## ABSTRACT

This report presents a statistical portrait of the demographic, social, and economic characteristics of American children and youth. The source of the data in U.S. government sources includes surveys, censuses, and vital statistics. In general, children are defined as persons under 14 years old, and youth as persons 14 to 24 years old. Exceptions to these age divisions sometimes occur in the report because of data restrictions by age. The analyses trace changes among children and youth in the areas of population growth and distribution, migration, education, family and marital status, living arrangements, fertility, mortality and health, labor force participation, occupation, income and poverty status, voting, and crime and victimization. Some historical perspective on the current socioeconomic conditions of American children and youth is also provided in the report. Selected topics are examined in time series beginning with 1950; trend data for other subjects are shown for a more recent time span. Some highlights of the report include the following: (1) in 1980, 92 million people (or about 4 out or every 10 Americans) were under 25; (2) a general movement away from, early marriage has been noted in recent years; (3) 53 percent of all children under 18 in 1980 who were living in families had mothers in the labor force; (4) 43 percent of children under 6 had mothers who were working or seeking work; and (5) 50 percent of youths 18 to 24 voted in 1972 while only 40 percent voted in 1980. (Author/RM)

## ACKNOWLEDGMENTS

This report was prepared by Jerry T. Jennings, Demographic Statistician, under the direction of Martin O'Connell, Chief, Fertility Statistics Branch, Population Division. Publication review assistance was provided by Rosa B. Taylor. Katherine Italiano provided secretarial assistance and statistical assistance was provided by Mary Hawkins. Overall supervision was provided by Arthur J. Norton, Assistant Division Chief (Demographic and Social Statistics Programs), Population Division. Diana Harley, Statistical Methods Division, performed the statistical review of the text.

Appreciation is also expressed to the other Government agencies whose data were used in this report, including the Bureau of Labor Statistics, Law Enforcement Assistance Administration, the National Center for Education Statistics, the National Center for Health Statistics, and the Office of Education.

# Characteristics of American Children and Youth: 1980

#### INTRODUCTION

This report presents a statistical portrait of the demographic, social, and economic characteristics of American children and youth. Data are compiled from U.S. Government sources: surveys, decennial censuses, and vital statistics. The majority of the data have been published previously in Bureau of the Census or other governmental reports but are consolidated in this report to provide a readily accessible and comprehensive set of data on children and youth.

The report focuses on the characteristics of persons under 25 years of age. In general, "children" are defined as persons under 14 years old, and "youth," as persons 14 to 24 years old. Exceptions to these age divisions sometime occur in this report because of data restrictions by age.

The analyses trace changes among children and youth the areas of population growth and distribution, migration, education, family and marital status, living arrangements, fertility, mortality and health, labor force participation, occupation, income and poverty status, voting, and crime and victimization.

Some historical perspective on the current socioeconomic conditions of American children and youth is also provided in the report. Selected topics are examined in time series beginning with 1950, trend data for other subjects are shown for a more recent time span.

The statistics in this report pertaining to children and youth update those presented in *Characteristics of American Children and Youth*, Current Population Reports, Series P-23, No. 66.

#### HIGHLIGHTS

The following sections of this report reveal that-

- In 1980, 92 million people, or about 4 out of every 10 Americans; were under 25 years old. Approximately twothirds of these children and youths lived in metropolitan areas, predominantly in the suburbs.
  - Approximately one-half of all children 3 to 5 years old in 1980 were enrolled in either nursery school or kindergarten, up from 29 percent in 1966; 37 percent of the children enrolled in these preprimary school programs in 1980 were in privately controlled schools.

- A general movement away from early marriage has been noted in recent years. Among women 20 to 24 years old in 1980, 50 percent were single, compared with only 28 percent in 1960; the corresponding proportions for men were 53 percent in 1960 and 69 percent in 1980.
- Young wives 18 to 24 years old in 1979 expected to complete their reproductive careers with about 2.2 births per woman, a sharp decline from 2.9 births per woman expected by wives of this same age in 1967. In addition, 55 percent of the wives in 1979 anticipated having only two children during their lifetimes, compared with only 37 percent of wives in this age group in 1967.
- The infant mortality rate in 1978 was 13.8 infant deaths per 1,000 live births, approximately one-half the rate recorded in 1960. Large and persistent differences exist between Whites and Blacks, with the infant mortality rates in 1978 being 12.0 and 21.1 per 1,000 live births, respectively.
- Fifty-three percent of all children under 18 years old in 1980 who were living in families had mothers in the labor force; 43 percent of children under 6, years old had mothers who were working or seeking work.
- In 1979, 9.7 million children under 18 years old were living in families with incomes below the poverty level.
   This represents approximately 16 percent of all children under 18 living in families.
- The proportion of young people 18 to 24 years old who voted in Presidential elections has continued to decline since 1972, the first year all 18 to 20 year olds were eligible to vote. Fifty percent of these youths 18 to 24 voted in 1972 while only 40 percent voted in 1980.

## POPULATION GROWTH AND DISTRIBUTION

Population growth. On July 1, 1980, the population under 14 years old numbered 46.3 million, representing 27 percent of the estimated total population of 222.9 million (table 1). Although the number of children increased rapidly during the 1950's, reflecting the high birth rates of the post-World War II "baby boom" years (table 2), the decline in fertility

ERIC Full Text Provided by ERIC

7

since the mid-1960's has resulted in a steadily decreasing proportion of children in the population from 30 percent in 1960 to 21 percent in 1980.

Future trends in the population under 14 depend primarily on the future course of fertility. The projected numbers presented in this report are from the Census Bureau's Series II projection which assumes that the average number of lifetime births per woman will be 2.1, a level which is currently consistent with the reported number of births expected by young women. Under this projection, the number of children would rise from about 46 million in 1980 to 53 million by the year 2000 (figure 1). Throughout this projection period, the population under 14 years is estimated to constitute about one-fifth of the total population.

The population of preschool age (children under 5 years old), which was 16 million in 1980, is projected to increase to over 19 million by 1990 but then decrease to about 18 million by 2000 (table 3). The kindergarten and elementary school age population (those 5 to 13 years old) is projected to rise from 30 million in 1980 to 35 million by 2000. The rapid fluctuations in the size of these age groups will significantly affect the future structure of educational institutions in terms of the size of the student population, the need for educational facilities, and the demand for elementary school teachers.

In 1980, American youths 14 to 24 years old numbered 45 million and constituted 20.3 percent of the total population (table 2). This represents an increase of some 18 million persons since 1960, when this age group constituted 15 percent of the population. This increase since 1960 represents the baby boom cohorts of the 1950's and early 1960's replacing the smaller cohorts of children born in the 1930's and 1940's who were 14 to 24 years old in 1960.

The population projections shown in this report for the youth population to 1990 can be viewed with relative certainty because the cohorts have already been born. Projections regarding the course of population change between 1990 and 2000 for this age group, however, are largely conditional on future fertility and hence are less certain.

Under the Series II projections, the population 14 to 24
1990 but then increase to almost 41 million by
1990 but then increase to almost 41 million by
1990 but then increase to almost 41 million by
1990 but then increase to almost 41 million by
1990 but the entire period from 1980 to 2000,
1990 persons of high school age (14 to 17 years
1990 increase slightly by about a 1 or 2 percent, but
1990 persons in this age group (table 4). Between 1980 and 1990, the number of persons age 14 to 17 would decrease from about 16 million to 13 million but would increase to 16 million again by the year 2000. The collection in 1980, would decline sharply to 15 million by 1990 and remain at that level to the year 2000.

Population distribution. Two-thirds of America's children and youths lived in metropolitan areas in 1980, including 28 percent who were residents of central cities (table A), the

Table A. Percent Distribution of the Population Under 25 Years Old, by Residence and Race: 1980

Residence	Total	White	Black
Total	100.0	100.0	100.0
Metropolitan areas	67.3 <i>-</i>	65.5	76.5
Inside central cities . Outside Central	7 י־2	22.6	56.2
citi <b>es</b>	39.6	42.9	20.3
Nonmetropolitan areas .	32.7	34.5	23.5

proportion of Blacks under 25 who lived in central cities was more than twice that of the corresponding figure for Whites (56 percent compared with 23'percent). Conversely, young Whites were much more likely than young Blacks' to reside in the suburbs (43 percent and 20 percent, respectively).

One out of every two persons 5 to 24 years old moved between March 1975 and March 1980; 23 percent of the population in this age group moved within the same SMSA (table 7). Rates of residential mobility over the 5-year period were very high at ages 20 to 24; 65 percent of the population 20 to 24 years old in 1980 reported moving in this period. Persons in their twenties are likely to move as they establish new households, enter or leave the military or school, and enter the labor force. Between 1975 and 1980, a low mover rate of 38 percent was recorded for persons 15 to 19 years old. It is possible that this relatively low rate was recorded for teenagers because their parents, recognizing the often disruptive effects of moving in the final years of school, may hesitate to move the family until the child's high school education is completed.

