**ABSTRACT**

In light of the increasing enrollment of part-time students at public two-year colleges, the question arises whether the conventional ratio (3:1 or so) for converting part-time to full-time equivalent (FTE) enrollment accurately represents the actual costs of providing services to part-time versus full-time students. A study was conducted to assess the relative effect of part-time versus full-time students on several types of expenditures in the two-year college. Using a translog model, costs were represented by reported expenditures; output by the number of full-time, part-time, and non-credit students; prices by average salaries for full-time faculty; and technological conditions by program emphasis, the percent of students earning a degree, and the system status of the institution. The study found that: (1) the marginal costs for instruction at small colleges were estimated to be \$1335 for a full-time student and \$245 for a part-time student, while costs at large institutions were estimated to be \$1941 for a full-time student and \$194 for a part-time student; (2) regardless of institutional size, the ratio of full-time to part-time marginal costs was greater in the instructional area than in student services; and (3) at the majority of the two-year colleges in the sample it cost only about one-fifth to one-seventh as much to provide instructional services for a part-time student as a full-time student. A five-page list of references and cost data for the 779 colleges in the study sample are appended. (EJV)

### Abstract

Marginal costs are estimated for part-time and full-time students at public two-year colleges. The estimated costs are compared across several expenditure categories including instruction and student services. The results indicate that part-time students typically consume fewer institutional resources than conventional full-time-equivalency ratios might suggest.

The Financial Impact of Part-Time Versus Full-Time Enrollments  
on Public Two-Year Colleges: A Marginal-Cost Perspective

The number of part-time students attending public two-year colleges increased rapidly during the 1970s. By the end of the decade, aggregate part-time enrollment constituted about 63% of total headcount enrollment at those institutions (National Center for Education Statistics 1982). Concern has been expressed about the financial implications of this trend from an institutional perspective. The question at issue is whether the conventional ratio (3:1 or so) for converting part-time to full-time-equivalent (FTE) enrollment accurately represents the actual costs of providing services to part-time versus full-time students (see, for example, Armstrong et al. 1979; Ohio Board of Regents 1981; Wattenbarger and Bibby 1981; Loftus, Hines, and Hickrod 1982). This question has not been explored empirically in the literature except for Kress (1977), tangentially, and Brinkman (1981).<sup>1</sup>

The conventional three-to-one ratio is not a hard and fast rule, but it is grounded in typical student behavior at least in the instructional area. While national data on student credit hours are not available, a sampling of reports published by state agencies indicates that a part-time student at a public two-year college generally does take about one-third as many credits as a full-time student, with some variation by state (Connecticut Board of Higher Education 1982; St. John and Sumner 1980; New York State Education Department 1983; Ohio Board of Regents 1981; Washington State Board for Community College Education 1980). Comparable data with respect to institutional services other than instruction are not available. Some would argue (see Ohio Board of Regents 1979 for an opinion survey on this issue) that for many of the activities included within

"student services," a part-time student may require almost as much by way of institutional resources as a full-time student requires. If so, then reliance on the three-to-one ratio for funding or allocation purposes could inadvertently have adverse effects on institutional finances.

The purpose of this paper is to assess the relative effect of part-time versus full-time students on several types of expenditures in two-year colleges. Institutional expenditures for instruction, student services, and (total) educational and general purposes are considered. The financial impact of part-time and full-time students are assessed in terms of marginal costs, that is, the change in total costs (expenditures) associated with the enrollment of one additional student. Marginal costs are estimated for both part-time and full-time students for each expenditure type. The estimates are compared with one another and the results are discussed in relation to ratios used for converting part-time to FTE enrollments.

Instruction and student services, as conventionally understood in higher education, account for a large proportion of the services that are provided directly to students. Traditional classroom teaching is the predominant activity within the instructional function, while student services includes a wide variety of activities (for example, registration, admissions, personal counseling, career counseling, testing, and financial aid processing). Disparate modes of operation in the two areas should be reflected in disparate expenditure patterns. In both cases, the overall resources required by a typical part-time student are surely less than those required by a typical full-time student. The difference should be greater for instruction than for student services, however, because the latter includes many activities, such as registration and personal

counseling, that often require the same amount of institutional effort regardless of whether the student has full- or part-time status. It is also hypothesized that the magnitude of the marginal-cost ratio between full- and part-time students will be roughly three-to-one for instruction, based on relative credit-hour loads for the two types of students (as mentioned earlier). It should be noted, however, that the ratio was found to be considerably higher than that in a previous study (Brinkman 1981). For student services the expectation is that the marginal-cost ratio will be somewhat less than three-to-one.

