ABSTRACT

This report focuses on the supply, distribution of, and requirements for nursing. The first chapter describes the supply of registered and licensed practical nurses. Characteristics of the overall nursing supply are discussed in terms of marital status, age, and employment patterns. Data are also provided on nurses newly licensed to practice, males, and minorities. Projections are made of the supply of registered and licensed practical nurses. Chapter 2 reexamines two approaches for determining requirements for registered nurses: the historical trend-based model that identifies the impact of health system changes on requirements and the criteria-based model that is designed from the development of health care goals. The two sets of requirement projections are compared with four sets of supply projections based on alternative assumptions about the number and types of graduates that might be available. Recommendations are made in chapter 3 for the role of the federal government in support of nurses training and for advanced preparation in nursing. Appendixes, amounting to approximately one-third of the report, include 41 data tables and a list of references. (YLB)

EXECUTIVE SUMMARY

This third report on the supply and distribution of and requirements for nurses is submitted pursuant to Section 951, Title IX, Nurse Training Act of 1975, Public Law 94-63 as amended by Section 12(h), Public Law 95-623. The report is due to the Congress October 1, 1981 and has been prepared at a cost of \$ 435,176.

Although the number of nurses in active practice has increased, there is mounting evidence to document the existence of a nursing shortage in all types of patient care settings.

Registered nurses are a vital part of the Nation's health care delivery system and constitute the largest single group of health care providers. As of September 1977, an estimated 1,401,633 persons held current licenses to practice, and 70 percent of this number were active participants in the nursing work force. An additional 3 percent were actively seeking nursing employment, a rate well below that for the U.S. labor force. Of the 27 percent who were neither working nor seeking employment, 27 percent were over 60 years of age and 19 percent were between 50 and 60 years of age.

Data from the 1977 National Sample Survey of Registered Nurses indicate that registered nurses in younger age groups are remaining active in the work force for longer periods of time, even during the child-rearing years. Moreover their employment rate is higher than that for their non-nurse counterparts in the labor force. However, nurses in older age groups whose retirement plans have reached maturity are leaving the work force at an earlier age. This report describes characteristics of the overall nurse supply in terms of marital status, age, and employment patterns, together with data on nurses newly licensed to practice. Information is also included on males and minorities in the work force.

Graduates from the three types of programs preparing for registered nurse licensure are the principal source of new additions to the nurse supply. For the academic year 1979-80, the total number graduated was 75,523, a decrease of approximately 1,625 from the preceding academic year. Small increases in the number of graduates from associate degree programs were insufficient to offset continuing decreases in the number of graduates from hospital-based diploma programs.

Graduates of foreign schools of nursing account for a relatively small portion of additions to the nurse supply. Regulations published in the Federal Register by the Immigration and Naturalization Service now require nonimmigrant nurses to possess a valid State license to practice nursing in the United States or to have successfully passed a screening examination in English language proficiency and in nursing given by the Commission on Graduates of Foreign Nursing Schools. Also, the Department of Labor requires immigrant aliens to pass that test in order to be certified for permanent employment in the United States. Use of the test has proved to be a reliable predictor of success in passing licensure examinations to practice as a registered nurse.

In addition to registered nurses, an estimated 715,000 practical nurses held licenses in 1980, of whom 77 percent were employed in nursing and 2.9 percent were unemployed. The number of programs preparing licensed practical nurses (1,318 in October 1979) has remained rather constant in recent years, but a slight decrease in the number of graduates occurred between 1975-1979. Projections to the year 2000 indicate a slow growth rate in the supply.

There are many dimensions to the shortage of nurses. There is an uneven geographic distribution of registered nurses among States and among counties within States. Inner cities and rural areas lack sufficient nursing services despite the fact that the number of nurse practitioners in rural areas has increased. Achieving a more equitable distribution of nurses is, however, dependent upon factors other than the willingness of the nurse to locate in underserved areas. There must also be employment opportunities in established health care delivery systems and provision for reimbursement to subsidize the cost of providing service. Distribution problems can also be viewed in terms of type of practice setting. Although more nurses are employed in hospitals than ever before, it is estimated that 80 percent of hospitals do not have an adequate supply of nurses. This report examines changes that have occurred in hospital nursing practice and summarizes data from recent studies regarding turnover of nurses in this practice setting.

Turnover is a significant problem in many acute care settings; it is costly to the institution and ultimately to the consumer and jeopardizes the quality and continuity of patient care. The causes are complex and inter-related. Dissatisfaction with professional working conditions is probably the single most important factor. Dissatisfaction stems from pressures in the hospital setting, inability to define and control nursing practice, lack of opportunity for professional growth, participation in decision making, and administrative support. Inadequate starting salaries and inadequate salary differentials for new and experienced staff have long been cited as a major factor contributing to turnover. However, findings from recent studies indicate that salary does not have a direct effect except as it becomes marginal to other determinants such as job satisfaction and the perception of recognition for a job well done. These problems cannot be solved by short term, stop gap remedies nor by relying on temporary nursing services. Solutions will require the concerted efforts of the health care industry and appropriate Federal initiatives to utilize appropriately nurses who are already in the work force. For example, a federally supported study is underway to document the effect of temporary nursing services on the supply of nurses, the quality of care, and the cost of providing nursing services.

The need for nurses in long-term care facilities is considered in the context of the characteristics of the nursing home population and the need for community health nurses as part of a national strategy to emphasize disease prevention.

Another concern is that the nursing work force be more representative of the population it serves. Data not previously available on minorities in nursing is included in this report.

Considering the characteristics of patient populations, both in institutional and community settings, and considering changes in practice resulting from the application of new knowledge and new technologies, it appears unlikely that the Nation's need for nursing services can be met by simply increasing the number of registered nurses.

As detailed in the report, the number of nurses prepared as expert clinicians in various specialties falls far short of the number needed for direct patient care. Schools of nursing lack sufficient faculty with the qualifications for teaching the number of students who will be needed to meet the demand for nurses during the next 20 years. In all types of practice settings, the number of well-prepared nurse administrators is insufficient to effect changes in the delivery of service to assure high quality care and, importantly, provide inducements for nurses to remain in practice.

Nurses are a national resource. Projections of supply and demand are necessary to determine whether the supply will be adequate not only in number but also in types of skills needed to respond to changes in the health care delivery system. This report includes supply estimates based upon four series of projections. With the exception of differences assumed for graduations and the effect of varying graduation rates on the total supply, the same set of assumptions was used for each of the four series. A conclusion common to all four series is the finding that the number of graduations by the year 2000 will be less than the number currently graduated and that the composition of graduates by type of preparation will differ as compared to earlier years.

Current data indicate that the supply of registered nurses in 1980 was overestimated in the Second Report to Congress, March 15, 1979 (Revised). The current estimate for the number of employed registered nurses as of January 1980 is 1,119,100 or 945,700 on a full-time equivalent basis. Based upon assumptions from the four series of supply projections, it is anticipated that there will be continued growth in the registered nurse supply over the next 20 years, although at varying rates. Projections for 1980 of the number of nurses with preparation at the graduate level proved to be underestimated. However, nurses with graduate degrees comprise only 5 percent of the total supply.

Two approaches used in the Second Report to the Congress for determining requirements for registered nurses have been reexamined for purposes of this report. One is an historical trend-based model which identifies the impact of health system changes on requirements. The other is termed the criteria-based model and is based upon the development of health care goals. The goals were originally established by the Panel of Expert Consultants appointed by the Western Interstate Commission for Higher Education and subsequently updated by a similar type group. Projections emanating from the latter model were somewhat larger than those from the historical trend-based model, due primarily to the criteria for requirements for registered nurse staffing in nursing homes and community agencies.

The two sets of requirements projections were compared with four sets of supply projections based on alternative assumptions about the number and types of graduates that might be available. The comparison of supply projections

and historical trend-based requirements projections for registered nurses for 1990 indicates there is reasonable balance between the two. By the year 2000, however, requirements projections exceed the supply estimates in three of the four series of supply projections. The comparison of supply projections and the criteria-based requirements projections for the year 1990, the only year for which projections were made, shows that requirements would outstrip supply, with the most serious deficit occurring in the number of nurses with specialized advanced training.

Options for future Federal support for nursing education should be considered in the context of national health care priorities, changes in the health care delivery system, and constraints in Federal spending. States, the private sector, the profession, and individual nurses have important roles to play in assuring an adequate supply of well-prepared nurses. Federal support should be targeted to areas of pressing need by increasing the number of nurses prepared: (1) at all levels for direct patient care in acute care settings, in nursing homes, and in the community positions; (2) as primary care providers; and (3) for positions as faculty and administrators of nursing services. In addition, the proportion of minorities in the nursing profession should be increased.

There is a special need to overcome barriers to the full utilization of nurses in all practice settings. Studies are needed to document changes in patient outcomes as a result of nursing service; and to demonstrate and evaluate the utilization of nurses in various practice settings. These efforts will take time, but in the long run they hold promise for strengthening the capability of our nurse training system to meet patients' needs.

INTRODUCTION

This is the Third Report to the Congress in response to the statutory requirements in section 951 of Public Law 94-63 directing the Secretary of Health and Human Services to provide the Congress, on a continuing basis, detailed information on the supply and distribution of and requirements for nurses as well as on factors affecting supply and distribution. These data were to be used to determine the adequacy of the supply, from the standpoint of type and level of preparation, in relation to population needs and demand for nursing services. Section 951 further directed the Secretary to incorporate in reports to the Congress recommendations for legislation that would achieve an adequate supply and equitable distribution of nurses nationally and within each State. The annual reporting requirement in section 951 of P.L. 94-63 was subsequently amended by P.L. 95-623 to require biennial reports.

Information was requested in two general areas: (1) the supply and distribution of and requirements for nursing personnel on a current and projected basis, for the Nation as a whole and within each State, and the demand for the services which these nursing personnel provide; and (2) the number and distribution of nursing personnel within the United States and within each State according to educational levels, activity status, rates of compensation, specialty preparation, and migration data on nurses entering the United States from other countries. A copy of section 951 is included in appendix 1.

Fulfilling the reporting requirements proved to be a complex task. In terms of sheer volume, information had to be collected and analyzed

on the 2.5 million nursing personnel who are employed in the health care system. Aggregate numbers are of less significance in determining adequacy of the nurse supply than are data on relatively small segments within the total supply. These data were examined and analyzed separately. The 2.5 million nursing personnel represent a range of competencies, from those with on-the-job training to those prepared for complex responsibilities in the management of patient care or the administration of nursing services. Moreover, they are distributed among a vast array of practice settings. Accordingly, an elaborate procedural plan was developed to acquire and analyze data to meet the statutory requirement. As a first step, the current status of existing sources of data collected on a regular basis by various agencies was identified to provide descriptive information or background essential for analytical interpretation. Where data were lacking, incomplete or in need of further refinement, the Division of Nursing intensified its efforts to develop new tools for analyzing nursing resources and requirements by initiating projects that would integrate analysis of data collected in a number of different ways and through a number of different sources.

The First Report to the Congress February 1, 1977 (USDHEW, Division of Nursing, 1977) relied, of necessity, on information that was already available and it therefore dealt primarily with information on the supply and distribution of nursing personnel. Meanwhile, several studies with different approaches and objectives were undertaken to project requirements for registered nurses since this was a more complex issue than that of supply. One of the projects undertaken (by Vector Research, Inc.) was an assessment of the impact of three anticipated changes in the health

care system: the introduction of national health insurance, the increased enrollment in health maintenance organizations, and the reformulation of nursing roles. The effect of these changes was examined on a State level as well as on a national level. A second project (System Dynamics National Model) approached supply and distribution from a national perspective through the analysis of factors affecting nursing requirements and resources and the interaction of each upon the other. Two other approaches were designed to develop techniques for determining requirement estimates to be used by groups at State or sub-State levels. The first of these (WICHE State Model) developed a systematic framework for determining the kinds of health care that might be needed as a basis for estimating requirements for nursing personnel. This framework was subsequently extended to produce nationally derived requirements estimates. A second approach to estimating requirements was intended for use at a sub-State level and consisted of a model incorporating demand and supply factors.

New models were also developed for making determinations of the anticipated nurse supply. These models had the capability to utilize data currently available and to incorporate new types of data as they became available. For purposes of analyzing the distribution of nursing personnel at a sub-State level, a model was developed to provide for a review of county data through a reallocation of registered nurse resources in terms of the population served. These activities made full use of data already in existence on supply and distribution of both nursing personnel and health care services. The methodologies for both the requirements and supply modeling efforts are fully described in the Second Report to the Congress March 15, 1979 (Revised) (USDHEW, Division of

Nursing, 1979).

The data from two requirements models were used to examine the relationship between supply and requirements in the Second Report. The models provided a wide range of projections for registered nurse requirements based upon the extent of change in the health care delivery system forecast in the models. These estimates were compared to two sets of supply estimates, one of which assumed discontinuance of Federal support for basic nursing education and the other, maintenance of current conditions and trends in Federal support. From an overall review of nurse supply and requirements, it was concluded in the Second Report (1979) that the aggregate supply of nurses would be roughly in balance with requirements in 1985. This conclusion was also based upon additional assumptions: (1) once a national health plan was enacted, a lead time of 2 or 3 years would be required for implementation, and phase-in of additional coverage and benefits might require several additional years; and (2) reformulation of nurses' roles would not increase to the extent anticipated in the model. If one or both of these assumptions proved correct, the rate of demand would be slowed.

The general conclusion that supply and requirements would be in balance was tempered by the acknowledgment that maldistribution might continue to exist in certain areas of the country, in certain practice settings, and among nurses with certain specialized training. Through work experience and advanced training, nurses prepare for practice in various sectors of the diverse health care delivery system. Those whose finely honed skills equip them for specialized intensive care units are not likely to perform with equal effectiveness in community settings where

assessment of health status and management of care are prime concerns. Similarly, skills required for expert clinical practice are not necessarily those most pertinent to administration of nursing services in a medical center complex. Hence, aggregate supply of nurses is not the sole determinant of balance between supply and requirements. As shifts occur in the delivery of health care from institutional to ambulatory care settings, more nurses who are skilled in assessing health status and in helping individuals and families cope with the effects of illness and disability will be needed. Pressures to control escalating costs of hospital care are likely to encourage greater use of nursing homes, rehabilitation centers, and convalescent care facilities where nurses are the primary providers of care and by and large are responsible for the management of these facilities. Moreover, the increased use of sophisticated treatment modalities will dictate the need for nurses with advanced preparation in other specialized areas of practice such as trauma centers.

In order to fill the gaps in existing data sources and to examine more closely factors affecting nurse supply, distribution, and requirements, a study was designed and initiated for a national sample survey of registered nurses. This report contains findings from the first such survey, conducted in August 1977 (Roth, et al., 1978). It also includes data from the Inventory of Registered Nurses conducted in 1977 by the American Nurses' Association under contract from the National Center for Health Statistics (USDHEW, NCHS, 1978).

In addition to the studies that furnished information for this report, other studies approaching the same general issues from different points of view are in progress. The first of these is a study mandated by Section 113,

Nurse Training Amendments of 1979 (P.L. 96-76), which required the Secretary to arrange for the conduct of a nursing study with the National Academy of Sciences acting through the Institute of Medicine (IOM). Three purposes are outlined for the 2-year study: to determine the need to continue a specific program of Federal financial support for nursing education; to determine the reasons nurses do not practice in medically underserved areas in order to develop recommendations for actions which could be taken to encourage nurses to practice in such areas; and to determine the rate at which and the reasons for which nurses leave the nursing profession and to develop recommendations for actions which could be taken to encourage nurses to remain or reenter the nursing profession, including actions involving practice settings conducive to the retention of nurses. In order to use this information in considering the nature and extent of future Federal support for nursing, the Congress required that the entity conducting the study report preliminary recommendations not later than 6 months after arrangements for the study had been concluded and a final report 18 months later. Both reports were to be accompanied by a similar report by the Secretary.

Delays were encountered in consummating the agreement between the Health Resources Administration, acting on behalf of the Secretary, and the IOM. Further, in view of the amount of work to be done in the 2-year study period, the IOM's request for a planning period was granted. The planning phase was completed on August 30, 1980, and a contract for the 2-year study was signed on January 12, 1981. The study design consists of three phases, the first of which is to be completed in August 1981 to fulfill the mandated 6-month reporting requirement. Phase II will

require 12 months for completion, and the final report will be due 6 months thereafter, in January 1983. Although findings from the study are expected to assist the Congress in determining the future Federal role in support of nursing, they will not be available for inclusion in this report.

A second study, initiated by the Health Resources Administration and being conducted under contract by Abt Associates, is assessing the impact of nurse training authorities from 1964 through 1979 and examining the extent to which skills of nurses graduated from various types of programs are in accord with the needs of hospitals, nursing homes, and ambulatory care facilities. Since a final report is not expected to be available by the time this report is submitted, study findings cannot be incorporated in this report. In developing future legislative proposals in support of nurse training, the Department will, however, consider findings from these two studies as well as data included in this report.

Chapter 1

REGISTERED NURSE AND LICENSED PRACTICAL NURSE SUPPLY

Factors Affecting the Supply of Registered Nurses

This section describes the supply of registered nurses, incorporating information about those who enter the nursing work force as graduates of schools of nursing, both domestic and foreign, who are licensed to practice.¹ In addition to describing characteristics, employment status, and distribution of the nursing work force as a whole, special segments of the supply such as newly licensed and minority nurses are highlighted.

Graduations from Initial Nursing Programs

The primary source of additions to the supply of registered nurses is graduates from nursing schools located in the United States.

Three types of programs awarding different credentials prepare their graduates for licensure as registered nurses:

- Programs based in hospitals are usually 3 academic years or approximately 27 calendar months in length and lead to a diploma.
- Programs located, for the most part, in community colleges are 2 academic or calendar years in length and lead to an associate degree. A few programs leading to an associate degree are based in senior colleges or universities.
- Programs located in senior colleges or universities most often

^{1/}No data is available on individuals who graduated from a school of nursing but did not take or pass the licensing examination, nor is data available on nurses who failed to renew their licenses. Consequently, this report deals exclusively with nurses who are licensed to practice.

lead to a baccalaureate degree. Baccalaureate programs are generally four years in length and are of two types: an integrated curriculum with nursing content throughout or an upper division, 2-year nursing-concentrated major following 2 years of prescribed study in liberal arts and sciences.