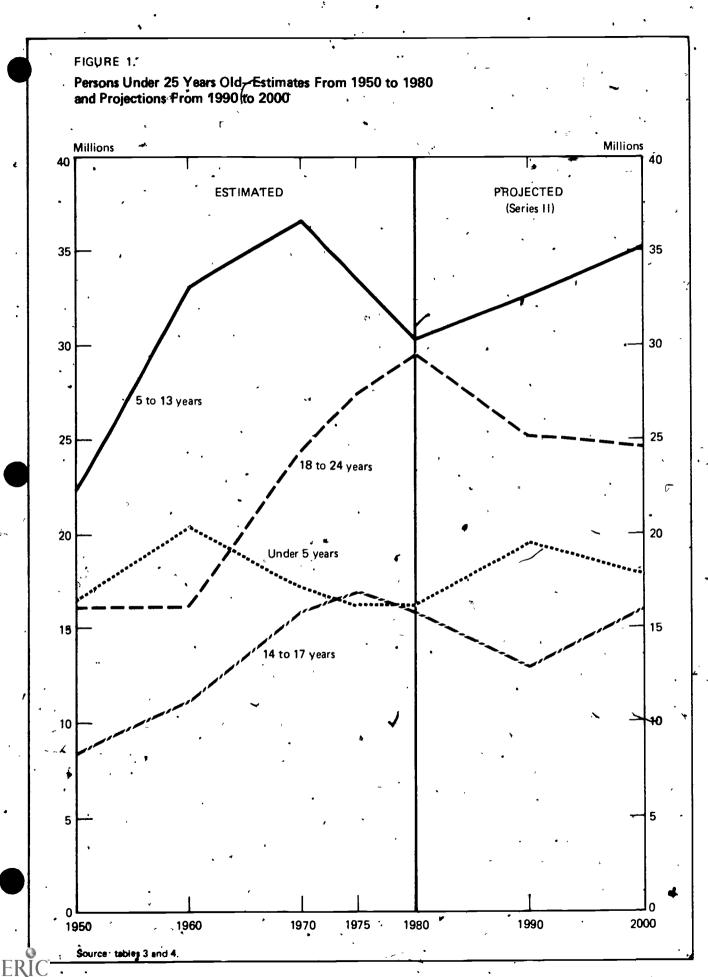

#### **EDUCATION**

Over the 1966-80 period, the number of children 3 to 5 years old enrolled in preprimary programs (nursery school and kindergarten) increased dramatically from 3.7 to 4.9 million despite the decline in the total number of children in this age group (table 9). Consequently, the enrollment rate increased from 29 percent in 1966 to 53 percent in 1980 with little difference noted between White children and Black children (table B). A large part of this increase can be explained by changes in the labor force participation of young

Table B. Percentage of 3-to-5-Year-Olds Enrolled in Preprimary School Programs, by Race: 1980, 1975, 1970, and 1966

Year	Total	- White	Black
		4	
1980	52.5	52.7	51.8
1975	48.7	48.6	48.1
1970	37.5	37.8	34.9
1966	29 4	29.9	27.0

women with children As more young mothers seek employment, they subsequently need more child care facilities for the daytime care of their young children. The enrollment of children in preprimary programs provides the mothers with the necessary child care services to enable them to work. In addition, the increased enfollment may also reflect the parent's desire to prepare their children for later enrollment in elementary school.

in 1980, nursery school enrollment was largely in privately controlled schools (68 percent), whereas kindergarten students were predominantly enrolled in public programs (84 percent) (table 10). The majority of Black nursery-school pupils, were enrolled in public programs (61 percent), while the majority of White nursery-school pupils were in private programs (74 percent).

The number of elementary-school-age children (persons 6 to 13) enrolled in school declined from 32.9 million in 1970 to 26.8 million in 1980, largely because of the continuing decline in fertility throughout the 1960's and 1970's. The number of high school youths (persons 14 to 17 years old) after rising by 900,000 between 1970 and 1975, dropped by 1.3 million to an enrollment of 14.4 million in 1980. However, large increases occurred in the enrollment of the college age population (persons 18 to 24) from 6.7 million in 1970 to 8.2 million in 1980 as the baby boom cohorts passed through this age range.

Among students of high school age in 1980, females were more likely than males to be enrolled in their modal grade (table 12)<sup>1</sup>. Blacks in high school, both males and females, were more likely to be below their modal grade than their White contemporaries. Children in elementary school are more likely than high school students to be in their modal grade, since they are younger and the number of lower grades that they could be enrolled in is limited.

In 1980, about 32 percent of all high school graduates 18 to 24 years old were enrolled in college, a slight decline from 34 percent in 1967 (table 14). However, a gain was recorded in the proportion of Black high school graduates going on to college in the 1967-80 period from 23 percent to 28 percent by 1980; the corresponding figures for White youths declined from 35 percent to 32 percent. By 1980, about 81 percent of all 18-to-24 year olds had completed at least a high school education, B3 percent of Whites and 70 percent of Blacks were high school graduates.

Figure 2 also indicates that post-secondary school education gains between 1960 and 1980 have been greatest for females. By 1980, little difference was noted between the proportion of male and female high-school graduates 20 to 24 years old who had completed at least 1 year of callege (48 and 46 percent, respectively). Back in 1960, only 33 percent of female high-school graduates in this-age group had some college education, compared with 42 percent for males.

Most notable among the changes in the major field of study of college students between 1966 and 1978 is the dictine in the number of education and mathematics or statistics majors and the more than doubling of the number majoring in business or commerce. Majors in the social sciences, however, increased sharply from 642,000 in 1966 to 954,000 in 1972, but then declined to 763,000 by 1978. Engineering, after a decline in 1972, gradually climbed back to about the same level of enrollment in 1978 (565,000) as in 1966 (534,000). The number of law students in 1978 (220,000) was at about the same level in 1972

## MARITAL STATUS AND LIVING - ARRANGEMENTS

Marital status. Delays in marriage among young adults have become more frequent in recent years. The proportion of women 20 to 24 years old who had never married rose from 28 percent in 1960 to 50 percent in 1980, the corresponding increases for young men were from 53 percent in 1960 to 69 percent in 1980 (table C). Black men and women 20 to 24

<sup>1</sup> Figures for 1960 include persons 14 years of age

years old in 1980 were more likely to have never been married than White men and women of the same age; about 47 percent of White women 20 to 24 years old, compared with 69 percent of Black women, were single in 1980. Comparable proportions for White men and Black men in 1980 were 67 percent and 79 percent, respectively (table 21).

Even among 19-year-olds, very sharp increases have occurred since 1960 in the proportions single, especially for women: about 3 but of every 5 women were single in 1960, while by 1980, approximately 4 out of every 5 women had never been married Part of this increase, undoubtedly, corresponds to increasing proportions of women who enter college (figure 2) and postpone marriage

<sup>&</sup>lt;sup>1</sup> The modal grade is the year of school in which the largest proportion of students of a given age is enrolled. It is the expected level of enrollment for a student of a given age.

6,

Living arrangements of children under 18. The increases indivorce during the past decade are evident in the living arrangements of children. Seventy-seven percent of children under 18 years old in 1980 lived in families in which both of their parents were present, a decline from 85 percent in 1970 (table 22 and figure 3). Concomitantly, the proportion of children living with only one parent rose from 12 percent to 20 percent over the same 10-year period.

Living arrangements of children vary considerably between the race groups. Eighty-three percent of White children lived with both parents in 1980 as compared with 42 percent of Black children. For both races, most children who live with only one parent live with their mother. Only about 4 percent of all children in 1980 were reported as living with neither parent, Black children were more likely (12 percent) to be living with neither parent than White children (2 percent)

Living arrangements of persons 18 to 24. The last majority (82 percent) of America's young adults 18 to 24 years old in 1980 lived in families, usually their own or their parents (table 24). Of this age group, 20 percent of the men were husbands maintaining a family and 33 percent of the women were wives in husband-wife families. Both White men and White women were about twice as likely as their Black counterparts to be either a husband or wife. Black women

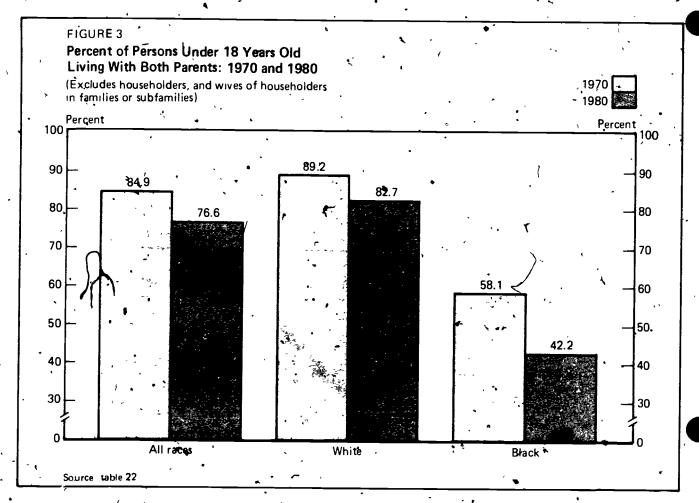

who were family householders with no husband present (15 percent) were almost as numerous as women who were wives (17 percent). Among White women in 1980, only 3 percent were family householders, while 35 percent were wives in a husband-wife family.

Altogether, about 16 percent of young adults were not living in a family situation. Of these, slightly more males (11 percent) than females (8 percent) maintained their own nonfamily households, and a small proportion (about 6 percent) were living in a household with a nonrelative

## FERTILITY

Since 1967, there has been a decline in the average number of lifetime births expected by young wives. For wives 18 to 24 years old, this number decreased from 2.9 to 2.2 between 1967 and 1975 and averaged between 2.1 and 2.2 births through 1979 (table 25). The birth expectations of young Black wives in 1979 were slightly higher (2.4 per woman) than for White wives (2.1 per woman). Similarly, the average number of births to date was higher for Blacks (1.2 per woman) than for Whites (0.8 per woman).

A comparison of the average number of lifetime births expected by currently married women and single (never married) women 18 to 24 years old in 1979 shows that

single women had a slightly lower expected average of 2.0 births per woman than did wives who anticipated a lifetime average of 2.2 births per woman (tables 25 and 26). The difference in the expected completed family size between young single women and married women reflects not only real differences in births to date (0.2 and 0.9 births per woman in 1979, respectively) but also diminishing marriage prospects at later ages and possible delays in eventual family-formation.

