#### ABSTRACT

Data from the Survey of Income and Program Participation (SIPP) conducted during 1984 and 1985 by the Bureau of the Census are displayed in tables and charts. Data are derived from disability questions which were divided into four groups. The first group asked about the ability of persons 15 years and older to perform such sensory and physical activities as seeing, hearing, walking, and speaking. The second group of questions were asked of persons 16 to 72 years old and focused on the ability to work at a job. The third group of questions asked persons 15 years and older whether the help of another person was required for such activities as doing light housework, preparing meals, taking care of personal hygiene, and getting around. The fourth group of questions concerned children under 18 years of age and asked if the child had a long-lasting physical condition that limited his/her ability to walk, run, or play or a long-lasting mental or emotional problem that limited his/her ability to learn or do regular schoolwork. Some of the charts present data in terms of race, age and sex. Appendices provide a SIPP overview, survey definitions and explanations, sources and reliability of estimates, and a facsimile of the 1984 SIPP Third Wave Questions on disability status. (CB)

# Disability, Functional Limitation, and Health Insurance Coverage: 1984/85

### INTRODUCTION

The third wave supplement to the 1984 panel of the Survey of Income and Program Participation (SIPP) conducted during the May-August 1984 period, contained a set of questions on disability status. A major purpose of the questions was to allow researchers and policy makers to learn more about the relationship between disability and program participation, but the data also have a more general interest in that they show the extent of disablement among the noninstitutional population and show how the characteristics of the disabled differ from those of the nondisabled.

The determination of disability status in a household survey is dependent upon the definition of disability that is used and on the question wording and other design features of the particular survey. The disability questions that were asked in the third wave of the 1984 SIPP are reproduced in appendix D. The SIPP disability questions can be divided into four groups. The first group asked about the ability of persons 15 years and over to perform a set of sensory and physical activities including (1) seeing, (2) hearing, (3) speaking, (4) lifting or carrying, (5) walking, (6) using stairs, (7) getting around outside, (8) getting around inside, and (9) getting into and out of bed. Except for the activity of speaking, persons with a difficulty performing the activity were asked whether they could perform the activity at all. The second group of disability questions were asked of persons 16 to 72 years of age and concerned the ability to work at a job or business. The third group was addressed to persons 15 years old and over and asked whether the help of another person was required for the activities of (1) doing light housework, (2) preparing meals, (3) taking care of personal needs (dressing, eating, and personal hygiene), and (4) getting around (outside the home, inside the home, or in and out of bed). The fourth group of questions was addressed to children under 18 years of age and asked if the child had (1) a long-lasting physical condition that limited his or her ability to walk, run, or play, or (2) a long-lasting mental or emotional problem that limited his or her ability to learn or do regular schoolwork.

Most of the material in this report concerns measures of disability status, but information is also presented on health insurance coverage status. Text table I shows information for the fourth quarter of 1985, and detailed table 10 shows information for eight quarters beginning with the first quarter of 1984.

## LIMITATIONS IN SPECIFIED FUNCTIONAL ACTIVITIES

Table A shows the number and percentage of persons 15 years of age and over who were limited in their ability to perform specific functional activities. The number who experienced difficulty in seeing words and letters in ordinary newsprint (even when wearing glasses or contact lenses) was 12.8 million, or 7.1 percent of the total universe of 181 million persons. The number with a severe limitation (not able to see words and letters at all) was 1.7 million, or 0.9 percent of the population. Persons 65 years of age and over were much more likely than younger persons to have difficulty seeing. Among the older group, 21.7 percent had difficulty and 4.5 percent were unable to see words and letters. The comparable figures for persons 15 to 64 years of age were 4.6 and 0.3 percent, respectively.

Approximately 7.7 million persons 15 years and over had difficulty hearing what was said in a normal conversation and 0.5 million were completely unable to hear such a conversation. Among those with a hearing problem, 4.0 million were 65 and over. The rate of hearing impairment was 2.4 percent among the younger group and 15.2 percent among the older group. (The rate among all persons 15 and over was 4.3 percent.)

The number of persons with a problem having his or her speech understood was 2.5 million, or 1.4 percent of the population 15 and over.

Approximately 19.2 million persons had difficulty walking a quarter of a mile, and 18.1 million had difficulty walking up a flight of stairs without resting. The number who were unable to walk a quarter of a mile was 8.0 million and 5.2 million could not walk up a flight of stairs on their own. Older persons were more likely than younger persons to have difficulty with or be prevented from performing these activities. The proportion of persons 65 and over who were unable to walk a quarter of a mile was 18.5 percent, and 12.8 percent were unable to walk up a flight of stairs.

A relatively large number of persons had difficulty with the task of lifting or carrying something as heavy as a full bag of groceries. About 18.2 million persons had difficulty lifting or carrying, and 7.8 million were unable to perform the task. The proportion of elderly persons unable to perform the task was 16.9 percent.

The final three functional activities asked about were getting around outside the house, getting around inside the house,

and getting into and out of bed. Approximately 6 million persons had difficulty getting around outside the house and 3.6 million were unable to get around outside the house without the help of another person. Approximately 2.5 million persons had difficulty getting around inside the house and 2.1 million had difficulty getting into and out of bed. The number of persons who were unable to get around inside their home without the help of another person was 1.2 million, and about the same number were unable to get into or out of bed without the help of another person. Among the elderly, 9.5 percent needed the help of another person to get around outside the home, and 3.1 percent needed help to get around inside the home. The comparable rates for persons under 65 years of age were 0.7 percent and 0.3 percent, respectively.

