being face valid, or that the selection procedure was not accepted within the company itself, usually because of time c money constraints.

One large trade organization for the insurance industry also stressed that biographical data need to be revalidated over time, since such data could not be counted on to maintain their validity over different years and different applicant populations. This is a problem which is grossly overlooked by organizations using other kinds of selection methods. The biodata's instability over time is a severe problem for that kind of data. We found few organizations outside of the insurance and petroleum industries which revalidated their selection procedures.

Organizations involved in validity research stress misuse of selection procedures as a problem. They found it difficult to conduct adequate research because operating groups often selected individuals on the basis of an unvalidated pilot instrument. Cost was also a hindrance for some sophisticated procedures such as assessment centers. This was particularly true when large capital outlays were necessary, and techniques were unfamiliar or nontraditional.

Our sample reported that data from selection procedures were usually maintained in company personnel files. Some companies

kept data in regional or central files with the intention of doing later research. Many organizations were sceptical about inquiries around the use and maintenance of selection data files. We can only assume that this scepticism arose from EEO concern. Most organizations reported no further use of selection data but those that did responded that the data were most often kept for one of three purposes: for maintaining compliance records (EEOC and Affirmative Action), for giving feedback to the applicants, or for validation on the instrument or selection techniques.

Organizations were asked what changes they anticipated in their selection process. Several companies predicted a trend toward increased job analysis, increased validation efforts (especially for such devices as the interview), and more behavioral methods of selection. Additionally, one organization spoke of an anticipated need to justify selection and promotion decisions to the applicant. In the past this had not been required but the anticipation seems reasonable.

When asked whether educational credentials were used as part of the selection process, those organizations that did use or consider educational credentials, did so primarily for high-skilled jobs. Organizations seldom specified either the validity of the educational credential as a predictor of job competence, or the weight given to the information about education when making a selection decision.

Analysis of Trends and Practices

The following data were noted for each of the 239 jobs,
outlined in Table 11, to permit a systematic quantitative
analysis: the taxonomic job classification (job function and
level of skill required), the sources of data considered in
making the selection decision, changes in use of each data
source over time (e.g., whether the data source increased,
remained constant, or decreased in use), and whether the data
source had been validated with respect to the job by the hiring
organization.

Based on supplementary information and notes taken during
the interviews the generic competencies required by the job
were also recorded. These competencies fell into three broad
groups: (1) intellectual competencies, including technical
knowledge problem solving, planning and organizing, and ab-
stract reasoning; (2) interpersonal competencies, including
communication, leadership, counseling, teaching skill and
self-presentation; and (3) psychomotor competencies, includ-
ing manual dexterity, agility, physical strength, eye-hand
coordination. and speed and accuracy. Each job was coded by
whether it required one or more of the competency group rather
than whether an employing organization selected for these
competencies.

Table 12 presents a summary of the descriptive statistics
regarding the use and validation of eleven sources of selection
data. The interview was, by far, the most frequently used

TABLE 12

Use and Validation of Selection Data

Source of Data	Frequency of use	Validated use	As percentage of frequency of use: (Decreased Use / Constant Use / Increased Use)		
1. Interview	73%[1]	7%	(0%	97%	3%)
2. Skill and Ability Test	38%	35%	(5%	92%	3%)
3. Work History	38%	3%	(0%	100%	0%)
4. Education	31%	5%	(18%	82%	0%)
5. Biographical Data	21%	33%	(8%	89%	3%)

source of selection information. The figure of 73% is in all likelihood a low estimate of the number of times both formal and informal interviews are conducted, to screen employees, given Scott's (1961) figure of 98% in his study of interviewing practices and the observation that many of the respondents in our sample did not volunteer information about use of the cursory personal interview. Data from skill and ability tests and from work histories, are therefore probably considered less than half as often as the interview. Despite the interview's popularity, or perhaps because of it, the interview was among the least well-validated sources of information used in making a selection decision. Among the sources of selection data listed, work history, educational background and recommendations were also frequently used yet seldom validated. The most widely validated source of information was the personality test, due mainly to the fact that most employers relied on published validation statistics to justify their use. Skill and ability tests and biographical data were two additional sources of information that were frequently used and relatively well validated in the field. The performance simulation, largely because of its complexity and the expense involved in its administration, received significant field validation, despite its infrequent use.

The remaining data in Table 12 are devoted to trends in the use of the various data sources. As a rule, the use of data sources has remained substantially unchanged for each selection

system. Nevertheless, conclusions may be drawn from the pro-
position of instances in which the use of a particular data
source was increased or decreased over the life of a selection
program. Specifically, the educational requirement and the
personality test show trends toward decreasing use, undoubtedly
reflecting recent court decisions striking down educational
requirements as unnecessarily discriminatory and personality
testing as not demonstrably relevant to job requirements. In
the absence of trends toward the increased use of other data
sources, one can conclude (1) that the selection interview, due
to its mere pervasiveness, is being counted upon more and more
heavily in making the final selection decision, even though it
is among the least reliable and valid of the selection
techniques; and (2) that the use of credentials and personality
test, though viewed as important sources of selection data, is
simply being discontinued for fear of reprisal in the courts.

Somewhat surprisingly, few differences in the use of par-
ticular data sources were found between major job functions.
The data in Table 12, therefore, present a largely accurate
picture of the use of data sources for production, maintenance,
managerial and boundary jobs. A few differences by job func-
tion, however, were obtained at statistical levels of signifi-
cance ($p < .01$). Skill and ability testing was nearly twice as
prevalent among maintenance jobs than among others, and educa-
tion and simulation data were considered twice as often for
managerial jobs than for production, maintenance or boundary
jobs.

Table 13 illustrates the characteristics of the job sample
in terms of the competencies required by the job according to
job function and skill level.* In the analysis of competen-
cies by job function, the majority of managerial and adaptive
jobs in the sample require some specified level of intellectual
competence; the majority of managerial, boundary, and adaptive
jobs were found to require interpersonal competence; and pro-
duction and maintenance jobs largely require psychomotor com-
petence. The second part of Table 13 shows the data collapsed
across job functions and examines required competency broken
down by the skill level specified by the job requirement.
The great majority of unskilled jobs require psychomotor
competencies to the relative exclusion of intellectual-
interpersonal competencies, while jobs designated as skilled
lean toward the requirement of psychomotor competencies but
are, in the main, more balanced in their requirements of the
three generic competency groups. The professional skill level
jobs in the sample require a much higher degree of intellectual
competencies than interpersonal or psychomotor competencies,
although these last two competency groups are significantly
represented. Considering all jobs in the sample together, the

---

* Note that the percentages listed which are percentages of
  the row total exceed 100%, since many jobs are represented
  under more than one competency.