The growing preference for the two-child family among young people is illustrated by the data in table 25. In 1979, 55 percent of wives 18 to 24 years old anticipated having exactly two children-during their lifetimes, compared with 37 percent of wives of this age in 1967. At the same time, the proportion of wives expecting to remain childless or to have only one child increased from 7 to 17 percent. These findings mean that in 1979 about 7 out of every 10 young married women expected to have two or fewer children as compared with less than 1 out of every 2 in 1967 (fgure 4). Among single women 18 to 24 years old in 1979, the two-child family was also the size most commonly expected (table 26). However, 1 out of every 6 single women 18 to 24 years old expected never to have any children.

There is reason to be cautious in the use of data on current birth expectations as indicators of long-term fertility intentions of women now in their early years of hildbearing. Although improved methods of family planning may allow

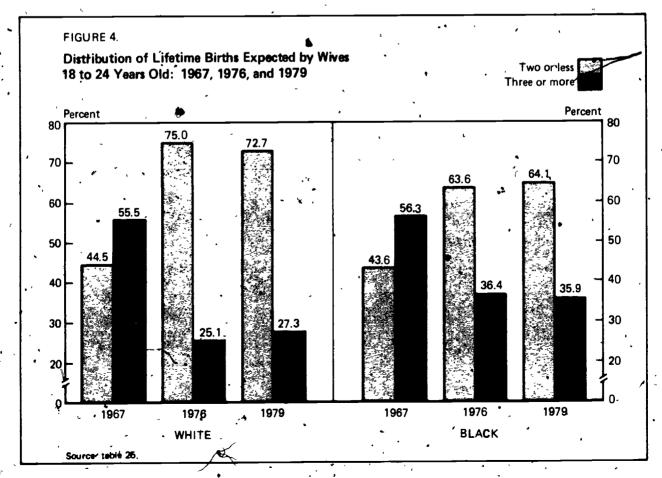

Table D. Out-of-Wedlock Births per 1,000 Women 15 to 24 Years Old: 1950 to 1978

Year	15 to 19 · years old	≠*20 to 24. Years old
1978	25.4	36.1
1975	24.2	- 31.6
1970	22.4	38.4
, 1960	<b>`15.3</b>	39.7
1950	12.6	` 21.3

young women of today to be more successful in having the number of children they expect, changes in personal circumstances and/or attitudes may lead women to change their expectations as they grow older.

The trend in the proportion childless among young evermarried women 20 to 24 years old increased from 24 percent in 1960 to 42 percent in 1976 and showed no change by 1979 (table.27). This increase in childlessness is reflected in the decline in the average number of children ever born to these young women from 1.4 births per woman in 1960 to 0.9 per woman in 1979.

Birth registration data on out-of-wedlock than to teenage women indicate sizable increases since 1950 with a tapering off in the rise in recent years (table D). In 1950, there were 12.6 births per 1,000 unmarried (single, widowed, and

13

divorced) women 15 to 19 years old, this figure rose to 22 4 per 1,000 in 1970 and to 25.4 per 1,000 by 1978. The birth rate for unmarried women 20 to 24 years old, however, followed a very different pattern from that of teenage women: it peaked early in 1960 at 39.7 per 1,000 unmarried women and has fluctuated between 30 and 40 per 1,000 since then.

The ratio of the number of out-of-wedlock births per 1,000 live births has more than tripled since 1950 for women 15 to 19 and 20 to 24 years old. By 1978, the latest year for which data are available, 44 percent of all births to women 15 to 19 years old and 16 percent of all births to women 20 to 24 years old were classified as occurring out-of-wedlock. The proportions are much higher for Black women than for White women; in 1978, approximately 8 out of every 10 births to Blacks 15 to 19, years old were born out-of-wedlock, compared with 3 out of 10 for White women this age. These differences between the two races can be traced to different patterns of contraceptive effectiveness and marriage. As previously shown, young Black women delay marriage to a greater extent than White women.

## MORTALITY AND HEALTH

Mortality. A key indicator of national well being is the infant mortality rate, which is the number of deaths of children under 1 year of age per 1,000 live births. This measure reflects not only the medical attention given to mother and child but also the quality of health delivery services given to different subpopulations in a cociety. Great reductions have been recorded in this indicator among both White and Black population groups, especially since 1960. In 1978, the infant mortality rate stood at 12.0 infant deaths per 1,000 live births for White infants and 21.1 for Black infants; these rates are approximately one half the level recorded in 1960. Throughout this period, however, the level of the Black infant mortality rate has been considerably above the level of the White mortality rate (table E).

Mortality rates for children 1 to 4 years old and 5' to 14 years old'also showed evidence of declines since between 1950 and 1978 (table 30) Death rates for young adults 16, to 24 years old, however, showed little overall change during this period. The rates for this latter group, by race, indicate that White young adults have experienced little improvement in their mortality rates since 1950. However, young Black adults 15 to 24 years old have experienced a considerable improvement in their mortality rates since 1950, although their death rates are still above their White counterparts.

Table E. Infant Mortality Rates, by Race: 1950 to 1978

(Number of infant deaths per 1,000 live births)

Year '	-	Total	White	Black and other races
1978 .	,	13.8	12 0	21 1
1970		20 0	17.8	30.9
1960		26.0	22,9	43 2
1950	·	29 2	26 8	. 44.5

Accidental death was the leading cause of death for children and youths of all ages in 1978 (table F), accounting for about one half of all deaths. Under the major classification of accidents, motor vehicle accidents took the fargest toll, making up 37 percent of all accidental deaths among children 1 to 4 years old, 51 percent among 5-to-14-year-olds, and 72 percent among youths 15 to 24 years old. White youths 15 to 24 years old had a mortality rate from motor vehicle accidents of 50 per 100,000, whereas the rate for Black youths was only 27 per 100,000 (table 30).

Among pre-school-age children 1 to 4 years old in 1978,\* congenital anomalies was the second leading cause of death, the death rate from this cause declined from 11 to 8 per 100,000 population between 1950 and 1978. Although not usually considered a childhood disease, malignant neoplasms (cancer) was the third leading cause of death among children

Table F. Death Rates for the Four Leading Causes of Death Among Children 1 to 24 Years Old: 1978

(Deaths per 100,000 population)

	pneumonia2 9°	Homicide . 13	neoplasms: 6.3

9

1 to, 4 years old in 1978 with a rate of about 5 deaths per 100,000 population. This represents a decline of 58 percent from its level in 1950. Mortality from influenza and pneumonia, the fourth leading cause of death in 1978, decreased by 85 percent during this period to 2.9 deaths per 100,000 population in 1978

Of all the age groups shown in table F, elementary-schoolage children 5 to 14 years old experienced the lowest mortality rate in 1978 (34 per 100,000 population). This is an age when many have already passed the stage of early child-hood and birth-related diseases but have not entered the age group with higher mortality due to the work environment and motor vehicle accidents. Still, at this young age, accidental death was the leading cause of death (17 deaths per 100,000 population), followed by malignant neoplasms (4 per 100,000), congenital anomalies (2 per 100,000), and homicide (1 per 100,000).

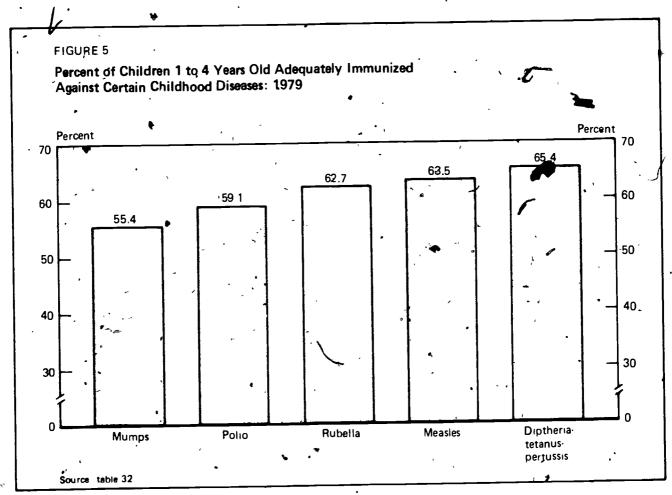

Homicide was the second leading cause of death in 1978 for youths 15 to 24 years old (13 deaths per 100,000) and accounted for 11 percent of all deaths. The mortality rate from homicide for 8lack youths was 41 per 100,000 which was about five times the rate for White youths of the same age (8 per 100,000). Among youths 15 to 24 years old, suicide was the third leading cause of death, in 1978, 12 out of every 100,000 youths committee suicide. This rate is nearly three times the level recorded in 1950. In 1978,

young men were four times as likely as young women to commit suicide (table 30) Malignant neoplasms, the fourth leading cause of death among youths in 1978, accounted for only 5 percent of all deaths of persons 15 to 24 years old.

Health. There is some evidence of laxity in recent years in the immunization of children 1 to 4 years old against polio (table 32), the proportion of children who had at least three doses of the vaccine fell from 70 percent in 1966 to 59 percent in 1978. Similarly, the proportion of children who had received at least three doses of diphtheria-tetanus pertussis (DPT) vaccine dropped from 75 percent in 1966 to 65 percent in 1978.

The proportion of children adequately immunized against other childhood diseases (measles, rubella, and mumps), however, has increased in the last 10 to 15 years. A large increase in the proportions receiving the rubella vaccine is noted between 1970 and 1971, about the time when the license of the rubella live-virus began and administration of the vaccine became popular Data on immunization for mumps have been collected only since 1973, when 35 percent of the children 1 to 4 years old received a vaccine. By 1979, still only a little more than one-half of the 1-to-4-year olds were immunized against mumps (figure 5).