## FUNCTIONAL LIMITATION STATUS BY SELECTED CHARACTERISTICS

Tables B and C show a summary measure of functional limitation status by selected characteristics. Persons were considered to have a functional limitation if they had difficulty performing one or more of the specific activities discussed above. They were considered to have a severe functional limitation if they were unable to perform one or more of the activities or if they needed the help of another person in order to perform one or more of the activities.

There were 37.3 million persons 15 years of age or older with a functional limitation and 13.5 million persons in this age group had a severe limitation.

Of those with a limitation, 21.8 million were under 65 years of age and 15.5 million were 65 and over. Of the 13.5 million with a severe limitation, 6.0 million were under 65, and 7.5 million were 65 and over. Females made up 59 percent of the population 65 years and over, and the difference between the sexes in age distribution contributed to the fact that females were more likely than males to have a functional limitation. The proportion of females with a functional limitation was 23.3 percent, and 9.4 percent had a severe limitation; the comparable rates for males were 17.7 percent and 5.4 percent. Females 65 years of age and over made up 8.6 percent of the population in general, but they made up 26.0 percent of those with a functional limitation and 38.4 percent of those with a severe limitation.

The rate of limitation among Blacks was higher than the rate among Whites or Hispanics. The rate was 24.9 percent among Blacks, 20.2 percent among Whites, and 19.2 percent among persons of Spanish origin (the latter two rates were not statistically different). Among the elderly, 75.0 percent of Blacks had a limitation, compared with 58.6 percent of Hispanics and 56.9 percent of Whites (the White and Hispanic rates were not statistically different).

The data in table C show the relationship between functional limitation status by detailed age categories and other selected characteristics. The functional limitation rate increased with age, from 5.2 percent for persons 15 to 24 years, to

<sup>&#</sup>x27;The terms "Hispanic" and "Spanish origin" are used interchangeably.

Persons of Spanish origin may be of any race.

34.2 percent for persons 55 to 64 years of age, 45.4 percent for those 65 to 69, 55.3 percent for those 70 to 74, and 72.5 percent for those 75 years of age and over. The rate of severe limitation also increased sharply with age, doubling between the 65-to-69 category and the category 75 years and over (from 18.8 percent to 41.2 percent). Persons 75 years of age and over made up 5.6 percent of the total population 15 years of age and older, 19.7 percent of those with a functional limitation, and 30.8 percent of those with a severe functional limitation.

Persons living alone were more likely than married persons to have a functional limitation. Among those living alone, 37.9 percent had a limitation and 16.7 percent had a severe limitation. The comparable rates for married persons were 20.0 percent and 6.4 percent. Of the 13.5 million persons with a severe functional limitation, 3.5 million, or 26 percent, lived alone.

Persons receiving program benefits were much more likely than the general population to have a functional limitation. Among those receiving Aid to Families with Dependent Children (AFDC) or general assistance, about 46 percent had a functional limitation and 23 percent had a limitation that was severe. Approximately the same proportions were recorded for those covered by Medicaid. Supplemental Security Income (SSI) is the low income assistance program for the elderly and disabled, and 77 percent of the recipients had a functional limitation and 48 percent had a severe limitation. Persons receiving food stamps and those living in public or subsidized housing had similar levels of limitation: 37 percent had a functional limitation and 17 percent had a severe limitation.

There was an inverse relationship between the level of household income and functional limitation status. Among persons with monthly household incomes below \$600, 40 percent had a functional limitation and 18 percent had a severe limitation; the comparable figures for those in households with monthly incomes of \$3,000 and over were 11 percent and 3 percent, respectively. Among the general population 15 and over, 27 percent lived in households with incomes less than \$1,200 a month. Among those with a severe functional limitation, 55 percent lived in such households.

Approximately 10 percent of the labor force under age 65 had a functional limitation, but only 1.5 percent had a severe limitation. Among persons 15 to 64 years of age, 74 percent were in the labor force. The labor force participation rate was 53 percent among those with a functional limitation and 29 percent among those with a severe limitation.

Persons with a functional limitation were less likely than the general population to be covered by private health insurance. The general rate of private health insurance coverage for persons 15 to 64 years of age was approximately 79 percent; the coverage rate was 66 percent among those with a functional limitation and 57 percent among those with a severe limitation. Among the 7.5 million persons 65 years of age and over with a severe functional limitation, 4.6 million had private health insurance coverage and 2.9 million did not.

As was the case for income, there was an inverse relationship between years of schooling and functional limitation status. Among those persons under 65 years of age, the pro-

portion with a severe functional limitation was 8 percent for those who were not high school graduates and 2 percent for those who were graduates. Among those 65 and over, 37 percent of nongraduates and 19 percent of graduates had a severe limitation.

#### **WORK DISABILITY STATUS**

Among the 151 million persons 16 to 64 years of age, 18.2 mi..ion, or 12.1 percent had a work disability (a condition that limited the kind or amount of work they could do). Approximately 8 million (5.3 percent) were prevented from working by their disability. Blacks had higher work disability rates than Whites or Hispanics. The work disability rate was 15.8 percent among Blacks and 9.2 percent were prevented from working; for Whites, the comparable rates were 11.7 percent and 4.8 percent, respectively. Among Hispanics, 10.8 percent had a work disability (a proportion not statistically different than the figure for Whites), and 6.9 percent were prevented

from working. Females were more likely to be prevented from working than males. Of the 8 million persons under 65 years who were prevented from working, 3.3 million were males and 4.7 million were females.