TABLE 13

Characteristics of Job Sample: Breakdown by
Job Type and Skill Level by Competencies Required by the Job[1]

Competency Required by Job

Job Function	n	Intellectual	Interpersonal	Psychomotor
Production	(109)	36%	9%	92%
Maintenance	(38)	34%	24%	68%
Managerial	(40)	65%	85%	0%
Boundary	(46)	28%	78%	3%
Adaptive	(6)	100%	83%	17%
All Jobs	(239)	41%	39%	59%

Competency Required by Job

Skill Level	n	Intellectual	Interpersonal	Psychomotor
Unskilled	(69)	10%	26%	74%
Skilled	(107)	34%	46%	58%
Professional	(63)	86%	43%	44%
All Jobs	(239)	41%	39%	59%

[1]Percentages are based on proportion of row totals

competency representation, although favoring psychomotor competencies to some degree because of the large number of production jobs surveyed, appears reasonably balanced.

With these descriptive statistics as background, trends in the use of particular selection data were examined by the level of skill and the competencies required by each job. Table 14 presents these data for the eleven data sources of the previous table. A consistent finding is that the frequency of use of selection data varies directly with the level of skill required in the job. This finding is consistent for the interview, work history, education, recommendation, past performance and license. Skill and ability tests show the only significant departure from this trend: employers who seek professional level skills tend to shun objective testing in general as a method for ascertaining competency, while significant numbers of employers who are hiring unskilled and skilled employees may not be able to assume the presence of minimal skills or abilities in applicants and therefore find skill and ability testing to be useful additions to a selection system. However, with all sources of selection data taken together, the median number of data sources considered across jobs is 1.3 for unskilled jobs, 1.8 for skilled jobs, and 3.3 for professional jobs, a highly significant linear trend in the use of selection devices with particular emphasis in professional-level jobs.

The final tables in this section illustrate the likelihood with which sources of selection data are used for jobs requiring intellectual, interpersonal or psychomotor competencies. As

TABLE 14

Frequency of Selection Data Use Related to
Level of Skill Required in Job

| Source of Data | *LEVEL OF SKILL* | | | Significant |
	Unskilled	Skilled	Professional	Trend
1. Interview	65%	70%	86%	linear (p < .01)
2. Skill and Ability Test	36%	50%	13%	nonlinear (p < .001)
3. Work History	22%	12%	67%	linear (p < .001)
4. Education	20%	22%	49%	linear (p < .001)
5. Biographical Data	28%	20%	18%

the use of selection devices was shown to be related to skill
level, which was itself correlated with type of competency re-
quired by the job (see Table 13), the figures in these tables
were adjusted for the correlation between level of skill and
competency requirements. Table 15 shows the relative degree
to which a source of data will be employed as a function of
whether or not a particular competency is required by the job.
It is evident here that work history, education and simulations
are more likely to be considered when intellectual skills are
required than when they are not; skill and ability tests are
the only devices that are by themselves more likely to be used
when interpersonal skills are required; and skill and ability
tests and licenses are more likely to be considered when psycho-
motor competencies are at issue.

In most cases however, it is likely that more than one
source of selection data will be used, so it is necessary to
examine which data sources tend to be used together most often
in selecting for certain competencies. To this end a discrim-
inant analysis was performed for each of the 11 sources of data
considered by whether or not a specific competency was required
for the job, and Table 16 presents the results. Taken together,
education and simulation data are more likely than chance to be
considered in selecting for intellectual skills while, curious-
ly, skill and ability tests are ignored to a degree greater
than would be expected by chance. Simulations, personality
tests and recommendations were found to be used more often when
interpersonal competencies were required by the job, while skill

-1.121-

and ability tests and licenses were considered less often.
Finally, when psychomotor competencies are required, licenses,
skill and ability tests and work samples tend to be used indi-
vidually or in combination in making a selection decision, while
simulations, personality tests and educational background are
the least likely sources of data to be considered. It is in-
teresting to note that many of the data sources which are like-
ly to be used in selecting for intellectual and interpersonal
competencies are the least likely to be used in selecting for
psychomotor competencies, while those sources of data used in
selecting for psychomotor competencies are correspondingly less
likely to be used in selecting for either intellectual or inter-
personal competencies.

Implications for Educators and Employers

It seems reasonable to expect that the selection devices
used by an employer to make a hiring decision would reflect in
some way the job competencies required of the applicant. In
practice, the degree to which this is true depends on how broad-
ly the job competencies are defined. If one is concerned with
selecting for specific skills, abilities or performer charac-
teristics such as manual dexterity, negotiating skill, the
ability to delegate tasks, knowledge of the latest health care
technology, or planning skill, the state of the practice in
selection is woefully inadequate. The primary reason for

this is not the often low reliability or validity of individual
selection devices, but rather the general absence of job an-
alyses on the basis of which selection devices could be devel-
oped. Selection procedures are chosen without much evidence
that they tap a relevant domain of job-related skills. With
the exception of training programs with practitioner-teachers
(for example, in the health care professions), there is very
little contact between the world of education and the world of
work. That will help educators do a better job preparing
students for life outside the classroom.

In reality the selection procedures used by most employing
organizations provide little insight into the specific know-
ledges, skills, abilities and characteristics required for
work. Without job analyses to inform selection systems, it
is surprising that any validity at all can be obtained by most
selection procedures currently in use. If measures of compe-
tency are undertaken at a more general level for selection,
however, some reassuring observations can be made. The present
empirical analysis of the state of the practice was focused
at generic competencies--intellectual, interpersonal and
psychomotor--then specific competencies within each of these
categories. With face validity being a prerequisite for the
use of selection techniques and the nature of inferences drawn
from the data collected through the use of these techniques,
current selection practices are more likely to detect compe-
tencies at the generic level which are related to job

requirements. For example, most jobs classified as boundary positions emphasize interpersonal competencies (see Table 13), and the selection interview, a device which is sensitive to general interpersonal skill, is used in the majority of employment situations requiring interpersonal skill (disregarding for the moment that the ubiquitous interview technique is used to select for nearly all jobs). Therefore, applicants for jobs which serve a boundary function have a high chance of being assessed on at least one relevant job dimension (interpersonal skill) given current selection practices, even in the absence of a thorough job analysis. Table 17 illustrates specific competencies grouped by generic competency category and measured by the sources of data considered in the previous sections of this chapter.

However, simply because a selection device is particularly sensitive to certain generic competency dimensions, that does not necessarily imply that information related to relevant dimensions will be extracted by the employer in making a final selection decision. One can only estimate the maximum availability of relevant selection data by comparing generic competencies required for a job and the use of a particular selection procedure which has a disposition to focus on these competencies. The data collected on the 239 jobs allowed such a comparison to be made. The generic competency measured by each selection device (See Table 17) was compared with the

required generic competencies of each job to derive an indication of how likely selection systems were to produce data on required intellectual, interpersonal or psychomotor competencies (whether or not these data were ultimately used in making a selection decision). For 95% of the cases in which either intellectual or interpersonal skills are required by the job, selection procedures were used which were appropriate sources of data on these competencies. In only 80% of the cases where psychomotor skills were required, however, did the selection procedures used have the potential to provide useable data in this competency area, due primarily to the fact that the interview, an inappropriate source of data on psychomotor competencies, is used in many of these jobs in preference to more direct measures of psychomotor skills.

