ABSTRACT

The feasibility of developing a refined national reporting classification system for colleges and universities to complement the present classification system of the National Center for Higher Education Management Systems (NCHEMS) which categorizes institutions into five major classes was studied. For some types of national reporting the NCHEMS classification may be too broadly defined, and creating more specialized institutional groupings might facilitate comparisons among peer institutions. Eight data variables were used to sector the 1,316 four-year institutions, presently categorized as Major Doctoral, Comprehensive, and General Baccalaureate. It was concluded that the current NCHEMS classification system ought to be left as it is and that it is not workable to create in advance lists of institutions that will be truly appropriate comparison groups for a significant set of potential users. A procedure to create lists of such comparison groups is currently available using the NCHEMS database and technical assistance. The forms that are used to facilitate this process are appended (i.e., criteria selection forms). Also appended are lists of alternate groupings for institutions using three NCHEMS school categories, as well as public/private control, land grant status, and the presence/absence of a medical school on campus. Information is included on three procedures used to create groups of institutions for comparative purposes: sectoring, clustering, factor analysis. (SW)

AN ALTERNATE CLASSIFICATION SYSTEM FOR INSTITUTIONS

I. INTRODUCTION

U.S. higher education is comprised of some 3200 accredited institutions. Aspects or dimensions on which those institutions differ are many. They may be publicly or privately controlled, offer degrees at various levels, provide specialized or diversified curriculums, and so on. Examining information based on a heterogeneous set of institutions has its uses. However, information based on subsets of more homogeneous institutions typically has wider utility.

Institutions can be segmented into numerous types of comparison groups. These types of groupings are not necessarily mutually exclusive. That is, an institution may fit into one group based on one set of inclusive criteria, but fit into a different group given a different set of criteria. The general kinds of comparison groups would seem to include at least the following:

1. Classes of institutions used for national reporting purposes

For national reporting purposes, various organizations have found it useful to divide the population of U.S. institutions into classes of roughly similar institutions. The Carnegie Commission, the National Center for Education Statistics, the American Association of University Professors, and the National Center for Higher Education Management Systems (NCHEMS) have each proposed classifications of institutions that have been widely used. These classification systems

are alike in that they disaggregate the universe of institutions using only a handful of institutional characteristics. They typically acknowledge only very substantial differences in size, levels of degrees awarded, research expenditures, and programs. Institutions within classes will be relatively similar (that is, relative to institutions in other institutional classes) along those dimensions, but considerable within-group variation often remains. In addition, institutions may span a wide range of values across various other dimensions not used as criteria for the classification system.

2. Special feature groups

A "special feature" refers to a particular characteristic of an institution that virtually all would agree has some social or economic significance. Presence or absence of the special feature usually has important implications for the mission of the institution. Institutional groupings based on a special feature include institutions with medical schools, land grant institutions, women's colleges, traditionally Black colleges, vocational-technical two-year colleges, limited, special purpose institutions (for example, free standing art, medical, or business schools), and so on.

Institutions within a special feature group have that special feature in common, but may differ in any number of other ways. Special feature groups may be useful at all reporting levels (national, state, institutional).

3. Special Issue comparison groups

"Special Issue" comparison groups derive from particular questions or issues that typically are raised at the institutional or state level. The difference between a "special issue" and a "special feature" is that the latter connotes an inherent difference between "have" and "have not" institutions while the former does not. To create comparison groups of institutions around a special issue means to group institutions based on dimensions that are relevant to that issue. For instance, if the issue were faculty salaries, relevant institutional characteristics might include the proportion of students at the graduate level, the extent of research conducted by the faculty, the size and control of the institution, regional cost of living, and so on. To take the obvious case, regional cost of living data, while relevant when comparing salaries, would have little, if any, relevance for other issues such as comparing governance structures or requirements for a degree.

Included under the category of special issue comparison groups are competitor groups and aspiration groups. An institution or a state system may want to gather data on institutions with whom they compete, or on institutions that they would like to emulate. In neither instance is there a requirement that the institutions in the comparison groups be similar to the institution with whom the comparison is being made.

Put another way, comparison groups need not be peer groups. It depends on the purpose for the comparison.

