ABSTRACT

Secondary school students who drop out of school are put at great social and economic disadvantage. If potential dropouts can be identified early, prevention may be possible. To construct a prediction model which, through readily available school information, will aid in the identification of students likely to drop out, schools in the Austin, Texas, school district provided data on students sampled according to birthdate (N=5,039). The longitudinal study encompassed four school years (1977-1981), and students were classified into four groups: non-leavers, transfers, dropouts, and other/unknown. The variables studied were gradepoint average (GPA), grade placement, sex, ethnicity, and number of serious discipline problems. Statistical analyses showed that students who had low GPA's, were behind in grade for their age, had been involved in serious discipline incidents, were female, and were non-black had a higher than average probability of dropping out. Most of these variables had face validity for predicting dropping out. Two findings were somewhat misleading: in fact, girls as a group had a lower drop out rate than boys; however, an individual girl with certain characteristics might be more likely than a similar boy to drop out. Although scores of Blacks on variables were similar to scores of Hispanics, Blacks were less likely to drop out, apparently due to influences outside of the variables scored. Altogether, about 78% of dropouts and non-leavers were correctly classified. (WAS)

DROPOUT PREDICTION

Objective:

The objective of the study was to construct a prediction model that aids in the identification of secondary students likely to drop out of school from readily available school information.

Educational Importance:

If potential dropouts can be identified early, prevention may be possible. A substantial portion of our students drop out of school. Such students are put at great social and economic disadvantage. In addition to the loss of school experience and skills, they are much less likely to find employment than graduates. In 1970, 48.3% of Austin male dropouts 16-24 years of age were unemployed. Only 18.4% of the same-age high school graduates, who were not continuing their education, were unemployed. (US Census Bureau)

Data from Austin's latest study (Doss, 1982) indicate a disproportionately high number of Hispanics drop out of school. Thus, while dropout prevention programs are probably in order, these programs must also address any special needs of the Hispanic students.

Review of the Literature:

A review of the literature was conducted to:

- identify variables with predictive potential
- examine methodology

Variables With Predictive Potential

In reviewing the research literature, twenty-four variables that are related to dropping out were identified. Table I summarizes the findings. It is obvious that some of these variables are likely to be readily available to a school district while others are much less likely to exist on a regularly maintained file. Differences in data collection and data management among school districts will assure a variabilility in the types of data readily available. However, it is likely that a core of information will be common among nearly all districts. Grade point average, average number of credits, ethnicity, achievement scores, and below grade placement are likely to be accessible from files already existing in the district. On the other hand, family history of dropping out, mother's and father's education, feelings toward authority, peer status, etc. most likely are not available without additional costly data collection efforts.

Our interest was in developing a statistical model that would not only identify potential dropouts accurately but that would be practical, i.e., no additional data need be collected.

As such, the variables accessible to our model included only:

Grade point average
Grade placement (grade in which student was enrolled)
Sex
Ethnicity
Number of serious discipline problems

Methodology Considerations

From a review of the literature, two major methodological flaws were identified that would tend to lessen the discriminating power of the prediction models.

- Many studies have attempted to discriminate dropouts from graduates within a group already selected by school authorities as being at risk for dropping out. This results in a restriction of range in variance problem. (Johnson, 1972; Delaney, 1972)
- Several studies have attempted to predict dropping out over a relatively short period of time--the nine-month academic year. This results in several misclassifications if the purpose is to predict long-term dropouts. (Degracie, 1974)

To alleviate those problems, the Austin study was longitudinal encompassing four school years, 1977-78, 1978-79, 1979-80, and 1980-81, and school leavers were classified into four basic groups:

- Those remaining in the Austin schools, "Nonleavers" (69.5%)
- Transfers (11.9%)
- Dropouts (11.7%)
- Other and unknown (6.9%)

All students enrolled in the regular Austin schools during the 1978-79 year who had birthdays between 9/2/63 and 9/1/64 were included in the data file for this study (N=5,039). Of these students 68% were on grade level (9th grade), 25% were below grade level, and 7% were above grade level.

Enrollment data for each year from 1978-79 until the fall of 1983 was collected from the district Master Student File. Test scores, special education status, and other variables were collected from other files. Students who entered the District in subsequent years were not added to the file.

Students who left the District and never returned were identified as "school leavers." Their records were checked in the schools in order to determine which ones were likely to be dropouts. Following the record checks, students were classified into three groups: nonleavers, dropouts, and other leavers (included transfers). Nonleavers were students who graduated or who were still enrolled in the fall of 1983. Dropouts were students for whom we could find no evidence that they transferred to another diploma-granting institution. Other leavers included those who transferred to another school district, who became associated with an organization that might grant a high school diploma such as the armed services or the state prison system, or students for whom we could find no permanent record card.

Discriminant analysis was used to determine how well dropping out could be predicted from readily available information in the District computer files. The students included in the analyses were limited to nonleavers and dropouts. The variables chosen for the analysis were those available at the beginning of the 1978-79 school year (the year they should have entered ninth grade): sex, eth-

nicity, grade point average, and the number of serious discipline incidents (e.g., corporal punishment, suspension, etc.) in which the student had been involved during the preceeding year. Ethnicity was entered as three binary variables--

Hispanic: 1 if Hispanic; 0, otherwise.
Black: 1 if Black; 0, otherwise.
Other: 1 if other than Hispanic or Black; 0, if Hispanic or Black

The analyses were run using the SPSS DISCRIMINANT program on the University of Texas CDC Dual Cyber system. A stepwise discriminant analysis procedure was used with the order of entry determined by the variable which would give the largest Mahalanobis distance between the two groups. Special education students were omitted from the analyses because their grade and GPA values were probably different in meaning from those of the other students.