This finding raises the issue of using selection devices which have a high probability of yielding data that are inappropriate to the requirements of the job. In reference to the previous example involving selection for psychomotor competencies, it is clear that reliance on the interview as the sole source of selection information may tempt an employer to base a selection for a job requiring psychomotor skills on information related to intellectual or interpersonal competencies which have either a tangential or a non-existent relationship to the job requirements. Indeed, in over 70% of the cases in which psychomotor skills were not required by the job, selection devices were used which had at least the potential of providing

information on such skills. Similarly, in 90% of the cases where intellectual competencies and interpersonal competencies were not required, selection devices were employed which provide data on these competencies. These percentages are probably inflated as representations of the actual use of inappropriate data in making a selection decision, but nevertheless they illustrate present dangers of such decision-making processes. As it is seldom clear even to employers what competencies are required by a job, further errors introduced by the application of inappropriate selection criteria make it difficult to predict whether an otherwise competent individual will pass the selection hurdle.

In summary, the major findings of the present empirical study of data sources considered in making a selection decision are as follows:

(1) With the exception of the personality test, the majority of selection devices and data sources have not been widely validated by employing organizations that use them. The selection interview in particular, though it is used by over 90% of employers, is not only among the least reliable and valid selection devices in existence but is also among the least validated of data sources within employing organizations.

(2) Differences in the use of selection devices do not vary with job functions themselves, but vary with the type of competency required by the job and with the level of skill

expected of the employee at the point of selection. The emphasis on the use of different selection data sources, as a general rule, increases with the level of skill required in the job, independent of the types of competencies required.

(3) General trends in the decreasing use of education and personality testing for employment selections, reflecting court decisions on cases involving employment practices and problems arising from attempts to comply with EEOC guidelines are not balanced either by trends in selection system validation or the increasing use of other selection devices. This suggests both an increasing reliance on other, perhaps less reliable or valid information sources and a lessened emphasis on entry selections in general.

(4) Though in many instances the techniques which are used to select for particular competencies are appropriate to the task, there are significant numbers of instances in which inappropriate sources of data are used to select for certain competencies while other, more appropriate measures are ignored. This appears to be due to both a general lack of good job analysis among the jobs we surveyed and the overuse of data services which are interpreted beyond their limitations.

Discrepancy Between Ideal and Actual Practice

Throughout the preceding pages we have described, analyzed,
and criticized both the research and the practice in competence
assessment for selection. The practice of selection has been
critiqued by comparison with the research on selection methods
and by comparison with more generalized prescriptions for im-
proving employment selection. Research on a variety of methods
has likewise been compared favorably with the ultimate goals of
near-perfect reliability and high validity. While the individ-
ual criticisms and comparisons throughout the text stand on
their own, this is an appropriate point to attempt to tie them
together and make a statement about the discrepancies between
ideal selection through systematic competence assessment, and
the reality of selection practices in functioning organizations.

As early as 1913, Munsterberg was studying street-car
motormen and prescribing methods for improving selection for
that job. At about that same time Otis was doing the basic
research on paper and pencil selection tests which he later
turned over to the Army for the development of the famous
"Alpha" and "Beta" tests used to select World War I soldiers.
Obviously, selection testing is not something new. For more
than 65 years employers been trying to develop devices to
identify people who will be competent workers in the organiz-
ation. Since the very early days of selection testing,

certain practices have been prescribed for optimizing the
validity and utility of selection techniques. It is both
heartening (in terms of foresight) and distressing to notice
how appropriate those prescriptions are to this day.

In 1923 Freyd published a series of three journal articles
in which he outlined in detail the principles and practices
of "Measurement in Vocational Selection." He argued that an
organization should identify that department in which the
greatest savings could be realized from improved selection.
The actual design of a selection instrument should then follow
10 steps.

1. Do a job analysis to identify what leads to success or
   failure on the job.

2. Identify a single measure of the criterion of success.

3. Select a sample. Inexperienced applicants are pre-
   ferred to incumbents. Identify and study age or sex
   differences.

4. Develop an exhaustive list of abilities required for
   the job and recommend procedures for evaluating each
   one.

5. Find or devise appropriate measuring instruments
   (not restricted to tests).

6. Administer the tests and measures under carefully
   controlled conditions.

7. Statistically compare testing results with the
   criterion.

8. Combine multiple measures for maximum correlation.

9. Justify the measuring instruments by comparing their predictive accuracy with selection methods already in use.

10. Only if the comparison is favorable should the new measures be installed, being sure they are properly used. Continuously monitor their predictive accuracy and adjust them to the type of applicant and changes in industrial demands. (Freyd (1923) as cited in Guion, 1965.)

As noted by Guion (1976) these "tenets of orthodoxy" are remarkably contemporary. Throughout this chapter we have made the exact same recommendations. We have criticized many current methods of selection because they don't specifically identify and tap job skills derived from job analyses (1). The criterion for employee selection is often unclear (2). Where criterion related validation is attempted, it is often of the concurrent variety, i.e., incumbents are measured against their current performance (3). Selection techniques often tap only one skill or a small subsample of the skills needed for the job (4,5). Selection procedures such as the interview are not consistently applied to all candidates (6). Statistical validation is avoided in favor of conceptual content validation (7). Decisions are made on the basis of a single piece of selection data such as one interview or an aptitude test (8). Cost benefit analyses are foregone (9) and new methods are quickly implemented (10). Freyd's caveats have gone unheeded to a large extent.

While not all selection instruments have been as rigorously
validated in research as Freyd would hope, academic research in
this area exceeds operational research in volume and quality.
Job analysis, rigorous test design and criterion related vali-
dation, however, have remained relatively uncommon in practice.
This discrepancy between the practice and the research is
discouraging. The methodology for doing all three of these
things is well documented. All that is really needed is time
and money to implement methods already proven by research. The
impact of new research on selection practices would be marginal
compared with that of the employment practice catching up with
the current state of the art.

In his 1976 review of selection practices for the Handbook
of Industrial/Organizational Psychology (Ed. Dunnette), Guion
contends that the aforementioned tenets of orthodoxy are still
contemporary as guides to good selection practice but that
they are often overlooked. He concludes that the 1970 EEOC
guidelines and court rulings in support of validation would
bring more companies back to the rigorous selection practices
prescribed in 1923 and today. While this seems to have been a
logical prediction, and clearly the intent of the EEOC and
Congress, our current data do not bear witness to such a trend.

Factors Underlying the Discrepancy

Considering the ever-growing body of research in employee
selection technology, why has there been so little progress in

the state of the practice? Though typical applications of the
selection procedures discussed yield poor reliability and vali-
dity, carefully managed studies involving job analyses and per-
formance criterion validation have shown that many of these pro-
cedures could be of high utility in employee selection. From a
competency based perspective, predictive validation is the key
to improved selection processes; that is, the data obtained
through a selection procedure should be related in some way to
the competencies required for performance of the job. A demon-
strated criterion relationship is important for choosing a se-
lection process that has utility in prediction (over chance
levels of accuracy) and is cost-effective. Why, then, are
there so few validation studies undertaken to demonstrate these
relationships?