4. General purpose peer groups

These are groups of institutions that are similar with respect to a large set of institutional characteristics that are thought to be generally important. No one specific purpose or issue underlies the objective for classification. Often those involved in the development of general purpose peer groups are hoping that specific issues, as they arise, can be addressed by comparative data based on these groups. In this case, the groups are formed around specific institutions. On other occasions, general purpose peer groups are a result of attempts to map the higher education universe at a higher level of resolution than is found in national reporting classification systems. In this case, the groups are not formed around any specific institutions.

The current NCHEMS classification system is a national reporting system which differentiates institutions into five major classes. The major classifications and the approximate number of institutions within each group include: Major Doctoral (173), Comprehensive (397), General Baccalaureate (746), Specialized (620), and Two-Year (1,212). Sub-classifications are defined within the Major Doctoral, Specialized, and Two-Year categories. This classification system is based on degree awarding patterns. The primary criteria measuring this dimension include the nature, number, and level of degrees offered; one additional characteristic, the amount of expenditures for sponsored research,

is used to further disaggregate doctoral level institutions. For most applications, the classifications thus derived are further disaggregated by control (public versus private).

For some types of national reporting the NCHEMS classification of institutions may be too broadly defined. The current alternatives to national reporting classification systems--the special feature groups, special issue comparison groups, and general purpose peer groups discussed above may be too narrow to be of use for national reporting. Is a more refined national reporting system possible?

NCHEMS objective in the project reported on in this document was to examine the feasibility of developing a refined national reporting classification system. This refined system would be complementary to, not a replacement for, the present NCHEMS classification system. If a refined NCHEMS classification could be developed, NCHEMS could utilize it for a two-fold purpose. The first purpose would be as previously mentioned, national reporting at a more disaggregated, presumably more precise level. Understanding the second purpose requires some background information. Individuals frequently ask NCHEMS to assist them in defining peer groups from the perspective of a specific institution. To fulfill the request, institutions with the same NCHEMS classification as that of the specified institution are usually designated as comprising the initial pool of institutions from which a comparison group will be drawn. Unfortunately, the number of institutions in several of the major NCHEMS categories is large, as is the extent of heterogeneity among the

Institutions in those categories. If a refined NCHEMS classification could be developed especially for the large categories, the initial pool of institutions within which to locate comparison groups would be smaller and more homogeneous. Consequently, a refined NCHEMS system would be useful as a resource instrument to facilitate the development of more specialized institutional groupings. These latter groupings would be useful for state and institutional level reporting purposes and would be in the form of special feature groups, special issue comparison groups, or general purpose peer groups.

In summary, there are four kinds of institutional groupings that have been widely utilized. An institution may fit into any number of groups, depending upon the objective(s) for classification. National reporting classification systems usually are based on only a few comparison dimensions. Special feature groups are based on the sharing of one outstanding institutional characteristic. Special issue groups are based on a set of institutional commonalities that derive their importance from having some sort of bearing on the issue in question. Finally, general purpose peer groups attempt to include "all" important characteristics. For some analysts' needs, the national reporting classification systems may be too broad, that is, may not discriminate sufficiently among institutions. Special feature and special issue groups typically have limited applications. General purpose peer groups typically are expensive to derive, and often appear inadequate in the face of specific applications. In the activity reported on here, NCHEMS intention was to find the middle group, if there was one, wherein moderately sized groups of institutions could be used for some national reporting purposes and as the

basis for a variety of users to quickly and inexpensively derive comparison groups specific to their own needs.

II. METHODS AND PROCEDURES TO CREATE INSTITUTIONAL COMPARISON GROUPS

Various methods of grouping institutions have been utilized at NCHEMS and elsewhere across the country. The method(s) of choice in a particular situation depends upon the kind of comparison group to be developed, the objective for classification, and the resources available for operationalizing the mechanics of the method (for example, deadlines, computer related allocations, availability of data). Grouping procedures need not operate independently. Given a particular purpose for grouping institutions, a combination of procedures may be most appropriate.