The relevance of a work disability concept decreases for persons in age groups that have low labor force participation rates, but there is general interest in the labor force characteristics of older persons. Among the 13.4 million persons 65 to 72 years of age, 5.3 million had a work disability and 4.0 million were prevented from working.

Table a shows a cross-classification of work disability status by functional limitation status. Persons may have a condition that limits the kind or amount of work they can do but the condition may not cause a limitation in the specific functional activities that were asked about in the third wave supplement. Likewise, persons with a functional limitation may or may not consider themselves to have a work disability depending upon such factors as training and education, work history, job requirements, and employer accomodations. The relationship

B Base less than 200,000.

between work disability status and functional limitation status for the 151 million persons 16 to 64 years of age is summarized below:

No functional limitation:

Of the 105.6 million persons 16 to 64 years of age with a job or business, about 7 million had a work disability. Approximately the same number had no work disability but did have a functional limitation.

## **NEED FOR PERSONAL ASSISTANCE**

Approximately 7.7 million persons needed the assistance of another person for activities such as getting around inside or outside the home, doing housework or preparing meals, and taking care of personal needs. Of those persons who needed help, 21 percent were 65 to 74 years of age, and 37 percent were 75 and over. There were 4.8 million females and 2.9 million males who required help. The number of persons needing personal assistance to get around inside or outside the home was 3.7 million; in addition, 6.0 million persons needed help with housework, 4.3 million needed help with meal preparation, and 2.5 million needed help with personal care activities.

Of the 7.7 million persons who needed personal assistance, 3.5 million lived with a spouse, 1.7 million lived alone, and 2.5 million had other living arrangements. Persons needing help tended to have lower household incomes than the general

one or more activities, 2.1 percent needed help with getting around inside or outside the home, 3.3 percent needed help with housework, 2.4 percent needed help with meal preparation, and 1.4 percent needed help with personal care activities.

Among those under 65 years of age, the proportion needing assistance was 2.1 percent. The proportion was 9.9 percent

for persons 65 to 74 and 28.1 percent for persons 75 and over. Females were more likely than males to require help; 5.1 percent versus 3.3 percent. Black persons were more likely to require help than White or Hispanic persons. The proportions needing assistance with one or more activities were 5.7 percent for Blacks, 4.1 percent for Whites, and 4.2 percent

X Not applicable.

for Hispanics (the latter two figures were not statistically different).

Persons who lived alone were more likely to need help (8.1 percent) than those who lived with a spouse (3.4 percent) or had other arrangements (4.4 percent). Among those persons in households with monthly incomes below \$600, 9.1 percent needed assistance; the figure was 1.8 percent for persons in households with incomes of \$3,000 or more.

Approximately 45 percent of all persons with a severe functional limitation needed the help of another person; 36 percent needed help with housework, 28 percent needed help with getting around, about the same proportion needed help with meal preparation, and 16 percent needed help with personal care activities.

#### **DISABILITY STATUS OF CHILDREN**

Children (persons under 18 years) were identified as disabled if they had either (a) a long-lasting condition that limited their ability to walk, run, or play, or, (b) a long-lasting mental or emotional problem that limited their ability to learn or to do regular school work. Table H shows that of 62.4 million children, 1.9 million (3.1 percent) had a physical, mental, or emotional disability. Of all disabled children, 1.6 million were White, 0.3 million were Black, and 0.1 million were Hispanic.

Disabled children were more likely to live in households with very low incomes (less than \$600 a month) than nondisabled children. About 19 percent of disabled children and 13 percent of nondisabled children lived in such households. Disabled children were also more likely than nondisabled children to live in a family with a female householder, no spouse present (32 versus 22 percent) and to be covered by Medicaid (22 percent versus 13 percent).

## **HEALTH INSURANCE COVERAGE STATUS**

As of the fourth quarter of 1985, 204.2 million persons, or 87 percent of the population, were covered by private or government health insurance; 31.3 million were not covered. (See table I.) Whites were more likely to be covered than Blacks, and Blacks were more likely to be covered than persons of Spanish origin. The rates of coverage among the three groups were 88 percent, 81 percent, and 73 percent, respectively.

The proportion of persons covered by private health insurance was 77 percent. Young people, Blacks, and Hispanics were less likely than the general population to be covered by private health insurance. The rate of private coverage was 71 percent for persons under 25 years of age and only about 55 percent for Blacks or Hispanics.

About 63 percent of the population was covered by employment-related health insurance (insurance obtained by the person or a relative through a current or past employer). The coverage rate for this type of insurance was relatively low for persons 16 to 24 (55 percent) and for persons 65 and over

(32 percent). The proportion of persons covered by employment-related health insurance was 65 percent among Whites, 46 percent among Blacks, and 49 percent among Hispanics.