The use of selection procedures satisfies an organization's
need to make a "careful decision". In their own eyes selection
data must first have a face-valid relationship with performer
qualities that seem to be important on the job. In most cases,
this satisfies the organization; studies are seldom undertaken
to test the criterion-related validity of face-valid tests that
reflect employers' assumtions about job-related character-
istics. In addition, the uniform guidelines, despite their
intention to apply fair and consistent standards for the
evaluation and use of selection devices, have made selection
testing less appealing to employers who feel that data used
in making a hiring decision can be used against them in a
discrimination suit. Also affecting the choice of whether or

not to validate is that most employing organizations are simply
too small in terms of jobs and people to make test validation
feasible. Either the costs of such a process are prohibitive
or there are too few people in a given job to make any valid-
ation statistics meaningful. Since many organizations either
ignore the state of the art and remain satisfied with face
validity, see the EEOC guidelines as a threat, or are simply
too small to afford validation, it is a wonder that validity
studies are carried out at all. .

All these trends, however, are counter to the intuitive
notion that good, valid selection should lead to greater organ-
izational performance and productivity. Why organizations find
the trade-offs too great in pursuing this goal seems a mys-
tery. Theirs is, in essence, a reactive mode which suggests
why the state of the practice has not improved over the past 50
years. Despite these factors, a number of organizations in our
sample have persisted in attempting to validate their selection
precedures. Data on those organizations suggest a model for
explaining differences in the nature of hiring organizations
themselves which, in combination with internal and external
pressures on the organization, largely determine whether or not
validation of selection procedures will be pursued. Likewise,
it will be proposed here that the lifecycle of an organization
has a strong impact on the state of the selection and valid-
ation strategies used in that organization.

Wright (1969), Rothschild (1976), and others have related
business planning to certain stages of organization

maturity and strategy. These stages largely characterize the behavior of an organization with respect to the role of management, strategic planning, policies, procedures, and information and measurement systems. Organizations may be characterized by four stages of maturity:

1. The embryonic organization is characterized by small size and initial rapid growth, technological change, and pursuit of customers for its products and services. Leadership in such an organization tends to take an entrepreneurial, seat-of-the-pants approach, and such an organization is therefore highly dependent on the environment for its continued support.

2. A growth organization is still growing rapidly but tends to be larger, better known and established and in a product or service area where new entry by other organizations is more difficult. Management, like the organization, remains market-oriented and is often torn between fulfilling boundary and managerial roles.

3. A mature organization is still growing albeit at a less rapid rate; holding and defending the products and services it has established is a primary concern. Here the managerial role becomes more administrative and the organization adopts a goal of stability and maintenance of market share.

4. An aging organization is faced with a lessening of demand, competition, and diversity of products and services. Management becomes opportunistic and relatively short-sighted. The goals of the organization are either to harvest the product for all it is worth, or to divest.

The proposition here is that the strategy to validate the use of employee selection instruments is bound together with the emerging organizational character defined by its level of maturity. A second factor affecting the likelihood that an organization will or will not undertake selection validation involves sophistication about testing and selection dthroughout the corporation and in the person of the personnel adminis- trators who choose and use selection methods. Sophistication in the use and design of selection instruments is likely to increase as an organization passes from the embryonic to the growth and then to the mature stage. By sophistication we mean the insight gained from experience with successful and unsuc- cessful selection attempts, as well as formal knowledge of the difficulties involved in defining selection criteria, con- structing predictors, analyzing predictions, and refining the use of the selection device for making equitable job-related employment decisions. Since the personnel function evolves and is elaborated over time as an organization grows (Katz & Kahn, (1978),sophistication in use of selection procedures should grow as the personnel function grows and the personnel staff becomes more specialized.

If you consider for a minute the orientations of organiz- ations at different stages, it is clear that personnel func- tions have an increasing potential over time to help an organ- ization maintain a stable, effective work force as the or- ganization approaches higher levels of maturity. When an

organization is aging, however, the personnel function may
atrophy because there is a decreased need for having, and no
long-term commitment to having, the best work force in the face
of less competition or decreased market share. Nonetheless,
regardless of the stage an organization has reached in its
lifecycle, more sophisticated corporate decision makers and
personnel staff will be informed and presumably more rigorous
in their efforts at design and evaluation of selection
procedures.

Factors outside the organization also come into play in
determining what strategy will be used for selection. One
factor that stands out as an important determinant of the
ultimate selection strategy is whether or not an organization
is monitored by the Federal government or the courts with re-
gard to its past and present selection practices. Monitoring
may come about through past violations of Title VII which have
surfaced in the courts, or by virtue of the organization's
being heavily regulated by government agencies.

Our observations suggest that regardless of the stage of
the organization's maturity and selection and testing
sophistication, if the organization is vulnerable to being
monitored, the strategy it will adopt is to <u>document</u> its
selection practices rather than to validate its procedures or
to continue with undocumented past practices. If one accepts
that the first goal of an organization is survival and the
second goal is growth, then it is unlikely that public scrutiny

of the organization's selection and hiring practices will be countered by amassing voluminous statistics documenting that no adverse impact occurs (i.e., hiring to conform to the 4/5 rule of the 1978 uniform guidelines on selections), but which do not necessarily document the validity of the selection criteria. This trail of paper is essentially a protective measure. Even if validation is to be undertaken ultimately, documentation of present practice, applicant flow, and impact is a necessary protective first step.

Figure 1 shows the logical relationships between stages of organization maturity, external factors, selection and testing sophistication, and the ultimate selection strategy adopted by the organization.

In light of our sample survey and of the factors we have identified above, this figure presents (in the form of Venn diagrams) our basic hypotheses about (1) why and when an organization devotes to a selection (hiring) process is a function of three sets of variables:

1. Stage of organizational development (the life cycle);

2. Visibility of the organization to previously excluded groups, consumers, monitoring agencies; and

3. Personnel and corporate sophistication about testing and selection.

At a very general level of analysis which will allow us to compare corporate resources of various types on one scale, we have identified four different levels of resource allocation to
Figure 1

Combinations of Factors Determining
Resources Devoted to Organizational Selection Practices

The interaction of circular areas depicting stage and the other factors represents
the resources devoted to selection.

In each case the stage of organizational development of life cycle is given.

CASE 1:

(STAGE)   (VISIBILITY)   (SOPHISTICATION)

    When an organization is neither visible nor sophisticated in selection
    practices there is no intersection and no extraordinary resources are
   devoted to selection.
    SELECTION IS AD HOC.

CASE 2:

(STAGE (VISIBILITY)   (SOPHISTICATION)

    When an organization is visible but not sophisticated in selection practices.
    resources will be put into the short range protective stategy of record
    keeping.
    SELECTION IS DOCUMENTED.

CASE 3:

(STAGE (SOPHISTI-CATION)   (VISIBILITY)
    When an organization is sophisticated in selection practices, but not visible,
    resources will be put into efforts to improve the accuracy of predictions of
    methods.
    SELECTION IS VALIDATED.