As of October 1980, there were 1,388 programs of nursing education preparing their graduates for licensure as registered nurses: 311 leading to a diploma, 697 to an associate degree, and 380 to a baccalaureate degree (NLN, 1981). These numbers document a trend in nursing education toward preparation in academic institutions, with a corresponding decline in the number of hospital-based diploma programs. The steady decline in the number of diploma programs from 900 in 1960 antedates passage of Public Law 55-851 (Nurse Training Act of 1964) and is the consequence of several social and economic factors. It reflects the preference of all students, including those whose career choice is nursing, for enrollment in programs that award academic credit. The decline is also attributable to the costliness of operating an educational program in a service agency in which income for the operation of the school is derived in large part directly or indirectly from patient revenues.

The number of baccalaureate programs has more than doubled in the same 20-year period, from 171 in 1960 to 380 in 1980 (NLN, 1980). These programs differ from diploma and associate degree programs in two significant respects: they prepare students to function as public health nurses in community settings as well as to provide service in institutional facilities and they provide the base for advanced study in a clinical or functional area.

The most dramatic increase, however, has been in the associate degree sector with a twelvefold increase in this same period of time. This growth was attributable in part to a conscious effort to make nursing education an integral part of the fabric of postsecondary education and to maintain the supply of nurses as the number of diploma programs continued to decline. Initiation of new nursing programs in community colleges has also contributed to meeting the social goal of putting nursing programs within the reach of individuals who could not undertake baccalaureate education either because of financial reasons or because of their need to remain in their home communities. In many areas, however, the number of schools and the size of enrollments grew disproportionately to the availability of clinical resources.

Since 1973, the overall number of programs has stabilized. This general pattern is expected to prevail for the foreseeable future, although shifts will continue to occur in the relative numbers of the three types of programs.

Changes in the number and types of programs are reflected in the number of graduates. Graduations from associate degree programs have increased significantly from 11,678 in the 1969-70 academic year to 36,034 in 1979-80. In the same 10-year period graduations from baccalaureate programs increased from 9,105 to 24,994, while graduations from diploma programs have declined from 22,856 to 14,495.

Three-quarters of the registered nurse population were estimated to have completed their basic nursing education in a diploma program. The proportion with diploma preparation, however, does represent a definite decrease from prior years, reflecting recent declines in the number of

graduates of diploma programs compared to those from the two other types of programs.

The most significant trend since 1972 is the almost threefold increase in the number of associate degree graduates in the nursing work force due to the fact that major growth in the number of these programs occurred in the 1970's.

Since 1972, the number of graduates whose initial preparation was in baccalaureate programs has grown by 43 percent to constitute 14 percent of the registered nurse population.

Additions to the Nursing Population from Immigration of Foreign Nurses

Since World War II, nurses from other countries have been entering the United States in increasing numbers. In the late 1960's and in 1970, changes in immigration laws made it possible for more foreign-trained nurses to enter the country. The rate of immigration of these nurses was further stimulated by increased employment opportunities in this country. To meet their staffing needs, hospitals began professional recruitment of foreign-trained nurses. Consequently, for the first time in over 2 decades, data from State boards of nursing showed steady increases in the number of foreign-trained nurses licensed for the first time in the United States (USDHEW, 1976; Hiestand, et al., 1976).

This report presents data, available for the first time, on the overall number and characteristics of foreign nurse graduates licensed in the United States. Excluded from the data are foreign-trained nurses already in the country who have not yet passed the licensing examination and those who have repeated their basic preparation for nursing in this

country and subsequently became licensed. Data from the 1977 National Sample Survey (Roth, et al., 1979) estimated that in September 1977, 52,436 nurses whose basic nursing education was received in a foreign country, were licensed in the United States. These nurses represented 3.7 percent of the nurse population.

The median age of foreign nurse graduates (40.6 years) exceeded that of their U.S.-trained counterparts (39.8). For 72 percent of foreign nurse graduates, a nursing diploma was the highest nursing-related educational credential; an associate degree was held by 3.5 percent, a baccalaureate by 20.9 percent, and a master's or higher degree by 3.6 percent.

Almost four-fifths (77.9 percent) of foreign nurse graduates were employed in nursing in 1977. The data reflected marked regional differences in the proportion of foreign nurse graduates overall. The Middle Atlantic and Pacific regions accounted for more than half (28.1 percent and 26.5 percent, respectively), while the East South Central States claimed the least. Due to the large number of active nurses, the percentage distribution of foreign nurse graduates employed in nursing by region showed a similar regional profile. It is probable that foreign nurse graduates tended to locate in regions where they were more likely to find employment opportunities and where higher concentrations of ethnic populations are found.

Characteristics of the Nursing Population

Newly Licensed Nurses

In describing the characteristics of the entire nursing work force, it may be useful to first examine the characteristics of newly licensed nurses. Although they represent a relatively small percentage of the

total nurse population (approximately 4 or 5 percent) and their employment and mobility patterns differ somewhat from the supply as a whole, the data on this segment of the nursing work force are valuable in monitoring these nurses as they enter the work force and as useful trend indicators. Building upon the design of a study first conducted in 1973 under contract with the Bureau of Health Manpower (now Bureau of Health Professions), the National League for Nursing has been collecting annual data on the employment status, geographic mobility, and characteristics of newly licensed nurses. The study questionnaire is sent to all those who took and passed the licensing examination 6 months after licensure. Preliminary data from the 1979 Survey indicated that 95 percent of the respondents were employed in nursing and an additional 1.7 percent were not employed but seeking employment (NLN, 1979). There was little variation among graduates of the three types of programs preparing for licensure in terms of their employment status. Thus, 97 percent of the graduates of diploma programs reported that they were employed in nursing and 1.3 percent indicated that they were not employed but looking for employment. Of the graduates of associate degree programs, 94 percent indicated that they were employed and 2 percent reported that they were not employed but looking for employment. Ninety-six percent of the graduates of baccalaureate programs were already employed in nursing and 1.7 percent reported that they were not employed but looking for employment. Among the graduates of foreign schools of nursing, 90 percent were employed in nursing while 3.9 percent were not yet employed but seeking nursing employment. It is significant, however, that although a very high proportion of all newly licensed graduates were already employed in nursing, 14 percent were looking for other nursing employment. Of this proportion,

graduates of baccalaureate programs accounted for 16 percent, graduates of associate degree and diploma programs, 12 percent, and graduates of foreign schools of nursing, 20 percent.

The extent to which the educational preparation of new graduates influences their choice of practice setting has been a topic of considerable interest. This is particularly true for graduates of baccalaureate programs since they are the only group of new graduates prepared to work in community as well as institutional settings. Under a contract awarded by the Division of Nursing, Bureau of Health Professions, Health Resources Administration, Abt Associates examined the relationships between nurses' clinical experiences during baccalaureate education, prenursing education employment experiences, prenursing educational employment preferences, and other factors relating to postgraduation employment, practice location, and specialty setting (USDHHS, Abt, 1981). Findings were based upon three separate surveys: a mail survey of a sample of 1979 graduates of accredited baccalaureate programs in the United States, a mail survey of all the accredited baccalaureate schools of nursing in the United States, and a telephone interview survey of a small sample of deans of these programs.

The study concluded that the work setting preference expressed before entering the nursing education program was the most important predictor of the graduates' subsequent choice of employment setting. For their first nursing position, however, nearly all (92 percent) of the recent graduates selected to work in inpatient hospital settings, three quarters of them in the same State in which they received their nursing education, and nearly half in the same city. The deans who were interviewed expressed the view that many graduates seek initial employment in general hospitals

in order to gain experience and sharpen their skills. This view is confirmed by the responses of the new graduates themselves. Those who had gained considerable experience with inpatients during the senior year of their baccalaureate education were less likely to feel the need for additional employment experience with inpatients prior to employment in other settings.

Choice of initial practice location is not, however, a predictor of choice of future practice setting. Three out of four nurses in the study intended to change jobs within the next 3 years, primarily to move from acute care to nonhospital-based community settings. The majority of the respondents reported a willingness to consider employment in either a rural area or a low income section of a metropolitan area. Those who stated a preference for employment in such settings were more likely to have expressed such an interest before entering the nursing program, were more apt to be from upper-middle-class backgrounds, to have attended privately supported schools of nursing, and to have had greater amounts of nonhospital-based experience during their training. Students who chose to have experience in nonhospital-based settings were heavily influenced by faculty who served as role models. Although most programs offered experience in urban or suburban community settings, primarily public health centers, schools, or nursing homes, relatively few students (28 percent) were provided practice opportunities in rural areas. Schools attributed their inability to make use of rural practice settings to lack of faculty to teach and supervise students in areas geographically remote from the school and to high costs of transportation.

Findings from this study are consistent with results from other studies of graduates of programs leading to a baccalaureate degree in

nursing. These graduates tend to work in settings that provide more opportunities for independence, self-direction, and initiative and tend to perceive hospitals and institutions as bureaucratic and restricting. A study by Knopf (1975), RNs One and Five Years After Graduation, is a case in point. Five years following graduation, only one-half of the graduates of baccalaureate nursing programs were employed in hospitals, in contrast to three-quarters of the graduates of associate degree and diploma programs who were working in hospitals.

Overall Nurse Supply

The National Sample Survey conducted in September 1977 estimated that 1,401,633 registered nurses were currently licensed to practice in the United States at that time, 70 percent of that number were employed in nursing, and 3 percent were actively seeking employment. This latter figure is slightly greater than the 1.7 percent unemployment rate for registered nurses reported by the Bureau of Labor Statistics for 1980 (USDOL, 1981).

Twenty-seven percent of the total nurse population were neither employed nor looking for nursing employment at the time of the survey. Among this group, approximately 27 percent were at least 60 years of age and about 46 percent were at least 50 years of age. The great majority of younger nurses in the group had children living at home, leading to the assumption they worked at home taking care of their families. Only 6 percent of this group were under the age of 50 and had no children at home. This latter group represented 1.4 percent of the total nurse population. Significantly higher activity rates were noted for those in the 30-34,

35-39, and 40-44 age groups and significantly lower rates were noted for those in the groups of nurses 55 years of age and older.

Many factors other than job availability determine whether nurses with current licensure are able or willing to remain in practice. Clearly, characteristics which apply to women in general, apply to nurses as well. The majority (72 percent) of registered nurses were married; 5 percent were widowed and 8 percent divorced or separated. Fourteen percent reported never having been married. Employment rates in nursing varied according to marital status, with the highest rates reported by nurses who were single, divorced or separated (85 percent), and the lowest by those who were married (66 percent) or widowed (54 percent).

The National Sample Survey showed an estimated 26,991 of the 1,401,633 nurses licensed to practice were men. While the number of men licensed as nurses has almost doubled since 1972, their relative proportion within the total nurse population reflected only a slight increase in the current survey, from 1.3 to 1.9 percent. A higher proportion (77 percent) of male registered nurses were employed in nursing than their female counterparts (70 percent).

For married women, ability or willingness to practice as a nurse was also found to be influenced by childrearing responsibilities. Half of the registered nurse population (50.8 percent) reported having children under the age of 17 in the household. Seven percent had children 1 year of age or younger, 17 percent had children between 2 and 5 years of age, and 39 percent had children between the ages of 6 and 17. Approximately 58.5 percent of the nurses who had children under 1 year of age were employed in nursing, in contrast to 71 percent of those who had no children

in that age group. The employment rate was slightly higher (64 percent) for those with infants. This is in contrast to findings from a Current Population Survey conducted in June 1977 (USDOL, BLS, 1981) which indicated that an estimated 35.1 percent of all women with children less than 5 years old were employed, 5.3 percent were looking for work, and the remaining 59.6 were not in the labor force. The employment rates were the same as for nurses with children between the ages of 6 and 17 as for those without children in that age grouping. These findings are consistent with data on activity rates for nurses by age group and confirm that nurses tend to drop out of the work force to care for young children and reenter practice once their children have reached school age. In the 1972 and earlier BLS surveys, there was a decline in the proportion of employed nurses in the 25- to 39-year age group. However, the 1977 BLS data indicate that nurses in the younger age groups remain active in nursing longer, which may reflect the growing tendency among the female population as a whole to postpone marriage and childbirth or to combine motherhood with gainful employment.

Age is also a factor in determining work force participation. The median age of the nurse population in the 1977 BLS survey was 39.5 years. There was a marked difference between the median age of nurses who were employed (37.7) and those who were not (46.1). Slightly more than one-fourth (27.4 percent) of employed nurses were under 30 years of age and two-thirds were less than 45. The data also revealed that nurses are retiring at earlier ages. In 1972 the activity rate for nurses 65 years of age and older was 43 percent; in 1977 it had declined to 19 percent. Availability of financial assistance for retirement in the health care

industry is a fairly recent occurrence, and the marked change in the proportion of older nurses who are working may indicate that retirement plans are now reaching maturity for a sizeable group of the nursing work force.

Salaries for nurses have improved significantly over the last 20 years, but the extent to which they are a compelling inducement to remaining in the work force is open to question. There is, of course, considerable difference between salaries according to employment setting, position level, and geographic location. The 1977 National Sample Survey indicated that for the nurse employed on a full-time basis in a hospital as a general duty staff nurse, the average monthly salary was \$1,021 or \$12,252 annually. There was little statistical difference between the median family income for those employed in nursing in comparison to those not employed in nursing. For married nurses, the total family income was almost double that of nurses who were single, divorced, separated or widowed. Although the median family income of those who were married was larger than for the nursing work force as a whole (\$23,005 as opposed to \$19,889), the median family income of employed married nurses was \$23,402, as opposed to \$21,910 for those who were married and not employed. Given the fact that there is relatively little difference between the median family income of employed and unemployed married nurses, one cannot conclude that salary alone is the decisive factor in a married nurse's choice to remain in the work force. It is possible that the most significant factor in the decision to remain in the work force is the income of the spouse relative to total family financial need rather than the relative value of the salary of the working married nurse. This suggests that there are nurses working

out of a perceived financial necessity as well as out of interest in pursuing a professional career.

With little salary differential provided for experience, demonstrated skills, or education, coupled with generally narrow or compacted pay scales, the economic incentive for nurses to continue employment over time is open to question. Surveys of women's participation in the labor force are relevant to this hypothesis (Brown, 1980; Strober and Weinberg, 1980). Based upon a number of studies, a Stanford University economist concluded that, with the exception of child care, employed women do not substitute market goods and services for their own household production to any greater extent than do home workers (Strober, 1980). Other studies have found that the husband's hourly wage was a more significant predictor of the use of paid household help than was the wives' earnings (Walker and Woods, 1976; Stafford and Duncan, 1977; Robinson, 1977). Because a considerable amount of the married nurses' salaries are consumed by the costs of working and because of the numerous pressures resulting from filling a dual role, families with employed wives are not necessarily better off than families in which the wife is a full-time homemaker.

Despite the fact that the total number of nurses has increased over the last decade and the number of nurses working in nursing has increased as well, there are persistent and widespread reports of a nursing shortage. According to testimony provided by the American Hospital Association, 80 percent of the Nation's hospitals and nursing homes cannot employ the number of nurses they need to fill a reported 100,000 nursing vacancies ("The Nurse Shortage ...", 1980). A problem of this dimension can be explained only by examining a number of complex and interrelated factors.

It is well known that the intensity of nursing care that patients require has increased substantially in response to advances in science, medical technology, and treatment modalities. These changes have made hospital nursing practice increasingly stressful. In the absence of compensation for pressures in the work setting, nurses move from one institution to another, or from hospital nursing practice to another field of nursing to find some level of professional and personal fulfillment. The resulting high turnover rates are a clear measure of dissatisfaction with practice in hospital settings. Although no national study has been done, it is estimated that approximately 25 percent of all nurses drop out of the work force temporarily (AJN, 1980), and there is a growing body of literature indicating that turnover, rather than inactivity, may be a more serious causative factor in nursing shortage.

Turnover, or the voluntary withdrawal from organizations by employees, is inevitable in all industries. In reasonable proportions, it has a salutary effect in weakening traditional operating procedures and paving the way for innovation (Price and Mueller, 1979). In nursing, however, the rate of turnover is, in many instances, excessive, ranging from 37 to 67 percent (Weisman, 1981), jeopardizing the quality and continuity of patient care and threatening the effectiveness and productivity of the hospital. Although most nurses who resign do not leave the nursing labor force, high turnover rates constitute morale and monetary problems for the health care industry.

Two groups of factors are consistently identified in literature dealing with nursing turnover--job context and job content. Job context includes remuneration (salary and fringe benefits), opportunity for growth

(clinical or administrative advancement and institutional commitment of time and money for professional development), organizational structure (work schedules, workload and type of nursing organization and assignment), and administrative support (organizational policies and responsiveness of nursing administrators). Job content includes three factors--autonomy, interpersonal relationships and job status. Autonomy is the control permitted one to define and initiate changes in one's practice and to make full use of one's abilities. It also includes the nurse's participation in nursing service management such as decisionmaking in establishing standards for nursing care and institutional policies and procedures. Interpersonal relationships include teamwork with peers as well as with the medical and administrative staff. Job status is characterized by perceptions of recognition from one's co-workers, patients, and the public. Factors comprising job context are considered to be important in drawing nurses to a job; those comprising job content are responsible for keeping a nurse in a given employment setting and affecting performance.

Over the past decade the importance of these factors on job satisfaction and hence on reducing the likelihood of leaving a job setting has been the subject of numerous research studies. Job satisfaction has been defined as the "degree of positive affect toward the overall job or its components" (Weisman, 1980). Although job satisfaction is determined by the characteristics of the individual as well as by characteristics of the job and the work setting, most of the studies have focused on elements over which management has control. One study correlated job satisfaction with opportunity to use one's ability and to practice in an environment relatively free of stress (Seybolt, 1978). Another, (Weisman,

1980) found that the nurse's perception of autonomy over practice and frequency of delegation of inappropriate tasks by physicians were consistently significant predictors of job satisfaction. A third study carried out in Texas (Wandelt, 1980), and subsequently replicated in other States with similar results (Lindeman, 1980), reported that nurses who remain outside nursing do so because of working conditions.