Overall, persons under 17 and 17 to 24 years old averaged more physician visits per year in 1979 than dental visits

(table 33). In 1979, persons under 17 had an average of 4.1 physician visits and 1.6 dental visits. The older cohort made an average of 4.3 physician visits and 1.6 dental visits during the year.

Although young males and females under 17 both averaged about four physician visits per year, females 17 to 24 years old averaged two more physician visits per year than males of the same age (five versus three).

## LABOR FORCE AND EMPLOYMENT STATUS

Labor force status. In 1980, about 31 million children, or 53 percent of all children under age 18 living in families, had mothers who were working or seeking work, a substantially higher proportion than the 39 percent in 1970. Among children of preschool age (those under 6), the proportion whose mothers were working or looking for work rose from 29 percent in 1970 to 43 percent in 1980 (table 36).

The impact of the dual role that a woman occupies as a mother and wage earner is experienced by a greater proportion of children who live with their mother only than by children who live with both parents. In 1980, 62 percent of children living in a household maintained by a woman with no husband present had mothers in the labor force, compared with 52 percent of children living in a married-

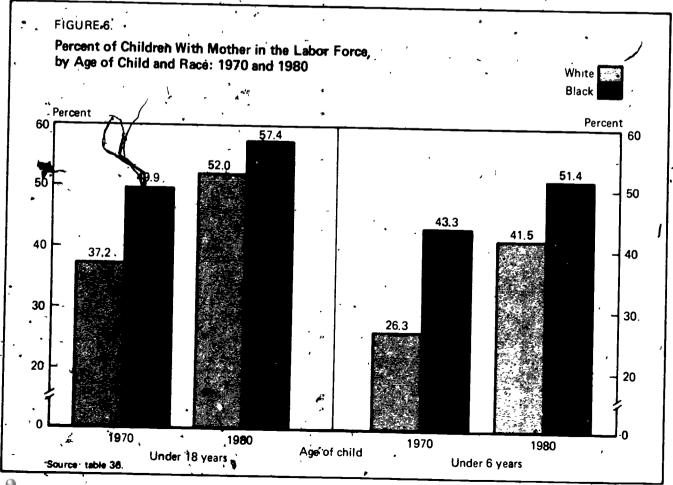

couple family. These figures represent a 9 and 14 percentagepoint increase, respectively, over comparable data from 1970 for both types of family units (table G)

Table G. Percentage of Children Under 18 Years Old With Their Mother in the Labor Force: 1980 and 1970

Year	All children	Children in married- * couple families	Children in families maintained by a woman
1980	£2.8	<b>5</b> 1.7	. 62.4
1970	38.8	37.6	53.2

Note Percents based on the civilian noninstitutional population

In 1980, 24.6 million youths 16 to 24 years old were in the civilian labor force, representing 68 percent of all persons in the civilian noninstitutional population in this age group (table 38). For young men, the rate of participation in the civilian labor force was 75 percent; for young women, the rate was 62 percent. In 1966, these figures were 69 percent for men and 47 percent for women (table 38). For this age group, 80 percent of men and 70 percent of women reported

some work experience for calendar year 1979, the latest lear for which data are available.<sup>2</sup>

During the 1980's, the number of the youths in the civilian labor force is projected to decline, reflecting the sharp drop in the birth rates during the 1960's. The percent of youths in the civilian noninstitutional population who are in the labor force is projected to increase from 68 percent in 1980 to 75 percent in 1990. This number is expected to total about 22.6 million, about 2.0 million less than in-1980 (table 37).

Employment status. Annual average data showed that 9 percent of young people 16 to 24 years old in the civilian labor force were unemployed in 1980 as compared with 15 percent in 1976 and only 9 percent in 1966 (table 38). Relatively little difference is found in the unemployment rates by sex at these young ages. Among those not enrolled in school, however, females had an unemployment rate to 12.8 percent versus 15.0 percent for young males 16 to 24 years old in 1980. Black youths not enrolled in school had an unemployment rate in 1980 of 29.2 percent, compared with 12.0 percent for White youths (table 40).

The number of young persons 17 to 24 years old serving in the Armed Forces has declined substantially since the peak of the Vietnam era in the late 1960's (table 41). In 1969, about 2.3 million young men served in the Armed Forces; this number declined by one-half to 1.1 million in 1980. The reduction has largely been among Whites as the proportion of Black Armed Forces personnel under 25 more than doubled, from 9 percent in 1969 to 22 percent in 1980.

## INCOME AND POVERTY STATUS,

The average child in a household maintained by a woman with no husband present grows up in an economically disadvantaged environment relative to his or her counterpart in a married-couple household. In 1979, about 31 percent of children living in families maintained by a woman with no husband present had family incomes below \$5,000, but only 3 percent of children in married couple families had family incomes below that level. At the upper end of the income scale, approximately 5 percent of children living in families maintained by a woman were in families with incomes above \$25,000, compared with 41 percent of children in married-couple families (table 42).

The median incomes of male and female year-round full-time workers are gloser among teenagers than in subsequent age groups (table H). Among workers 15 to 19 years old, females in 1979 had a median income of \$6,719, 90 percent of male median income in the corresponding age group. Among persons 25 years old and over, females had a median income level of only 59 percent of their male counterparts. These increasing differences with age can partly be explained by the discontinuities in a woman's occupational career

caused by childbearing and thuldrearing, during the teenage years, this is less likely to occur.

Table H. Median Total Money Income of Year-Round, Full-Time Workers, by Age and Sex: 1979

Vii	1		Ratio:
Age	Male	Female	, female
L'ac			to male
•	*		_ income
15 to 19 years	\$ 7,494	\$ 6,719	0.90
20 to 24 years	11,477	8,575	· 075
25 years and over	18,711	11,072	0.59

Poverty status. In 1979, there were 9.7 million children under 18 years of age in families whose incomes placed them below the poverty level (table 45), representing about 16 percent of all related children under 18 years old. Although this represents a decline from 12.1 million in 1966, the percentage of all children living below the poverty level was about the same in both years (17 percent in 1966).

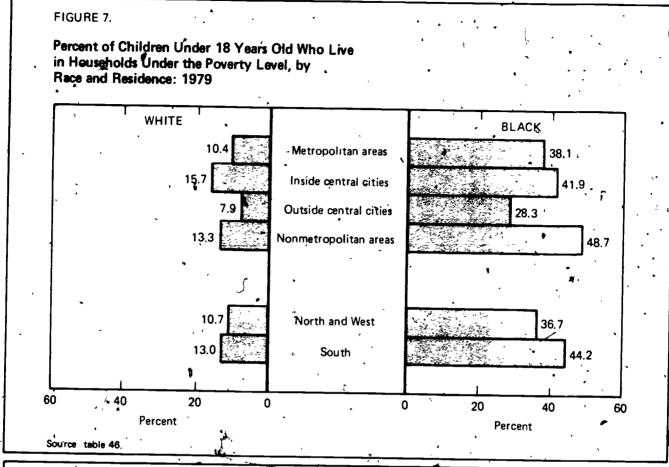

The poverty rate in 1979 for related White children under 18 in families was 11 percent, compared with 41 percent and 27 percent for Black and Spanish-origin children, respectively. Among children living in households maintained by a woman with no husband present, 39 percent of White, 63 percent of Black, and 62 percent of Spanish-origin children lived in households below the poverty level (table 46). Regardless of race, children living in suburban areas were less likely to live in poverty than those in either central cities of metropolitan areas or in nonmetropolitan areas (figure 7). Regionally, children in the South-were more likely than children in the remainder of the Nation to be members of poor families (20 and 14 percent, respectively).

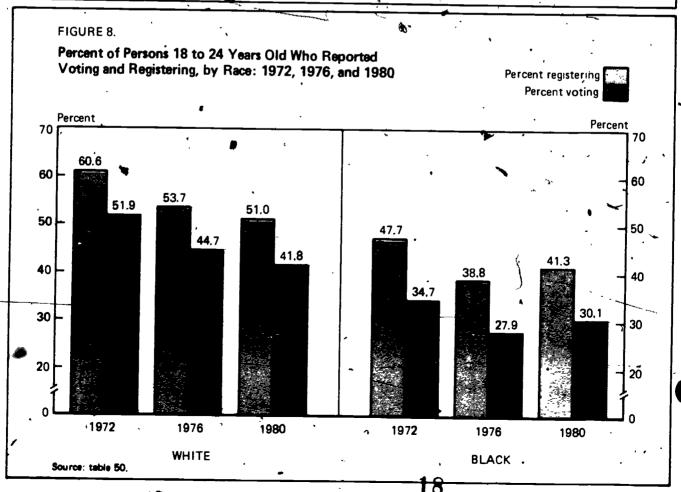

A considerable number of young persons also face their first years of adult life in poverty (table 48) Among youths 18 to 21 years old, 1 out of every 8 was poor as of 1979. Differences were very pronounced between White and Black youths with 1 of every 10 Whites and 3 out of every 10 Blacks living in poverty. Poverty rates for persons 22 to 24 years old were somewhat lower with 1 out of every 10 persons of this age living below the poverty level.

#### VOTING

Young people in the United States have consistently shown little interest in registering and voting. In the 1980 Presidential election, only 40 percent of the 18-to-24-year-olds voted compared with 64 percent for those 25 years and over. White youths were more likely to vote than Black youths: 42 percent of Whites 18 to 24 years old reported voting in the 1980 Presidential election as compared with a 30 percent of Blacks (figure 8) Within the 18-to-24-year-old age group, young people 18 to 20 years old had a voter

inpublished data from the Bureau of Labor Statistics.

turnout rate of only 36 percent, compared with the 43 ercent reported by persons 21 to 24 years old

The 40 percent voter turnout among 18-to-24 year olds in the 1980 Presidential election was 10 percentage points below that reported in the 1972 Presidential election, the first year of enfranchisement for all persons 18 years and over. Declines were modest between 1972 and 1980 for the population 25 years and over, only falling by two percentage points during this period to 64 percent in 1980 (table 50).