Educational and general expenditures include expenditures for both instruction and student services, as well as for numerous other functions (academic support, institutional support, operation and maintenance of the plant, and so forth). Relating this composite expenditure category to full- and part-time enrollments is a means of assessing the relative impact of the two student types in the context of a broad measure of institutional finances. Because of the preponderant weight of the instructional function within the total budget of most two-year colleges, the ratio of full-time to part-time marginal costs for educational and general purposes should be similar to that for instruction.

The results of the analysis are intended to provide background information for assessing the appropriateness of particular funding formulas, tuition rates, and fee levels. Estimates of the relative cost of providing services to full-time versus part-time students will also be useful for enrollment planning, in that the estimates provide a basis for assessing the financial impact of various enrollment-mix alternatives.

### Model

The relationship between expenditures and enrollment was examined by estimating several translog cost functions. Theoretically, an industry's cost and production structure can be equivalently analyzed using either a cost function or a production function. When the level of output is determined exogenously, as is generally true in public higher education, the former approach is preferable (Nerlove, 1963). Using cost functions is often more convenient as well, especially when analyzing multiproduct enterprises. In any case, it is the predominant approach in recent literature.

The general form of a cost function may be expressed as

$$C = C(Q, P; T) \quad (1)$$

where total cost,  $C$ , is represented as a function of output,  $Q$ , the prices of inputs,  $P$ , and a set of technological conditions,  $T$ , that may have some effect on the relationship between  $C$  and  $Q$  (McFadden, 1978). Under theoretically ideal circumstances (i.e., intent to minimize costs coupled with full knowledge of all production relationships), the cost function specifies the minimum cost for a given level of output. As it is generally agreed that the actual circumstances prevailing at higher education institutions do not fit the theoretical model (Bowen, 1980), the cost functions estimated here simply reflect average institutional behavior (for a similar situation with respect to hospital costs, see Pauly [1978]). Cohn (1979) refers to such cost functions as "approximate."

Selecting a particular form for the cost function is essentially a matter of deciding what can and cannot be assumed about the relationships and overall behavior of the variables in the function. In recent years,

econometricians have turned increasingly to one or other version of the translog model because it imposes the fewest restrictions on cost and production behavior (Brown, Caves, and Christensen 1979; Spady 1979). In the translog function, all variables are expressed as natural logarithms, and all independent variables are interacted with one another and taken to the second power.<sup>2</sup> So constituted, the function contains no separability or homogeneity of output assumptions. That is, the behaviors of the independent variables are not assumed to be unrelated to one another, nor are total costs assumed to increase exactly in proportion to increases in output. Such assumptions can lead to distorted estimates of marginal costs (Brown et al 1979). The translog function does incorporate two regularity conditions: total costs must increase in proportion to an increase in the prices of inputs, and in the same direction as an increase in output. Generally, in the absence of prior knowledge about the proper functional form, the more flexibility that is preserved, the better.

#### Variables

In the translog model used for the present study, costs were represented by reported expenditures, output by the number of full-time, part-time, and non-credit students, prices by average salaries for full-time faculty, and technological conditions by program emphasis, the percent of students earning degrees, and the system status of the institution (i.e., free standing or part of a system). Reported expenditures for the instructional and student services functions represent direct costs only--for labor primarily, along with supplies, travel, and certain other expenses. Educational and general expenditures are also predominantly for personnel, but also include the cost of utilities, library acquisitions, and so forth.