The procedures to create groups of institutions for comparative purposes can be organized as follows:

1. Sectoring

The method of grouping similar institutions based on categorical variables will be termed "sectoring" in this paper. One type of categorical variable, called a nominal variable, provides the basis for easily discriminating between sets of institutions. These nominal characteristics include control (Public/Private), religious affiliation (yes/no), landgrant (yes/no), and so on. Nominal variables have neither magnitude nor interval properties.

Most institutional characteristics cannot be expressed as nominal variables and thus do not provide such an obvious means of distinguishing among institutions. Important characteristics such as revenues and expenditures, numbers of students, and percents of differing types of degrees, etc., come to mind. These characteristics are measured on an interval scale: their values have magnitude and equal intervals. For example, 900 students is more than 500 students (magnitude) and the difference between 800 and 900 students is the same difference as between 1,000 and 1,100 students (equal intervals). Unfortunately, sectoring precludes the use of interval variables with an indefinite, or even a "large" number of intervals.

To circumvent this restriction, one can create cut-off or threshold values to categorize interval variables. For example, categories for number of students could be defined as small (<1,000 students), medium (1,000-5,000 students), and large (>5,000 students). This categorization of a variable measured on an interval scale converts it to an ordinal variable. Values of an ordinal variable have magnitude but not equal intervals. For example, the medium student category is larger than the small student category (magnitude), but the difference between the small and medium categories is not the same difference as between the medium and large categories.

The sectoring method can utilize either nominal or ordinal variables. Interval variables can remain in their original form or be transformed

to other values (e.g. standard scores, logarithms) before being categorized into ordinal form. If the objective is to formulate classifications of institutions (for example, National reporting systems, special feature groups), then one could assign institutions to particular classes according to the distribution of the combination of selected variables. Alternatively, if the objective is to identify institutions in relation to a specific institution (for example, special issue comparison groups), one could select those institutions that display values closest to that of the target institution's values. If the selection is to be done manually, then the number of variables and the number of institutions under consideration should be small.

The sectoring approach is conceptually simple. If the institutional characteristics under consideration are limited to easily categorized variables, then the sectoring method can also be operationally simple. For instance, utilizing the sectoring approach to create a special feature group, which is public, landgrant, and has a medical school, would seem not only possible but simple. As would be expected, the sectoring method loses its viability as the number of characteristics having interval properties are increased. For one thing, the greater the number, the greater the difficulty in obtaining the consent of all interested parties regarding the threshold values for the variables that need to be categorized. Obviously, the larger the matrix of institutions and variables, the greater the need for judgments--many of which are likely to be quite arbitrary.

2. Clustering

To obviate the necessity of declaring threshold values for interval variables, as required by the sectoring approach, a multivariate clustering routine could be performed. A clustering procedure groups cases (institutions) that are most similar across the given variables.

Clustering is a mathematically tedious procedure when even just a few variables are considered in the analysis. Since clustering algorithms are iterative, not only the number of variables must be considered, but also the number of cases (institutions). Computer programs that perform clustering, a virtual necessity for this procedure, will often specify the maximum number of variables and/or cases that can be included. Usually the number of variables and number of cases has a non-linear relationship with the amount of computer resources required.

In one of the common clustering algorithms, clusters are formed by first calculating statistical distances between cases and then grouping the cases on the basis of those distance measures. The distance measure often selected is the square root of the sum of squares of the differences between the values of two cases (institutions). The way in which distances are calculated and clusters are formed in the computer program utilized by NCHEMS (BMDP2M) is illustrated in the following example:

- a. Initial distances between institutions are calculated as follows, given the data shown:

Institution	Data value 1	Data value 2
A	.68	.84
B	.53	.90
C	.76	.39

Distance from A and B: $\text{sqrt}[(.68-.53)**2 + (.84-.90)**2] = .162$
Distance from A and C: $\text{sqrt}[(.68-.76)**2 + (.84-.39)**2] = .457$
Distance from B and C: $\text{sqrt}[(.53-.76)**2 + (.90-.39)**2] = .559$

- b. Clusters are created by comparing the distances between institutions, where the first cluster consists of the two institutions with the smallest distance between them. The distance between A and B is the smallest measure, so the first cluster would consist of institutions A and B. This cluster would now be considered as if it were a single institution and the data values become simply the means of the data values over A and B. Again distance measures are calculated between all clusters and institutions and the next cluster is the pair with the smallest distance between them. In this example, the next cluster consists of cluster 1 (A and B) and C. Had there been additional institutions in the analysis, the process would continue to iterate until there is only one final cluster incorporating all institutions. It is a decision of the analyst to select the most appropriate set of clusters.