The decline in voter turnout was accompanied by a lower level of registration of young persons of voting age. Between 1972 and 1980, registration levels declined from 58 to 45 percent for persons 18 to 20 years old and from 60 to 53 percent for persons 21 to 24 years old. The special effort made to register these young persons following the enfranchisement of 18-to-20-year-olds in all States may have contributed to the higher registration of this age group in 1972 than in either 1976 or 1980.

## CRIME: VICTIMS AND OFFENDERS

Victims. Persons 12 to 24 years old in 1979 were more likely to be victims of both violent crimes and crimes of theft than older people (table 51). Around 5 to 8 percent of these

young people were victims of rape, robbery, or assault in 1979, victimization rates of around 4 percent for violent crimes, however, were noted for persons 25 to 34 years old but only between 1 and 2 percent for those over 35 years of age.

Among measured offenses, theft was the most frequently reported crime against persons in each age group. Among the White population, about 1 out of every 7 youths 12 to 24 years old was the victim of a theft, for Black youths the same age, the victimization rate was about 1 out of every 8 youths: (figure 9).

Offenders, The youth population constituted a substantial proportion of inmates of local jails in 1978 (table 52). The 1978 Survey of Local Jails showed that about 49 percent (77,000) of all inmates were 14 to 24 years old, of these inmates, 58 percent were White and 40 percent were Black

Almost one-half of all inmates 14 to 24 years old were charged with crimes against property, of which one-half of these crimes were burglary. About 30 percent were charged, with crimes of violence, and 8 percent were incarcerated for drug offenses. Youths 14 to 19 years old were less likely (5 percent) to be incarcerated for offenses involving drugs than were young adults 20 to 24 years old (10 percent).

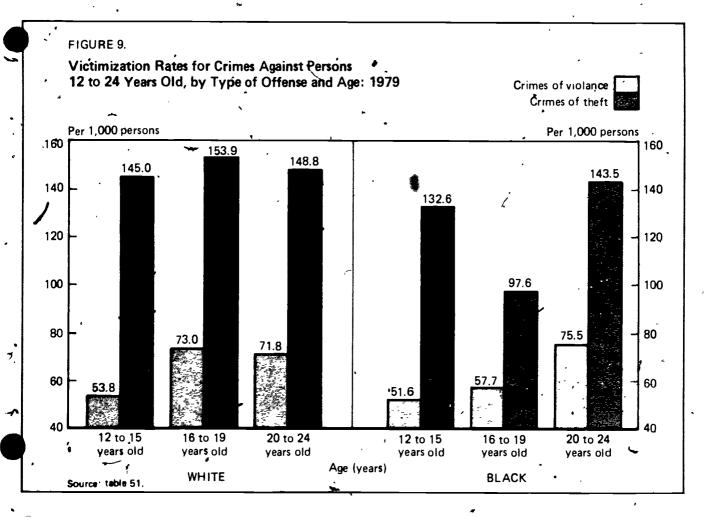

Table 1. Population Under 25 Years Old, by Age, Race, and Sex: 1980 (Numbers in thousands Estimates as of July 1, including Armed Forces overseas)

_ / ` .		All races		White			, Black

# Appendix A.

# Definitions and Explanations

Symbols. A dash/(-) represent to or rounds to zero. The symbol "B" means that the batter the derived figure is less than 75,000. An "X" means not applicable, "Z" means the figure rounds to less than 0.1, and "NA" means not available. The symbol "r" means revised.

Age. The age classification is based on the age of the person at his last birthday.

Race. The population is divided into three groups on the basis of race: White, Black, and "other races." The last category includes Indians, Japanese, Chinese, and any ather race except White and Black.

Spanish origin. Information on origin or descent was obtained by asking "What is (this person's) origin or descent?" Responses generally refer to a person's perceived national or ethnic lineage and do not necessarily indicate the country of birth of himself or his parents. The eategory Spanish origin includes persons of Mexican, Puerto Rican, Central or South American, and other Spanish origin.

Mobility status. The population 5 years old and over was classified according to mobility status on the basis of a comparison between the place of residence of each individual at the time of the March 1980 survey and the place of residence 5 years earlier. Nonmovers are all persons who were living in the same house at the end of the period as at the beginning of the period. Movers are all persons who were living in a different house at the end of the period than at the beginning. Movers are further classified as to whether they were living in the same county, State, or region; were movers of from abroad; were living in the same or different central city or SMSA; or had made some other type of move.

Metropolitan residence. The population residing in Standard metropolitan statistical areas (SMSA's) constitutes the metropolitan population. Except in New England, an SMSA is a county or group of contiguous counties which contains at least one city of 50,000 inhabitants or more, or "twin cities" with a combined population of at least 50,000. In addition to the county or counties containing this "central citte" contiguous counties are included in an SMSA if, according to certain criteria, they are essentially metropolitan in character and are socially and economically integrated with the central county. In New England, SMSA's consist of towns and cities, rather than counties. The metropolitan population in this report is based on SMSA's defined.

in the 1970 census and does not include any subsequent additions or changes. The terms "nonmetropolitan" and "outside SMSA's" are synonymous. The "balance of the SMSA" refers to the remainder of the SMSA outside the central city or cities, and is synonymous with the term "suburbs." The "size of the SMSA" refers to the number of persons living in the SMSA at the time of the 1970 census.

School enrollment. The school enrollment statistics from the current survey are based on replies to the enumerator's inquiry as to whether the person was enrolled in a Enumerators were instructed to count as enrolled anone who had been enrolled at any time during the current term or school year in any type of graded public, parochial, or other private school in the regular school system. Such schools include nursery schools, kindergartens, elementary schools, high schools, colleges, universities, and professional schools. Attendance may be on either a full-time or parttime basis and during the day or night. Thus, regular schooling is that which may advance a person toward an elementary or high school diploma, or a college, university, or professional school degree. Children enrolled in nursery schools and kindergarten are included in the enrollment figures for dejular" schools, and are also shown separately.

"Special" schools are those which are not in the regular school system, such as trade schools or business colleges. Persons attending "special" schools are not included in the enrollment figures.

Persons enrolled in classes which do not require physical presence in school, such as correspondence courses or other courses of independent study, and in training courses given directly on the job, are also excluded from the count of those enrolled, in school, unless such courses are being counted for credit at a "regular" school.

College enrollment. The college enrollment statistics are based on replies to the enumerator's inquiry as to whether the person was attending or enrolled in college. Enumerators were instructed to count as enrolled anyone who had been enrolled at any time during the current term or school year, except those who have left for the remainder of the term. Thus, regular college enrollment includes those persons attending and year or 2-year college, university or professional school (such as medical or law school), in courses that may advance the student toward a recognized college or university degree (e.g. BA or MA). Attendance may be either full time or part time, during the day or night.

Level of school. The statistics on level of school indicate the number of persons enrolled at each of five levels: Nursery, kindergargen, elementary school (first to eighth grades), high school (ninth to twelfth grades), and college or professional school. The last group includes graduate students in colleges or universities. Persons enrolled in junior high school through the eighth grade are classified as in elementary school and the others as in high school.

Nursery school. A nursery school is defined as a group or class that is organized to provide educational experiences for children during the year or years preceding kindergarten. It includes instruction as an important and integral phase of its program of child care. Private homes in which essentially custodial care is provided are not considered nursery schools. Children attending nursery school are classified as attending during either part of the day or the full day. Part-day attendance refers to those who attend either in the morning or in the afternoon; but not both. Full-day attendance refers to those who attend both in the morning and afternoon.

Modal grade Enrolled persons are classified according to their relative progress in school, that is, according to whether the grade or year in which they were enrolled was below, at, or above the model (or typical) grade for persons of their age at the time of the survey. The modal grade, then, is the year of school in which the largest proportion of students of a given age is enrolled.

Distance to school. The one-way distance actually traveled to school was reported to the closest mile. Respondents were instructed not to people the direct distance if the means of transportation required a circuitous route. The best estimate possible was obtained by the interviewer if the respondent was not certain of the distance.

Time of travel. The total time traveled one way between home and school was reported to the closest minute. Six time intervals were included: less than 15 minutes, 15 to 29 minutes, 30 to 44 minutes, 45 to 59 minutes, 1 hour to 1 hour 29 minutes, and 1 hour 30 minutes or more.

Year of school completed. Data on years of school completed in this peport were derived from the combination of answers to two questions: (a) "What is the highest grade of school he has ever attended?" and (b) "Did he finish this grade?"

The questions on educational attainment apply only to progress in "regular" schools. Such schools include graded public, private, and parochial elementary and high schools (both junior and senior high), colleges, universities, and professional schools, whether day schools or night schools. Thus, regular schooling is that which may advance a person toward an elementary school certificate, high school diploma, or a college, university, or professional school degree. Schooling in other than regular schools was counted only if the

credits obtained were regarded as transferable to school in the regular school system.

Marital status. The marital status classification identifies four major categories: single, married, widowed, and divorced. These terms refer to the marital status at the time of the enumeration.

The category "married" is further divided into "married, spouse present," "separated," and "other married, spouse absent." A person was classified as "married, spouse present" if the husband or wife, was reported as a member of the household, even though he or she may have been temporarily absent on business or onvacation, visiting, in a hospital, etc., at the time of the enumeration. Persons reported as separated included those with legal separations, those living apart with intentions of obtaining a divorce, and other persons permanently or temporarily separated because of marital discord. The group "other married, spouse absent" includes married persons living apart because either the husband or wife was employed and living at a considerable distance from home, was serving away from home in the Armed Forces, had moved to another area, or had a different place of residence for any other reason except separation as defined above.