In order to check the stability of the classification resulting from applying the discriminant function, a second analysis was done using the variable identified in the original analysis but only a 60% random sample of the students. The new weights were determined using the direct method. They were then applied to the classification of the remaining 40% of the sample.

Information was available on a few variables not included in the discriminant analysis. These variables were LEP (limited English proficiency) status and reading and math achievement scores. They were omitted from the discriminant analysis for several reasons. LEP status was omitted because there was some question of the validity of the designation for the year 1978-79 and because the number of LEP students was so small compared with the number of non-LEP students. The achievement scores were omitted because the students in the analysis were found at both junior high and high school. Different tests were given at those grade spans, and no reasonable way was found to equate the tests. Therefore, the dropouts and nondropouts were compared on these variables after the discriminant analysis to determine how the groups differed on them.

Results

The data file contained records on 5,039 students. A total of 4,752 were included in the discriminant analyses after special education students were removed. Figure 1 shows their drop status as of the fall of 1982. These students are of the age so that they should have graduated in May, 1982.

Figure 2 shows the dropout rate for the students by sex and ethnicity. Note that transfer students and "other leavers" were removed from the analyses when the percentage dropping out was calculated. The percentages reported in the table are the proportion each group represents in the population about which a dropout-nondropout distinction could be made. The results show that the dropout rate for males was slightly higher than for females. Hispanic students had the highest dropout rate followed by Blacks then Anglo/Others. Within ethnicity, males had a higher dropout rate than females with the exception of Anglos/Others where the reverse was true. The dropout rate for Hispanics is about twice the rate for Anglo/Others.

Figure 3 presents the number and percentage of students who dropped out during the regular school year or during the summer (i.e., they did not return to school the following year). These results show that students who complete a school year are likely to come back the following fall if only for a short time.

Figure 5: STANDARDIZED AND UNSTANDARDIZED CANONICAL DISCRIMINANT FUNCTION COEFFICIENTS

From a stepwise discriminant analysis five variables were identified that contributed to discrimination between the groups--grade point average, grade, the variable for Black ethnicity, the number of discipline incidents, and sex. The overall canonical correlation was .51. Figure 4 shows the order in which the variables entered the equation. The standardized canonical discriminant function coefficients are displayed in Figure 5. The only variables not to enter the formula were the Hispanic and Anglo/Other binary ethnicity variables. Had one of these variables entered the analysis, the other would have been redundant.

Figure 6 provides descriptive information comparing dropouts, nonleavers, and others. Figure 7 provides descriptive information for all students by ethnicity. Figure 8 provides the probability of dropping out by ethnicity within sex category.

Discussion

What can we learn from the discriminant analysis? The results showed that students who have low GPA's, who are behind in grade for their age, who have been involved in serious discipline incidents, who are female, and who are non-Black have a higher than average probability of dropping out. An examination of Figure 6 and 8 indicates that most of these variables have face validity for predicting dropping out. The GPA of dropouts is lower than that of students who stay in school. Similarly, the percentage below the 9th grade is three times as high for dropouts as for nonleavers. The average number of serious discipline incidents is five times as high for dropouts.

However, two findings appear puzzling at first glance. One finding that appears to be counter intuitive is that girls are more likely to drop out than boys. Figure 8 shows that the dropout rate for girls is lower than that of boys. However, what the equation says is that "all things begin equal," girls are more likely to drop out than boys. But all things are not equal. Girls do not appear to be retained as often as boys, they may have higher GPA's than boys, and they are involved in fewer discipline incidents. Therefore, even if an individual girl tends to drop out more readily than a similar boy, as a group they drop out less frequently than boys. Furthermore, the variables included in the formula are very limited in scope. The emergence of sex as a predictor indicates that some variables outside the scope of the formula affect girls more negatively than boys. It seems likely that pregnancy would be one of those variables.

The way that ethnicity entered the formula is also surprising. What the formula says is that "all things being equal," Blacks are less likely to drop out than Hispanics or Anglo/Others who are equally likely to leave school. An examination of Figure 7 shows that generally the Hispanic students have mean scores on the variables used in the equation that are very similar to those of Blacks (except on the number of discipline incidents). One might expect the percentage dropping out to be similar for the two groups. However, there apparently are some influences operating that tend to keep Black students in school when similar Hispanic and Anglo/Other students drop out. Those influences appear in the formula as the positive weight on the variable for Black ethnicity. One factor that may be important in producing this positive influence is participation in extracurricular activities. A recent evaluation in AISD (Berrier and Carsrud, 1981) showed that the percentage of Black high school students participating in extracurricular activities was greater than the percentage of Hispanic students.

the information readily available in a large city school district computer files. It is likely that students who are at risk but do not drop out also could benefit from dropout prevention programs. (A potentially valuable study that needs to be done is to compare those at risk for dropping out who stay in school with those who leave in an attempt to identify influences that keep one group in school but not the other.) A review of the literature indicates that the prediction could be improved if other variables such as economic need, the presence of a father in the home, and the schooling history of other members of the family could be included in the analyses. One might argue that school personnel who are more familiar with the students could do as good or better job than a central analysis. That may be true for most students. However, the central analysis has the advantage of complete coverage. School personnel may overlook many students who quietly blend into the work than leave when they get far behind.

The **second implication** is that **dropout prevention programs need not be culturally specific** in their content. That is, there do not seem to be any ethnic-specific characteristics of Black and Hispanic students which operate to increase dropout rates independent of academic accomplishment. Improvement of academic accomplishment as reflected by GPA and grade for age would appear to be the most important target for dropout prevention. Addressing ethnic-specific characteristic may be important in that effort, however.