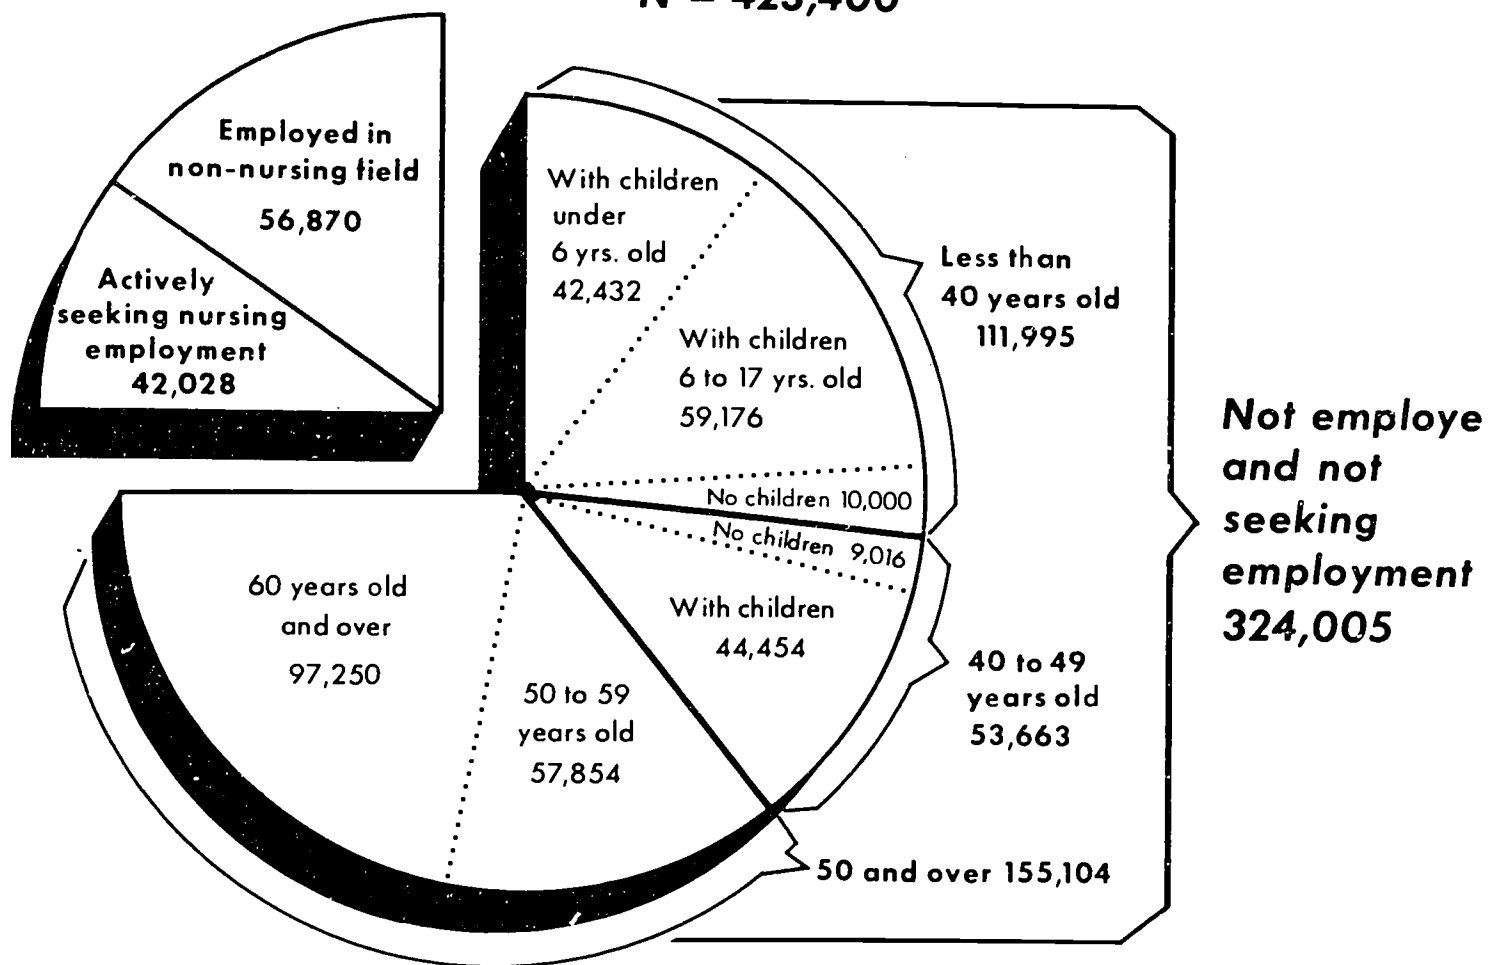

At the heart of the problem is the conflict between hospital administration and nurses as to the distinction between nursing practice and the job of nursing. The definition of nursing practice used by the Wandelt study was "The unique function of the nurse is to assist the individual, sick or well, in the performance of those activities contributing to health or his recovery (or to peaceful death) that he would perform unaided if he had the necessary strength, will, or knowledge. And to do this in such a way as to help him gain independence as rapidly as possible." The nursing job was defined as including nursing practice and other elements such as work schedule, rotation, coordination of patient support services, and interactions with other departments, visitors and staff. "Nurses perceive themselves as professionals engaging in nursing practice while administration views them as employees carrying out the job of nursing." As professionals, nurses are accountable for their practice yet they operate by institutional rules that fail to recognize their authority for making independent decisions concerning nursing care. These conditions of practice, as Aiken (1981) observes, that were tolerable for nurses in the past who spent limited amounts of time in the work force are not acceptable to the nurse of today who spends most of her adult life in part-time or full-time employment.

Inadequate starting salaries and inadequate salary differentials for new and experienced staff have long been cited as a major cause of the nursing shortage. Price and Mueller (1979) observe that economists assign primary responsibility to pay as a determinant of turnover, but they caution that the relative importance of this variable can be assessed only when considered in relation to other factors. Recent studies (Everly, 1976; Price and Mueller, 1979), however, reveal that salary does not have a direct effect on turnover except as it becomes marginal to other determinants such as job satisfaction and the perception of recognition for a job well done. The significance of salary as a factor in turnover should certainly not be discounted, however, for as more nurses become primary full-time wage earners, salary may assume greater importance in relation to other determinants (Price and Mueller, 1979).

Mounting dissatisfactions with professional working conditions, coupled with pressures inherent in the high stress (work) environment of a hospital, are the principal causes of the "burnout" phenomenon. This process includes symptomatology such as exhaustion and chronic fatigue, boredom, judgemental thinking, disillusionment, and keeping one's distance from patients. Not all nurses are equally vulnerable; those working in intensive care, burn, or oncology units and those who care for terminally ill patients are at greater risk. Other factors in the work setting heighten the underlying frustration which leads to "burnout." Experienced nurses resent the fact that there is little, if any, monetary reward for clinical experience. They take exception to the emphasis placed by hospitals on recruitment of new staff, as opposed to increasing the incentives of those already employed to remain in practice at the hospital. For example,

Figure 1. -- Characteristics of registered nurses not employed in nursing, September, 1977.

N = 423,400

Source: 1977 National Sample Survey of Registered Nurses

the California Hospital Association estimates net recruiting costs for attracting new staff average \$7,548 per nurse (Friss, 1981). Newly graduated nurses, on the other hand, suffer frustrations in handling assignments or positions disproportionate to their background experience. Nursing literature is replete with evidence that nurses are concerned with the quality of care they are able to provide. When quality is compromised, dissatisfaction increases, frequently to the point of burnout, and they leave the practice of nursing.

Registered Nurses with Minority Backgrounds

Two new data sources have yielded valuable information on nurses with minority backgrounds. The first of these, the 1977 National Sample Survey, has provided descriptive information on the characteristics of nurses with minority backgrounds in the work force. The second source is the final report of a retrospective longitudinal study of federally supported grants and contracts whose purpose was to increase the number of disadvantaged and underrepresented persons in the nursing profession (Hernandez and Pick, 1980). Although the two surveys dealt with different population groups, the general conclusions tend to corroborate one another.

According to the National Sample Survey, an estimated 6.2 percent (87,386) of the registered nurses in the United States had racial or ethnic minority backgrounds. Of this number, approximately 2.5 percent were black, 2.1 percent were Asian, 1.4 percent Hispanic, and 0.2 percent were American Indian. Almost one-fourth (24.8 percent) of all nurses with racial/ethnic minority backgrounds were located in the Pacific States, constituting 11 percent of the nurse supply in the Pacific area. The

Middle Atlantic States ranked second (24.6 percent) in terms of geographic location of nurses with minority backgrounds, followed by the East North Central States (14.5 percent) and the South Atlantic States (13.9 percent). Relatively fewer proportions of the minority nurses were in the other regions. The proportion of minority in relation to nonminority nurses was also the smallest (2 - 3 percent) in the New England, Mountain, and West North Central States.

Black nurses were more likely (30 percent) to have completed their initial preparation for nursing in an associate degree program than were nonminority nurses (11 percent). Nurses from Asian or Pacific Island backgrounds were more likely (30 percent) than their nonminority counterparts (13 percent) to have had their initial preparation in baccalaureate nursing programs. For all nurses with minority backgrounds, 72 percent had a diploma or associate degree as their highest level of educational preparation in nursing; 23 percent, a baccalaureate degree; and 5 percent, a master's or doctoral degree. Among nonminority nurses, the corresponding percentages were 79, 17, and 4, respectively.

Minority nurses were more likely to be employed in nursing (83 percent) than nonminority nurses (69 percent) and among those employed, a larger proportion (85 percent) were working on a full-time basis as compared to nonminority nurses (67 percent).

The contract "Retrospective Longitudinal Study of the Full Utilization of Nursing Talent" (Hernandez and Pick, 1980) was undertaken to document accomplishments made through 34 federally supported grants and contracts to recruit individuals from disadvantaged and underrepresented population groups into schools of nursing and assist them to complete their study

programs. The study was also designed to provide information on the extent to which individuals who had received support under these grants and contracts subsequently found employment in shortage areas. The full utilization program spanned a period of more than 10 years, during which time its emphasis changed significantly. During the initial period of funding (1967-1971), the program emphasis was on reaching financially disadvantaged junior or senior high school students and assisting them to undertake and complete programs of nursing education. As concern mounted for augmenting the nurse supply, particularly in shortage areas, the program objectives broadened to encompass new target groups, including men, veterans, unlicensed graduate nurses in need of further training, licensed practical nurses, medical corpsmen, and older women as well as individuals from underrepresented ethnic and racial groups. Among the survey respondents, however, 36 percent had racial or ethnic minority backgrounds. Twice as many black respondents lived in inner cities as opposed to rural areas. Hispanics, also, were a predominately inner-city group. Nurses who had originally come from inner cities initially chose employment in the same type of setting (89 percent). Although other data from the survey were not disaggregated by minority background, findings indicate the respondent group as a whole worked with population groups composed of minorities, elderly, and economically disadvantaged. This tends to support the hypothesis that individuals who are themselves either economically disadvantaged or members of ethnic minorities and underrepresented groups are motivated to serve disadvantaged populations.

Distribution of Registered Nurses Among the States

Since the number of nurses in each State and area of the country varies, the measure used to compare the availability of nurses in each area is the ratio of nurses to population. Wide variation exists from State to State and from county to county in the number of employed nurses available to the population of the area, as measured by the ratio of employed nurses per 100,000 population. Data from the 1977 Inventory of Registered Nurses (ANA, 1977) updates the data available from earlier Inventories discussed in the earlier reports in this series. The 1977 Inventory showed that, on a State-by-State basis, the nurse-population ratio varied from a low of 267 in Arkansas to 885 in the District of Columbia and 782 in New Hampshire. Although the nurse population ratios in each State had increased since the last Inventory was made in 1972, the variation among the States remained about the same.

As is true for the States, wide variation in these ratios also exists from county to county, with the heavily populated counties generally having higher ratios of nurses to population. In this connection, it should be noted that higher nurse-population ratios may not necessarily be an indication that more nursing service is available for the population of the area. It could be an indication of concentration of nursing services in one area used by a wider population group than the residents of the area. For example, the larger teaching and research hospitals, which require proportionately greater levels of nursing personnel, are located in more populated areas in the country.

Further, registered nurses, for the most part, require a facility or organized service setting in which to practice. Therefore, relatively

low nurse-population ratios could be an indication of the absence of such facilities or services rather than a lack of nursing personnel, per se. Of interest here is that 82 percent of the estimated employed nurses in the 1977 Inventory of Registered Nurses were in metropolitan areas. The ratio of nurses per 100,000 population in metropolitan areas was 518, compared to an overall nurse-population ratio for all employed registered nurses in the country of 472.

Characteristics of the Registered Nurse Work Setting

This section examines data on the current supply of nurses in terms of the settings in which they work and the characteristics of the populations they serve.

Acute Care

More nurses are employed in hospitals than in any other type of practice setting. The 1977 National Sample Survey of Registered Nurses found that of the estimated 978,234 employed registered nurses, 61.4 percent (601,011) were working in hospitals, representing an increase of 15.9 percent over 1972. Over 70 percent of all hospital-employed nurses were working full time (USDHEW, 1977) and approximately 75 percent held either an associate degree or diploma as their highest credential (Moses, 1979). An estimated 4 percent of registered nurses have master's level preparation and only 30 percent of those prepared at the master's level are employed in hospitals (Moses, 1979).

More nurses are employed in hospitals than ever before, yet the American Hospital Association has estimated that over 80 percent of hospitals

do not have an adequate supply of nurses ("Nurse Shortage," 1980). This results from greater concentration of acute care beds and from by the changing context of nursing practice in acute care settings. Advances in the basic sciences and the development of sophisticated technologies have revolutionized medical and nursing practice. Medical and surgical interventions not thought possible 20 years ago are now commonplace, with each day bringing newer, more complex procedures into the mainstream of hospital care. Accordingly, the nature of the patient population has changed. Those who are admitted into hospitals have more severe illnesses and more complex problems, yet their length of hospitalization is shorter, which presents nurses with a more dependent and more seriously ill patient population than in the past.

The role of the nurse in acute care settings has evolved in response to these changes. Findings from research in the basic and behavioral sciences as well as in nursing itself have expanded the scientific base of nursing practice and sharpened its clinical focus. As a result, nursing practice has necessarily become more specialized and complex. The skills and knowledge needed for interventions based on expert assessments and clinical judgments differ from one patient population to another and nursing experience in one area of practice is not necessarily transferable from one setting to another.

Expertise in a given area of practice can be developed in the practice setting itself, through continuing education or through formal programs of advanced training. However acquired, there is evidence to support the hypothesis that the higher the qualifications of the nursing staff, the better the quality of care (Davis, 1974; Davis, 1972; Waters, et al.,

1972). For example, in a study designed to explain wide variations in hospital postoperative mortality rates, the qualifications of nurses for direct patient care, the ratio of nurses to non-nurses, and the extent to which decisions regarding nursing management were centralized at the nursing unit level were important determinants of quality of care (Scott, et al., 1976). Further, in a community setting, the use of expert interdisciplinary teams, including master's prepared nurse clinicians, was essential to successful implementation of a triage health care delivery system (Hodgson and Quinn, 1980).

While the overall number of hospitals in the Nation has not changed over the past few years, the number of units within existing hospitals providing specialized care and using sophisticated technologies has grown, resulting in a need for increased numbers of well-qualified and specialized registered nurses to provide care. This growth in sophistication and specialization has the effect of intensifying rather than reducing the number of staff required.

Most of the care given to hospitalized patients is provided by nurses employed by the hospital. However, self-employed private duty nurses supplement, although to a decreasing extent, care provided by the hospital-employed staff. These nurses are usually employed directly by patients or their families to provide individualized care for a selected interval. They usually care for only one patient at a time. In 1977 an estimated 3 percent (28,563) reported private duty as their field of employment with more than half indicating they were employed full time. The number of private duty nurses represents a decrease of 29.3 percent since 1972, reflecting the impact of increasing health care costs and the trend for

the institution to assume increasing responsibility for care of the acutely ill in specialized units. As a group, private duty nurses are older (median age 52.3 years) and hold a diploma as their highest educational credential.

Temporary nursing services are another source of supply used by hospitals to supplement their employed staff.² When nurses from temporary agencies are used, they are expected to provide services similar to those provided by staff nurses employed by the hospital. The rise of these agencies as a factor in the market for registered nursing services is so recent that neither its magnitude nor its significance is yet documented. Numerous articles in nursing and hospital literature of the past 5 years, however, attest to the growing importance of such temporary nursing agencies as intermediaries between the nurse labor supply and the demand for these services by health care providers. Since this type of employment was not included in the list of employment settings from which respondents to the 1977 National Sample Survey could choose an answer, a low estimate was made of 0.4 percent (4,266) nurses so employed, based upon replies of those who added this setting to the list.

There is considerable difference of opinion as to the effect these agencies may have on the supply of nurses, the quality of care, and the cost of providing nursing services. To answer these questions, the Division of Nursing, in August 1980, launched a nationwide survey of temporary nursing services, of nurses employed by them, and of institutions and agencies that utilize temporary nurse staffing. Findings from the survey,

²/A "temporary nursing service" is an agency that employs registered nurses and assigns them to work on a temporary or supplemental basis for its clients. These clients, including hospitals, nursing homes, other health care institutions, and individual patients, pay the temporary nursing service for the services of its employees.

available in the first quarter of 1982, will provide information useful for planning for nurse resources and the delivery of care.

Long-Term Care

The current number of elderly Americans and the projected growth rate for this segment of the population are major contributors to the current and anticipated future demand for nursing home care. Between the years 1953 and 1978, the population over age 65 increased by 76.3 percent; assuming a declining mortality rate, the aged population will be the fastest growing segment of the population, increasing 59 percent by 2203 while the population of all ages increases only 28 percent (Hatch, 1980).

The rapid increase in the number of nursing homes and in the number of beds in nursing homes reflects the vulnerability of an aging population to organic and functional impairment. Although "long-term care" and "nursing home care" are frequently used interchangeably to refer to extended care of aged patients, important distinctions should be made between the terms. Most long-term care is provided by families in homes, with support from various other private and public agencies. Long-term care is also provided in institutional settings such as psychiatric or chronic disease hospitals, adult day care centers and a variety of community-based institutions such as multipurpose senior citizen centers. Nursing homes comprise the largest number of facilities providing institutional long-term care serving individuals of all ages. The term "nursing home" is applied to those inpatient facilities where nursing is the principal service provided, whether for long-term residents or for those who require

shorter term, more intensive convalescent care. Since data from the 1977 National Sample Survey (Roth et al., 1977) regarding type of practice setting were collected and analyzed in terms of the employing agency, the following discussion is specific to nurses employed in nursing homes in which 86 percent of the patients were 65 years of age or over.