The BMDP2M clustering program produces two diagrams to allow the analyst to decide which iteration provides an appropriate set of clusters. These two diagrams are an initial distance matrix and a tree flowchart. The distance matrix lists the initial distance of each institution from all other institutions, resulting in an institution by institution matrix with a distance value in each cell. This matrix can be used to rank-order institutions based on their distance from a specified institution. Although any number of institutions can be selected for inclusion into each of the clusters, the larger the number selected, the more heterogeneous the group tends to become.

The tree diagram traces the flow of all institutions into groups. The basic assumption of this clustering algorithm is that initially each case (institution) constitutes a "group". Then, based on the initial distances, cases can be collapsed into larger groups. New distance calculations based on the means of the new groups lead to clustering of the clusters. Through examination of these flowcharts, institutions can be segmented into groups or considered so unique as to not belong in any of the clusters.

The actual specification of institutions into groups involves a varying number of analytic decisions, depending upon the clustering program selected and the hoped for outcome of the procedures. Also, when institutions are easily seen to cluster less human intervention

will be needed than in the instance when institutions appear to be more heterogeneous.

The clustering technique does away with the need for the analyst to make judgments about appropriate threshold levels for the interval variables included in the analysis. It also allows for the simultaneous consideration of a larger number of characteristics and institutions than is practical in the sectoring approach. However, as the number of criterion variables increases, the possibility of the redundant specification of variables measuring the same or similar institutional characteristic increases. A set of highly intercorrelated variables representing one institutional trait could be unintentionally weighted relative to another institutional characteristic represented by only a single measure.

3. Factor analysis

To obviate some of the basic problems of the simple clustering approach--the threat of having multiple variables measuring the same trait and the limitation on the number of variables--a factor analysis could be performed as a first step. Factor analysis is a standard technique for reducing the number of variables required, and for providing an independent (uncorrelated) set of factors or components should that be desired. Each factor would ideally be a measure of a different, unique institutional characteristic or dimension. A factor score could then be computed for each institution, and, based on these

factor scores, clustering or sectoring could then be used to group institutions.

Utilizing factor analysis implies recognition of the assumptions and problems implicit in the factor analytic model, which in some instances may be considered serious limitations. The assumptions include having normally distributed variables and more cases than variables. Typical problems have to do with the appropriateness of transforming skewed variables and deciding how to deal with dichotomous variables.

Another research decision related to assumptions about the data is the choice of the type of factor analysis and the type of rotation to use. In addition, the analyst must decide on the number of factors that adequately represent the original set of descriptors. The measure that lends assistance in this decision is the amount of variance in the original data explained by a set of factors. The analyst decides what level is satisfactory and selects the corresponding number of factors.

The analyst may group institutions by one, or a combination of, the procedures outlined above. If multiple groups of institutions are the goal, as in the case of national reporting systems or, in some instances, general purpose peer groups, the "goodness of fit" of institutions within each group can be examined using discriminant analysis. The discriminant analysis provides (1) statistical measures indicating the power of each of the specified

Institutional variables to discriminate between the institutions, (2) probability estimates indicating the likelihood of each institution belonging in the assigned group, and (3) an overall comparison of how discriminant analysis would have assigned institutions to groups.

In any of the three procedures discussed above, the variables or factors employed could be assigned the same or differing importance (differing weight). In order to assign differing weights to one or more variables or factors, not only must some variables or factors be deemed "more important" than others, but magnitudes of importance must be decided upon. Again, this decision is dependent upon the objective for the institutional grouping.