CASE 4:

(STAGE)(VISIBILITY)
(SOPHISTICATION)
    When an organizaion is both visible and sophisticated it will be under short
    term pressure to protect itself and long term pressure to improve selection
    practices.
    SELECTION IS DOCUMENTED AND VALIDATED.
    Some resource expenditures will benefit both efforts but overall resources
    required will increase.

selection practices. They include: (a) Ad hoc selection which
requires no extraordinary resources to function; (b) Documen-
tation which requires time, money and manpower to record and
maintain demographic data on applicant flow; (c) Validation
which requires time, money, manpower, and a research and
development commitment; (d) Documentation and Validation which
requires a greater resource pool to accomplish both. Figure 1
suggests which level of resource allocation will follow from a
given combination of the three sets of factors we have
identified.

In addition to using the three sets of factors to identify
what level of resource expenditure can be expected in a given
firm, we can hypothesize how visibility and sophistication will
be distributed across stages of development. Given that dis-
tribution we can also predict during which stages the goal of
validating selection measures of competence is likely to be
attained. Thus, on the basis of what we observed in our sample
survey we propose:

1. Visability is low for new, young, embryonic organiz-
ations which have yet to establish themselves in the public
eye or grow to proportions qualifying them for monitoring.
Otherwise, visibility is constant with a slight decline possi-
ble among aging firms that have survived previous monitoring.

2. Sophistication increases as an organization develops
(see Katz & Kahn, 1964), evolving a personnel function and

expanding its influence. This function and its forces atrophy in aging organizations with decreased hiring and less active competition.
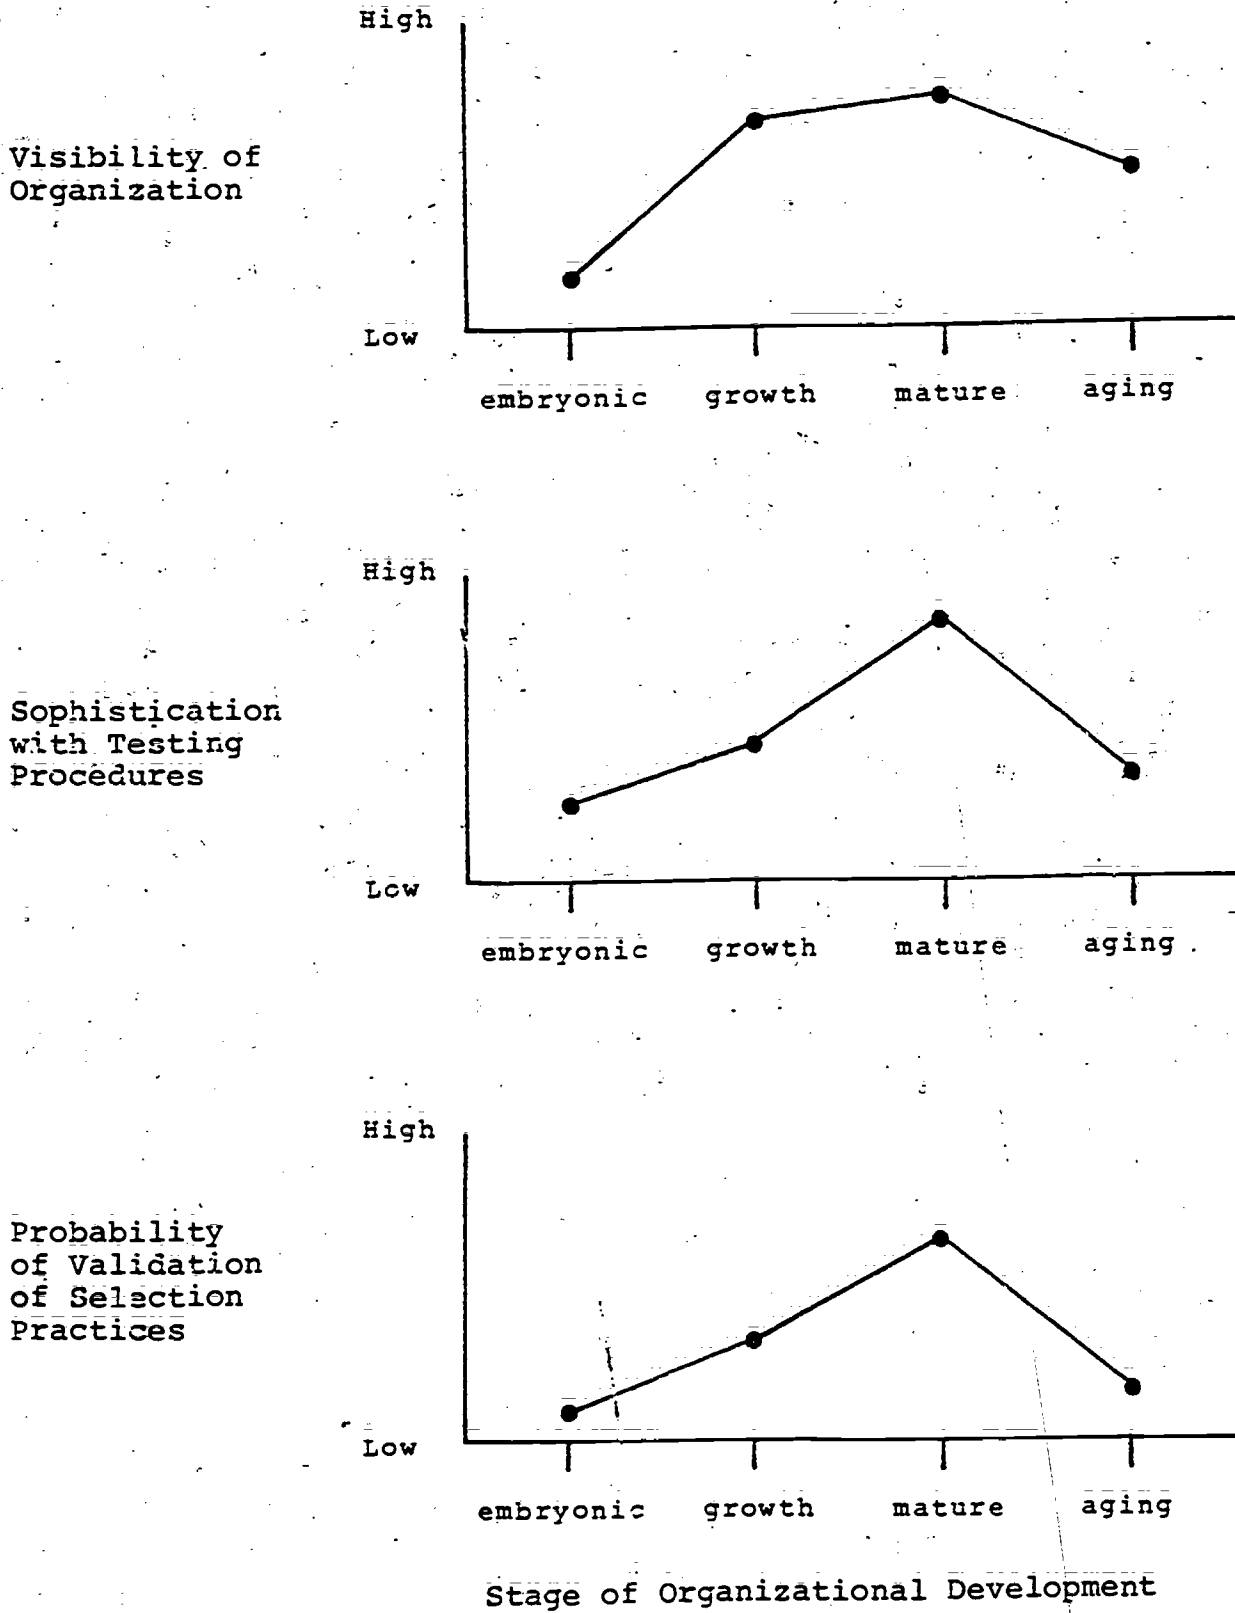

3. Validation (or the documentation/validation combination) is likely to occur in mature organizations most often, followed by growth organizations, and is least likely in early or late stages of an organization's life cycle.