Properly speaking, the number of students enrolled is only a proxy for output. It is appropriate for the purpose of this study because funding of two-year public colleges is often enrollment-driven. By using both full- and part-time enrollments as output measures in the model, we can estimate their respective impact on total costs without resorting to the use of FTE enrollment data. The latter data are subject to inconsistent reporting across institutions. The third type of output, non-credit enrollment, is not a major cost factor at the typical two-year college (on average, only about 4 to 5 percent of instructional expenditures are for this purpose according to Dickmeyer and Cirino [1982]). It does add a relevant dimension, though, when outputs are characterized in terms of enrollment.

From the perspective of this study's primary objective--obtaining marginal cost estimates for full- and part-time students--the remaining variables in the model serve as controls, or intervening variables (Johnston 1960). The prices of inputs will differ from one institution to another. Data are available on one key input price, the average salary paid to full-time faculty. In the instructional cost model, this price is used to represent not only faculty costs (for both full- and part-time instructors) but also non-faculty costs. In other words, it is assumed that institutional differences in clerical wages, for example, as well as in salaries for part-time faculty, will be highly correlated with differences in salaries for full-time faculty, and thus that all of these costs can be adequately represented by the one variable. In the student services cost model, average faculty salaries are again used--for lack of better data--on the assumption that salaries for student services personnel will typically be highly correlated with faculty salaries. Similarly, for educational and general expenditures, average faculty salaries are used to

represent price differentials across institutions for a variety of inputs. With only one price variable in the model, no interaction terms involving that variable are needed--there are no substitution possibilities to accommodate.

Two-year colleges also differ with respect to the composition of their enrollments and their curricula, both of which could affect unit costs. In addition to the full-time versus part-time issue, which is already being addressed in the model, a higher percentage of degree completers might be expected to lead to higher per-student costs in both the instructional and student services areas. To complete a degree, students must take advanced, presumably more expensive, courses. They may also need additional counseling or other assistance along with degree certification. With respect to the curriculum, differences in the unit costs of programs, such as the cost of a student credit hour in engineering versus one in arts and sciences, have been well documented (Fickett 1977; Spitz 1979; Warren, Anderson, and Handin 1976). For the present study, the extent of an institution's commitment to (relatively) high cost programs is represented by the combined percentage of degrees awarded in mechanical and engineering technologies, health services, and natural science programs.

Public two-year colleges can be part of a system of institutions or they can be in a stand-alone situation. If, in the former case, some administrative functions are carried out at a system office, the effect will be to lower institutional expenditures relative to a comparable stand-alone institution that must handle all administrative functions. In dealing with this matter in the present study, so-called "branch campuses" were eliminated from the sample altogether. For the remaining institutions, a dummy variable was used to distinguish between those with

some sort of system or multi-campus arrangement (value=0) and the stand-alone institutions (value=1). So constituted, the expected sign on the variable is positive, or, in other words, the cost function is expected to be shifted upwards for stand-alone institutions. (See Cowling and Holtmann [1983] for a similar use of dummy variables in a translog cost function.)

### Data

Raw (untransformed) mean values for each of the variables are shown in table 1. All variables except the dummy for system status appear as natural logarithms in the estimating equation. All data are for 1979-80. The source for all data was HEGIS, except for data on non-credit enrollments which came from the annual directory of the American Association of Community and Junior Colleges (Gernhart 1981). While HEGIS data have been shown to contain errors (e.g., Minter and Conger 1979), there is no reason to suspect the presence of systematic error that could bias the study.

The number of institutions in the sample studied was 779. As of 1979-80, this constituted about 75% of all public two-year institutions; excluded institutions consisted primarily of those lacking one or more data elements, enrolling fewer than 200 FTE students (full-time headcount plus one-third of part-time headcount), or having the status of a branch campus. A handful of outliers were also excluded. The sample was not randomly drawn, then, but it was broadly representative of public two-year colleges.

The model was estimated using ridge regression. The abundance of squared and interaction terms in a translog model usually leads to multicollinearity problems. By introducing a small amount of bias into the system, ridge regression makes it possible to estimate parameters that are

more stable when severe collinearity is present than those estimated by ordinary least squares under the same circumstances (Hoerl and Kennard 1970; Churchill 1975; Vinod 1978; Krakower 1980; and, for critical commentary, Judge et al. 1980).