Data based upon a sample of nursing homes surveyed in the National Nursing Home Survey (USDHEW, NCHS, 1979), indicate that the number of residents in these facilities increased by slightly more than a quarter of a million between 1974 and 1977. The rapid increase in the number of "very old," 75 years of age or more, is well documented. Indeed, residents 75 years of age and over accounted for more than half of the 250,000 increase in nursing home residents. Since only 5 percent of those 65 and over are institutionalized in nursing homes at any given time, it follows that the most dependent and most vulnerable aged are represented in the institutionalized group of aged persons. Since the effects of illness and injury are incremental, the older the patient, the greater the need for nursing care.

Residents from the sample of nursing homes were also classified in terms of their ability to carry out activities of daily living: dressing, toileting, mobility, continence, and eating. Almost 70 percent (69.4 percent) of the residents required assistance in dressing; over half (52.6 percent) were partially or totally dependent upon assistance with toileting; two-thirds needed help in walking or were chairfast or bedfast; more than half (53.3 percent) had difficulty controlling bowel or bladder function or required ostomy care; almost one-third (32.6 percent) needed assistance with eating. The data conclude that of the resident population surveyed,

only 9.6 percent were independent in all five areas of daily living. These data do not classify patients in terms of functional impairment due to senile psychoses, organic brain damage, or mental retardation, but other sources estimate that between 55 and 80 percent of the patients in nursing homes have some degree of mental impairment (Moss, Halamandaris, 1980). These problems are as compelling in terms of need for nursing care as are physical limitations. However, findings from a recent study showed that the severity of patients' physical problems was the single determinant in the allocation of nursing time to patient care (Brown, 1980).

As reported in the 1977 National Sample Survey, this patient population is cared for by 79,647 registered nurses, or 8.1 percent of the active work force, 58 percent of whom were employed on a full-time basis. Although the number of nurses employed in nursing homes is a 42-percent increase over 1972, only 11 percent of all nursing home employees are registered nurses. According to data from the National Nursing Home Survey, there were 4.8 full-time equivalent registered nurses for every 100 beds; 6.1 licensed practical nurses, and 30.3 nurse aides. In other words, aides provided six times as much nursing care as did registered nurses and five times as much as licensed practical nurses. Since nurse aides are minimally prepared for their responsibilities and are unlicensed, they require more instruction and supervision than more experienced staff. The need for supervision of inexperienced personnel is compounded due to their high turnover rate, estimated at approximately 75 percent. This has the effect of diluting still further the amount of professional nursing time for direct patient care.

According to the 1977 National Sample Survey, almost one-half (49 percent) of the registered nurses working in nursing homes provided bedside nursing care; 24 percent were head nurses or supervisors; 21.7 percent were administrators. Consultants accounted for 1.5 percent of the total, and clinical nursing specialists for only 0.3 percent. The largest proportion of nurses employed in nursing homes held a diploma as their highest level of educational attainment.

Community Health Nursing

Growing understanding of causes and risk factors associated with premature morbidity and mortality and concern with escalating costs of institutional care have underscored the need for community-based services aimed at health promotion and disease prevention. According to the Bureau of the Census (U.S. Department of Commerce, 1978), only 1 percent of the total U.S. population are in acute, long-term care, or other institutional settings at any one time. The other 99 percent, over 228 million people, are at school, at work, or at home. This is the population served by 9 percent of the registered nurse work force employed in public or community health. During the 5-year period 1974-79, the supply of registered nurses working both full time and part time in community settings increased by one-third, from 61,036 to 81,219 (JSDEHS Division of Nursing, 1979).

Community health nurses are concerned primarily with health promotion, health maintenance, health education and management, and coordination and continuity of care within the community. The distinguishing characteristic of the care they provide is its focus on unmet health needs of individuals, families, and communities and helping to cope successfully

with threats to health and with problems of illness. Whereas the focus in institutional settings is on the individual and his family, the focus of community health nursing is on the community and its interaction with the population it serves.

Community health nurses are employed in a variety of agencies and organizations and at various levels of government with mandates to protect the health of the public. The latest Survey of Public Health Nurses (USDHHS, Division of Nursing, 1979) reports 69,294 registered nurses employed full time in community health in 1979. Of these, by far the largest number (63,893) work in official or voluntary agencies at the local level. These include visiting nurse services, official health units, health maintenance organizations, hospital-based home care programs, hospices, free standing neighborhood health centers, senior citizen centers, day care centers, congregate living facilities and boards of education. An additional 2,801 registered nurses are employed by State agencies.

The largest proportion of community health nurses, approximately 80 percent, are providing direct patient care. However, about one-third of this work force, those educationally prepared for the full scope of community health nursing practice, are devoting some portion of their time to directing the work of less well-prepared staff. The second largest proportion of nurses in community health, 8 percent, are engaged in supervision of nursing personnel in various practice settings and in overseeing the services provided by home health aides, homemakers, and numerous other workers providing supplementary support services. Administrators account for 7 percent of the nurses in community health while those providing consultant services in specialized practice areas account for an additional 2 percent.

Working with groups within a community affords nurses an opportunity to improve health through early identification of personal or environmental factors which act as barriers to health and health care. Groups may be bound together by any one of many common features or interest--ethnic background, age or occupation, to mention only a few. Two population groups have traditionally claimed the attention of nurses in community settings--school-aged children and adults in their places of employment.

In addition to the nurses employed in community health agencies and organizations, the community health area takes in, as well, those nurses employed in occupational or industrial settings. During the 1970's, about 2.5 percent of the employed nurse population worked in these settings, an estimated 24,000 nurses, according to the 1977 National Sample Survey of Registered Nurses.

Other Ambulatory Care Settings

An estimated 69,263 nurses reported working in the offices of physicians or dentists, a 27.4 percent increase since 1972. Forty-three percent, however, worked on a part-time basis (Roth, et al., 1979). In 1977 the largest proportion (44.1 percent) were employed by physicians or dentists who had solo practices; approximately one-third (33.9 percent) were working for physicians or dentists who had partnership arrangements; and 20.6 percent were employed by a group practice.

Registered nurses working in these types of settings were generally graduates of diploma programs. Most were married and had children at home. Therefore, they may have been attracted to this type of practice because of the convenience of the working hours, despite generally lower

salaries than those paid by hospitals, fewer fringe benefits, and less opportunity to participate in programs of continuing education.

Other Fields of Employment

Only a small number (0.5 percent) of nurses in the work force reported self-employment in the 1977 National Sample Survey. However, since the data on the field of practice related to the previous position of the nurse, this may be a low figure. Those who may have combined self-employment with part- or full-time employment as their primary position would not have undertaken their self-employment positions. Nurses who worked primarily on a fee-for-service basis reported a variety of position titles: patient care education, utilization review coordinator, nurse anesthetist, consultant, etc.

Approximately 1,500 nurses reported working in central or regional offices of a Federal agency, 207 in State boards of nursing, 1,079 in nursing or health-related associations, and 70 in health planning agencies.

Rates of Compensation for Registered Nurses

The 1977 National Sample Survey of Registered Nurses estimated that the average annual salary of a full-time registered nurse was \$12,950 in September 1977. Salaries of registered nurses tend to vary according to the type of setting in which the nurse works and the level of position as well as the geographic location of the employment. Thus, the sample survey shows a range of average salaries for full-time nurses in major areas of employment from \$11,540 in student health services to \$14,800

in nursing education. On a geographic basis, the average salary for all full-time registered nurses in the area ranged from \$12,500 in the South to \$13,900 in the West.

Of concern, as well, in a review of the compensation of registered nurses, is the entry salary of a beginning professional. Preliminary, unpublished data from the National League for Nursing's annual study of newly licensed nurses show that in 1979, full-time employed registered nurse respondents had a median salary of \$12,700 six months after licensure. Some differences in the median salaries for the newly licensed nurses were noted when the type of educational program from which the new licensee came was taken into account. The median salary of a diploma graduate was \$12,400. Associate degree graduates had a median salary of \$12,500 and baccalaureate graduates, \$13,100. Salaries of these new entrants to nursing varied according to the area of the country in which they were located. With the exception of the western part of the country, where there was little difference among the various types of graduates, median salary for the baccalaureate graduate tended to be somewhat higher than the medians for the other types of graduates. The eastern part of the country had the most marked differences.

The studies made by querying employers of nurses augment the generalized data cited above and provide more specific data on compensation in various types and locations of employment. The latest data from employer surveys, and the studies from which they came appear in table 27. Perhaps of greatest interest, because it represents data on the major source of employment for registered nurses, is the study conducted by the Bureau of Labor Statistics (USDOL, BLS, 1980) in non-Federal hospitals in selected metropolitan areas.

This study, carried out in September 1978, is the latest in a series of such studies and is the source of data for this report.

In the 22 metropolitan areas in which BLS collected data, the average annual earnings of a staff nurse in a non-Federal hospital ranged from \$12,077 in Buffalo, New York, to \$17,306 in San Francisco, California. Since hospital salaries tend to vary according to the size of the hospital as well as the size and location of the community, the data shown for these metropolitan areas overstate possible salary levels for hospital nurses on a national basis. These data, however, might be particularly helpful in tracking changes over time since the BLS surveys have been carried out on a 3-year-cycle basis for a number of years. A comparison between the area average earnings reported in this study and those found in the August 1975 study shows wide variation in the increases experienced during that period. The average annual percent increases in staff nurses' average earnings ranged from 2.9 percent in New York and 3.8 percent in Baltimore to 9.7 percent in Houston.

Educational Preparation and Specialty
of the Registered Nurse Supply

Basic nursing education prepares all nurses for direct patient care in institutional settings; programs leading to a baccalaureate degree prepare graduates for community settings as well. However, the diversity of nursing practice dictates the need for specialized skills in clinical practice areas, or in the functional specialties of teaching or administration. This section of the report examines the supply of registered nurses in terms of types and levels of educational preparation. Five major categories

have been singled out for discussion: nurse practitioners, nurse educators, nurses with doctoral degrees, nurse administrators, and nurse clinicians.

Nurse Practitioners

Federal interest in the training of nurse practitioners gained momentum as the demand for primary care services increased in the face of a shortage of primary care providers and the lack of access to these services which became a recognized public concern. Well before support for nurse practitioner training was authorized, however, Federal dollars supported projects to define the role, to document the quality of care provided by this type of health care practitioner, and to evaluate and test the safety and efficacy of this new role (USDHEW, Division of Nursing, 1979).

In November 1971 the Report of the Secretary's Committee to Study Extended Roles for Nurses, entitled "Extending the Scope of Nursing Practice," (1972) was published. This followed the President's Health Message (1971) of that year, highlighting the significant contribution that specialized nurse practitioners could make in extending health services. The Nurse Training Act of 1971 broadened the authority for special project grants to include nurse practitioner training, and both the Nurse Training Act of 1975 and the Nurse Training Amendments of 1979 included discrete authorities and authorizations for appropriations for this purpose. From 1975, with passage of the Nurse Training Act of that year, through fiscal year 1980, \$50 million has been invested in nurse practitioner training. Of this amount, \$3.4 million has been used during the past 3 years for student support under the traineeship authority (USDHEW, Division of Nursing, 1980).

Nurse practitioners are registered nurses whose additional formal preparation equips them for expanded functions in the dimensions of nursing care, which includes diagnostic and treatment needs of patients. In addition to delivering the traditional nursing services, they are qualified to perform some services more often delivered by physicians such as managing common self-limiting conditions and stabilized chronic illnesses. Their scope of practice is necessarily broad since they both facilitate access into the health care delivery system and provide continuity within the system as the patient moves from one part of the system to another. Because they are licensed in their own right as nurses, they are accountable for their nursing practice, which includes numerous functions based upon independent nursing decisions. In the performance of those components of their role traditionally provided by physicians, nurse practitioners view themselves as collaborating with physicians in the delivery of primary health care. Parameters of practice have been established and nurse practitioners refer patients to physicians and to other health professionals based upon assessment of the patients' needs.

Nurses who practice as nurse practitioners are a relatively small segment of the registered nurse work force. They are, however, a national resource and for this reason the Division of Nursing initiated in 1973 a longitudinal study to provide national data for evaluating programs that prepare nurses for expanded specialty roles. The study, carried out under contract by the State University of New York at Buffalo (SUNY), has been conducted in three phases. Phase I, whose findings were reported in the First Report to the Congress, described nurse practitioner education in programs initiated prior to January 1974 and included descriptive

information about the students who were enrolled. In the second phase of the study, the students identified in phase I were followed to determine the type and success of their subsequent employment and aspects of their role and functions as nurse practitioners. Findings from this phase of the study were reported in the Second Report to the Congress. Data from phase III, discussed in this report, include information on programs initiated or continuing between 1974 and 1977 and employment data on graduates of programs initiated after 1974 (Sultz, et al., 1980). The data are important not only for identifying the influences shaping nurse practitioner training but also for pointing the future direction of nurse practitioner practice.

In January 1974 the SUNY study identified 133 nurse practitioner training programs that met the study criteria. Between 8,000 to 10,000 students were graduated from these programs by the end of 1975. There are now approximately 200 nurse practitioner programs, representing only modest growth since January 1979 when the SUNY study reported 178 in existence. Of this 200, approximately 105 receive Federal support. As of January 1981, current supply of nurse practitioners is estimated at 18,000.

The completion of the third phase of the SUNY study has made it possible to document trends on the basis of data collected over a 9-year period. Several trends are worth noting. The first is the shift within the primary care practice specialties for which nurse practitioners are being prepared. Programs established in the early years of the nurse practitioner movement focused on pediatric practice. By 1973 the number of programs in this specialty stabilized, reflecting a sensitivity to

the employment market and to health care needs. After that year, the specialty emphasis shifted to family and adult health, which encompasses a large geriatric population. Initiation of these programs accounted for growth in number of programs as well as number of graduates.

Although the number of programs leading to a certificate (117) still outnumber those leading to a master's degree (61), there has been a greater rate of growth in the latter type of program and a significant growth in the proportion of graduates from these programs. In the 3-year period from 1974-1977, the number of graduates awarded master's degrees increased by more than 6 percent to account for 26 percent of the total. These data suggest that graduates of master's programs will constitute an increasing proportion of nurse practitioners.

Responsibility for physical and psychosocial assessment and for management of care must be founded on advanced preparation in physiology and in other physical and social sciences. Moreover, the nurse practitioner's competence in a given clinical area such as family or gerontological nursing is dependent upon mastery of clinical content in these fields. Programs leading to a certificate have increased in length and have become more discriminating in student selection. The requirements for graduation are focused primarily on knowledge and skills related to primary health care, whereas programs leading to a master's degree include, in addition, advanced preparation for teaching and research.

A third important trend is the increase in number of both certificate and master's programs that are monitoring the experience of graduates as a means of keeping educational program content consonant with expanded practice roles. Characteristics evaluated by the programs included the

match of the graduates' functions and responsibilities with those for which they were trained, their competency in practice, and the degree of independence with which they function.

In terms of geographic distribution of nurse practitioner training programs, the South ranked first with 35 percent, followed in rank order by the Northeast (29 percent), the West (21 percent) and the Midwest (15 percent). On an individual State basis, California had a slight edge (six) on New York and Arkansas (five each), but four other States (Alabama, Colorado, Mississippi, and Utah) followed closely with four per State.

The shift in program emphasis from pediatric to family nurse practitioner training is reflected in the distribution of the student population. More than two-thirds of the students (68.9 percent) enrolled in training programs in 1977 were preparing for practice as adult or family nurse practitioners, and the number preparing for pediatric practice had declined to slightly more than 10 percent. The percentage of students preparing for midwifery practice remained fairly stable (4.7 percent), as did the smallest percentage of students (1 percent) who were preparing for psychiatric nursing practice in primary care settings.

Characteristics of the student population have not changed significantly during the course of the longitudinal study. Although the group studied in phase III was somewhat younger (more than two-thirds were under 35 years) and more likely to be married (59 percent) than were their predecessors, they were predominately female (97.1 percent) and white (91 percent). Students enrolled in certificate programs were generally older and had had more years of professional experience than those in master's programs; more than one-half of the certificate students lacked a baccalaureate

degree before entering nurse practitioner programs. Since hospitals are the largest employers of nurses, it is not surprising that most students' previous experience in nursing had been hospital-based.

Data gathered from the SUNY study indicate that the number of graduates engaged wholly in nurse practitioner practice (53.5 percent) has increased over time, with a corresponding decrease in the number who reverted to practice in traditional roles (16.5 percent). Other graduates (30.0 percent) practiced in both the nurse practitioner and traditional roles, for example, those who were teaching in nurse practitioner training programs or providing consultation to other nursing staff. Changes have also occurred in the practice setting locations in which nurse practitioners work. The proportion employed in rural areas has substantially increased (from 16.2 percent in 1974 to 21.6 percent in 1977), while the proportion working in inner cities has decreased from 32.7 percent to 22.6 percent. Whether engaged in practice in inner cities or rural areas, almost half of nurse practitioners' patients had annual incomes of less than \$4,000. Over half (54 percent) of the graduate program respondents surveyed by the study reported they were the first nurse practitioners to be employed in their particular practice setting. This finding indicates that nurse practitioners are moving into new health care delivery sites.

Approximately 90 percent of the graduates surveyed reported they were employed: more than 60 percent in ambulatory clinical practices such as community clinics, 17 percent in physicians' private practice settings, 10 percent in health departments or home health agencies, and 5 percent in extended care facilities. The reason most frequently given by employers (44.2 percent) for employing a nurse practitioner was to

improve the quality of care by providing better patient education, by permitting greater attention to secondary problems, or by permitting a division of responsibility which allowed the physician to spend more time on complex problems. Increasing access to care was cited by an additional 39.3 percent of employers. This included increasing the number of patients in a practice, extending care to those previously unserved or establishing a new health service such as a school health clinic. Utilization of physicians for consultation was influenced by a number of factors such as the availability of the physician, the type of setting and the practice specialty. However, nurse practitioners who had graduated from master's degree programs generally had less need to consult physicians on matters relating to patient management.

Eighty-five percent of nurse practitioners were employed full-time and salary was the source of virtually all income. Their average gross annual income ranged from \$12,600 to \$15,400, averaging approximately \$2,250 more than earnings before their advanced training. Although the income of nurse practitioners in rural settings is less than that earned by practitioners in urban settings, the gap is narrowing.

Taken together, findings from the study confirm that nurse practitioners are well accepted both by employers and by the public. Ninety-three percent of surveyed employers considered the use of nurse practitioners cost effective, and those few who did not felt that their practice was not sufficiently large to use a nurse practitioner's time to maximum advantage. The findings clearly show that nurse practitioners are being readily absorbed into the work force and are being employed to improve quality of care and provide access to the health care delivery system. Moreover, they are using their

newly acquired skills appropriately. Characteristics of the patient populations they care for and the settings in which they practice attest to their contribution in improving primary health care.