Figure 2 reflects the relative likelihoods of these conditions. The axes on the probability distributions are not scaled because at this point the graphs are only suggestive. These predictions reflect findings from the present state of the practice survey. In general, industries on the decline (for example, supermarkets and railroads companies) reduce their use of formal assessment procedures, while organizations which are both on the increase and have a vested interest in maintaining future stability (for example oil and other energy-related industries, and insurance companies) show an increase in selection research. But even when an organization is mature, growing, and seeking stability, it still must be relatively free of external scrutiny or must also possess a management team with a sophistication in selection procedures which can produce a long-range manpower strategy to support a validation effort. Otherwise the tendency will be either to document past practices or to continue selecting on an ad hoc basis.

This model raises interesting implications for a prescription to change the state of the practice in employee selection.

FIGURE 2

Relationships Between Organizational Maturity and Factors Related to Selection Validation

Visibility of Organization

Sophistication with Testing Procedures

Probability of Validation of Selection Practices

Stage of Organizational Development

As was originally envisioned, the EEOC guidelines were intended
to have a facilitating effect on ensuring validation of selec-
tion procedures while maintaining fairness in hiring. Recent
court decisions, however, have resulted in employers reducing
their reliance on objective testing for selection, turning
instead to less rigorous sources of data such as the interview
and retyping to content validity as their accepted standard for
selection practices. The model suggests that no amount of
Federal policy regarding selection practice will encourage val-
idation programs within an organization unless the organiza-
tion is at a stage of maturity sufficient to foster a sophis-
ticated understanding of the potential of valid tests for con-
tributing to a long-range manpower strategy. Organizations are
indeed looking for good selection procedures that satisfy their
needs for face validity, predictive validity, and fairness, and
would adopt such techniques if they were generally available.
A major block toward adopting such devices is the perceived
need to validate them in each user's organizations in order
that they are job-related. Little incentive exists for
organization to assimilate the latest and most valid selection
practices. Recent advances in selection, documented in aca-
demic journals, do not fit the need of organizations which must
still take the extra step to insure that a new selection pro-
cedure or device will be both valid and fair in its intended
application. The relative costs of valdation for an
organization are high in terms of both time and resources,

presenting a further obstacle to widespread validation within organizations.

Future policy regarding valid nondiscriminatory selection practice should therefore encourage research by creating incentives for developing new procedures and techniques in conjunction with specialists in selection and competency measurement. Cooperative validation projects could be supported in which organizations would work together with employee selection experts to develop reliable, valid and fair measures of competencies required for successful job performance. Indeed much work is currently being conducted in the insurance and oil industries, funded by a number of separate companies and involving outside experts to carry out just this kind of investigation. The incentives for participating organizations would be minimal assessment development costs, and later unrestricted use of the most workable procedures. The benefits to the funding agencies would be dissemination of high quality research practices to a larger set of organizations and more movement toward using job related standards for fair and equal treatment of qualified job applicants.

Implications for Educators, Employers, and Policymakers

Implications for Educators

On the basis of the literature on different selection techniques, a comparison of techniques, and our survey of selection practices in the field, we can draw certain implications for

159

education. For example, employers have grown skeptical of the utility of paper and pencil tests for identifying competent job applicants. While test reliability may be strong, the only moderate validity of tests, the test anxiety of applicants, skepticism about face validity, and corporate anxiety over the need to validate tests have led to a down turn in their use since 1972. The result is that student job applicants are less likely to take a selection test than they are to go through an interview or other selection process which they haven't experienced in school. Two of the most common selection techniques are the interview and the application blank, neither of which taps job-related skills by taking any measurements. Both methods are essentially self-report indicators of skills. An applicant may say he or she knows how to operate a drill press but only a job sample, skill test or check with a former employer can verify that report. An interviewer can assess intelligence and interpersonal skills in the employment interview (with or without using rating scales to indicate his or her judgments), and can also obtain a crude reading on literacy, ability to follow directions, and neatness from the application blank. Seldom, however, are these skills the focus of student preparation for a career.

The preceding discussion leads us to the simple conclusion that the skills which play a critical role in surviving the selection process are largely unlike the skills needed to do the job, nor are they skills in which most students have had any significant preparation. An implication for educators,

therefore, is that students need to prepare for the special demands of the selection process. The job applicant who is best prepared to handle a new job is often ignored in favor of one who is more skillful in responding to the questions of an interviewer. As we have seen, even those jobs requiring only psychomotor skills (contrasted with intellectual or inter-personal skills) invariably require an interview, a technique which is strongest in identifying interpersonal skills. Edu-cational institutions would do well to make their students aware of, or better, to educate their students in, the skills required to survive the job search. Further, as each selection method has the potential to provide some unique information about the applicant, educators should also prepare students to take advantage of each method as a way to convey information about themselves. For example, a neat application blank, a well organized and confident resume, and a relaxed but atten-tive manner in an interview all convey something extra beyond the written or spoken word. Students who have learned to understand these different methods make a better impression on the person charged with the selection decision.

What else can employers tell educators that will help them better prepare students for the world of work? For one thing, educators could avail themselves of analyses of jobs that students are likely to enter upon graduation. However, we should be aware that task analyses, the most common form of job analysis, can supply only a very limited account of com-petence. This is to say that the skills required to perform

job tasks satisfactorily are often quite different from the
competencies that enable one to perform the whole job well. A
nurse, for example, needs to acquire many task-specific
technical skills to perform at a level of basic competence, but
the competencies that supervisors and patients value, such as
personal warmth, keeping cool under pressure, and being able to
handle a number of tasks simultaneously and efficiently, are
not likely to emerge from a task analysis. The example of the
nurse is not different from most other complex jobs in that,
although task analyses can be worded to derive readily the
minimal competencies (competencies needed for survival), task
analyses do not lend themselves well to identifying optimal
competencies (competencies related to excellence). Viewed in
this light, task analyses may not serve the educator well, and
schools which teach only to tasks to be performed in jobs
trivialize the notion of competence.