# Appendix A. Overview of the SIPP Program

#### **BACKGROUND**

The Survey of Income and Program Participation (SIPP) provides a major expansion in the kind and amount of information available to analyze the economic situation of households and persons in the United States. The information supplied by this survey is expected to provide a better understanding of the level and changes in the level of well-being of the population and of how economic situations are related to the demographic and social characteristics of individuals. The data collected in SIPP will be especially useful in studying Federal transfer programs, estimating program cost and effectiveness, and assessing the effect of proposed changes in program regulations and benefit levels. Analysis of other important national issues, such as tax reform, Social Security program costs, and national health insurance can be expanded and refined, based on the information from this new survey.

The first interviews in the SIPP took place in October 1983, nearly 8 years after the research and devalopmental phase, the Income Survey Development Program (ISDP), was initiated by the Department of Health, Education, and Welfare, in 1975. Between 1975 and 1980 extensive research was undertaken to design and test new procedures for collecting income and related socioeconomic data on a subannual basis in a longitudinal framework. Much of the work centered around four experimental field tests that were conducted in collaboration with the Bureau of the Census to examine different concepts, procedures, questionnaires, and recall periods. Two of the tests were restricted to a small number of geographic sites; the other two were nationwide. In the first nationwide test, the 1978 Resemble Panel, approximately 2,000 households were interview in Because of the relatively small number of interviews, conclude experimental comparisons of alternatives were not possible; however, the panel did demonstrate that many new ideas and methods were feasible. It also laid a foundation for the largest and most complex test: the 1979 Research Panel. This panel consisted of a nationally representative sample of 8,200 households and provided a vehicle for feasibility tests and controlled experiments of alternative design features.

In the fall of 1981, virtually all funding for ISDP research and planning of the continuing SIPP program was deleted from the budget of the Social Security Administration. The loss of funding for flucal year 1982 brought all work on the new survey to a halt. In fiscal year 1983, however, money for initiation of the new survey was allotted in the budget of the Bureau of the Census. Work began almost immediately in preparation for the survey start in October 1983. The design

of the questionnaire for the first interview was similar in structure to that used in the 1979 ISDP panel study with two important exceptions. First, the reference period for the questions was extended from 3 months to 4 months in order to reduce the number of interviews and, therefore, lower costs. Second, the questions covering labor force activity were expanded in order to provide estimates that were closer, on a conceptual basis, to those derived from the Current Population Survey (CPS). The design also incorporated a number of other modifications resulting from experience with the 1979 pilot study.

#### SURVEY CONTENT

There are three basic elements contained in the overall design of the survey content. The first is a control card that serves several important functions. The control card is used to record basic social and demographic characteristics for each person in the household at the time of the initial interview. Because households are interviewed a total of eight or nine times, the card is also used to record changes in characteristics such as age, educational attainment, and marital status, and to record the dates when persons enter or leave the household. Finally, during each interview, information on each source of income received and the name of each job or business is transcribed to the card so that this information can be used in the updating process in subsequent interviews.

The second major element of the survey content is the core portion of the questionnaire. The core questions are repeated at each interview and cover labor force activity, the types and amounts of income received during the 4-month reference period, and participation status in various programs. Some of the important elements of labor force activity are recorded separately for each week of the period. Income recipiency and amounts are recorded on a monthly basis with the exception of amounts of property income (interest, dividends, rent, etc.) Data for these types are recorded as totals for the 4-month period. The core also contains questions covering attendance in postsecondary schools, private health insurance coverage, public or subsidized rental housing, low-income energy assistance, and school breakfast and lunch participation.

The third major element is the various supplements or topical modules that will be included during selected household visits. The topical modules cover areas that need not be examined every 4 months. Certain of these topical modules are considered to be so important that they are

viewed as an integral part of the overall survey. Other topical modules have more specific and more limited purposes. No topical modules were included in the first or second waves of SIPP during the first year of the survey. (See the following section on sample design and table A-1 for a definition of the term "wave.") The third wave topical module covered (1) educational attainment, (2) work history, and (3) health characteristics (including disability). The fourth wave topical module covered (1) assets and liabilities, (2) pension plan coverage, and (3) housing characteristics. The fifth wave topical module covered (1) child care, (2) child support agreements, (3) support for nonhousehold members, (4) program participation history, and (5) reasons for not working. The sixth wave topical module covered (1) calendar year income and benefits, (2) taxes, and (3) education and training. The seventh wave topical module updated information collected in the fourth wave, and the eighth wave topical module covered (1) support for nonhousehold members, (2) marital history, (3) migration history, and (4) fertility. The ninth wave topical module collected data on (1) calendar year income and benefits, (2) taxes, and (3) school enrollment and financing.

#### **SAMPLE DESIGN**

The SIPP sample design for the 1984 panel consists of about 26,000 housing units selected to represent the noninstitutional population of the United States. (See appendix C for more details on the procedures used to select the sample.) About 20,900 of these were occupied and eligible for interview. Table A-1 shows the sample design for the first panel of SIPP. Each household in the sample was scheduled to be interviewed at 4-month intervals over a period of 21/2 years beginning in October 1983. The reference period for the questions is the 4-month period preceding the interview. For example, households interviewed in October 1983 were asked questions for the months June, July, August, and September. This household was interviewed again in February 1984 for the October through January period. The sample households within a given panel are divided into four subsamples of nearly equal size. These subsamples are called rotation groups and one rotation group is interviewed each month. In general, one cycle of four interviews covering the entire sample, using the same questionnaire, is called a wave. This design was chosen because it provides a smooth and steady work load for data collection and processing.