III. INSTITUTIONAL CHARACTERISTICS

Differences in institutional characteristics reflect diversity across institutions. Among the numerous dimensions along which institutions display their individuality are governance structures, basic activities, programs, clientele, and finance. To measure the characteristics that comprise these dimensions, data must be readily available and reliable. In some instances, longitudinal data are needed. The following list illustrates the sort of variables that typically are used in grouping institutions for comparison purposes:

Governance/Environment

1. Public, Private (Non-profit), Private (Proprietary)
2. Religious affiliation

3. Physical location (e.g. state/region, within or outside SMSA)
4. Landgrant/Non-landgrant

Basic Activities

1. Research expenditures
2. Hospital expenditures
3. Public service expenditures
4. Instructional expenditures

Programs

1. #degrees and #programs at varying levels
2. %degrees in varying fields
 - a. at the two-digit HEGIS program level or at an aggregate level (e.g. Humanities, Physical&Life Science)
 - b. at the four-year level or at the four-year and two-year level
3. A degree dispersion measure incorporating one of the set of proportions in #2 above.
4. Percent of two-year degrees

Clientele

1. Percent of Undergraduate FTE Students of Total FTE Enrollment
2. Percent of Lower/Upper Division FTE of Total FTE Undergraduates
3. Percent of Part-time students of Total students
4. Percent of First-time Freshmen FTE of Total FTE
5. Percent of Minority FTE of Total FTE (data collected every other year)
6. Percent of Post-BA FTE to Total FTE
7. Number of FTE students (absolute, by sex, by race, by level)
8. Sex
9. Race

Finance

1. Percent of revenue sources of total revenue
2. A revenue dispersion measure of financial independence

This list is not meant to be all-inclusive of the variables that might be needed. The objectives for grouping institutions and the type of institutions involved will dictate the actual selection of variables. An under-specification of variables may produce very large groups, while an over-specification of variables may produce very small groups.

IV. A REFINED NATIONAL REPORTING CLASSIFICATION SYSTEM

Our objective was to examine the feasibility of developing a refined national reporting system as an alternative to the four types of institutional groupings previously outlined (i.e. national reporting systems, special feature groups, special issue comparison groups, general purpose peer groups). The intent was to refine the NCHEMS national reporting system which currently categorizes institutions into five major classes. It was decided that this initial effort would focus on the 1,316 four-year institutions categorized as Major Doctoral, Comprehensive, and General Baccalaureate. Institutions within the NCHEMS categories of Specialized and Two-year were deemed to be adequately treated within the current classification system.

One of the first decisions we faced was whether to begin by ignoring the current NCHEMS categories of Major Doctoral, Comprehensive, and General Baccalaureate, or to create groups of institutions within each of these three classes. The NCHEMS classification system utilizes a sectoring approach with interval variables that have been categorized to ordinal scale. For the primary categories, all of the variables have to do with degrees awarded and degree programs offered. The degree-related criteria include:

Major Doctoral:

#PHD degrees \geq 30 and #PHD programs \geq 3
or #PHD degrees \geq 30 and any PHD inter-disciplinary program

Comprehensive:

Does not meet Major Doctoral criteria AND
#Post-BA degrees \geq 30 and #Post-BA programs \geq 3
or #Post-BA degrees \geq 30 and any Post-BA inter-disciplinary program

General BA:

Does not meet Comprehensive criteria AND

#BA degrees>0 and #BA programs>=3 and %BA+Post-BA degrees>75%
or any BA inter-disciplinary program and %BA+Post-BA degrees>75%

It is reasonable to believe that institutions could display values along the borders of the above threshold values. Institutions could be categorized as one type of institution, but be more similar in non-degree awarding patterns to institutions in a different category. For this reason, it was decided that the NCHEMS boundaries of Major Doctoral, Comprehensive, and General Baccalaureate would be ignored in this study.

Sectoring and clustering were the classification procedures selected. Both of these methods function efficiently with a small number of data variables, and a relatively small number of variables seemed appropriate for the task at hand. The use of a large number of variables would almost inevitably result in numerous very small classes of institutions unsuitable for national reporting purposes. Furthermore, we took the point of view that groups should be formed around similarity of institutional role and scope. It appeared that in terms of available data, a modest number of variables could adequately characterize institutional role and scope. It should perhaps be noted that analysts will occasionally group institutions on the basis of resource utilization patterns. While this is not wrong in a theoretical sense, it appears to be a questionable approach in a practical sense, because it is so frequently just those same resource utilization patterns that administrators are trying to evaluate using comparative data. There is less chance of confounding that evaluation if the patterns to be evaluated are left out of the criteria used to build comparison groups.