Competency identification through task analysis is also a
two-edged sword for employers. We have found that relatively
few organizations have conducted adequate job analyses on the
basis of which selection strategies are chosen, even though the
courts have ruled against selection practices that have not
been suggested by such analyses. But it seems that employers
have come to an intuitive realization that job analysis, and
task analysis in particular, does not provide evidence for the
qualities they would like to see in applicants such as integ-
rity, interpersonal skill, intelligence, and initiative, to
name just a few ill-defined characteristics. All evidence.

shows that employers, through the use of a variety of selection
devices and their own decision-making process, are trying to
select for optimal competencies as well as minimal ones.
Unfortunately, organizations do not think in terms of compe-
tencies: They are seldom able to articulate just what these
important performer characteristics are so that educators can
teach them. And, as we have seen, employers are mediocre, at
best, in making selection decisions based on these elusive
competencies. In the general absence of information, all that
educational institutions can do, at present, is guess at many
of the competencies that are implied by job analyses.

The reliance on employers for guidance in curriculum
design, however, can be carried to an undesirable extreme.
The goals of a liberal education must not be confused with the
goals of employment. Imparting job related skills is dif-
ferent from enabling an individual to be a more constructive
participant in society. Current practices of employee selec-
tion are nevertheless driving educational institutions to
provide training more closely related to the demands of the
job, even though there is no assurance that the qualities on
the basis of which one is selected into an organization are at
all redeeming in terms of long-term job or career effective-
ness. Although educators could learn from available job analy-
ses, they would do better to focus on generic levels of compe-
tency which subsume job-related specifics. If more direct
translation between job tasks and a program of instruction were

193

carried out, the result would be a technical school approach
to education which, although a worthy alternative for some
purposes, would do little to forward the goal of creating a
greater awareness of one's environment and development of
skills that help one to adapt to changing situations.

It is our conclusion that, with the exception of
professional and vocational schools, employers are generally
better prepared to impart specific job-related skills, and
educational institutions are better prepared to address
themselves to generic competencies. Indeed, employers, recog-
nizing the limitations of entry selection practices, are
beginning to commit more resources to training and develop-
ment of people already on the job than to selecting people in
advance for the right combinations of skills. Employers can-
not realistically expect new employees to come to them fully
prepared in terms of the skills required for their first jobs.
Within many organizations there exists a current trend away
from selection and toward training and career development as a
way of acquiring individuals who possess the important compe-
tencies for carrying out the work of the organization. This
is certainly a costly method of gaining individuals with the
appropriate mix of skills, knowledges and abilities, but it may
be more efficient in the long run than expecting those combi-
nations of competencies to be available in a job applicant
regardless of previous educational experience. Therefore,
it appears that educational institutions will be asked more
and more to emphasize the development of generic, optimal

competencies. Although educators should be aware of the requirements of the world of work, they would do themselves and their students an ultimate disservice by looking to selection criteria as the only standards against which student performance is to be measured.

Implications for Employers

Current trends in the use of selection techniques, the type of data that these techniques are likely to yield, the reticence of organizations to carry out predictive validation studies and the increased emphasis on training in the job suggest several implications for employing organizations. Employers clearly need to begin undertaking job analyses before implementing any selection screening process. They should begin systematic, empirical documentation of what it takes to do jobs well, rather than the prevalent armchair-theoretic approach to job analysis. Then, documented or undocumented, employers should have a better chance of choosing selection techniques which are appropriate to gathering information on desired job qualities. This is a first step to ascertaining whether hiring decisions made through the use of a given selection program are related to performance in critical job functions.

Employers also need to become more aware of the systematic biases that are introduced into the decision making process by using selection devices that measure factors that are inappropriate and unrelated to job requirements. Employers as a rule

185

tend to overselect for interpersonal skills and general intelligence, characteristics which have great face validity but may not have any positive relationship to job performance. General intelligence, specifically, has been called into question by McClelland (1973), who noted that this construct appears not to correlate with job performance within career areas, including those professions that appear to demand a high degree of intellectual competence. Systematic job analyses will not, in themselves, insure that these biases will be overcome and given the residual unreliability of even the best selection devices administered under controlled conditions, it is unlikely that these biases will be completely eradicated.

Employers should also recognize that new employees will have many opportunities to train the workers for specific positions once they are on the job. The task of selection, then, becomes more one of identifying needed competencies that are unlikely to be developed on the job rather than trying to account for all competencies needed to do the job at entry. A possible outcome of this strategy is providing greater access to jobs by nontraditional applicants, including women and minorities. Under the state of the practice, previous experience in similar jobs is a powerful factor that determines whether a person will be hired; to cite an example, sales is one area where previous experience weighs in favor of the applicant, regardless of the competence demonstrated by the applicant in previous employment experience. Some of the

minimal competencies required (e.g., product knowledge and knowledge of sales procedures) can be learned ideally on the job, while some of the more critical optimal competencies (e.g., achievement orientation and influence skills) are harder to develop. Employers under most current selection systems over-select for the more easily acquired minimal competencies at entry, placing at a disadvantage women, minorities, and others who have been denied equal access to such jobs in the past.

In theory, there is less likelihood that previously excluded applicant populations possess many optimal competencies to a lesser extent than do the currently favored population. Supporting evidence comes from the experience of the first author in implementing a competency-based sales selection system in a Fortune 500 company. Under the new system, which focused exclusively on selecting for optimal competencies, more women and fewer people with prior sales experience were accepted than was the case under the old system; nevertheless the sales generated by the new applicant group were signficantly greater compared to previous groups, with less than half the employee turnover rate. Not only has the competency-based selection strategy provided greater benefit to the employer, but it has also recognized the distinction between competencies that are developed on the job and those that are needed at entry, while providing greater opportunities for members of applicant subgroups that have been denied access to jobs in the past.

A clear recommendation is that employers and vocational organizations seek to identify the competencies required for the performance of job tasks and then to choose or develop appropriate selection techniques. The competency identification process is not the same as a job analysis. A job yields a listing of general tasks to be performed but does not, in itself, reveal anything about the knowledges, abilities, or other characteristics of the person who performs the tasks well. Rather than to repeat the mistakes of the majority of employers who take only a face validity-based approach to the inference of skills from the job tasks, the most logical approach is to identify, first, those results that a are taken as evidence of satisfactory or outstanding job performance, and then to discover the competencies that are possessed to a greater degree by the satisfactory or outstanding performer than by the less-than-satisfactory job incumbent. Competency "models" of the good performer in the job would supplant job description as the driving force in employment selection. Specifying the most critical job tasks that are performed, and the competencies needed to perform the whole job well, would go a long way toward improving the utility and validity of selection systems. Additionally, this information would be of enormous benefit to educators who find current job classifications and task analyses largely useless in improving a curriculum.

The long-term benefit of competency-based selection to employers extend beyond ensuring that new hires will be able to

perform their jobs adequately. Properly designed, such selection systems would identify training needs for new employees in addition to applicants' suitability for hire. A key shortcoming of selection systems that rely on biograpical data and personality testing is that it is not clear what the individual can do to develop the needed characteristics, since these sources of data rely heavily on things the person has reported doing in the past. By contrast, the direct measurement of key competencies tells the employer in a straightforward way if the applicant displays the characteristics associated with success and where the skill gaps are that can be developed. Therefore, this new approach to selection is more likely to indicate training needs rather than fixed characteristics.