Table 1  
Means and Standard Deviations for Variables

<u>Dependent</u>	$\bar{X}$	S.D.
CI (total expenditures for instruction)	\$3,524,000	\$3,463,000
CS (total expenditures for student services)	\$610,000	\$676,000
CE (total educational and general expenditures)	\$7,006,000	\$6,951,000
<u>Independent</u>		
FTS (number of full-time students)	1,645	1,588
PTS (number of part-time students)	2,840	3,614

AVGSAL (average salary of full-time faculty)	\$18,578	\$3,765
DEGP ((number of degrees awarded/ number of full-time students) x 100)	29.0%	13.4%
HCP ((proportion of degrees earned in engineering + natural science + health services) x 100)	36.2%	19.9%
SYS (dummy, where 1=stand-alone institution; 0=part of system or multi-campus)	.693	.461

### Results

The results of estimating the translog function are shown in table 2. The general results are about as expected. The models explain much of the

variation in total costs among institutions, especially for instruction and educational and general expenditures. The output variables (in second-order form), along with average salaries, are positively related to expenditures across all three expenditure categories. Several other variables and interaction terms also appear to be important in the model.<sup>3</sup> Of course, the full effect of a variable that is interacted or taken to a second power can only be assessed in terms of a set of coefficients; pertinent data are provided in table 3. With the exception of the dummy

variable (SYS), each regression coefficient shown in table 2 can be read as an elasticity, i.e., as the percentage change in total costs associated with a one percent change in the value of the corresponding variable. Note that the elasticity for average faculty salaries is less than one. This can be interpreted to mean that the salary component is reflecting only a portion (64% to 83% across the three equations) of the cost of a

hypothetical unit of input. The sign for SYS is as expected in the three models but the variable has little impact; the coefficients are to be read as percentage increases in total costs associated with being a stand-alone institution.

Table 3

Numbers shown are F scores for the change in R<sup>2</sup> associated with removing each set of variables from the model; \* p < .01.

Table 4 shows the marginal cost estimates for full- and part-time students, and the ratio between them, for each of the three expenditure categories analyzed in the study.<sup>4</sup> For example, the marginal costs for instruction at small institutions are estimated to be \$1335 for a full-time student and \$245 for a part-time student, a ratio of 5.45 dividing the former by the latter. As is evident from the table, the estimates and the ratios differ from one level of enrollment to another. The category "small institutions" refers to institutions lying within the smallest five percent of those in the sample (as measured by enrollment). Data on 10 such institutions, randomly chosen, were averaged to create a data set for a "typical" small institution--284 full-time and 221 part-time students. In a similar fashion, data for a typical large institution were created--4,665

full-time and 12,885 part-time students. Between these extremes, two types of middle-range institutions are also represented in table 4. Section C shows the results of using raw enrollment means for the entire sample--1645 full-time and 2840 part-time students--to represent one such institution.

Table 4  
Marginal Cost Estimates, Public Two-Year Colleges, 1979-80

<b>D. Large</b>			
FT Student	\$1941	\$257	\$3116
PT Student	\$ 194	\$ 32	\$ 303
FT/PT	9.94	8.03	10.28

Section B shows the results of using the logarithmic enrollment means for the entire sample--1150 full-time and 1366 part-time students--to represent the other. The raw data distributions for enrollments (and expenditures) were positively skewed, so the means of the logarithmic data were smaller.

Fully two-thirds of all the institutions in the sample had enrollments equal to or less than the raw mean values.

In order to evaluate marginal costs at those various enrollment levels, values for the other independent variables in the model also had to be chosen. For the results shown in table 4, the following conditions were imposed: the raw mean values for percent of degree completion (29%) and percent of high cost programs (36.2%) were used in all sections; with respect to noncredit enrollment, the average of actual values was used for section A (165 students), the log mean value for section B (354 students), and the raw mean value for sections C and D (4335); and for faculty salaries the log mean value was used for section B (\$18,215), the raw mean value for section C (\$18,578), and the average of actual values for sections A (\$13,625) and D (\$23,949). Neither degree completion nor program emphasis were correlated with full- or part-time enrollment levels; thus it was reasonable to leave them at their respective mean values. Noncredit enrollment to some extent, but particularly average faculty salaries, were correlated with full- and part-time enrollment levels; thus values other than those at the mean were required to adequately represent typical combinations of institutional characteristics across the (credit) enrollment spectrum.