Eight data variables representing four comparison dimensions were chosen to represent institutional role and scope:

Governance and Environment	Public/Private Landgrant/Non-Landgrant
Institutional Output	Sponsored Research Expenditures/ Instructional Expenditures (R:I) Medical school
Program Emphasis	Percent of PHD plus First Professional degrees (% PHD+FP) Percent of MA degrees (%MA) Percent of degrees in Professional fields* (% PROF)
Clientele	Number of total FTE students (TFTE)

*Professional fields include agriculture, architecture, computer science, engineering, health, home economics, business, communication, education, law, library science, military science, public affairs and first professional.

Proportions of degrees rather than the actual number of degrees were used because the latter tend to be more indicative of size than of program emphasis. Also, due to the possible time lag of the awarding of doctorate and first professional degrees, the proportion of degrees is likely to be a more stable measure over time than is the number of degrees. Proportions of degrees also provide a proxy measure of the structure of the student body, and thus could also be listed as measures of clientele.

The eight data variables were selected from three 1979-80 HEGIS surveys: Degrees and Other Formal Awards Conferred, Opening Fall Enrollment, and Financial Statistics. After institutions lacking complete information across all three surveys and institutions located in U.S. territories were dropped,

the pool of institutions numbered 1,300. The first sectoring decisions were based on three nominal variables: control, landgrant, and the presence or absence of a medical school. Given those three criteria the following preliminary groups were established:

Landgrant (no) + medical school (no)	Public	374
	Private	795
Landgrant (no) + medical school (yes)	Public	40
	Private	1
Landgrant (yes) + medical school (no)	Public	28
	Private	36
Landgrant (yes) + medical school (yes)	Public	26
	Private	0

Sub-grouping within the latter three categories would have produced overly small groups, so no further sectoring was attempted. Consequently, attention was concentrated on the non-landgrant and non-medical school public and private groups.

Separately, within the public and private groups, each of the remaining five interval variables was standardized to the group mean. By definition, values that have been standardized have a mean of zero and a standard deviation of one. Attempts were then made to categorize each of the variables based on their standardized values. Values within -1 and $+1$ were judged to be "average," while those beyond those limits were considered as below or above average. For the public ($n=374$) and private ($n=795$) groups the five variables were categorized as follows:

		Below Average	Average	Above Average
TFTE	Public	<1,000	1,000-12,000	>12,000
	Private	<1,000	1,000-4,000	>4,000
%PHD+FP	Public	0%	1-5%	>=6%
	Private	0%	1-10%	>=11%
%MA	Public	1-5%	6-29%	>=30%
	Private	0%	1-26%	>=27%
R:I	Public		0-.2	>=.3
	Private		0-.2	>=.3
%PROF	Public	0-44%		>=45%
	Private	0-22%		>=23%

For %PROF the average and above average categories were collapsed, due to the small number of cases in the above average category. The zero percent defining the below average categories for %PHD+FP and %MA is also a departure from the "normal distribution approach" that was generally employed; this decision was based on the relatively large number of institutions not offering any of these degrees.

Public and private institutions were separately grouped using the sectoring method and the above categories. Actual values of the five selected variables were then listed for each institution along with other background data such as number of PHD plus First Professional degrees, number of MA degrees, and amount of sponsored research expenditures. Examination of these listings revealed that in a few cases the percentage figures did not accurately reflect the institution's mission, due to the magnitude of the raw numbers involved in the calculation of the percentages. For instance, one institution with a FTE enrollment of 19,000 awarded 5,865 degrees, 1,148 of which were MA degrees.