Nurse Educators

The 1977 National Sample Survey of Registered Nurses estimated there were 37,826 registered nurses employed in nursing education programs, 3.9 percent of all employed registered nurses. More detailed, comprehensive data on nurse-faculty are available from the National League for Nursing biennial surveys of the number of faculty employed by schools of nursing. In the most recent published data on registered nurse programs only (NLN, 1979), the League estimated there were 22,395 full-time and 4,938 part-time nurse-faculty in these programs. On a full-time equivalency basis, the estimated total was 24,864, 6.6 percent more than in 1976.

Baccalaureate and higher degree programs gained 15.7 percent and associate degree programs, 9.8 percent, offsetting the loss of faculty (9.8 percent) in diploma programs. Despite this gain, it was estimated that there were 909 unfilled faculty positions in 1978, 13 percent greater than the estimated vacancies in 1976. This increase was due in large part to the rising demand for faculty in baccalaureate and higher degree programs.

Some progress has also been made in increasing the number of full-time faculty educationally prepared for their responsibilities as teachers. The schools reported 1,062 prepared at the doctoral level. They represented 5.3 percent of the total full-time faculty, a gain of one percentage point since 1970. Those prepared at the master's level increased to 62.5 percent

of all full-time faculty, in comparison to the 57 percent in 1976. However, 32 percent of full-time faculty still lacked the minimal acceptable academic preparation for teaching. Over 90 percent of full-time faculty employed in baccalaureate or higher degree programs had master's or doctoral degrees. In associate degree programs, less than two-thirds of the full-time faculty (64.8 percent) had acceptable academic preparation, and in diploma programs, less than one-third (32.6 percent) were so prepared. It is also significant that hospital-based diploma programs employed greater numbers of non-nurse faculty than did programs based in academic settings which have ready access to teaching resources in other departments. There are also regional variations in terms of the level of faculty preparation; the West fares better than any other region (85 percent in the West were prepared versus 65 percent for the other regions together).

Of all the full-time nurse faculty whose highest earned credential was a master's degree, four-fifths had majored in nursing. Master's degree graduates teaching in baccalaureate programs were more likely to have nursing majors (90.7 percent) than those in either associate degree (73.4 percent) or diploma programs (56.2 percent).

All three types of initial nursing programs responding to the NLN January 1978 nurse-faculty study reported a total of 1,270 administrators. These administrators are more likely to have higher level academic credentials than the faculty. In the baccalaureate and higher degree programs, 70 percent of the administrators had doctoral degrees. Almost all administrators had at least a master's degree in the associate degree and diploma programs, 98 percent and 95 percent, respectively.

Registered Nurses with Doctoral Degrees

Doctorally prepared nurses are a small but extremely important cadre within the nursing profession. They provide key leadership in the improvement of nursing practice, in the development of programs of nursing education, and in the design of innovative health care delivery systems. A 1973 survey of nurses with earned doctoral degrees identified 1,019 nurses so prepared (ANA, 1973). In a more recent study, conducted in 1979 by the American Nurses' Association under a grant from the Division of Nursing, Health Resources Administration, the number identified had increased to 1,564 or 0.2 percent of the nurses holding current licenses to practice. The report of this study (ANA, 1980) has been published and lists these nurses, together with data regarding their characteristics, distribution, and productivity. While most of these data have yet to be analyzed, it is clear that three-quarters of the nurses who participated in this study.

Preliminary analysis from 1,964 respondents to the survey questionnaire indicate considerable diversity in types of doctoral education. Before 1965, the Ed.D. was the most common doctoral degree earned by nurses; since that time the number of nurses earning the research degree (Ph.D.) has increased steadily to constitute one-half of all those who have completed doctoral study. The shift from Ed.D. to Ph.D. as the degree of choice followed the establishment in 1962 of the federally supported Nurse Scientist Training Program designed to finance research training at the doctoral level in basic science departments or disciplines related to nursing. Currently, most nurses seeking doctoral degrees enroll in programs awarding the degree in the field of nursing. Most of these programs in nursing offer the Ph.D. degree. The Doctor of Nursing Science, a professional

degree, has also been awarded since the early 1960's, and the number of graduates from programs offering this degree, although not large, has shown a fairly steady increase. The shift toward doctoral programs in nursing parallels the profession's recognition that a solid and substantial body of nursing knowledge is being developed, based on a foundation in the behavioral and biomedical sciences. A small number of nurses hold other degrees such as the Dr.P.H., Sc.D., and D.P.A.

As was true in the earlier survey, many fields of study are represented among the recipients of doctoral degrees. Slightly over 40 percent of the respondents majored in some field of education. Majors in the social and behavioral sciences ranked second. Advanced nursing was a major for slightly more than 20 percent of the respondents, but it represents a rapidly growing focus of study.

The typical nurse with a doctoral degree is female, married, and approximately 49 years of age. Most respondents received their basic nursing education in a diploma program, and the average length of time which elapsed between the award of the first credential and the doctoral degree was 19 years. Once a nurse was admitted to the doctoral program, the average length of time for completion of the degree requirements was 4.59 years. Generally speaking, doctorally prepared nurses had majored in nursing at the baccalaureate and master's levels and in a field other than nursing at the doctoral level. Most nurses needed some financial support for their advanced training and Federal awards were the single most important source of such assistance.

Nine out of 10 doctorally prepared nurses in the study were employed, most of them full time. Although they work in a variety of settings,

such as hospitals, community health organizations, and Federal, State, and local government agencies, the majority are employed in programs leading to a baccalaureate or higher degree in nursing. Teaching was the primary function for which most nurses with earned doctorates were employed. Administrative positions were held by one-third of the survey respondents and positions which included combined responsibilities for teaching, administration, and research were held by another 15 percent. Research as a major function was reported by less than 7 percent of the nurses in the study.

Nurse Administrators

Considerably less data is available on administrators of nursing service than on nurses in other clinical and functional specialties. A 1977 study of some 7,000 hospitals by the American Society for Nursing Service Administrators (ASNSA, 1977) is the principal source of data on directors of hospital nursing services. Nurses who served in this capacity typically rose through the organizational ranks of hospital nursing services, working first as staff nurses, and subsequently as head nurses and supervisors. Ninety-two percent had been assistant or associate directors before being named to their present positions. Slightly less than half (45.9 percent) held a diploma as their highest educational credential; 2.5 percent held an associate degree and another 23.6 percent a baccalaureate degree. Only 28 percent had preparation at the master's or doctoral level, the generally accepted level for management in nursing, as in other fields of endeavor. The survey also showed a positive correlation between size of hospital and level of formal education; the

larger the hospital, the more likely it is to have a qualified nursing service administrator.

Although the nursing service department is the largest single unit within the hospital, administrators of nursing service reported varying levels of participation in overall hospital management. For example, two-thirds of the nursing service administrators reported that they participated in overall hospital management and over half helped to plan their institution's budget, but less than half were involved in priority-setting functions. Although 73 percent established the nursing budget, only 56 percent had full administrative responsibility for it.

Information on preparation of administrators of community nursing services is derived from the 1979 Survey of Community Health Nursing (USDHHS, Division of Nursing, 1981). In this survey the count of 11,431 full- and part-time nurses in administrative positions included not only directors but consultants, supervisors, and service coordinators. Of this number, 2,371 held a graduate degree awarded by schools of public health or by schools of nursing. A small number (198) had advanced preparation in fields other than public health nursing, bringing the total with advanced preparation to 2,569 or 22.5 percent of those in administrative positions. Nurses in administrative positions in local official and voluntary agencies accounted for almost half of this group; 824 were employed in official agencies and 495 in visiting nurse services and other voluntary agencies. Proportionately, 4.9 percent of nurses with graduate preparation had administrative positions in nonofficial agencies, while only 2.9 percent held such positions in official agencies. A group of agencies (1,290) classified as providing only home health care and mostly

proprietary, employed 247 nurses (out of a total of 10,224) in administrative positions, of whom 2.4 percent had advanced preparation commensurate with the level of their responsibility.

Nurse Clinicians and Clinical Nursing Specialists

Respondents to the 1977 National Sample Survey questionnaire were instructed to indicate the nature of their nursing position from a list of 26 position titles. An estimated 8,065 indicated they had the title of clinical nursing specialist; 7,045, the title of nurse clinician. These numbers constitute 0.8 percent and 0.7 percent, respectively of employed registered nurses. Because these numbers represent a rather small proportion of the study sample, as well as the overall nurse supply, they should be treated as rough approximations.

Nurse clinicians and clinical nursing specialists, as the titles imply, are expected to be expert in a clinical practice area. They provide patient care and develop, through teaching and by example, the competencies of less experienced nurses and students to meet the needs of patients whose nursing care management requires special knowledge and skills.

Among those indicating that their position title was nurse clinician, 70 percent had as their highest educational credential a diploma or associate degree; only 11 percent had a master's degree. Of the clinical nursing specialists, about half had a diploma or an associate degree and 29 percent, a master's degree. Although advanced educational preparation in nursing is recommended by the nursing profession for practice in specialized areas of practice, these percentages suggest that the majority of nurses now

functioning in these roles developed their expertise on the job, through programs of continuing education, or through independent study. Data from the 1977 National Sample Survey do not describe different patterns of functioning in relation to level of educational preparation. They do indicate, however, that for both practice groups, the largest percentage of time during a usual workweek was devoted to direct patient care (57.8 percent for nurse clinicians and 65.1 percent for clinical nursing specialists). The combined functions of consultation, supervision, and teaching ranked second. Only small percentages of time were devoted to administrative activities (6-7 percent) and to research (4-6 percent).

Projections of the Supply of Registered Nurses

Overview of Model

Section 951 of P.L. 94-63 directed that the adequacy of the supply of registered nurses for the future be considered according to level of educational preparation and within each State as well as nationally. These directives led to the development and refinement of new and revised methodologies, the base for which was described in the First Report to the Congress, February 1, 1977 and Second Report to the Congress, March 15, 1979 (Revised). The model used to project the registered nurse supply for this report evolved from the prior models and is based on the methodological research outlined in the prior reports. The current model was developed by staff of the Bureau of Health Professions to be directly responsive to the requirements of Section 951.

There are three types of projections made on a State-by-State basis:

- . The nurse population: those with current licenses to practice.
- . The nurse supply: all those practicing nursing, either full time
- . or part time.
- . The full-time equivalent supply: nurses practicing full time plus one-half of those practicing part time.

In each of the above instances, the projections are divided into three levels of highest educational preparation: associate degree or diploma; baccalaureate; master's and doctorate. To arrive at the nurse population, supply, and full-time equivalents migrations between States, inputs from the educational system (new graduates, post-RN baccalaureate and higher degree graduates), mortality, and licensure phenomena are first taken into account.

To properly identify effects of the changes in the nurse population, each aspect of change is developed in the model as a function of age. There are 10 age groupings identified in the model base. Thus, the projections that are produced as a result of the model show the registered nurse population and supply (total number or full-time equivalent) on an annual basis as a function of three characteristics of that population: (1) the 50 States and the District of Columbia; (2) three levels of highest educational preparation; and (3) age groups. Allowing for summary values on a national basis, a total of 1,560 cells or cohorts are necessary to describe the population and supply according to these characteristics.

Data Considered in the Projections

The current projections are initiated from a data set based on the 1977 National Sample Survey of Registered Nurses (Roth, et al., 1978) amplified by data from the 1972 Inventory of Registered Nurses (Roth et al., 1974). The same model is used to provide annual current estimates of the registered nurse population and supply as well as future projections of what might be available. The differences here are dependent on the treatment of graduation inputs. For "current estimates," graduation data are based on actual numbers taken from the annual surveys made by the National League for Nursing (NLN Nursing Data Book, 1979). For future projections, separate models have been developed which project the number of graduates from the varying types of programs based on assumptions made about the production of basic-entry-level or advanced-educational-level registered nurses. The assumptions used for the

projections of future supply included in this report will be presented in the section below, Assumptions Underlying the Projections.

Other data inputs necessary to determine the nurse population on an annual basis include migration factors, mortality rates, licensure phenomena, and age distributions involved in the dynamics of change. Additionally, to determine the annual supply, the so-called activity rates, the proportion of the population which is working, are required. Unlike the educational input data, since most of these data are derived from comprehensive studies of the nurse population, there is no annual, or even regular, routine source for them which could be used for "current estimates." As is true for the future projections, the "current estimates" are based on the assumptions made about possible trends in these areas since they were last studied. The last comprehensive study of the nurse population for which data are available is the 1977 National Sample Survey.

A sample study of registered nurses that will provide data on the nurse population for November 1980 is currently being conducted by the Research Triangle Institute under a contract with the Division of Health Professions Analysis, Bureau of Health Professions, Health Resources Administration. It is anticipated that the data from this study will be available by the end of 1981. At that time the data base, along with a number of these input variables, will be reviewed and updated as necessary. A review of the data can aid in determining the degree to which the "current estimates" reflected true counts of the nurse population and supply for the years between 1977 and 1981.

Assumptions Underlying the Projections

As indicated previously, a number of assumptions about the output of the nursing education system as well as work and licensing behavioral patterns of registered nurses are required for the projections. With the exception of the assumptions regarding graduations from nursing education programs, only one set of assumptions is used for all the projections series in this report. Thus, the variation in the projections from one series to another is due solely to differences assumed for graduations and the effect of the varying graduation rates on the total nurse supply.

A number of considerations entered into the decision to maintain the same assumptions for all except the educational areas in the different series. First, it clearly demonstrates the impact of the effects of varying levels of graduates. Secondly, since the data for most of the other variables are rather sporadic, it is difficult to develop consistent trend patterns. Finally, it is believed that for the most part, there would not be any major changes in the patterns as they now exist, given no marked revisions in current conditions and scope of practice. Therefore, in all four series of projections of registered nurse supply included in this report, assumptions about behavioral patterns of registered nurses are based on the following data and considerations:

1. Mortality Rate

To determine the losses to the nurse population through death, age-specific mortality rates based on the 1976 life tables for white females, (the closest population cohort to the registered nurse population) are used throughout the projection period.

2. "Net Loss "Rates

In addition to mortality, changes in the registered nurse population result from lapsed and reinstated licenses. Since at present there are no available data upon which assumptions can be based for the separate determination of reinstated or lapsed licenses, a factor providing for a "net loss" in licenses has been derived from data obtained from the American Nurses' Association's annual licensure statistics (ANA, 1980), the 1972 Inventory of Registered Nurses (Roth, et al., 1977) and the 1977 National Sample Survey of Registered Nurses (Roth, et al., 1978). The same rate, relatively small, is used throughout the projection period. While the overall rate would undoubtedly change as the age distribution of the nurse population changes over the years, the low net loss rate suggests that refinements along this line might not yield significantly different results in the overall projections. The total resulting from this "net loss" rate is made age-specific from data included in these same data sources.

3. New Licensees

The number of new licensees from United States nursing education programs is determined from the latest available State Board examination passage rates. These rates are kept constant throughout the projection period. An examination of the data for the last years (through 1977) for which data were available when the assumptions were developed showed that the diploma and associate degree passage rates were relatively stable. Baccalaureate rates seemed to have

declined slightly but, on the premise that they would not decline further, the latest rate was used.

To account for the non-U.S. graduate new licensees, a constant total of 3,700 foreign-trained nurses was included throughout the projection period. This estimate is based on the 1976 licensing data, (ANA, 1977) the last year's data available at the time the estimate was made. Since the requirement that foreign-trained nurses must take the licensing examination was first adopted in most States in the mid-1970's, trend data based on this requirement is not available. Furthermore, future implications of current immigration restrictions described earlier in this report are difficult to determine. Therefore, it was judged best to maintain the constant number. The age distribution of both the U.S. and non-U.S. new licensees is based primarily on data from the 1977 National Sample Survey of Registered Nurses.

4. Activity Rates

Aside from the assumptions made about the output from nursing education programs, which are discussed in a separate section below, the last major consideration relates to activity rates. Activity rates, that is, the proportion of the population employed in nursing, were maintained throughout the projection period on the assumption that the rates have nearly peaked for the younger nurses and the overall rate is the highest it has been. An examination of the activity rates for all women with educational background similar to that of registered nurses suggests that the rate for nurses may be somewhat higher than that of other women and that the "pattern" of

age-specific rates for the registered nurses was similar to that of other women.

It is important to note that the rates as they are used in the model are "age-specific." Thus, while the individual age group rates were not varied throughout the projection period, the overall activity rate for the total population does vary since it is dependent on the age distribution of the nurse population. While rates for the younger nurses have continued to increase over the years, rates for the older nurses have decreased. An examination was made of the limits of each of the age group activity rates. Although the limits explored are somewhat theoretical, given the aging nurse population, the end result noted from this exploration indicated lower overall population activity rates than the ones in the projections for this report.

Assumptions About Nursing Education Graduations

Data available on nursing education programs for the Second Report to the Congress seemed to suggest clear trends in the number of programs and students within each program so that projections of graduations could be based on assumptions about what might occur should changes be made in the financing for these programs. Later data, however, suggest changes in the trends. Consideration of these later trends led to the approaches undertaken in the present four series of graduation projections.

Series A

Series A has been developed as a "middle" level projection. It represents a "baseline," considering recent trends. In Series A, diploma

program admissions continue to decline at a rate consistent with the prior data with the provision that some programs will operate throughout the projection period. Associate degree admissions are assumed to be most likely for the 17- to 34-year-old female component of the population, and future admissions to these programs would decline slightly as a proportion of this total population group. Baccalaureate admissions come basically from new high school graduates, as do the diploma admissions, and together, these two admissions groups are examined as a proportion of new high school graduates attending nursing programs. This proportion continues the negative trend it has shown in the late 1970's. The graduation rates applied to these admissions data were developed from an examination of trends in specific class graduation rates for the past 8 or 9 years. It should be noted here that, with the exception of the baccalaureate, which was more variable, the graduation rates varied very little for each program in the last three or four years. The rates used were 73 percent for diploma; 69 percent for associate degree, and 63 percent for baccalaureate (this last is based on a conversion of all baccalaureate admissions to a 4-year basis). Post-RN baccalaureates from generic programs are a function of the basic graduates from these programs, with an additional fixed factor for those graduating from nongeneric programs. Master's degree graduates were determined from the maintenance of the linear trend in the number of programs, maintenance of the trend increases in average enrollment per program, and the proportion who were full-time students stabilizing at 50 percent. Graduations were determined to be 35 percent of enrollments, which is the proportion noted for the 2 years the full-time enrollment rate was 50 percent. In addition, to account for the

master's graduates from non-NLN-counted nursing programs, an additional fixed factor is applied to the graduate totals.