New panels of smaller size were introduced in February 1985 and 1986 and a new panel is scheduled to be introduced in February of 1987. This overlapping design provides a larger sample size from which cross-sectional estimates can be made. The overlap also enhances the survey's ability to

measure change by lowering the standard errors on differences between estimates for two points in time.

#### SURVEY OPERATIONS

Data collection operations are managed through the Census Bureau's 12 permanent regional offices. A staff of interviewers assigned to SIPP conduct interviews by personal visit each month with most interviewing completed during the first 2 weeks of that month. Completed questionnaires are transmitted to the regional offices where they undergo an extensive clerical edit before being entered into the Bureau's SIPP data processing system. Upon entering this processing system the data are subjected to a detailed computer edit. Errors identified in this phase are corrected and computer processing continues.

Two of the major steps of computer processing are the assignment of weights to each sample person and imputation for missing survey rasponses. The weighting procedures assure that SIPP estimates of the number of persons agree with independent estimates of the population within specified age, race, and sex categories. The procedures also assure close correspondence with monthly CPS estimates of households. In almost all cases, a survey nonresponse is assigned a value in the imputation phase of processing. The imputation for missing responses is based on procedures generally referred to as the "hot deck" approach. This approach assigns values for nonresponses from sample persons who did provide responses and who have characteristics similar to those of the nonrespondents.

The longitudinal design of SIPP dictates that all persons 15 years old and over present as household members at the time of the first interview be part of the survey throughout the entire 2½ year-period. To meet this goal the survey collects information useful in locating persons who move. In addition, field procedures were established that allow for the transfer of sample cases between regional offices. Persons moving within a 100-mile radius of an original sampling area (a county or group of counties) are followed and continue with the normal personal interviews at 4-month intervals. Those moving to a new residence that falls outside the 100-mile radius of any SIPP sampling area are interviewed by telephone. The geographic areas defined by these rules contain more than 95 percent of the U.S. population.

Because most types of analysis using SIPP data will be dependent not on data for individuals but on groups of individuals (households, families, etc.), provisions were made to interview all "new" persons living with original sample persons (those interviewed in the first wave). These new sample persons entering the survey through contact with original sample persons are considered as part of the sample only while residing with the original sample person.

# Appendix B. Definitions and Explanations

**Population coverage.** The estimates in this report are restricted to the civilian, noninstitutional population of the United States and members of the Armed Forces living off post or with their families on post. The estimates exclude group quarters.

Householder. Survey procedures call for listing first the person (or one of the persons) in whose name the home is owned or rented as of the interview date. If the house is owned jointly by a married couple, either the husband or the wife may be listed first, thereby becoming the reference person, or householder, to whom the relationship of the other household members is recorded. One person in each household is designated as the "householder." The number of households, therefore, is equal to the number of households.

Household. A household consists of all persons who occupy a housing unit. A house, an apartment or other group of rooms, or a single room is regarded as a housing unit when it is occupied or intended for occupancy as separate living quarters; that is, when the occupants do not live and eat with any other persons in the structure and there is either (1) direct access from the outside or through a common hall or (2) a kitchen or cooking equipment for the exclusive use of the occupants.

For this report, the household composition was determined as of the interview date. A household includes the related family members and all the unrelated persons, if any, such as lodgers, foster children, wards, or employees who share the housing unit. A person living alone in a housing unit or a group of unrelated persons sharing a housing unit as partners is also counted as a household. The count of household, excludes group quarters. Examples of group quarters include rooming and boarding houses, college dormitories, and convents and monasteries.

Family. A family is a group of two or more persons (one of whom is the householder) related by blood, marriage, or adoption and residing together; all such persons (including related subfamily members) are considered members of one family.

Family household. A family household is a household maintained by a family; any unrelated persons (unrelated subfamily members and/or secondary Individuals) who may be residing there are included. The number of family households is equal to the number of families. The count of family household members differs from the count of family members, however, in that the family household members Include all persons living in the household, whereas family members include only the householder and his/her relatives.

Nonfamily households. A nonfamily household is a household maintained by a person living alone or with nonrelatives only.

Race. The population is divided into three groups on the basis of race: White, Black, and "other races." The last category includes American Indians, Asian/Pacific Islanders, and any other race except White and Black.

Persons of Hispanic or Spanish origin. Persons of Hispanic or Spanish origin were determined on the basis of a question that asked for self-identification of the person's origin or descent. Respondents were asked to select their origin (or the origin of some other household member) from a "flash card" listing ethnic origins. Persons of Hispanic or Spanish origin, in particular, were those who indicated that their origin was Mexican, Puerto Rican, Cuban, Central or South American, or some other Spanish origin. It should be noted that persons

M nthly income. The monthly income estimates shown in this report for households are based on the sum of the monthly income received by each member of the household age 15 years old or over at the date of interview.

Will a job. Persons are classified as "with a job" during the period if, during the four-month reference period, either (a) worked as paid employees or worked in their own business or procession or on their own farm or worked without pay in a family business or farm or (b) were temporarily absent from the little with or without pay.

Looking for work. Persons who "looked for work" during the entire period are those who (a) were without a job during at least 1 week during the four-month reference period, (b) tried to get work or establish a business or profession and (c) were available to accept a job.

Layoff. In general, the word "layoff" means release from a job because of slack work, material shortages, inventory taking, plant remodeling, installation of machinery, or other similar reasons; the released workers anticipate recall at some future date, either specified or not.