Due to the large number of total degrees awarded, the number of MA degrees was only 20 percent of the total. This happened to be a public institution, so the 20 percent figure placed it in the "average" category. But 1,148 MA degrees was a very large number relative to others in the public group, so it appeared that the institution would be better placed in the above average than the average MA category. For this reason, the number of PHD plus First Professional degrees, number of MA degrees, and amount of research expenditures were also standardized to the group mean. Again, using the criterion of beyond +1 standard deviation defining the "above average" category, the following categories were readjusted thusly:

		above average
%PHD+FP	Public	$\geq 6\%$ and/or ≥ 130 PHD+FP degrees
	Private	$\geq 11\%$ and/or ≥ 85 PHD+FP degrees
%MA	Public	$\geq 30\%$ and/or ≥ 700 MA degrees
	Private	$\geq 27\%$ and/or ≥ 280 MA degrees
R:I	Public	$\geq .3$ and/or ≥ 7 million \$s in research
	Private	$\geq .3$ and/or ≥ 3 million \$s in research

The public and private institutions were again grouped according to the five criteria. With three variables having three levels each and two variables having two levels each, the maximum number of groups possible is 108. In actuality, the public institutions (n=374) grouped into 37 cells. Some cells had as few as one institution, while the largest cell had 154 institutions. The institutions in four cells exhibited consistent sets of characteristics and were defined as unique groups. In order to collapse some of the related remaining 33 cells together, a cluster analysis was used. BMDP2M was the

computer program utilized for clustering. A priori importance was given to similar levels of total FTE students, %PHD+FP degrees and %MA degrees, and the following three groups of public institutions were separately clustered:

	Total FTE	%DR+FP degs	%MA degs	n	#clusters
1.	average	below average	average	172	5
2.	average	avg + above avg	any level	33	1
3.	above avg	any level	any level	49	2

As previously described in Section II, the BMDP2M program provides an initial distance matrix and tree diagram to aid the analyst in determining clusters of institutions. Since the objective was to group, or classify in this case, all institutions in the universe, rather than to match institutions to one target institution, the tree diagram was the most useful output. Some institutions did not cluster into any of the readily identifiable groups. The net result was eight additional clusters of institutions to go along with the four groups previously determined by sectoring.

Using the sectoring approach, the private institutions (n=795) separated into 53 cells. The number of institutions in cells ranged from one to 233. An attempt was again made to cluster institutions in similar cells. However, the resultant clusters still contained a relatively small or relatively large number of institutions. Clusters with a few or a large number of institutions were not an improvement over the results from the simple sectoring approach. In addition, examination of the large clusters revealed an undesirable level of institutional dissimilarity over the five criterion variables. Consequently, the results from the clustering program were ignored and results of the

original sectoring were again studied. It was decided that collapsing of similar cells could be done manually, on intuitive grounds; as a result the 53 cells were reduced to 18 cells.

Listings of values for each of the public and private institutions were then made. Institutions were listed according to their newly assigned group, and simple descriptive statistics were displayed for each group. Examination of the institutional data in this format led to decisions to combine some groups and to move some institutions from one group to another. The result was fourteen groups for the public institution pool and groups for the private institution pool. Listings for these groups, as well as the landgrant medical school groups, follow in Appendix B. These groups of institutions are not meant to be definitive; they are simply the result of an attempt to examine the feasibility of a refined national reporting classification system.

V. SUMMARY AND CONCLUSION

A national reporting system such as the NCHEMS classification system is useful for reporting aggregate information at a national level. Special feature group and special issue comparison groups accommodate specific needs, while general purpose peer groups may fulfill general purpose reporting needs at the state or institutional level. It was proposed that a refined national reporting system might be developed as an alternative to those four kinds of institutional groupings. A somewhat more disaggregated national reporting system would not only be useful for some additional national reporting

purposes, but would provide NCHEMS with a resource instrument to facilitate the development of more specialized institutional groupings as a service to members of the higher education community. An attempt was made to develop this type of classification system for those institutions currently classified by NCHEMS as Major Doctoral, Comprehensive, and General Baccalaureate. Sectoring and clustering were selected as the methods of classification.

Eight data variables were utilized to sector the 1,316 institutions in those categories. The first assignment to groups was based on three nominal variables: control, landgrant status, and the presence or absence of a medical school on the campus. This criteria produced four groups of satisfactory size and two groups that were much too large for classification purposes. Attempts to further disaggregate the two large sized groups revealed the following:

1. Sectoring based on five ordinal scaled variables resulted in most groups containing too few institutions. In other words, as few as five criteria could produce a degree of discrimination that was too great for the purposes at hand. The resulting groups tended to appear more like general purpose peer groups than as intermediate classes of institutions. In addition, a few very large groups still remained.
2. After sectoring based on the five criteria, clustering produced satisfactory results in the public group of institutions, but unsatisfactory results in the private group of institutions. Satisfactory results were defined as ending up with a moderate number of institutions in a cluster and reasonable similarity on each of the five data variables across the institutions in a cluster.