Series B

Series B is the so-called "higher" series. It is based on the assumption that current concerns about shortages of registered nurses would lead to reversals in the present admissions trends to basic programs, to increased higher level educational opportunities, and to an increased number of students. Specifically, assumptions made define diploma program trends as the same as in Series A, but reverse associate degree program trends in that Series. Thus, in Series B, the decreasing trend in the proportion of 17- to 34-year-old females entering associate degree programs would reverse so that, about 1985-86, it would become the proportion it was in the mid-1970's and remain at that level through the rest of the projection period. Also, the trend of the combined baccalaureate and diploma admissions as a proportion of new high school graduates would reverse and by 1985-86 become the proportion it was in the early 1970's and remain at that level through the rest of the projection period. The proportion graduating from baccalaureate programs would become 65 percent, the estimate for the latest data, while the rates for the other programs would remain the same as in Series A. In addition to these higher levels of basic nursing graduates, it was assumed that the number of master's degree programs would increase to 328 by the end of the projection period. This figure is based on an intramural study made of colleges and universities with an apparently proper milieu for added master's programs (USDHHS, 1979). It was further assumed that the trend toward part-time enrollment would reverse so that by the end of the projection period, 75 percent of the enrollees would be full-time; thus changing the proportions of

enrollments that graduated each year accordingly. The increase in the availability of "nursing" master's programs would offset, to some extent, the number of students attending "non-nursing" programs.

Series C

Series C is based on the premise that present concerns about the baccalaureate degree as the entrance level into practice would lead to a sharp decline in the proportion of 17- to 34-year-old females entering AD programs and a sharp increase in the number of baccalaureate programs available (an increase of 200 programs by the end of the projection period). This increase in baccalaureate programs was derived from the study mentioned earlier examining colleges and universities having apparently proper milieus for added master's programs but without a current nursing baccalaureate program. Admissions to diploma programs were determined as they were in Series A and the master's degree assumptions, as in Series B.

Series D

Series D is the most constrained set of projections, consisting of a combination of diploma and baccalaureate projections from Series A and the associate degree projections from Series C. In essence, it assumes that current discussions about the entrance level into practice leads to a sharp decline in admissions to associate degree programs. At the same time, however, there is no offsetting increase in baccalaureate admissions. Instead, baccalaureate admissions continue recent trends as demonstrated in data gathered by NLN from the schools. Series D also maintains the type of trends noted in the master's degree programs in Series A.

Projections of Basic Nursing Education Graduations

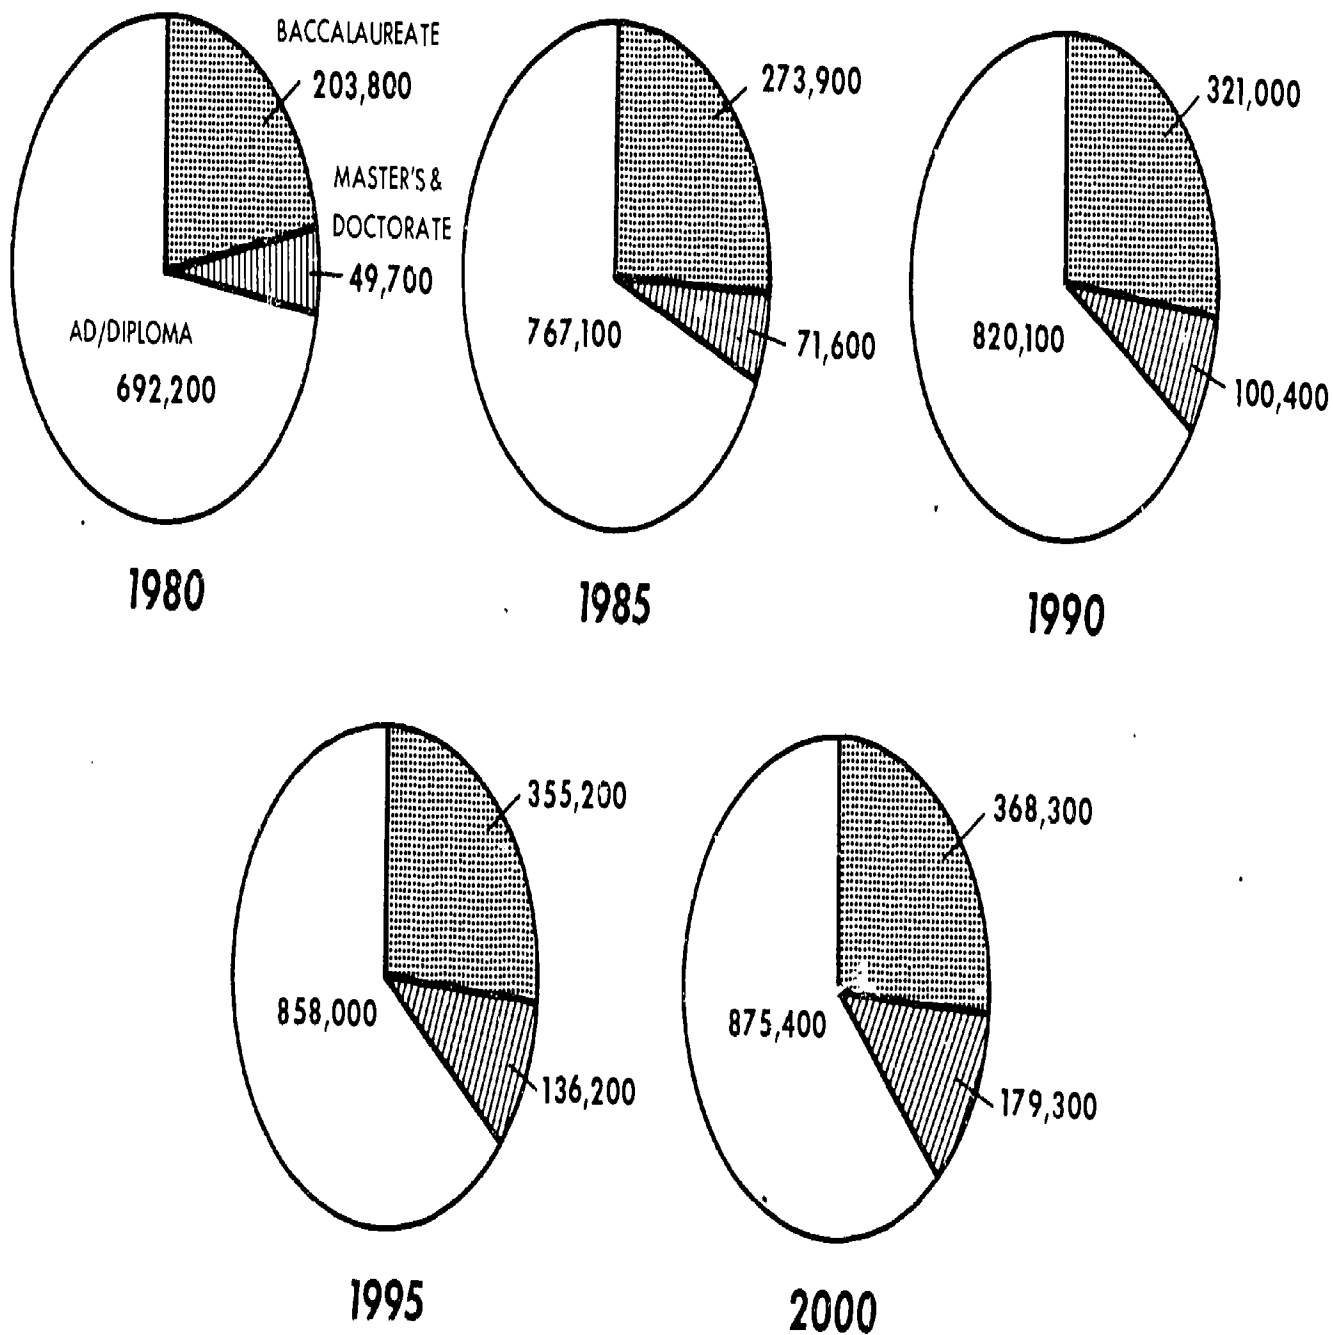

The projections of graduations from basic nursing educational programs resulting from these assumptions appear in tables 22 and 23. In all of the series, it is projected that the number of graduations by the year 2000 will be lower than the 77,000 being graduated currently. Series B, which is the most "optimistic" of the graduation projections, however, shows only a moderate decline following an increase occurring in the 1980's. Series A which provides for no changes in current, recent trends shows a continual decrease until total graduations reach the 1971-72 level of 51,300. Series D projects even further decreases in the overall number of graduates, to levels prevalent in the latter half of the 1960's.

In all cases, however, the "mix" of graduates will be different from that shown for the earlier years. In 1979-80, 48 percent of the graduates were from associate degree programs. In the "baseline," or Series A projections, the number of associate degree graduates represented 59 percent of the total graduates by 1999-2000. Only in the Series C projections, were the number of associate degree graduates less than half the total graduates by the year 2000; they represented about a third of the total graduates.

Projections of Supply to Year 2000

Data from the 1977 Sample Survey of Registered Nurses and the 1977 Inventory of Registered Nurses suggest that the estimates of registered nurse supply included in the Second Report to Congress were too high. Based on the 1977 Sample Survey, it was estimated that, as of January 1, 1977, there were 981,500 employed registered nurses in comparison to the 1,011,000 estimate included in the Second Report. Furthermore, as mentioned earlier, the number

Figure 2.-- Distribution of full-time equivalent registered nurses according to highest educational preparation, (series A) selected years 1980-2000.

-74-

Source : Estimates prepared by Division of Health Professions Analysis, Health Resources Administration, U.S. Department of Health and Human Services, 1981.

of graduates anticipated each year in the Second Report was higher than the actual number graduating during the latter half of the 1970's. This led to projections of supply for future years which were higher than those made at this time. Thus, the current estimate for the number of employed registered nurses as of January 1, 1980 is 1,119,100, or 945,700 on a full-time equivalent basis. This supplants the earlier projections of 1,152,000, or 974,000 full-time equivalent nurses.

Based on the assumptions regarding graduations from nursing education programs outlined above it is anticipated that there will be continual growth in the nurse supply in the next 20 years in all the series presented, although at varying rates. Thus, in the projections based on Series D, which show the least growth, projected supply for 2000 is 1,562,200 (1,336,800 on a full-time equivalent basis). In the Series D projections, while there is an increasing number of nurses throughout the projection period, when considered in relation to the general population, between 1994 and 2000 the growth in the nurse supply just keeps pace with the population growth. On the other hand, the Series B projections show substantially higher growth rates. The estimated total number in the registered nurse supply in Series B by the year 2000 is 1,862,000 (300,000 above the Series D projection), and the nurse-population ratios increase throughout the period. Series A, the "baseline" series, projects a total of 1,666,000 and Series C, 1,707,800 for the year 2000. (See tables 24 to 27.)

Data collected in the 1977 National Sample Survey of Registered Nurses indicated that earlier projections of the number of nurses with higher level educational credentials were underestimated. Thus, currently, it is estimated that as of January 1, 1980, 833,000 nurses in the supply had associate degrees

or diplomas as their highest degree; 232,300 had baccalaureates; and 53,800 had master's or doctoral degrees. Under the Series A assumptions, the number with associate degrees or diplomas would increase by 26 percent by the year 2000, as compared to a 49-percent increase in the overall supply. The number with baccalaureates would increase by 83 percent. The number with master's or doctoral degrees, would be 191,000, more than three times higher in 2000 than it was in 1980.

Series C, which assumes a sharp decrease in the associate degree programs but a sizeable increase in the baccalaureate and master's degree programs, shows by the year 2000 only an 11-percent increase in the nurses with associate degrees or diplomas but an increase of more than double the 1980 supply for nurses with baccalaureates (a total of 566,600). The master's or doctoral complement was four times higher than the 1980 supply. Currently, it is estimated that nurses with master's or doctoral degrees constitute about 5 percent of the supply. The projected number of nurses with master's or doctoral degrees by the year 2000, in each of the series, will represent about 12-13 percent of the total nurse supply.

The effect of these national assumptions about graduations and the other factors causing change in the supply on a State-by-State basis are shown in tables 28 to 31. In general, while it is anticipated that some of the States or regions with lower nurse-to-population ratios would have higher increases than those with higher ratios, fairly wide variation from State to State is expected throughout the 20-year projection period.

Factors Affecting the Supply of Licensed Practical Nurses

Data sources on the licensed practical nurse population are much less extensive than those for registered nurses. The 1974 Inventory of Licensed Practical Nurses (Roth, Schmittling, 1977) is the most recent complete descriptive survey of this group of nursing personnel. Based upon this inventory and annual graduation data, it is estimated that 715,000 practical nurses held licenses to practice in 1980. A significant number have been licensed by waiver as States have moved to enact licensing legislation. Of the number licensed, 549,000, or 77 percent, were employed in nursing. The Bureau of Labor Statistics (USDOL, BLS, 1981) reported the unemployment rate for practical nurses at 2.9 percent in 1980.

Graduations from Practical Nursing Programs

Preparation for licensure as a practical nurse is generally offered in postsecondary programs of a calendar year in length. In recent years, a few programs have been established in publicly supported junior or senior colleges. Their curriculums are designed to facilitate career mobility and to permit individuals to defray a part of their educational costs through part-time employment. After a year of study, the individual is prepared to take the examination for licensure as a practical nurse. At this point the individual may enter the work force or remain in school for a second year to obtain an associate degree and complete the requirements for taking the registered nurse licensing examination. If the individual then completes 2 additional years of study, a baccalaureate degree in nursing is awarded.

Data on practical nursing education programs in the United States compiled annually by the National League for Nursing (NLN, 1980), show that

the number of these programs has remained rather constant in recent years. In October 1975 there were 1,315 State-approved practical nursing programs in the United States, with an enrollment of 58,460 students. By October 1979 the number of programs was 1,318, with an enrollment of 52,232, reflecting a decrease in the average enrollment per program from 44 to 40. In 1979, 85 percent of those enrolled in October graduated at the end of the year. A slight decrease was noted in the actual numbers of practical nurse graduates from 1975 to 1979.

Characteristics of the Nursing Population

Like registered nurses, most licensed practical nurses are women (98 percent) and married (60 percent); their median age, as reported in the 1974 Inventory, was 38.8 years. Of those who indicated they were employed in nursing, the 1974 Inventory reported 73.3 percent as working on a full-time basis and 23.5 percent on a part-time basis. As was true for registered nurses, variation existed from area to area in the country in the proportion of those employed of the total nurse population, and in the proportion of those working on a part-time basis. States in the northeastern part of the country tended to show lower proportions of those employed in nursing than the Southern States.

Distribution of the Nurse Supply Among States

The Division of Health Professions Analysis, Bureau of Health Professions, Health Resources Administration, estimated that the number of licensed practical nurses in the nurse work force was 549,300 in 1980 and the full-time equivalent supply, 480,100. Much variation exists from area to area

in the proportion of employed practical nurses to the total nurse population and to the proportion of those who worked on a part-time basis. The South Central States had a much higher ratio of practical nurses to potential patients than either the New England or Middle Atlantic States. Higher practical nurse ratios were also noted in the Pacific States. Tables 34 and 35 show distribution of licensed practical nurses within each State.

Employment Characteristics

Preliminary data from the latest National League for Nursing study of employment opportunities for newly licensed practical nurses (NLN, 1981) showed that 88 percent were employed in nursing 6 months after licensure and 3.7 percent, twice that for newly licensed registered nurses, were not employed but seeking work. A significant number, however, reported that they were neither employed nor seeking employment. Some of this group includes individuals who were students in diploma, associate degree, or baccalaureate programs, and chose to take the licensing exam for practical nursing despite the fact that they were continuing their studies preparing to become registered nurses.

Licensed practical nurses work under the supervision of a physician or registered nurse. By far the largest proportion work in institutional settings: 63 percent in hospitals, 17 percent in nursing homes, and 7.5 percent in private duty, including care provided in institutions or in the patient's home. Of the small number working in community settings, the majority were employed in the offices of physicians or dentists.

Rates of Compensation

A number of data sources report information on earnings for both licensed practical nurses and registered nurses. These data are reported in the tables in appendix 2. A review of the data shows that practical nurses generally average about 70 to 80 percent of the earnings of a registered nurse in a staff position. Nurses licensed for the first time in 1979 reported, in the National League for Nursing study of employment opportunities of newly licensed nurses (NLN, 1979), a median annual salary of \$9,000. Newly licensed registered nurses reported in that same study a median salary of \$12,700.

Projections of the Supply of Licensed Practical/Vocational Nurses

The Model

In addition to requiring data on registered nurses, Section 951 of P.L. 94-63 called for the projection of the supply of licensed practical/vocational nurses in the future for the country as a whole and within States. For these projections, the level of educational preparation would not be relevant since any additional education achieved by practical nurses after licensure would most likely be education preparing for practice as a registered nurse. They would then seek licensure as a registered nurse and become part of the newly licensed registered nurse component in that model.

As noted earlier, the model used to prepare the registered nurse supply projections for this report resulted from refinements made in the approaches used for earlier reports, particularly the one used in the Second Report to Congress March 15, 1979 (Rev.) (USDHEW, 1979). The refinements were largely made possible by the availability of a new data source, the 1977 National Sample Survey of Registered Nurses (Roth et al., 1978). In addition to

providing some of the necessary data, the survey also permitted updating of the data base. For licensed practical nurses, however, no such data source is available. The latest information is the 1974 Inventory of Licensed Practical Nurses (Roth, et al., 1977). Because no new data were available to either refine the methodology or update the data base, the model, as well as the data base for the model, used to make the projections for licensed practical nurses in this report are the same as the one used in the Second Report to Congress. A description of the modelling approach and the data base used was included in the prior report.

As was true for registered nurses, projections of licensed practical nurses are made for the nurse population, nurse supply, and full-time equivalent supply. The projections are for the United States as a whole and for each State. Here, too, the same model is used for both "current estimates" and future projections with the "current estimates" based on actual graduations (NLN, 1979) and the projections for the future based on assumptions about the number graduating each year.