With labor force activity. The term "with labor force activity" as used in this report includes all persons with a job (as defined above) and those looking for work or on layoff from a job for at least 1 week during the four-month reference period. Conversely, those persons "with no labor force activity" had no job, were not on layoff from a job and made no effort to find a job during the entire four-month reference period.

Antic Line Company and the contract of the con

# Appendix C. Source and heliability of Estimates

#### SOURCE OF DATA

The data were collected during the third wave of the 1984 panel of the Survey of Income and Program Participation (SIPP). The SIPP universe is the noninstitutionalized resident population of persons 15 years and older living in the United States. However, information collected from persons living in group quarters is *not* included in this report.

The 1984 panel SIPP sample is located in 174 areas comprising 450 counties (including one partial county) and independent cities. Within these areas, the bulk of the sample consisted of clusters of 2 to 4 living quarters (LQ's), systematically selected from lists of addresses prepared for the 1970 decennial census. The sample was updated to reflect new construction.

Approximately 26,000 living quarters were designated for the sample. For Wave 1, interviews were obtained from the occupants of about 19,900 of the designated living quarters. Most of the remaining 6,100 living quarters were found to be vacant, demolished, converted to nonresidential use, or otherwise ineligible for the survey. However, approximately 1,000 of the 6,100 living quarters were not interviewed because the occupants refused to be interviewed, could not be found at home, were temporarily absent, or were otherwise unavailable. Thus, occupants of about 95 percent of all eligible living quarters participated in Wave 1 of the survey.

For the subsequent waves, only original sample persons (those interviewed in the first wave) and persons living with them were aligible to be interviewed. With certain restrictions, original sample persons were to be followed even if they moved to a new address. All noninterviewed households from Wave 1 were automatically designated as noninterviews for all subsequent waves. When original sample persons moved without leaving forwarding addresses or moved to extremely remote parts of the country, additional noninterviews resulted.

Noninterviews. Tabulations in this report were drawn from interviews conducted from May through August 1984. Table C-1 summarizes information on nonresponse for the interview months in which the data used to produce this report were collected.

¹The noninstitutionalized resident population includes persons living in group quarters, such as dormitories, rooming houses, and religious group dwellings. Crew members of merchant vessels, Armed Forces personnel living in military barracks, and institutionalized persons, such as correctional facility inmates and nursing home residents, were not eligible to be in the survey. Also, United States citizens residing abroad were not eligible to be in the survey. With these qualifications, persons who were at least 15 years of age at the time of interview were eligible to be interviewed.

Some respondents do not respond to some of the questions. Therefore, the overall nonresponse rate for some items such as income and other money related items is higher than the nonresponse rates in table C-1.

Estimation. The estimation procedure used to derive SIPP person weights involved several stages of weight adjustments. In the first wave, each person received a base weight equal to the inverse of his/her probability of selection. For each subsequent interview, each person received a base weight that accounted for following movers.

A noninterview adjustment factor was applied to the weight of every occupant of interviewed households to account for households which were eligible for the sample but were not interviewed. (Individual nonresponse within partially interviewed households was treated with imputation. No special adjustment was made for noninterviews in group quarters.) A factor was applied to each interviewed person's weight to account for the SIPP sample areas not having the same population distribution as the strata from which they were selected.

An additional stage of adjustment to persons' weights was performed to bring the sample estimates into agreement with independent monthly estimates of the civilian (and some military) noninstitutional population of the United States by age, race, and sex. These independent estimates were based on statistics from the 1980 Census of Population; statistics on births, deaths, immigration, and emigration; and statistics on the strength of the Armed Forces. To increase accuracy, weights were further adjusted in such a manner that SIPP sample estimates would closely agree with special Current Population Survey (CPS) estimates by type of householder (married, single with relatives or single without relatives by sex and race) and relationship to householder (spouse or other).2 The estimation procedure for the data in the report also involved an adjustment so that the husband and wife of a household received the same weight.

#### **RELIABILITY OF ESTIMATES**

SIPP estimates in this report are based on a sample; they may differ somewhat from the figures that would have been obtained if a complete census had been taken using the same questionnaire, instructions, and enumerators. There are two

<sup>&</sup>lt;sup>3</sup>These special CPS estimetes are slightly different from the published monthly CPS estimates. The differences arise from forcing counts of husbands to agree with counts of wives.

types of errors possible in an estimate based on a sample survey: nonsampling and sampling. We are able to provide estimates of the magnitude of SIPP sampling error, but this is not true of nonsampling error. Found below are descriptions of sources of SIPP nonsampling error, followed by a discussion or sampling error, its estimation, and its use in data analysis.

Nonsampling variability. Nonsampling errors can be attributed to many sources, e.g., inability to obtain information about all cases in the sample, definitional difficulties, differences in the interpretation of questions, inability or unwillingness on the part of the respondents to provide correct information, inability to recall information, errors made in collection such as in recording or coding the data, errors made in processing the data, errors made in estimating values for missing data, biases resulting from the differing recall periods caused by the rotation pattern and failure to represent all units within the universe (undercoverage). Quality control and edit procedures were used to reduce errors made by respondents, coders and interviewers.