3. After sectoring and clustering were performed, it still seemed that subjective rearrangement of some institutions between groups was required to enhance the face validity of the results.
4. The resultant number of groups in both the public and private sectors was larger than desired. That is, there were simply too many classes of institutions to be practical for national reporting purposes.

On the basis of these results, it would appear that the universe of institutions is perhaps most accurately characterized as looking like Figure 1.

Fig. 1

That is, it is a universe that is characterized by both similarity, as suggested by the large subsections in Figure 1, and by uniqueness, as reflected in the many small subsections.

The dilemma that we face in attempting to refine the basic NCHEMS classification system can thus be summarized as follows. If we attempt to refine the system by bringing in more discriminating power (that is, use more institutional characteristics in the analysis), the net result is the virtual disintegration of some parts of the system into far too many very small pieces. On the other hand, refining the system by tinkering with the thresholds of the

categories used in the current system (a procedure which we contemplated but did not engage in) could not fail to be arbitrary--and thus be a refinement in name only.

Thus, we conclude that for general national reporting purposes the current NCHEMS classification system ought to be left as it is. However, for certain national reporting purposes such as comparing state expenditures on higher education, it may be appropriate to reconfigure the universe of institutions in recognition of particularly important variables. In the case of state expenditures, for example, the presence of a hospital on a campus may need to be recognized and built into the classification system.

It was noted at the outset that NCHEMS had another purpose in mind in investigating the prospects for further disaggregating the universe of institutions. The second purpose was to create, if possible, a set of institutional groupings that could be made available to higher education administrators who want lists of institutions more homogeneous than the institutions in a NCHEMS class, yet who do not have the resources or the inclination to do the thorough analysis needed to produce institutional comparison groups.

On the basis of the study reported on here, we have come to two conclusions on the matter. First, it is simply not workable to create in advance lists of institutions that will truly be appropriate comparison groups for a significant set of potential users. There are simply too many options open--with respect to institutional characteristics and analytical procedures--to preclude

legitimate second guessing. Put another way, for NCHEMS to provide lists of institutions that are claimed to be quite similar, or even "peers," is to unnecessarily subject the organization to possible criticism, as well as to possibly mislead the less well informed (those who are naive about the difficulty of generating unassailable comparison groups).

The second conclusion follows from the first. If we cannot have ready-made lists of institutions available, then the only way to be helpful to the higher education community is to have a ready-made procedure available to create those lists. Such a procedure has in fact been developed and is now in place. It allows for a happy marriage between the final selection of variables by the user (who ought to be responsible for this aspect), guidance from NCHEMS regarding the selection of variables (which we can provide on the basis of considerable experience--including the project reported on in this paper), and ready access to the NCHEMS data base. The forms we are now using to facilitate this process is shown in Appendix A.

Essentially, the criteria selection form allows the institutional administrator, coordinating board staffer, or other analyst, to quickly strip away large segments of the non-relevant institutional universe through the use of nominal variables (basically "special features" in the terminology employed above). Then the persons who are developing the comparison groups decide on the importance of each of the continuous variables preselected by NCHEMS, and also set the range for each of those variables. Additional variables can be added at the discretion of the users. All of their choices are guided,

presumably, by the "special issue" that created the need for comparative data. Hopefully, their choices will also reflect the exigencies of the political process within which the comparative data will eventually be used.

The use of the criteria selection form is part of a process that is likely to be iterative. Once the form is filled out, NCHEMS can quickly respond with a list of possible comparison institutions and their data values for each variable on the criteria selection form. The users can then decide on the appropriateness of the variables they choose to emphasize and the ranges they selected. They may or may not wish to submit a revised selection form. In any case, they will be able to virtually hand pick a comparison group that meets their needs, and to do so in a structured, relatively inexpensive way. The next step, which is to obtain more detailed information regarding the comparison group institutions, can then readily be fulfilled through reports made available through NCHEMS Information Services.