The results shown in table 4 can be summarized as follows. First, for all four institutional sizes, the ratio of full-time to part-time marginal costs is greater in the instructional area than in student services, but especially so at small institutions. Second, the larger the institution, the greater the disparity in marginal cost between the two types of students. Third, even at the smallest institutions in the sample, the marginal-cost ratio for student services is greater than three-to-one.

Fourth, the marginal-cost ratios for educational and general expenditures are quite similar to those for instructional expenditures, regardless of institutional size.

In interpreting the change in marginal costs from small to large institutions, it is useful to recall that the salary data used in the calculations for sections A and D in table 4 reflect the respective averages for the two institutional sizes, rather than the sample mean. By paying their full-time faculty a far lower wage rate, on average, than do the larger institutions, the small institutions overcome a portion of the diseconomies of scale that would otherwise accrue to their small size. For example, if the wage rate were held constant at the sample (raw) mean, the marginal cost for a full-time student in the instructional area would be \$1628 instead of \$1335 at small institutions. Conversely, a portion of the apparent diseconomies of scale at large institutions is due to relatively high wage rates. If salaries for full-time faculty at large institutions were at the sample (raw) mean, the marginal cost of instruction for a full-time student would be \$1680 instead of \$1941.

Several other results (not tabled) may be of interest. In institutions where the curriculum consists primarily of relatively high-cost programs (as measured by the variable HCP), the marginal-cost ratios between full- and part-time students are higher for instruction but lower for student services, when compared to institutions at the mean. The differences are modest: for an institution with HCP at 80 percent, but otherwise at the (raw) means for the sample, the marginal costs of instruction are estimated to be \$1798 and \$233 for full- and part-time students, respectively, or a ratio of 7.72 compared to the 7.41 figure

shown in table 4. For student services, the corresponding estimates are \$210 and \$43, or a ratio of 4.88 as opposed to 5.53 in table 4.

For an institution with (raw) mean characteristics, the marginal-cost estimates per non-credit student are \$53, \$6, and \$93, for instruction, student services, and educational and general purposes, respectively; in other words, about one-thirtieth, or so, of the marginal cost of a full-time student for those same expenditure categories. These figures reflect considerable scale economies; excluding student services, marginal costs for non-credit enrollment are estimated to be substantially higher at low enrollment levels. On a related matter, the model predicts that enrolling the mean number of non-credit students, as opposed to enrolling no such students, increases total instructional costs at a typical institution by slightly more than 4 percent--about the same as the 4 to 5 percent calculated by Dickmeyer and Cirino (1982) using accounting procedures.

### Discussion

It was hypothesized at the outset that the difference in resources demanded by full-time versus part-time students (as measured by marginal costs) would be greater in the instructional area than in student services. The results of the study appear to confirm that hypothesis. Differences between marginal costs for full-time and part-time students were estimated to be about 19 to 38 percent greater in the instructional area, depending on the size of the institution.

It was also hypothesized that for instruction, the marginal cost of a part-time student would be about one-third that of a full-time student. But the results of the study indicate that at the majority of two-year colleges it apparently costs only about one-fifth to one-seventh as much to

provide instructional services for an additional part-time student. These results are comparable to those found in an earlier study of instructional costs at two-year colleges using different models and samples (Brinkman 1981). We might infer, then, that these institutions make use of different production technologies in providing instructional services to part-time as opposed to full-time students; for example, they may use part-time students to fill course sections or they may depend heavily on part-time (much less expensive) faculty to teach part-time students. The latter possibility was also suggested by the findings in Kress' (1977) study of costs at California community colleges.

The somewhat lower cost ratios in student services suggest that in this area it is more difficult for institutions to employ alternative, cost-saving technologies in serving part-time students. Still, the ratios were higher than expected. In the face of various one-to-one relationships in the production technology of student services, ratios in the four-to-one and higher range may indicate that many part-time students do not avail themselves of some of the services provided. They have to be admitted and registered, of course, and pay their fees, but perhaps they make relatively little use of more expensive services such as counseling.