Undercoverage in SIPP results from missed living quarters and missed persons within sample households. It is known that undercoverage varies with age, race, and sex. Generally, undercoverage is larger for males than for females and larger for blacks than for nonblacks. Ratio estimation to independent age-race-sex population controls partially corrects for the bias due to survey undercoverage. However, biases exist in the estimates to the extent that persons in missed households or missed persons in interviewed households have different characteristics than the interviewed persons in the same age-race-sex group. Further, the independent population controls used have not been adjusted for undercoverage in the decennial census.

The Bureau has used complex techniques to adjust the weights for nonresponse, but the success of these techniques in avoiding bias is unknown.

Comparability with other statistics. Caution should be exe. cised when comparing data from this report with data from earlier SIPP publications or with data from other surveys. The comparability problems are caused by the seasonal patterns for many characteristics and by different nonsampling errors.

Sampling variability. Standard errors indicate the magnitude of the sampling error. They also partially measure the effect of some nonsampling errors in response and enumeration, but do not measure any systematic biases in the data. The standard errors for the most part measure the variations that occurred by chance because a sample rather than the entire population was surveyed.

The sample estimate and its standard error enable one to construct confidence intervals, ranges that would include the average result of all possible samples with a known probability. For example, if all possible samples were selected, each of these being surveyed under essentially the same conditions

and using the same sample design, and if an estimate and its standard error were calculated from each sample, then:

- Approximately 68 percent of the intervals from one standard error below the estimate to one standard error above the estimate would include the average result of all possible samples.
- Approximately 90 percent of the intervals from 1.6 standard errors below the estimate to 1.6 standard errors above
  the estimate would include the average result of all possible samples.
- Approximately 95 percent of the intervals from two standard errors below the estimate to two standard errors above the estimate would include the average result of all possible samples.

The average estimate derived from all possible samples is or is not contained in any particular computed interval. However, for a particular sample, one can say with a specified confidence that the average estimate derived from all possible samples is included in the confidence interval.

Standard errors may also be used for hypothesis testing, a procedure for distinguishing between population parameters using sample estimates. The most common types of hypotheses tested are 1) the population parameters are identical versus 2) they are different. Tests may be performed at various levels of significance, where a level of significance is the probability of concluding that the parameters are different when, in fact, they are identical.

All statements of comparison in the report have passed a hypothesis test at the 0.10 level of significance or better, and most have passed a hypothesis test at the 0.05 level of significance or better. This means that, for most differences cited in the report, the estimated absolute difference between parameters is greater than twice the standard error of the difference. If other differences have been mentioned, the estimated absolute difference between parameters is between 1.6 and 2.0 times the standard error of the difference. In such a case, the statement of comparison is qualified in some way (e.g., by use of the phrase "some evidence").

Note when using small estimates. Summary measures (such as percent distributions) are shown in the report only when the base is 200,000 or greater. Because of the large standard

Table C-1. Sample Size, by Month and Interview Status

Month	Eligible	Inter- viewed	Non- inter- viewed	Non- response rate (%)
May 1984	5400	4900	500	10
June 1984		4800	700	13
July 1984		4700	700	13
August 1984		4700	700	14

Note: Due to rounding of all numbers at 100, there are some inconsistencies. The percentage was calculated using unrounded numbers.

Table C-2. Standard Errors of Estimated Numbers of Persons

(Numbers in thousands)

Size of estimate	Standard error	<b>010</b> C 01	
200	63	30,000	721
300	77	50,000	883
600	109	80,00	1.020
1,000	141	100,000	1.062
2,000	199	130,000	1.062
5,000	312	135,000	1,05
В,000	<b>39</b> 2	150,000	1.02
11,000	457	160,000	987
13,000	494	180,000	886
15,000	528	200,000	72
17,000	560	210,000	609
22,000	629	220,000	446
26,000	678		440

errors involved, there is little chance that summary measures would reveal useful information when computed on a smaller base. Estimated numbers are shown, however, even though the relative standard errors of these numbers are larger than those for the corresponding percentages. These smaller estimates are provided primarily to permit such combinations of the categories as serve each user's needs. Also, care must be taken in the interpretation of small differences. For instance, in case of a borderline difference, even a small amount of non-sampling error can lead to a wrong decision about the hypotheses, thus distorting a seemingly valid hypothesis test.

Standard error param sters and tables and their use. To derive standard errors that would be applicable to a wide variety of statistics and could be prepared at a moderate cost, a number of approximations were required. Most of the SIPP statistics have greater variance than those obtained through a simple random sample of the same size because clusters of living quarters are sampled for SIPP. Two parameters (denoted "a" and "b") were developed to calculate variances for each type of characteristic.

The "a" and "b" parameters vary by subgroup. Table C-4 provides "a" and "b" parameters for characteristics of interest in this report. The "a" and "b" parc.. 2147s may be used to directly calculate the standard error for estimated numbers

and percentages. Because the actual variance behavior was not identical for all statistics within a group, the standard errors computed from parameters provide an indication of the order of magnitude of the standard error for any specific statistic.

For those users who wish further simplification, we have also provided general standard errors in tables C-2 and C-3. Note that these standard errors must be adjusted by an "f" factor from table C-4. The general standard errors presented in tables C-2 and C-3 are less accurate. Methods for using these parameters and tables for computation of standard errors are given in the following sections.

Standard errors of estimated numbers. The approximate standard error,  $s_{\chi}$ , of an estimated number of persons shown in this report can be obtained in two ways.