Implications for Policymakers

The public endorsement of equal employment opoortunity has been received and implemented in ways which imply two different public policy goals. The first and most common interpreation of this endorsement is to see public policy as encouraging and enforcing employment parity, or employing equal or proportional numbers of majority and minority group members. The second interpretation of EEO policy is to see it as encouraging productivity by selecting employees with job-related skills regardless of workers' group status. Both of these policy positions are implied by the often conflicting messages of the courts and enforcement agencies. Which is the intended policy? Once the

Federal Government makes a policy choice between employment

parity and productivity, different action steps exist for reach-

ing either of these goals.

The interpretation that the primary goal of public policy

is to encourage employment parity is not congruent with what

Justice Burger identified as the intent of Title VII of the

Civil Rights Act. When he wrote the landmark Griggs decision,

(Willie S. Griggs, et al, v. Duke Power Co. Supreme Court Case

124, October term, 1970. Opinion delivered March 8, 1971), he

said:

> "Nothing in the Act precludes the use of testing or
> measuring procedures; obviously they are useful. What
> Congress has forbidden is giving these devices and mechan-
> isms controlling force unless they are demonstrably a
> reasonable measure of job performance. Congress has not
> commanded that the less qualified be preferred over the
> better qualified simply because of minority origins. Far
> from disparaging job qualifications as such, Congress has
> made such qualifications the controlling factor, so that
> race, religion, nationality, and sex become irrelevant.
> What Congress has commanded is that any tests used must
> measure the person for the job and not the person in the
> abstract."

Unfortunately, and not surprisingly, the public, including

many employers, have come to think of equal employment oppor-

tunity in terms of rigid affirmative action goals, consent

decrees with minority quotas, and the four-fifths (4/5) rule

for identifying job discrimination (as described in the 1978

Uniform Guidelines). Employers suspect that compliance offic-

er are vigilantes eager to punish businesses that don't "have

their numbers up." They therefore protect themselves by

hiring members of protected classes (i.e., individuals identi-
fiable on the basis of race, creed, color, sex, national ori-
gin, age, handicap, marital status). This has often resulted
in resentment by employers who feel that they have been pres-
sured to hire individuals on the bases unrelated to job
skills. In essence, this trend results in selection that is
not performance based. Resources are devoted to documenting
demographics of the work force. Thus the current practice of
using federal compliance officers for monitoring of organiza-
tions does not contribute to improved job-related selection (as
identified by Burger), but rather to employment parity which
could as easily be accomplished by an unbiased lottery! If
simplistic employment parity is the government's policy goal,
then current mechanisms should continue to operate unchanged.

On the other hand, if the intent of Congress and the public
is to encourage job-related and unbiased selection, then the
policy goal really is one of productivity. Job-related selec-
tion is related to productivity in the sense that improved
performance-based selection can upgrade skills of a work force,
reduce needed training resources, decrease attrition by workers
who don't fit the job, and reduce the expense of replacing
incompetent workers. Prescreening for competence to do a job
is cost effective in terms of the reduction it effects on those
later, online expenses. These kinds of improvements or pro-
ductivity gains are obviously of value to all employers and
thus ultimately to the nation. The Commerce Department,

Government Accounting Office, and a cabinet level committee
have all devoted time and resources to the issue of pro-
ductivity. In a 1979 report to the President by the Council
of Economic Advisors, the productivity issue arose as an
important concern for government and policy. As described
above, fair employment practice laws and validation of com-
petency measures for selection have great potential to contri-
bute to a policy of encouraging productivity, but as currently
understood, enforced and practiced, they are presently not
contributing much. Current enforcement has had the effect of
organizations resorting to employment parity strategies, those
organizations that have chosen to implement criterion-related
validation being in the distinct minority. Clearly new strat-
egies need to be adopted if public policy is to encourage
productivity through fair employment practices and selection
validation.

One inexpensive procedure for improving productivity is
to elucidate the policy of validating competence measures by
preparing and distributing an informational pamphlet to
employers. The return on investment for putting dollars into
validation of selection measures is real. Examples exist of
organizations greatly reducing turnover costs with valid
selection strategies. For those organizations which are
too small in size or unwilling to devote resources needed,
cooperative studies and validity generalization studies are
low-cost options. While the potential impact of this
information sharing is unknown, more employers might be

encouraged to validate selection procedures if validation were phrased not in terms of public policy and social justice, but rather in terms of the employers' self-interest with regard to productivity, return on investment, and the bottom line.

More active efforts could exist to encourage validation of competency measures to use for selection. For example, it is not unreasonable to think of job competency test validation as an investment for which the Internal Revenue Service could give credit. Currently, all personnel system efforts are business expenses, but documentation of applicant flow is not likely to improve an organization's productivity. While efforts to meet the four-fifths (4/5) rule are not investments, money and man-power resources put into design and validation of a selection measure of job competence is an investment in improving the business's productivity. Perhaps some system of allowing investment tax credits for rigorous design and validation of selection strategies could be an incentive for increasing validation (and ultimately productivity).

Small companies without sufficient manpower, expertise or resources for the level of validation effort necessary to earn an investment tax credit could be encouraged to take advantage of other options. For example, organizations with limited resources might be able to qualify for smaller credits pro-vided they invest in and cooperate in a study of similar jobs within one industry, across companies. Cooperative studies for validity generalization is the trend of the future. Organizations with small numbers of jobs can band together with

other organizations, establish the similarity of their jobs,
statistically correct for restriction of range and other sample
biases, and thereby establish the validity of a procedure to be
used for selecting competent applicants. Small businesses who
participate in such cooperative efforts might be enabled to do
so with the assistance of low-interest SBA loans. This is
another possible incentive which could persuade organizations
to invest in validation.

As already suggested, using federal compliance officers to
monitor organizations with high visibility (to government, pub-
lic or consumer) is not sufficient to bring about validation of
selection systems. Information, appeals to the "bottom line"
logic of managers, and financial incentives may facilitate more
validation. Another possibility would involve efforts to up-
grade the expertise of corporate personnel staff in the area
of test design and validation. As one study revealed, the
level of corporate expertise in these areas seems to be re-
lated directly to the amount of effort organizations put into
validation. While organizations without personnel selection or
measurement expertise may hire external consultants and finance
selection research and development, one way to increase the
number or organizations validating might be to build their own
staffs. For example, the Federal government could mandate or
finance fellowship programs to provide personnel managers or
corporate decision makers with an opportunity to develop some
knowledge of or expertise in design, validation and use of

selection measures. On the basis of that knowledge, they could then direct their own organizations in these areas or make a more informed choice to employ qualified external consultants.

When considering policy options and the wisdom of validating, it is important to remember that an organization which chooses to aim for productivity and job-related, validated selection, is also choosing methods which can be used to detect and eliminate adverse impact, as indicated by the earlier discussion of differential validity and test bias. Organizations which are primarily concerned with equitable unbiased selection of previously disadvantaged groups might best serve that goal by vigorous design and validation of competency measures for selection. At the same time they will increase the probability of hiring a competent, productive work force.