Assumptions About Practical Nursing Education Graduations

Two sets of projections were produced for licensed practical nurses based on alternative assumptions about the number of graduates from practical nursing programs from the year 1985 on. Since the most likely group from which the practical nurse student today might be drawn is the 17- to 34-year-old females (as was true for the associate degree RN students), the number of practical nurse enrollees was considered in relation to that population cohort. For Series I, it was assumed that the proportion of the 17- to

34-year-olds enrolled in practical nurse programs would continue to decline as it had in the recent past until 1985-86, at which time it would level off. For Series II, the declining trend was continued after 1985-86. Graduations were determined from these enrollments based on the latest graduation rate which was kept constant throughout the projection period. The graduation projections appear in table 32. In both series, the number of graduates decreases throughout the projection period. In Series II, the decrease is substantial. The conversion of these new graduates to newly licensed practical nurses was determined from the latest State Board examination passage rates available at the time the data were compiled. These rates were kept constant throughout the projection period, similar to the treatment of the rates in the registered nurse projections.

Projections to Year 2000

As was the case for registered nurses, the assumptions regarding future graduations, coupled with fewer actual graduations than those anticipated in the latter part of the 1970's, lead to lower projections of the licensed practical/vocational nurse supply for this report than were in the Second Report. At this time, it is estimated that as of January 1, 1980, there was a supply of 549,300 licensed practical/vocational nurses, or 480,100 on a full-time equivalent basis. By 1990, it is projected, using the Series I assumptions, that there will be 666,900 practical nurses in the supply and 661,500 using Series II assumptions. By the year 2000, the projected supply under Series I assumptions is 755,400 and 694,500 under Series II assumptions. When the supply of licensed practical nurses is examined in

relation to the projected population in the country, the Series I projections show a very slow rate of growth between the mid-1980's and the year 2000. The Series II projections show almost no change during this period and a slight decline toward the end of the period (table 33). The relationship between the national assumptions about the projections of graduations and other factors such as migration and "net losses" in the State supply of licensed practical/vocational nurses is shown in tables 34 and 35.

Chapter 2.

REQUIREMENTS FOR NURSING PERSONNEL

The Second Report to Congress provided an extensive review of several different approaches taken to determine the requirements for nursing personnel, particularly registered nurses.^{1/} The report indicated that the differing approaches taken were designed for different purposes and to provide different interpretations of "requirements." In this report, two of the approaches are reexamined. The data are updated where it is possible to do so. Some of the assumptions identified in the earlier versions are revised on the basis of consideration of later data and to extend the projections further into the future than they were in the earlier versions.

^{1/} For a full description of the process involved in the initial model development, see Second Report to the Congress, March 15, 1979 (Revised). Nurse Training Act of 1975. DHEW Pub. No. HRA 79-45. Government Printing Office, Washington, D.C., pages 7-43. See also Elliott, J. E., and Kearns, J. Analysis and Planning for Improved Distribution of Nursing Personnel and Services. Final Report. DHEW Pub. No. HRA 79-16. U.S. Government Printing Office, Washington, D.C., 1978, chapter VI; and Analysis and Planning for Improved Distribution of Nursing Personnel and Services: National Conferences. DHEW Pub. No. HRA 77-3, U.S. Government Printing Office, Washington, D.C., 1976. The Panel of Expert Consultants was a 21-member body which included representation from the various fields of nursing practice and types and levels of nursing education programs. In addition, the body included representation from the major professional associations (both nursing and medical) and from the fields of higher education, hospital administration, public health and economics.

One of the two approaches reconsidered is the model developed by Vector Research, Inc. to identify the impact of health systems changes on the requirements for registered nurses (Doyle, 1978) using the so-called "baseline" scenario. The other is the set of projections which was developed as a result of the criteria established by the Western Interstate Commission on Higher Education Panel of Expert Consultants (Elliott, 1978). In both cases, the time frame for the projections was extended.

The Historical Trend-Based Model

The model originally formulated by Vector Research, Inc. was revised and updated by Bureau of Health Professions staff. Future national requirements are estimated for full-time equivalent and total number of registered nurses through the consideration of requirements for registered nurses occurring in the major sectors of the health care system where registered nurses are employed: non-Federal short-term general and other special hospitals, all other hospitals, nursing homes, physician offices, community health, health maintenance organizations (HMOs), nurse education and private duty, and miscellaneous settings. Currently, in this updated version of the model, the projections are based upon data that fall into three major categories: general civilian and HMO population; provided services on a per capita basis (e.g., inpatient days, outpatient visits, etc.), and numbers of full-time equivalent registered nurses utilized per unit of provided services or time.

The model operates internally with each of the major sectors of the health care system in one of two methods. The magnitude of the population taken with the per capita demand for provided services determines the total

amount of services provided; the number of full-time equivalent registered nurses utilized per unit of provided service is applied to that result to determine the total estimated number of required full-time equivalent registered nurses. If the per capita provided services is not known, the total estimated number of full-time equivalent registered nurses is calculated by extending historical trends on the numbers of nurses employed. The former method is used to estimate approximately two-thirds of the registered nurse requirements.

A large number of data sources were drawn upon to establish the analytical relationships necessary to estimate future RN requirements, including data from the Bureau of the Census; Office of Health Maintenance Organizations, PHS, DHHS; the American Hospital Association; National Center for Health Statistics. DHHS; Health Resources Administration, DHHS, DHHS; the American Nurses' Association; the American Medical Association, and the National League for Nursing. While all data sources used are important to the operation of the model, the 1977 Sample Survey of Registered Nurses (Roth, et al., 1978) and the 1972 Inventory of Registered Nurses (Roth, et al., 1974) were especially significant because, in great part, they essentially form the basis for the projections of future estimated RN requirements.

Assumptions of the Model

Perhaps the dominant assumption of the model is that historical trends (including the most recent data available) determine the future trends that will take place in the health care system. The degree to which this assumption has validity is dependent on the degree to which the system does not undergo significant change in whole or in part. For example, the onset of

the Medicare program in the late 1960's produced a marked change in the care provided to older Americans. Presently, if national health insurance were to be initiated (or some other major change in the system under which health care is delivered), a similar gross effect on provided services could occur and distort the historical trends applied in the model.

As indicated earlier, there are two types of projection techniques employed in the model. The first type uses both historical trends in provided service, and utilization of registered nurses per unit of provided service. The second uses the historical trend of employed registered nurses per unit of time. The first is employed in the areas of short-term general and other special hospitals, physician offices, nursing homes, and some areas of community health. The remainder of the nursing employment areas employ the second technique. Each of these areas projected would be susceptible to changes in the health care system, both from the standpoint of direct impact on specific areas of registered nurse employment and from indirect effects (e.g., a significant increase in HMO enrollment could well decrease the services provided in hospitals and physician offices that are apart from HMOs).

Projections to the Year 2000

As can be noted from a review of the data from the Vector Model in the Second Report, the total requirements for full-time equivalent registered nurses in the current revised and updated model are somewhat higher than those indicated by the original Vector model for the baseline case.^{2/} For 1985,

^{2/} The baseline case assumes no introduction of national health insurance, an HMO growth which is a continuation of historical trends, and a utilization of full-time equivalent registered nurses per provided services based on historical trends. Also, vacancies in hospitals are not considered.

the last year for which projections were made by Vector Research, Inc. with the original model, current projections of requirements call for 1,113,000 full-time equivalent registered nurses in contrast to the 1,003,000 in the earlier version.

The major cause for the changes in the numbers projected lies in the utilization of full-time equivalent registered nurses per unit of provided service. This has shown a significant increase since the data were originally developed in the earlier version of the model. Therefore, while current trends for provided services are somewhat below those previously anticipated, the number of registered nurses required to provide those services has increased sufficiently to more than offset the diminished rate of services provided. For example, the current rate of registered nurse utilization in the majority of nursing homes was 40 percent greater than that indicated by the earlier data in the model before its revision and update. This phenomenon was experienced as well in most other areas (including hospitals) of the health care system employing registered nurses. Given a continuation of the present historical trends, this model projects a requirement for 1,503,000 full-time equivalent registered nurses by the year 2000.

However, changes such as those noted above can obviously have a significant effect on estimated requirements for registered nurses in the future. The Bureau of Health Professions is currently pursuing refinements to the present model and is also anticipating use of data from the 1980 National Sample Survey of Registered Nurses, which should clarify the employment trends of registered nurses and thereby afford a better basis for estimating future requirements for registered nurses.

Projection of State Requirements for Registered Nurses

In addition to determining national requirements, this approach is used to project requirements at the State level. The model employed to estimate the future requirements for full-time equivalent registered nurses at the State level is conceptually and structurally the same as that used at the national level. The same trend identifications for the same employment settings required for the national model were identified for each of the 50 States and the District of Columbia.

The reliability of the projections at the State level is affected by a number of factors. The quality of the data themselves present the major concern. A number of the sources used in the data analyses are sample surveys, and the variability of an estimate can increase markedly as the size of the sample diminishes. Even those data sources which are the result of complete or near complete enumerations suffer at greater levels of disaggregation because significant groups of data may have been omitted or not collected uniformly at some point. The impact on the State model is usually manifested in two ways: the growth (or decline) of provided services at the State level is substantially different from that of the Nation, and the number of full-time equivalent registered nurses used per unit of provided services or per unit of time is inordinately large (or small) when compared to nationwide utilization.

Nonetheless, even with a number of such anomalies in the model trends, reasonable estimates of the requirements for registered nurses into the early 1980's are provided. After this early period, the requirements estimates can

MICROCOPY RESOLUTION TEST CHART
NATIONAL BUREAU OF STANDARDS
STANDARD REFERENCE MATERIAL 1010a
(ANSI and ISO TEST CHART No. 2)

only be considered as indicators of the relative changes in the magnitude of the requirements. Included in this report are projections of State requirements to 1990. The aggregation of these State requirements varies somewhat from the overall national requirements estimates made, although the differences are relatively minor. In 1980 the percentage difference between the State aggregate and the national projection is 1.4 percent. This difference increases to 4.1 percent by 1990.

The Criteria-Based Model

The second of the two updated approaches arose out of a project which established a design to determine nursing requirements through use of an analytical framework for developing assumptions and criteria relevant to considerations of the requirements. The model was developed by the Western Interstate Commission for Higher Education (WICHE). Subsequent to the development of this model, WICHE established a Panel of Expert Consultants in 1977 to develop assumptions and criteria considered applicable, from a national standpoint, to a 5-year projection of nursing requirements by State and for the country as a whole. These projections, for 1982, were reported in the Second Report to the Congress.

In recognition of recent changes in the health care environment and the need to extend the requirements further into the future, the Bureau of Health Professions determined that the criteria and assumptions established by the Panel should be reviewed and updated. Therefore, in November 1980, a workshop was held to review the particular areas of acute care, long-term care and community health. Among the workshop participants were registered nurses

involved in services and education, hospital administrators, and other leaders in the health field, including some persons who had participated in the original WICHE Panel. In their review of the Panel's criteria, the workshop participants looked toward their applicability to the year 1990.

Assumptions of the Model

Central to this modeling approach is the establishment of health care goals which are used as the underlying determinants of nursing requirements. Consequently, requirements in this approach refer to the number and levels of educational preparation of nursing personnel needed to meet a particular set of health care goals. The model requires that a planning group make the determinations. This planning group, while taking into account experience and current practice, uses its expert judgment to develop the criteria in the form of staffing and service utilization ratios which will best accomplish the developed health care goals. Nurses prepared in associate degree and diploma programs were considered as a single group because they are prepared to function in institutional settings while those from baccalaureate programs are prepared for community settings as well.

Two sets of criteria were developed by the original Panel of Expert Consultants, and were carried forward in the present work of the workshop participants. These were identified as the "lower bound" and the "upper bound." The expectation was that all States would meet the lower bound by the year for which the criteria were being considered and that many would move toward meeting or exceeding the upper bound in the time period.

Figure 4. -- Projected requirements of full-time equivalent nursing personnel according to criteria-based model by educational preparation, 1990.

Source : Prepared by Division of Health Professions Analysis, Health Resources Administration, U.S. Department of Health and Human Services from criteria presented in Figure 3.

While the workshop participants reviewed and revised the criteria for the acute care, long-term care, and community health areas, they did not identify the trends to be anticipated by 1990 for utilization of hospital facilities and nursing homes, nor in population growth and distribution. Nor did they evaluate the overall nursing requirements estimates that would result from the established criteria.

The overall nursing requirements were developed by the Division of Health Professions Analysis. To permit comparisons between the data generated by the historical trend-based model and the criteria-based model, the same trends of services provided by hospitals and nursing homes, as well as the same population trends developed for use in the projections for the historical trend-based model, were used in developing the nursing requirements for this criteria-based model.

Projections to the Year 1990

As pointed out earlier, the workshop participants were looking toward 1990 in their review of the Panel criteria. Therefore, the requirements projections made as a result of these criteria are for 1990, both on a State and national basis. Unlike the historical trend-based model, this approach does not allow for data to be prepared for each of the intervening years between the present and the future date considered because the criteria were specifically established with the latter date in mind. The criteria do include, however, the level of educational preparation required for the registered nurse and the utilization of the practical nurse and the nursing aide. For the historical trend-based model, consideration was given to developing only a projection of the overall requirements for registered nurses.

The overall requirement for full-time equivalent registered nurses in the lower bound for 1990 according to the criteria-based model was 1,784,000; in the upper bound, it was 2,373,000. Full-time equivalent licensed practical nurses in the lower bound was 331,000, and in the upper bound, 334,000. The aide requirements were 524,000 and 589,000, respectively.

Requirements--A Comparative Analysis

As the approaches described above for the historical trend-based model and the criteria-based model would suggest, significant differences in the requirements projections from each of these models will be noted. The earlier material on the historical trend-based model points out that there are no allowances in the projections for changes in the trends as they are considered for the future. Also, the requirements projections presently developed from the historical trend-based model is an extrapolation of present employment trends without taking into account any possible short-falls such as vacant positions. The requirements projections in the criteria-based model are derived from a set of criteria developed by a planning group using its expert judgment on what would be the most appropriate use of resources to accomplish a series of health care goals which they have developed. An examination of the two different sets of projections demonstrates the main sources of difference between the two approaches.

In summary, these differences in projected nursing personnel requirements for 1990 between the criteria-based and historical trend-based models can be traced to differences in the approach to forecasting future needs. The criteria-based model begins with a determination by the study panel of

desirable, reasonable, and achievable health care goals for the future and then attempts to determine nursing staffing according to education preparation and service utilization that would be most appropriate to meet these goals. The historical trend-based model has as a principal assumption that historical population trends demand for services and staffing are primary determinants of future trends, and hence will be a main influence on nursing personnel requirements. The extent to which each of these models might provide a projection of the total number of full-time equivalent registered nurses required in 1990 would depend on how much of a determinant of future requirements historical trends might be; the availability of a pool of nursing personnel to fulfill requirements, and a willingness to substitute for historical patterns expert judgment of what might be desirable, achievable, and reasonable for the health field.

The group developing the criteria for the criteria-based model anticipated that all States, and therefore the country as a whole, would meet the lower bound criteria by 1990. The projections developed as a result of those criteria are used in this examination. The historical trend-based model results showed only registered nurses; therefore the data examined here does not take into account licensed practical nurse or aide requirements projections developed in the criteria-based model. In addition, the data in this comparative analysis do not consider educational preparation of registered nurses, since the historical trend-based model does not take that into account.

On an overall basis, for 1990, the criteria-based model projected a need for 1,784,400 full-time equivalent registered nurses, 43 percent above the

1,245,400 projected requirements for 1990 in the historical trend-based model. The basis for this difference is of particular note. Both sets of projections are fairly close when one considers the projections for hospital-employed nurses, a difference of 4.0 percent between the projections in each of the models. Here, apparently, the consideration of what might be appropriate staffing patterns for 1990 was somewhat similar to the projection from extrapolated trends of those employed in relation to the services provided. In the nursing education area, the criteria-based model, using projections of enrollment based on the assumptions included in the supply model and faculty-to-student criteria developed by the Panel of Expert Consultants, projected a requirement for 37,700 full-time equivalent faculty and school administrators in comparison to the 47,100 in the historical trend-based model. The latter was based on trends in those employed.

The major differences between the two projections were in the nursing home and community health areas. The projection based on the criteria established for registered nurses staffing nursing homes by those assembled for the November 1980 workshop was five times higher than the projection for 1990 from the historical trend-based model. The nursing home criteria considered by the November workshop participants were promulgated on a fundamental change in the approach to staffing nursing homes from the provision of the traditional, custodial, type care to an assumption of an increase in the therapeutic content of nursing care. The group considered as outcomes of the staffing pattern they envisioned for nursing homes such improvements in care as reduction of incontinence, maintenance of skin tone, reduction in the number of contractions, improved oral care, increased

discharge rate, closer monitoring of medication effects, and reduction in complications. They also considered an increase in surveillance of nutrition and its effectiveness, and an increase in family supported services, as well as an increased component of staff training since the group believed that much of the present auxiliary staff is minimally trained for the job.

The final criteria and projections of registered nurses in nursing homes also reflect considerations of the proportion of nursing home residents that might be considered in need of acute care as a result of both early discharges from hospitals and a practice of maintaining residents in the nursing home when they become acutely ill instead of the previous practice of transferring them to hospitals. Thus, it was premised that about one-third of the residents might be in need of acute care and the staffing in the nursing home would need to take this into account. To care for these residents, staffing requirements would be more like that of acute care facilities, requiring 3.6 total nursing hours of care per patient day with about two-thirds of this registered nurse care. For the remaining residents, to provide the therapeutic nursing care envisioned, it was determined that there was a need for 2.5 total nursing care hours with about one-third to be delivered by registered nurses (Proceedings, 1980). At present, according to a 1977 study, about 12 percent of the full-time equivalent nursing personnel in nursing homes are registered nurses (USDHHS, NCHS, 1979). Achieving this level of care for a rapidly growing elderly population has profound implications for nursing but more importantly for the American public who must ultimately make decisions regarding allocation of national resources.

For the community health area, the projection from the criteria-based model was more than twice that of the historical trend-based model. Among the factors the group saw as requiring increased levels of nursing care in the community health setting, were early discharges from hospitals and the aging population. Not only would persons tend to live longer and be subject to more chronic illnesses, they would also be more likely to live alone and need more professional support to do so. The impact noted from these factors was an increase in the proportion of the population to be helped with home visits, the number of home visits to be made, and the time these visits would take, thus necessitating increased levels of staffing.