In relating the findings of this study to funding algorithms that convert part-time to full-time equivalent enrollment, we note first of all that most funding formulas that are based on unit cost calculations employ average rather than marginal costs. It cannot be assumed that the relationship between marginal and average costs for full-time students is identical to that for part-time students. Thus we cannot assume that the full-time to part-time ratios for average costs are identical to those for marginal costs. It is reasonable to assume, though, that the marginal cost

ratios are a pretty good indicator of the corresponding average-cost relationships over much of the observed enrollment range.

Second, from a marginal-cost perspective, it does not appear that current algorithms typically work to the detriment of institutions that are enrolling increasing numbers of part-time students, at least not on the basis of part-time to full-time-equivalent conversions. The data in this study suggest that, for many two-year colleges, educational and general expenditures for an additional full-time student are five to seven times higher than for an additional part-time student. Few, if any, funding formulas appear to involve a conversion factor that high (Gross 1982; Dougherty, Hyde, and Van de Water 1982). Indeed, most formulas are more likely to reflect something close to the conventional three-to-one ratio, because most formulas are directly or indirectly based on student credit hour data--which, as noted earlier, are the foundation for the conventional ratio. So, it appears that, on average, two-year public colleges have been receiving more funds than they have been expending per additional part-time student. Of course, this situation does not imply anything at all about the adequacy of the overall funding of these institutions. Furthermore, it should be kept in mind that the cost estimates in this study are meant to reflect conditions at the majority of institutions. Nothing in the analysis precludes the possibility that a given institution might find itself in a situation where the relationship between the costs of full-time and part-time students is quite different than the ratios presented in table 4. Indeed, the marginal cost estimates for individual institutions show that a number of institutions are estimated to be spending considerably more for part-time students than suggested by the three-to-one FTE conversion ratio (not tabled).

Finally, the cost estimates in this study are the product of estimating a particular model in a particular way. The model employed would certainly be improved theoretically by the inclusion of additional data on the prices of inputs, especially salaries for part-time faculty, and perhaps by more data on variations in programs or on the environment surrounding the respective institutions. Whether any of these modifications would materially affect the primary results of the study cannot be known a priori. Given that some of the results run contrary to expectations, there is ample reason to develop additional evidence regarding the costs of providing services to part-time students.

## Notes

1. See Hyde and Augenblick (1980) for a pertinent review of the literature on community college finance through mid 1980. For recent, wide-ranging discussions of community college finance, see Garms 1977; Richardson and Leslie 1980; and Breneman and Nelson 1981.

2. In general form, using the notation from equation 1, the translog cost function can be written as

$$\begin{aligned} \ln C = & a_0 + \sum_r a_r \ln Q_r + \frac{1}{2} \sum_r \sum_s a_{rs} \ln Q_r \ln Q_s + \sum_i b_i \ln P_i \\ & + \frac{1}{2} \sum_i \sum_j b_{ij} \ln P_i \ln P_j + \sum_k d_k \ln T_k + \frac{1}{2} \sum_k \sum_l d_{kl} \ln T_k \ln T_l \\ & + \sum_{ri} q_{ri} \ln Q_r \ln P_i + \sum_{rk} h_{rk} \ln Q_r \ln T_k + \sum_{ik} m_{ik} \ln P_i \ln T_k + e_c. \end{aligned}$$

estimation. Nonetheless, one may not assign significance levels to the ratio between the regression coefficients and their standard errors shown in table 2, because the sampling distribution for the ratio is unknown under conditions of bias. See Vinod (1978) for a discussion of this issue.

4. With respect to the specific translog model estimated for this study, the marginal cost of the  $r$ th output is equal to

$$\frac{\partial \ln \hat{C}}{\partial \ln Q_r} \cdot \hat{C} \quad \text{where} \quad \frac{\partial \ln \hat{C}}{\partial \ln Q_r} = a_r + \sum_s a_{rs} \ln Q_r + \sum_k h_{rk} \ln T_k$$

In other words, the marginal cost of a particular output is equal to the partial derivative of the estimated cost function with respect to that output, multiplied by the estimated value of total costs per unit of that output.