Household. A household consists of all the persons who occupy a housing unit. A house, an apartment or other group of rooms, or a single room, is regarded as a housing unit when it is occupied or intended for occupancy as separate living quarters, that is, when the occupants do not live and eat with any other persons in the structure and there is either (1) direct access from the outside or through a common hall or (2) a kitchen or cooking equipment for the exclusive use of the occupants.

A household includes the related family members and all the unrelated persons, if any, such as lodgers, foster children, wards, or employees who share the housing unit. A person living alone in a housing unit, or a group of unrelated persons sharing a housing unit as partners, is also counted as a household. The count of households excludes group quarters.

Group quarters. Group quarters are now defined in the Current Population Survey as noninstitutional living arrangements for groups not living in conventional housing units or groups living in housing units containing five or more persons unrelated to the person in charge. Inmates of institutions (starting in 1972) are not included in the Current Population Survey.

Head versus householder. Beginning with the 1980 CPS, the Bureau of the Census discontinued the use of the terms "head of household" and "head of family." Instead, the terms "householder" and "family householder" are used Recent social changes have resulted in greater sharing of household responsibilities among the adult members and, therefore, have made the term "head" increasingly inappropriate in the analysis of household and family data. Spe-

cally, the Bureau has discontinued its longtime practice always classifying the husband as the reference person (head) when he and his wife are living together.

In this report, the term "householder" is used in the presentation of data that had previously been presented with the designation "head." The householder is the first adult householder member listed on the questionnaire. The instructions call for listing first the person (or one of the persons) in whose name the home is owned or rented. If a home is owned jointly by a married couple, either the husband or the wife may be listed first, thereby becoming the reference person, or householder, to whom the relationship of other householder members is to be recorded.

Householder. The householder refers to the person (or one of the persons) in whose name the housing unit is owned or rented (maintained) or, if there is no such person, any adult member, excluding roomers, boarders, or paid employees. If the house wowned or rented jointly by a married couple, the householder may be either the husband or the wife. The person designated as the householder is the "reference person" to whom the relationship of all other household members, if any, is recorded.

Prior to 1980, the husband was always considered the household head (householder) in married-couple households. The number of householders is equal to the number of householders is equal to the number of families.

Family. The term "family," as used here, refers to a group of two persons or more related by birth, marriage, or adoption and residing together; all such persons are considered as members of one family. A lodger and his/her spouse who are not related to the person or persons who maintain the household, or a resident employee and his/her spouse living in, are considered as a separate family. Thus, a household may contain more than one family. However, if the son of the person or couple who maintains the household and the son's wife are members of the household, they are treated as part of the parent's family. A person maintaining a household alone, or with unrelated persons only, is regarded as a household but not as a family. Thus, some households do not contain a family.

Primary family. A primary family is a family that includes among its members the person or couple who maintains the household. In the text of this report the term "family households" is used in discussing the households of primary families—a term used in the detailed tables.

purposes, is a husband and wife enumerated as members of the same household. The married couple may or may not have children living with them. The expression "husband-wife" or "married-couple" before the term "household," by," or "subfamily" indicates that the household,

family, or subfamily is maintained by a husband and wife Detailed tables which display data for characteristics of the head (e.g., age, sex, race) for households or families show characteristics of the husband in husband-wife households or families.

Unrelated individuals. Unrelated individuals are persons (other than inmates of institutions) who are not living with any relatives. An unrelated individual may be (1) a person living alone or with nonrelatives only, (2) a lodger or resident employee with no relatives in the household, or (3) a group quarters member who has no relatives living with him/her.

Primary individual. A primary individual is a person maintaining a household while living alone or with nonrelatives only.

Secondary individual. A secondary individual is a person in a household or group quarters such as a guest, lodger, or resident employee (excluding primary individuals and inmates of institutions) who is not related to any other person in the household or group quarters.

Size of houshold, family, or subfamily. The term "size of household" includes all persons occupying a housing unit "Size of family" includes persons in the living quarters who are related to each other by birth, marriage, or adoption. "Size of subfamily" includes the husband and wife or the lone parent and their sons and daughters under 18 years of age who constitute a subfamily. If a primary family has a subfamily among its members, the size of the primary family includes the members of the subfamily.

Related persons and family members. In the classification of households by number of related persons, the person or couple who maintains the household or pousing unit and all persons in the household related to them are included. In the classification of families by number of family members, all persons in the family are included. The number of family members is the same as the size of the family.

Own children and related children. "Own" children in a family are sons and daughters, including stepchildren and adopted children, of the householder. Similarly, "own" children in a subfamily are sons and daughters of the married couple or parent in the subfamily. "Related" children in a family include own children and all other children in the household who are related to the householder by birth, marriage, or adoption.

Children ever born. This term issued to refer to the number of live births a woman has ever had (excluding stillbirths). The number includes children born to the woman before her present marriage, children no longer living, and children away from home as well as children who were all living in the home.

Births to date. In some tables showing birth expectations, the number of "births to date" is also shown. This term has the same meaning as the number of children ever born.

Lifetime births expected. This number refers to the total number of births a woman expects to have during her lifetime

Labor force and employments status. The definitions of labor force and employment status in this report relate to the population 14 years old and over.

Employed. Employed persons comprise (1) all civilians who, during the specified week, did any work at all as paid employees of in their own business or profession, or on their own farm, or who worked 15 hours or more as unpaid workers on a farm or in a business operated by a member of the family, and (2) all those who were not working but who had jobs or businesses from which they were temporarily absent because of illness, bad weather, vacation, or labormanagement dispute, or because they were taking time off for personal reasons, whether or not they were paid by their employers for time off, and whether or not they were seeking other jobs. Excluded from the employed group are persons whose only activity consisted of work around the house (such as own home housework, painting or repairing own home, etc.) or volunteer work for religious, charitable, and similar organizations

Unemployed. Unemployed persons are those civilians who, during the survey week, had no employment but were available for work and (1) had engaged in any specific job-seeking activity within the past 4 weeks, such as registering at a public or private employment office, meeting with prospective employers, checking with friends or relatives, placing or answering advertisements, writing letters of applications, or being on a union or professional register. (2) were waiting to be called back to a job from which they had been laid off, or (3) were waiting to report to a new wage or salary job within 30 days.

Labor force. Persons are classified as in the labor force if they were employed as civilians, unemployed, or in the Armed Forces during the survey week. The "civilian labor force" is comprised of all civilians classified as employed or unemployed.

Not in the labor force. All civilians who are not classified as employed or unemployed are defined as "not in the labor force". This group who are neither employed nor seeking work includes persons engaged only in own home housework, attending school, or unable to work because of long-term physical or mental illness, persons who are retired or too old to work, seasonal workers for whom the survey week fell in an off season, and the voluntary idle Persons doing only unpaid family work (less than 15 hours) are also classified as not in the labor force.

Occupation. The data on occupation of employed person refer to the civilian job held during the survey week. Person employed at two or more jobs were reported in the job at which they worked the greatest number of hours during the week.

The occupation groupings used here are mainly the major groups used in the 1970 Census of Population. The composition of these groups is shown in Volume 1, *Characteristics of the Population*, Part 1, United States Summary, Chapter D.

Total money income. The algebraic sum of money wages and salaries, net income from self-employment, and income other than earnings represents total money income. The total income of a family is the algebraic sum of the amounts received by all income recipients in the family.

The income tables for families and unrelated individuals include in the lowest income group those who were classified as having no income in the income year and those reporting a loss in net income from farm and nonfarm self-employment or incrental income. Many of these were living on income "in kind," savings, or gifts, or were newly constituted families, uhrelated individuals who had recently left families, or families in which the sole breadwinner had recently died or had left the household. However, many of the families and unrelated individuals who reported no income probably had some money income which was not recorded in the survey.

Median income. The median income is the amount which divides the distribution into two equal groups, one having incomes above the median, and the other having incomes below the median. The medians for families and individuals are based on all families and individuals. The medians for persons are based on the distributions of persons with income. The medians for wage or salary income, income from nonfarm self-employment, income from farm self-employment, and income other than earnings are based on the distributions of persons or families and individuals having these types of income.

Mean income. The mean income is the amount obtained by dividing the total income of a group by the number of units in that group (families, unrelated individuals, or persons). The means for families and unrelated individuals are based on all families and individuals. The means for persons are based on the number of persons with income. The mean for a particular type of income is based on the number of persons or families with the particular type of income.

Poverty status in 1979. Families and unrelated individuals are classified, as being above or below the poverty level using the poverty index adopted by a Federal Interagency Committee in 1969. This index provides a range of income cutoffs o 'poverty thresholds' which vary by family size, number of children, sex, and age of the family householder or unrelated individual and farm nonfarm residence. The poverty cutoffs for farm families are set at 85 percent of the nonfarm levels. The income cutoffs are updated each year to reflect the

change in the Consumer Price Index. The poverty threshold a nonfarm family of four was \$7,412 in 1979. For a detailed explanation of the poverty definition, see Current Population Reports, Series P-60, No.128, Characteristics of the Population Below the Poverty Level: 1979.

Reported voter participation. Voter participation data were derived from replies to a direct question asked of all persons of voting age, except in 1978 and 1980, when the questions on voting and registration were asked only of citizens. All persons of voting age are classified as "voted" or "did-not vote." Generally, this "did not vote" class includes those reported as "did not vote," "do not know if voted," "not a U.S. citizens," and nonrespondents.