It should be noted that no attempts were made to examine specifically what effects current cost-efficient ways of delivering and obtaining health care would have on requirements for nursing personnel. Various interventions could shift the need for nursing care from one setting to another. Thus, the transfer of care from the hospital to a less costly setting, such as community health agencies and home care, could result in the hospital becoming an even more intensive care setting requiring a higher ratio of highly skilled personnel per patient, even though there could be fewer beds and overall staff. Concomitantly, the shift to a less costly setting would affect the skill level required for nursing personnel in these settings since they tend to be staffed, on the average, with more highly skilled personnel than those employed in hospitals. Further, concentration on prevention in health care creates a transfer of need for health personnel rather than a direct increase in requirements.

Efforts currently underway to stimulate competition in the health care industry could also affect nursing manpower requirements. However, it would be premature to speculate on the nature or extent of this influence.

A Comparison of National Future Supply and Requirements

The various alternative assumptions and considerations reviewed for this report led to the provision of two sets of requirements projections for registered nurses based on two different types of approaches to the development and interpretation of requirements and four sets of supply projections based on alternative assumptions about the numbers and types of graduates that might be available. The projections for full-time equivalent registered nurses for 1990 and 2000 are summarized below:

<u>Year</u>	<u>Requirements</u>		<u>Range of Supply Projections</u>
	<u>Model</u>	<u>Estimates</u>	
1990	Historical Trend-Based	1,245,400	1,206,800-- 1,307,800
	Criteria-Based		
	Lower Bound	1,784,400	
	Upper Bound	2,440,200	
2000	Historical Trend-Based	1,502,900	1,336,800-- 1,593,600

In looking first at the historical trend-based model, the data suggest that the requirements projection for 1990 falls somewhere in the middle of the range of supply projections. The lower limit of the supply projections is based on the assumptions made on graduations in Series D, a rather constrained view of what might occur in nursing education. The upper limit of the supply projections is based on the Series B assumptions about graduation, the most optimistic of the views of nursing education. It essentially sees the level

Figure 5. -- Projections of supply of full-time equivalent registered nurses according to four sets of assumptions about nursing school graduations and projections of requirements from historical trend-based model, 1980-2000.

of graduations reverting back to the trends of the early 1970's with actual growth in the numbers of graduates in the 1980's. This is a condition generally not considered likely today given the competition from other occupations for women seeking career education in post-high school settings and the diminishing pool from which the student body can come. The Series A production projections, based on the maintenance of recent trends in the attraction of students to nursing education, is perhaps the best of the four series to use for comparison purposes to the historical trend-based requirements projections since neither envisions any major changes in the current trends. A comparison between the Series A supply projections and the historical trend-based requirements projection for the year 1990 shows that both projections are about the same, 1,241,500 full-time equivalent nurses in the supply as compared to 1,245,400 required. Looking further into the future, however, to the year 2000, a different picture emerges. Here, it is only in the Series B projections that the requirements are not greater than the supply. In Series A, it is projected that there will be 1,423,000 full-time equivalent registered nurses in the supply as compared to the historical trend-based model requirements projection of 1,502,900.

As can easily be seen from the figures quoted earlier, the requirements projections for registered nurses from the criteria-based model far exceed the projections of supply. The fact that this is a result of the basic changes the group believed were necessary to make in the delivery of nursing care is evident when one examines the data for all nursing personnel:

	1990	
	Criteria-Based Model Requirements (Lower Bound)	Range of Supply Estimates (FTE)
Total Registered Nurse	1,784,000	1,206,800-1,307,800
AD/Diploma	767,600	781,600-848,000
Baccalaureate	747,500	321,000-354,200
Master's and Doctorate	269,300	100,400-105,600
Licensed Practical Nurse	331,000	578,500-583,200
Nursing Aide	524,000	Not available

No projections are made of the supply of nursing aides since these individuals are primarily trained on-the-job and it is assumed that the supply needed would come from those available in the general labor force. However, in reviewing the above data, it should be noted that currently there are about 1,000,000 nursing aides at work. (The Bureau of Labor Statistics, DOL, in their recent manpower projections estimated that in 1978 there were 1,037,000 employed.) Given those data, it would appear that the 524,000 full-time equivalent nursing aide positions projected as required in the criteria-based model represents a decrease from current employment levels. The licensed practical nurse supply projections suggest that the supply will contain about 66 to 73 percent more practical nurses than will be required, on a full-time equivalent basis, according to the criteria-based model. In terms of those registered nurses whose highest level of educational preparation is an associate degree or diploma, the supply and the requirements would be roughly in balance or the supply would be slightly greater than needed, depending upon the assumptions about graduations.

Therefore, the major lack noted between the projected available supply and requirements, according to the assumptions and criteria included in the

criteria-based model, is for registered nurses with baccalaureate and master's or doctoral degrees. A comparison between the baccalaureates in the supply and those required indicates that the supply would be less than half of what would be required. For the master's or doctoral group, the supply would only be about a third of what would be required.

A Comparative Review of Future Supply and Requirements in States

The previous material centers on the relationship between the requirements projections and between the supply and requirements from a national standpoint. It is important, however, to note the impact on the States of the various assumptions. While it is found on a national basis that one type of relationship exists, it is highly probably that a particular State may show exactly the opposite, since a considerable amount of variation exists from State to State. State projections were made for all the areas discussed previously on a national basis. Since in all instances projections were made for the year 1990, all comparisons made here will relate to what the situation might be at that time.

It is important to note several points about the State data used in these comparisons. For one, in all instances, the approaches taken were based on national assumptions and criteria. This does allow for direct comparisons across all States. However, at the same time, it does not take into account any unique approaches or particular considerations in which a State may be interested. Another point is that both the supply and requirements data are dependent on data for the State in a national data base. As indicated in earlier descriptions of the model developments, a number of these national

data bases were derived from sample data which would have varying degrees of reliability on a State basis, depending upon the size of the sample and/or the completeness of the data for the particular State.

This national consideration of State data leads to certain anomalies in the data. For example, past trends lead to significant increases in nursing home patient days in Texas by 1990 but to a decline in California. Since as previously indicated the number of nursing personnel required for nursing homes in the criteria-based model has a particular impact on the overall numbers needed, this, in a large measure, is responsible for Texas requiring more registered nurses than California in the criteria-based model results. Presently, there are about twice as many nurses in California as there are in Texas.

With these caveats in mind, however, it is useful to examine the effects of these assumptions on State requirements and supply and how they relate to one another. In comparing the requirements for full-time equivalent registered nurses in each State, according to the historical trend-based model, with the full-time equivalent supply envisioned under the Series A assumptions, the diversity among the States is very evident. On a national basis, when this type of comparison is made, the supply and the requirements in terms of these overall numbers of registered nurses are projected to be equal for 1990; however, on a State-by-State basis, there could be sizeable differences between the supply and requirements in at least half the States. In about 70 percent of these cases, or 20 States, the supply could be greater than the requirements but in the others, the opposite is noted, and the requirements were projected to be far greater than the supply in 1990.

As one might anticipate from the fact that on an overall national basis, the requirements under the criteria-based model assumptions were considerably higher than the projected supply, these same results were also evident for the majority of the States. However, in 11 States and the District of Columbia, the projections of what the full-time equivalent supply might be (Series A) were greater than the requirements. These 11 States included all but Washington in the Pacific area of the country, 3 States in the Mountain area and 4 in the Eastern area.

Chapter 3

RECOMMENDATIONS

Recommendation 1: Supply and Requirements

The role of the Federal Government in support of nurse training must shift to a more targeted approach emphasizing preparation of nurses for practice in designated national priority areas and to improve utilization of nursing personnel. Federal support has been an important instrument in increasing the supply of registered nurses. Despite the fact that there are more registered nurses in practice than ever before, persistent shortages are reported in virtually every practice setting. Factors responsible for the shortage are numerous, complex and interrelated. Solving the problem will require the combined efforts of the Federal Government, States, the health care industry and the profession. Using the resource-building capacity that has been stimulated and supported by the Federal Government, the non-Federal sector must now take responsibility for maintaining enrollments and for subsidizing the costs of any further necessary increases. The Federal Government and health care industry must share responsibility for instituting corrective measures designed to reduce the problems of retention and turnover. These measures are essential in a period of restrained Federal spending and consistent with the Federal responsibility to allocate resources to programs which promote the achievement of national priorities. Accordingly, the Administration's legislative proposal authorizes support through special project grants and contracts for training, education and improved utilization of nursing personnel with special consideration for projects to train or increase the supply of nurses in institutional settings.

Recommendation 2: Special Initiatives

a. Federal initiatives should be continued to improve the geographic distribution of nurses as well as the distribution among the nursing specialties and practice settings. Progress has been made in increasing the number of nurses in inner cities and rural areas. Many such areas, however, lack institutional facilities or community agencies that provide employment opportunities for nurses. Therefore, overcoming problems of geographic maldistribution requires attention of both the Federal and non-Federal sectors to a broad range of factors other than those relating to nursing such as support for area health education centers, remote clinical site training, and reevaluation of present mechanisms for reimbursement of services.

Federal initiatives for improving the distribution of nurses in terms of nursing specialty and practice settings are included in the special project grant, advanced nurse training and nurse practitioner authorities in the Administration's legislative proposal.

b. Federal support to schools of nursing to recruit, retain and graduate disadvantaged students should be continued. Nurses from minority backgrounds are an essential component of the nursing work force. Continued Federal support is essential both to attain the social goal of placing educational opportunities within reach of disadvantaged individuals and to achieve a more balanced representation of minorities in the nursing work force.

Recommendation 3: Advanced Preparation in Nursing

a. Nurse Practitioner Training

Extension of the existing authority for nurse practitioner training is recommended in order to meet the dictates of a redirected national health strategy emphasizing the promotion of health and prevention of disease, thus reducing the need for institutional care. Evidence accumulated over a decade indicates that nurse practitioners are well accepted by patients; they improve access to care, and under some circumstances, reduce the cost of care. Practice in an expanded role encompasses some functions which have traditionally been the prerogative of the physician, but it also includes assessing health states of individuals and families, instructing and counseling in the areas of health promotion and maintenance, assisting patients to comply with medical regimens, and collaborating with health care providers and agencies to coordinate health care services. These functions directly support the achievement of national health goals. Since ultimately the services provided by nurse practitioners will have to be paid for by consumers directly, by third party insurers, or by the public, the costs of providing care will have to be justified by the relevance and effectiveness of the service. For this reason, it is imperative that systematic evaluations be initiated and carried out over a sufficiently long period of time to document patient care outcomes attributable to nursing intervention. Such studies are essential as a basis for formulating future Federal policy for nurse practitioner training.

b. Advanced Nurse Training

The number of nurses with advanced nurse training should be augmented to assure sufficient numbers of expert clinicians, particularly in acute care settings, to direct the learning and clinical practice of students, and to effect changes in the delivery of services both in institutions and community settings.

Findings from research in the basic and behavioral sciences as well as in nursing itself have expanded the scientific base of nursing practice and sharpened its clinical focus. As nursing practice, particularly in acute care settings, has become more complex, the need for nurses who can make expert clinical judgments and act upon them decisively has intensified. It is imperative that the supply of well prepared hospital-based nurses be increased to improve the quality of patient care and to provide models of practice essential for strengthening programs of basic, graduate, and continuing nursing education.

In the nursing home sector, expertise in geriatric nursing is the critical element in maintaining patients at the maximum level of productive functioning. In communities, advanced training in community health nursing is essential for the protection and promotion of the well-being of the populations as a whole. Efforts must therefore be continued in the non-Federal sector to support the preparation of expert nurse clinicians to provide direct patient care, faculty essential for assuring the quality of educational programs, and nursing service administrators who must institute change in management practices that will improve the quality of care and contribute to the retention of nurses in all practice settings.

Appendix 1.

SECTION 951, TITLE IX, PUBLIC LAW 94-63 AND
SECTION 12(h), PUBLIC LAW 95-623

PART D—MISCELLANEOUS

INFORMATION RESPECTING THE SUPPLY AND DISTRIBUTION OF AND REQUIREMENTS FOR NURSES

SEC. 951. (a) (1) Using procedures developed in accordance with paragraph (3), the Secretary of Health, Education, and Welfare (hereinafter in this section referred to as the "Secretary") shall determine on a continuing basis—

(A) the supply (both current and projected and within the United States and within each State) of registered nurses, licensed practical and vocational nurses, nurse's aides, registered nurses with advanced training or graduate degrees, and nurse practitioners;

(B) the distribution, within the United States and within each State, of such nurses so as to determine (i) those areas of the United States which are oversupplied or undersupplied, or which have an adequate supply of such nurses in relation to the population of the area, and (ii) the demand for the services which such nurses provide; and

(C) the current and future requirements for such nurses, nationally and within each State.

(2) The Secretary shall survey and gather data, on a continuing basis, on—

(A) the number and distribution of nurses, by type of employment and location of practice;

(B) the number of nurses who are practicing full time and those who are employed part time, within the United States and within each State;

(C) the average rates of compensation for nurses, by type of practice and location of practice;

(D) the activity status of the total number of registered nurses within the United States and within each State;

(E) the number of nurses with advanced training or graduate degrees in nursing, by specialty, including nurse practitioners, nurse clinicians, nurse researchers, nurse educators, and nurse supervisors and administrators; and

(F) the number of registered nurses entering the United States annually from other nations, by country of nurse training and by immigrant status.

(3) Within six months of the date of the enactment of this Act, the Secretary shall develop procedures for determining (on both a current and projected basis) the supply and distribution of and requirements for nurses within the United States and within each State.

(b) Not later than February 1, 1977, and February 1 of each succeeding year, the Secretary shall report to the Congress—

(1) his determinations under subsection (a) (1) and the data gathered under subsection (a) (2);

(2) an analysis of such determination and data; and

(3) recommendations for such legislation as the Secretary determines, based on such determinations and data, will achieve

(A) an equitable distribution of nurses within the United States and within each State, and (B) adequate supplies of nurses within the United States and within each State.

(c) The Office of Management and Budget may review the Secretary's report under subsection (b) before its submission to the Congress, but the Office may not revise the report or delay its submission, and it may submit to the Congress its comments (and those of other departments or agencies of the Government) respecting such report.

(approved for such purpose by the Commissioner of Education) that compliance by such school with such requirement will prevent it from maintaining its accreditation.”.

HEALTH PROFESSIONS REPORTS AND PROGRAMS

SEC. 12. (a) Section 708(d) of the Public Health Service Act is amended (1) by striking out “not later than September 1 of each year”, and (2) by inserting at the end the following: “Such report shall be submitted biennially, and the first such report shall be due not later than October 1, 1979.”. 42 USC 292h.

(b) Section 709(b) of such Act is amended by striking out “January 1, 1979” and inserting in lieu thereof “February 1, 1980”. 42 USC 292i.

(c) Section 751(i) of such Act is amended by striking out “December” and inserting in lieu thereof “March”. 42 USC 294i.

(d) Section 771(b)(2)(B) of such Act is amended by striking out “45 days after the date for which the determination is made” and inserting in lieu thereof “the first December 31 occurring after the date for which the determination is made”. 42 USC 295f-1.

(e) Section 782(c) of such Act is amended by striking out “September 30, 1979” and inserting in lieu thereof “March 1, 1980”. 42 USC 295g-2.

(f) Section 788(b)(6) of such Act is amended by striking out “September 30, 1978” and inserting in lieu thereof “October 1, 1979”. 42 USC 295g-8.

(g) Section 793(c) of such Act is amended (1) by striking out “annually” and inserting in lieu thereof “biennially”, and (2) by striking out “December 1, 1978” and inserting in lieu thereof “October 1, 1979”. 42 USC 295h-2.

(h) Section 951(b) of the Nurse Training Act of 1975 is amended by striking out “Not later than February 1, 1977, and February 1 of each succeeding year” and inserting in lieu thereof “Not later than October 1, 1979, and October 1 of each odd-numbered year thereafter”. 42 USC 296 note.

(i)(1) Section 702(d) of the Health Professions Educational Assistance Act of 1976 is amended by striking out “not later than two years after the date of enactment of this Act” and inserting in lieu thereof “not later than October 1, 1979”. 42 USC 295h-4 note.

(2) Section 903(a)(2) of the Health Professions Educational Assistance Act of 1976 is amended by striking out “January 1, 1979” and inserting in lieu thereof “April 1, 1979”. 42 USC 292h note.

(j) Section 772(e) of the Public Health Service Act is amended by inserting before the period a comma and the following: “except that a student who, for other than academic reasons, withdraws from a year class before the end of an academic year or does not complete an academic year shall not be considered as having been enrolled in a year class in that academic year”. 42 USC 295f-2.

MISCELLANEOUS

SEC. 13. (a)(1) Section 111(h) (42 U.S.C. 7411) of the Act of July 14, 1955, as amended by Public Law 95-95, is amended by adding the following at the end thereof: 42 USC 7401 note.

“(5) Any design, equipment, work practice, or operational standard, or any combination thereof, described in this subsection shall be treated as a standard of performance for purposes of the provisions of this Act (other than the provisions of subsection (a) and this subsection).”.

<u>Occupational health-RN</u>	\$14,586		Bureau of Labor Statistics Occupational Earnings in All Metropolitan Areas
<u>Physician's office-RN</u>		\$13,780	Owens, Arthur, "What your Colleagues are Paying Assistants." <u>Medical Economics</u> , March 1981

^{1/} For the hospital and nursing home fields, this is the range of estimated average salaries among the metropolitan areas covered in the studies.

^{2/} Estimated average annual salary was converted from hourly earnings, based on average standard workweek in each metropolitan area from 1972 hospital survey. Standard 40-hour week was assumed for certain localities and positions not surveyed in 1978.

^{3/} Estimated average annual salary was converted from hourly earnings, based on average standard workweek in each metropolitan area as indicated by data in 1978 nursing home survey.

Note: This table makes no attempt to compare estimated salaries for years given.

Table 18. -- Median annual salaries of nurses newly licensed in 1979 and employed in nursing on a full-time basis six months after licensure, by type of educational preparation and geographic location

Region	Registered nurses				Practical Nurse
	Total	Diploma	Associate degree	Bacca-laureate	
United States	\$12,700 ^{1/}	\$12,400	\$12,500	\$13,100	\$ 9,000 ^{1/}
New England	12,520	12,180	12,270	12,790	10,040
Middle Atlantic	12,970	12,270	12,880	13,570	9,740
East North Central	13,350	13,170	13,110	13,680	9,640
West North Central	12,130	11,870	12,120	12,490	8,510
South Atlantic	11,880	11,820	11,780	12,070	8,510