It may be obtained by use of the formula

$$s_x = fs$$
 (1)

where f is the appropriate "f" factor from table C-4, and s is the standard error on the estimate obtained by interpolation from table C-2. Alternatively,  $s_\chi$  may be approximated by the formula

$$s_{x} = \sqrt{ax^{2} + bx} \tag{2}$$

from which the standard errors in table C-2 were calculated. Use of this formula will provide more accurate results than the use of formula 1 above. Here x is the size of the estimate and "a" and "b" are the parameters associated with the particular type of characteristic being estimated.

Illustration. SIPP estimates from text table A of this report show that there were 12,802,000 persons 15 years and older who experienced difficulty in seeing words and letters. The appropriate "a" and "b" parameters and f-factor from table C-4 and the appropriate general standard error from table C-2 are

a = -.0009028, b = 8.031, f = 0.64, s = 490.000

Table C-3. Standard Errors of Estimated Percentages of Persons

Base of estimated percentage (Thousands)	>1 or <99	2 or 98	5 or 95	10 or 90	25 or 75	50

Table C-4. Generalized Variance Parameters for SIPP Estimates

	•	<u>b</u>	f factor
PERSONS			
Total or White			
16+ program participation			
sad beaefits (2):			
Both sexes	-0.0000943	16,059	0.90
Male	-0.0001984	16,059	0.90
Female	-0.0001796	16,059	0.90
16+ income and labor			
force (4):		E 47E	0.52
Both sexes	-0.0000321	5,475	0.52
Male	-0.0000677		
Female	-0.0000612	5,475	0.52
Health and dissbility (3)	-0.0000028	8,031	0.64
All others (5):			
Both sexes	-0.0000864	19,911	1.00
Male	-0.0001786	19,911	1.00
Female	-0.0001672	19,911	1.00
Black (1)			
Both sexes	-0.0002670	7,366	0.61
Male	-0.0005737	7.366	0.61
Female	-0.0004933	7,366	0.61

Note: For cross-tabulations, use the parameters of the characteristic with the smaller number within the parentheses.

Using formula 1, the approximate standard error is

$$s_v = 0.64 \times 490,000 = 314,000$$

Using formula 2, the approximate standard error is

$$\sqrt{(.0000028)(12,802,000)^2 + (8,031)(12,802,000)} = 320,000$$

Based on the standard error from formula 2, the 95-percent confidence interval as shown by the data is from 12,162,000 to 13,442,000. Therefore, a conclusion that the average estimate derived from all possible samples lies within a range computed in this way would be correct for roughly 95 percent of all samples.

Standard errors of estimated percentages. The reliability of an estimated percentage, computed using sample data for both numerator and denominator, depends upon both the size of the percentage and the size of the total upon which the percentage is based. When the numerator and denominator of the percentage have different parameters, use the parameter (and appropriate factor) of the numerator. If proportions are presented instead of percentages, note that the standard error of a proportion is equal to the quotient of the standard error of the corresponding percentage and 100.

For the percentage of persons, the approximate standard error,  $s_{\rm p}$ , of the estimated percentage p can be obtained by the formula

$$s_{n} = fs \tag{3}$$

In this formula, f is the appropriate "f" factor from table C-4 and s is the standard error on the estimate from table C-3. Alternatively, it may be approximated by the formula

$$s_p = \sqrt{\frac{b}{x}p (100-p)}$$
 (4)

from which the standard errors in table C-3 were calculated. Use of this formula will give more accurate results than use of formula 3 above. Here x is the size of the subclass of persons which is the base of the percentage, p is the percentage  $(0 \le p \le 100)$ , and b is the parameter associated with the characteristic in the numerator.

Illustration. Text table A shows that an estimated 7.1% of all persons 15 years and older had difficulty seeing words and letters. Using formula 3 with the "f" factor from table C-4 and the appropriate standard error from table C-3, the approximate standard error is

$$s_D = 0.64 \times 0.2\% = 0.13\%$$

Using formula 4 with the "b" parameter from table C-4, the approximate standard error is

$$s_p = \sqrt{\frac{8,031}{180,987,000}}$$
 7.1%(100%-7.1%) = 0.17%

Consequently, the 95-percent confidence interval using the standard error from formula 4 is from 6.8% to 7.4% as shown by the data.

Standard error of a difference. The standard error of a difference between two sample estimates is approximately equal to

$$s_{(x-y)} = \sqrt{s_x^2 + s_y^2}$$
 (5)

where  $s_x$  and  $s_y$  are the standard errors of the estimates x and y.

The estimates can be numbers, percents, ratios, etc. The above formula assumes that the sample correlation coefficient, r, between the two estimates is zero. If r is really positive (negative), then this assumption will lead to overestimates (underestimates) of the true standard error.

Illustration. Again using text table A, 2.4% of persons 15 to 64 years of age had a problem hearing normal conversation, while for those 65 and over the figure was 15.2%. The standard errors for these percentages are computed using formula 4, to be 0.11% and 0.62% respectively.

Assuming that these two estimates are not correlated, the standard error of the estimated difference of 12.8 percentage points is

$$s_{(x-y)} = \sqrt{(0.11\%)^2 + (0.62\%)^2} = 0.63\%$$

The 95-percent confidence interval on the difference is from 11.5 to 14.1 percentage points. Since this interval does not contain zero, we conclude that the difference is significant at the 5-percent level.