Reported registration. Registration is the act of qualifying to vote by formally enrolling on a list of voters. In a few States, no formal registration is required, voters merely present

themselves at the polling place on election day with proof that they are of age and have met the residence requirements

Victimization. A specific criminal act as it affects a single victim, whether a person or household. In criminal acts against persons, the number of victimizations is determined by the number of victims of such acts; ordinarily, the number of victimizations is somewhat higher than the number of incidents because more than one individual is victimized during certain incidents, as well as because personal victimizations that occurred in conjunction with commercial crimes are not counted as incidents of personal crime. Each criminal act against a household is assumed to involve a single victim—the affected household.

Victimization rate. For crimes against persons, the victimization rate, a measure of occurrence among population groups at risk, is computed of the basis of the number of victimizations per 1,000 resident population.

# Apendix B.

# Source and Reliability of the Estimates

### **SOURCE OF DATA**

Most of the estimates in this report are based on data obtained from the Bureau of the Census collected in the Current Population Survey (CPS) and the Decennial Censuses of Population Other data were from surveys such as the Immunization Survey, the Health Interview Survey, the National Crime Survey, the Survey of Inmates of Local Jails and the Survey of Economic Opportunity (SEO) Other data are from vital statistics. The source of data in each table and for each figure can be found at the bottom of that table or figure

Current Population Survey (CPS). Most of the CPS estimates in this report are based on data obtained in various months of 1980. Some estimates are based on data obtained in earlier years. The monthly CPS deals mainly with labor force data for the civilian noninstitutional population. Questions relating to labor force participation are asked about each member 14 years old and older in each sample household. In addition, supplementary questions are asked in most months about various population characteristics. The present CPS sample was initially selected from the 1970 census files with coverage in all 50 States and the District of Columbia. The sample is continually updated to reflect new construction. The current CPS sample is located in 629 areas comprising 1,133 counties, independent cities, and minor civil divisions in the Nation. In this sample, approximately 68,000 house-

holds were eligible for interview. Of this number, about 3,000 occupied units were visited but interviews were not obtained because the occupants were not found at home after repeated talls or were unavailable for some other reason.

The following table provides a description of some aspects of the CPS sample designs in use during the referenced data collection periods.

The estimation procedure used in the CPS survey involved the inflation of the weighted sample results to incependent estimates of the total civilian noninstitutional population of the United States by age, race, and sex. These independent estimates were based on statistics from decennial censuses; statistics on births, deaths, immigration, and emigration; and statistics on the strength of the Armed Forces. The estimation procedure in March for the data in the report also involved a further adjustment so that husband and winof a household received the same weight.

Immunization Survey. Immunization data are published by the Center for Disease Control, Department of Health and Human Services. The Immunization Survey is based on data obtained every September in a subsample of households interviewed for the EPS.

Health Interview Survey (HIS). The HIS data are collected by the Bureau of the Census acting as collection agent for National \*Center for Health Statistics, Department of Health

### Description of the Current Population Survey

Fime period	· [	Housing units eligible				
	Number, of Sample areas	Interviewed	Not interviewed			
January 1980 to present	420					
sanuary 1978 to December 1979	629	65,000	3,000			
lugust 1972 to December 1977	614	54,500	3,000			
ugust 1971 to July 1972	461	45,000	. 2,000			
anuary 1967 to July 1971	449	45,000	2,000			
larch 1963 to December 1000	449 ],	48,000	2,000			
arch 1963 to December 1966.	357	33,500	•			
anuary 1960 to February 1963	<sup>2</sup> 333	33,500	1,500			
my 1956 to December 1959	330	33,500	, 1,500			
ebruary 1954 to April 1956	230	21,000	1,500			
ugust 1947 to January 1954	68	21,000	500-1,000			

Beginning in May 1956, these areas were chosen to provide coverage in each State and the District of Columbia.

<sup>&</sup>quot;Three sample areas were added in 1960 to represent Alaska and Hawaii after statehood.

and Human Services. The population covered by the sample for the HIS is the civilian noninstitutional population of the United States living at the time of the interview. The sample does not include members of the Armed Forces or U.S nationals living in foreign countries

Decennial Census of Population. Decennial census data in this report are based on complete counts or on the samples associated with the census as indicated in the list of sources. Descriptions of samples from the census are found in the appropriate census publications. To determine if the 1950, 1960, and 1970 data in a table of this report are based on complete counts or on the samples associated with the census, refer to the source of data at the bottom of that table.

Vital statistics data. Data on mortality rates are published by the Division of Vital Statistics Analysis of the National Center for Health Statistics, U.S. Department of Health and Human Services. Data on number of deaths (numerators of death rates) are gathered from the offices of vital statistics of State governments, with the assistance of the Public Health Service. The departments of death, rates are decennial census figures by age, sex, and race, adjusted to account for changes in the population since the census.

Crime data. Data on crime are published by the Law Enforcement Assistance Administration, Department of Justice, and are the result of the National Crime Survey and the Survey of Inmates of Local Jails.

1967 Survey of Economic Opportunity (SEO). The 1967 SEO sample was spread over 357 areas comprising 701 counties and independent cities. These areas were chosen to provide coverage in each State and the District of Columbia.

The SEO sample was selected so that there was a disproportionately large sample from the Black-and-other-races population. The weights applied to each sample case were adjusted to reflect this. This sampling procedure was used to provide more reliable estimates for Black-and-other-races population although it was known that reliability of estimates not broken down by race and of estimates for Whites would be reduced.

#### RELIABILITY OF SAMPLE ESTIMATES

Estimates based on a sample may differ somewhat from the figures that would have been obtained if a complete census had been taken using the same questionnaires, instructions, and enumerators. There are two types of errors possible in an estimate based on a sample survey sampling and nonsampling. The standard errors provided for this report primarily indicate the magnitude of the sampling error. They also partially measure the effect of some nonsampling errors in response and enumeration, but do not measure any systematic biases in the data. The full extent of nonsampling error is unknown. Consequently, particular care should be

exercised in the interpretation of figures based on a relatively small number of cases or on small differences between estimates.

Nonsampling variability. Nonsampling errors can be attributed to many sources, e.g., inability to obtain information about all cases in the sample, definitional difficulties, differences in the interpretation of questions, inability or unwillingness on the part of the respondents to provide correct information, inability to recall information, errors made in collection (such as in recording or coding the data) errors made in processing the data, errors made in estimating values for missing data, and failure to represent all units with the sample (undercoverage).

Undercoverage in the CPS results from missed housing units and missed persons within sample households. Overall undercoverage, compared with the level of the decennial census, is about 5 percent. It is known that CPS undercoverage varies with age, sex, and race. Generally, undercoverage is larger for males than for females and larger for Blacks and other races than for Whites. Ratio estimation to independent, age-sex-race population controls partially corrects for the bias due to survey undergoverage. However, biases exist in the estimates to the extent that missed persons in missed households or missed persons in interviewed households have different characteristics than interviewed persons in the same age-sex-race group. Further, the independent population controls used have not been adjusted for under coverage in the 1970 census, which was estimated at 2.5 percent of the population, with similar undercoverage differentials by age, sex, and race as in CPS.

A coverage improvement sample was included in computing CPS estimates beginning in 1978, in order to provide coverage of mobile homes and new construction housing units which previously had no chance for selection in the CPS sample. This sample is composed of approximately 450 sample household units which represent 237,000 occupied mobile homes and 600,000 new construction housing units. These new construction units are composed of those units where building permits were issued prior to January 1970 and construction was not completed by the time of the 1970 census (i.e., April 1970). The inclusion of this coverage improvement sample in the CPS does not have a significant effect on the estimates. The extent of other sources of housing underdoverage is unknown but believed to be small.

Sampling variability. The standard errors given in the following tables are primarily measures of sampling variability, that is, of the variation that occurred by chance because a sample-rather than the entire population was surveyed. The sample estimate and its standard error enable one to construct confidence intervals—ranges that would include the average result of all possible samples with a known probability. For example, if all possible samples were selected and each of these was surveyed under essentially the same general conditions using the same sample design, and an estimate and

its standard error were calculated from each sample, then:

- Approximately 68 percent of the intervals from one standard error below the estimate to one standard error above the estimate would include the average result of all possible samples.
- 2. Approximately 90 percent of the intervals from 1.6 standard errors below the estimate to 1.6 standard errors above the estimate would include the average result of all possible samples.
- 3. Approximately 95 percent of the intervals from two standard errors below the estimate to two standard errors above the estimate would include the average result of all possible samples.

The average estimate derived from all possible samples may or may not be contained in any particular computed interval. However, for a particular sample, one can say with a specified confidence that the average estimate derived from all possible samples is included in the confidence interval.

Standard errors may also be used to perform hypothesis testing, a procedure for distinguishing between population parameters using sample estimates. The most common types of hypotheses appearing in this report are 1) The population parameters are identical and 2) they are different. An example of this would be comparing the mean annual income of men with the mean annual income of women. Tests may be performed at various levels of significance, where a level of significance is the probability of concluding that the parameters are different when, in fact, they are identical.

All statements of comparison in the text have passed a hypothesis test at the 0.10 level of significance or better, and most have passed a hypothesis test at the 0.05 level of significance or better. This means that, for most differences cited in the text, the estimated differences between parameters is greater than twice the standard error of the difference. For the other differences mentioned, the estimated difference between parameters is between 1.6 and 2.0 times the standard error of the difference. When this is the case, the statement of comparison will be qualified in some way, e.g., by use of the phrase "some evidence."

Comparability with other data. Data obtained from the CPS and other governmental sources are not entirely comparable. This is due in large part to differences in interviewer training and experience and in differing survey processes. This is an additional component of error not reflected in the standard error tables. Therefore, caution should be used in comparing results between these different sources. Also, caution should be exercised in comparing metropoliten and nonmetropolitan area estimates from CPS from 1976 and later years to each other and to those from earlier years. Methodological and sample design changes have occurred in these recent years resulting in relatively large differences in the metropolitan and nonmetropolitan area estimates.

Note when using small estimates. Summary measures from CPS (such as percent distributions) are shown in the report only when the base of the measure is 75,000 or greater Because of the large standard errors involved, there is little-chance that summary measures would reveal useful information when computed on a smaller base. Estimated numbers are shown, however, even though the relative standard errors of these numbers are larger than those for corresponding percentages. These smaller estimates are provided primarily to permit such combinations of the categories as serve each user's need.

Standard errors for data based on the decennial census. Sampling errors of all data from the samples of 1950, 1960, and 1970 decennial censuses shown in this report are small enough to be disregarded

Standard errors for data based on surveys other than CPS. Standard errors for data based on surveys other than CPS can be found in the appropriate publications footnoted at the end of the tables

## CPS STANDARD ERROR TABLES AND THEIR USE

In order to derive standard errors that would be applicable to a large number of estimates and could be prepared at a moderate cost, a number of approximations were required. Therefore, instead of providing an individual standard error for each estimate, generalized sets of standard errors are provided for various types of characteristics. As a result, the sets of standard errors provided give an indication of the order of magnitude of the standard error of an estimate rather than the precise standard error

The figures in tables B-1 and B-2 provide approximations to standard errors of estimated numbers and estimated percentages. Standard errors for intermediate values not shown in the generalized tables of standard errors may be approximated by linear interpolation. Estimated standard errors for specific characteristics cannot be obtained from tables B-1 or B-2 without the use of factors in table B-3. These factors must be applied to the generalized standard errors in order to adjust for the combined effect of sample design and estimating procedure on the value of the characteristic.

Two parameters (denoted "a" and "b") are used to calculate standard errors for each type of characteristic, they are presented in table B-4. These parameters were used to calculate the standard errors in tables B-1 and B-2, and to calculate the factors in table B-3. They also may be used to directly calculate the standard errors for estimated numbers and percentages. Methods for direct computation are given in the following sections.

Standard errors of estimated numbers. The approximate standard error,  $\sigma_{\chi}$ , of an estimated number shown in this

report can be obtained in two ways. It may be obtained by use of the formula

$$\sigma_{\mathbf{x}} = \mathbf{f}\sigma$$
 (1)

where f is the appropriate factor from table B-3, and  $\sigma$  is the standard error on the estimate obtained by interpolation from table B-1. Alternatively, standard errors may be approximated by the following formula (2) from which the standard errors were calculated in table B-1. Use of this formula will provide more accurate results than the use of formula (1) above.

$$\sigma_{x} = \sqrt{ax^2 + bx} \tag{2}$$

Here x is the size of the estimate and a and b are the parameters in table B-4 associated with the particular type of characteristic. When calculating standard errors for numbers from cross-tabulations involving different characteristics, use the factor or set of parameters for the characteristic which will give the largest standard error.

Illustration of the computation of the standard error of an estimated number. Table 23 of this report shows that in 1980 there were 61,602,000 persons under 18 years old living in households. Using formula (2) with a = -0.000017 and b = 3500 from table B-4, the approximate standard error<sup>1</sup> is

$$\sqrt{(-0.000017)(61,602,000)^2 + 3500(61,602,000)} = 389,000$$

The chances are 68 out of 100 that the estimate would have been a figure differing from the average of all possible samples by less than 389,000. The chances are 95 out of 100 that the estimate would have been a figure differing from the average of all possible samples by less than 778,000 (twice the standard error), i.e., the 95-percent confidence interval for the number of children under 18 years old living in a household is from 60,824,000 to 62,380,000.

Standard errors of estimated percentages. The reliability of an estimated percentage, computed using sample data for both numerator and denominator, depends upon both the size of the percentage and the size of the total upon which the percentage is based. Estimated percentages are relatively more reliable than the corresponding estimates of the numerators of the percentages, particularly if the percentages are 50 percent or more. When the numerator and denominator of the percentage are in different categories, use the factor or parameters from table B-3 or B-4 indicated by the numerator. The approximate standard error,  $\sigma_{(\mathbf{x},\mathbf{p})}$ , of an estimated percentage can be obtained by use of the formula

$$\sigma_{(\mathbf{x},\mathbf{p})} = f\sigma$$
 (3)

In this formula, f is the appropriate factor from table B-3, and  $\sigma$  is the standard error on the estimate from table B-2. Alternatively, standard errors may be approximated by formula (4), from which standard errors in table B-2 were calculated: direct computation will give more accurate results than use of the standard error tables and the factors.

$$\sigma_{(x,p)} = \sqrt{\frac{b}{x}} \cdot \rho (100 - p) \tag{4}$$

Here x is the size of the subclass of persons, families and unrelated individuals, households, or householders which is the base of the percentage, p is the percentage ( $0 \le p \le 100$ ), and b is the parameter in table B-4 associated with the particular type of characteristic in the numerator of the percentage.

Illustration of the computation of the standard error of a percentage. Table 23 shows that of the 50,991,000 White persons under 18 years in 1980, 82% percent lived in households with both parents. From table 8-4, the appropriate b parameter is 3500. Using formula (4), the approximate standard error on 82.7 percent is

$$\sqrt{\frac{3500}{50,991,000}}$$
 (82.7) (17.3)  $= 0.3$  percent<sup>2</sup>

Consequently, the chances are 68 out of 100 that the estimated percent would be within 0.3 percentage points of the average of all possible samples. Chances are 95 out of 100 that the estimate would be within 0.6 percentage points of the average of all possible samples, i.e., the 95-percent confidence interval for the percentage of White persons under 18 years living in households with both parents is from 82.1 to 83.3 percent.

Standard error of a difference. For a difference between two sample estimates, the standard error is approximately equal to

$$\sigma_{(x-y)} = \sqrt{\sigma_{x-y}^2 + \sigma_{y}^2}$$
 (5)

where  $\sigma_{\rm X}$  and  $\sigma_{\rm Y}$  are the standard errors of the estimates x and y, the estimates can be of numbers, percents, ratios, etc. This will represent the actual standard errors quite accurately for the difference between two estimates of the same characteristics in two different areas, or for the difference between separate and uncorrelated characteristics in the same area. If, however, there is a high positive (negative) correlation between the two characteristics, the formula will overestimate (underestimate) the true standard error.

<sup>63</sup> 

<sup>\*</sup>Using formula (1), the appropriate factor from table 8-3 (1.4) indicable 8-1, the approximate standard error is 1.4 × 283,000 = 28,000

<sup>&</sup>lt;sup>3</sup>Using formula (3), the appropriate factor from table B-3 (1.4) and table B-2, the approximate standard error is also 0.3 percent.

Illustration of the computation of the standard error of a difference? As stated earlier, table 23 shows that in 1980, 82.7 percent of all White persons under 18 years lived in households with both parents. Table 23 also shows that in 1980, 42.2 percent of all Black persons under 18 years (9,290,000) lived in households with both parents. Thus, the apparent difference between the percent of White persons and Black persons under 18 years living in households with both parents in 1980 is 40.5 percent. Using formula (4) and the appropriate b parameter (5020) from table 8-4, the approximate standard error on the 42.2 percent is 1.1 percent. Therefore, using formula (5), the standard error of the estimated difference of 40.5 percent is about

$$\sqrt{(0.3)^2 + (1.1)^2} = 1.1$$
 percent

This means that the 68-percent confidence interval for the difference between White and Black persons under 18 years living in households with both parents in 1980 is from 39 4 to 41 6 percent, and the 95-percent confidence interval is from 38 3 to 42.7 percent

Standard error of a fertility ratio. Table B-5 provides standard errors for both number of children ever born and number of expected lifetime births per 1,000 women. The sampling variability on the ratio of children born per 1,000 women.

depends on the shape of the distribution on which the ratio is based, the size of the sample, the sample design and the use of ratio estimates.

It should be noted that for data involving only one kind of event per woman, e.g., one additional birth expected, table B-2 and table B-3 should be used. For data involving two or more possible events per woman, table B-5 should be used.

Illustration of the computation of the standard error of a fertility ratio. Table 26 of this report shows that in 1979 single women 18 to 24 years old expected 1,993 lifetime births per 1,000 women. Table 26 also shows that there were 5,480,000 single women in this age group.

, Table B-5 shows the standard error of a ratio of 1,993 births on a base of 5,480,000 women to be approximately 36 per 1,000. Consequently, the chances are 68 out of 100 that the estimate would have been a fertility ratio differing from the average of all possible samples by less than 36 per 1,000. Chances are 95 out of 100 that the estimate would have been a fertility ratio differing from the average of all possible samples by less than 72 per 1,000, i.e., the 95-percent confidence interval is from 1,921 to 2,065 lifetime births expected per 1,000 single women 18 to 24 years old in 1979.

Table B-1. Standard Errors of CPS Estimated Numbers: 1967 to 1980

(68 chances out of 100. Numbers in thousands)

# Need Help in Locating Up-To-Date Statistics on the U.S. Population?

Subject Index to CURRENT POPULATION REPORTS:

**December** 

1980

This index to Current Population Reports is the first bibliographic inventory of all Current Population Reports and is designed to provide a ready resource for users of statistics from the Current Population Survey.

Individual reports are listed sequentially by subject, series number, year covered, area/level of coverage, and title.

Series listed in the index are:

- P-20 Population Characteristics
- P-23 Special Studies
- P-25 Population Estimates and Projections
- P-26 Federal-State Cooperative Program for Population Estimates
- P-27 Farm Population
- P-60 Consumer Income.
