IDENTIFIERS Survey of Public Participation in the Arts

ABSTRACT

The primary purpose of this report was to compare data obtained from the 1982 and 1985 "Survey of Public Participation in the Arts." Comparisons of core questions and responses indicate that: (1) 1985 results are very close to those obtained in 1982; (2) there was a statistically significant decline in musical theater performance atterdance; and (3) the only performing arts attendance group to increase was ballet attendees. Recreational activity participation increased in exercise related activities and declined in movie attendance, amusement park activities, gardening, and sewing crafts. Declines were also found in participation through watching plays and musical theater on television, and increases were noted for participation in arts related craft classes. An increased number of U.S. adults indicated that they liked jazz, soul/blues, rock, mood/easy listening, and hymns/gospel music, while preferences for country/western music declined. Tables are included, and appendices report: (1) the demographic predictors of participation; (2) demographic comparisons of 1982 and 1985 samples; and (3) differences by 3-year age cohort categories. INTRODUCTION

INTRODUCTION

The purpose of this report is to compare estimates from 1982 and 1985 surveys on the extent of American participation in the arts. The 1985 estimates come from the second and most recent Survey of Public Participation in the Arts (SPPA'85). These SPPA data from the first six months of 1985 are compared with data collected in the 1982 SPPA data set. Such comparisons can be seen both as a technical check on the reliability of the 1985 results and as an analysis of trends in arts participation between 1982 and 1985.

The January through June 1985 data contained in this report differ from the 1982 study in that only six months, not twelve months, of data were collected. However, the sample size per month was larger for this 1985 survey and thus the total sample size of 13,675 is almost as large as the SPPA'82 sample size of 17,254. The U.S. adult population was estimated to have grown during this period from 164 million to 171 million potential arts participants over age 18.

As in the 1982 survey (SPPA'82), data for these first six months of 1985 contain both "core" and rotating items. The core items refer to a series of nine questions dealing both with attendance at, and personal performance in, seven types of live public arts events; a tenth core item asks about the reading of various forms of literature. The core items were asked of all respondents in all six months of the survey and they are tallied in this report for all 13,675 respondents interviewed in the first half of 1985.

The rotating items analyzed in this report consist of the arts socialization questions asked only in January (n=2357), the "arts barrier" questions asked only in February (n=2374), the general recreational (or

i

life-style) questions asked only in March (n=2294), the arts facilities and music preference questions (n=2151) asked only in April, the arts-related life-style questions asked only in May (n=2374), and the mass media questions asked only in June (n=2125). Thus the 1982-1985 differences for these rotated questions are based on smaller samples than are the core question differences, and they require larger percentage differences to be statistically significant.

Comparisons are also made between the 1985 six-month data and the parallel first six months' data (n=9263) obtained in the SPPA'82 study. It will be seen that the six-month (January through June) responses in the 1982 survey do differ somewhat from the January through June data of 1985. With such analyses it is possible to gauge whether there has been a statistically significant increase or decrease in arts activity, or whether people's reported behavior in 1985 is essentially unchanged from what it was in 1982.

For readers unfamiliar with statistical testing procedures, some explanation is needed on how to interpret the figures on statistical significance of 1982 vs. 1985 differences treated in this report. Such figures are based on a mathematical formula that essentially takes two factors into account: the size of the sample and the estimated percent of the population who engage in the activity (or have some other sample characteristic).

Thus, taking sample size into consideration, the reader will find that a shift of six percentage points for a population characteristic estimated at 50% will be significant for one group (say men) when the sample size is more than 1000 respondents; but it would not be significant for another group (say blacks) when the sample size is less than .00 respondents. Similarly, a six point difference for a population characteristic estimated to be at 50% may not be significant (for a given sample size, say 500), while it would be

significant if the population estimate were 10%.

The following table gives some idea of the gradations involved. It shows the percentage differences that would be statistically significant at the 95% confidence level (the norm in statistical testing) when comparing two groups for four selected sample sizes and three population estimates:

Population Estimate

| Sample size | <u>50%</u> | 25% | 10% |
|-------------|------------|----------|------------|
| n = 250: | 10 points | 9 points | 6 points |
| n = 500: | 7 points | 6 points | 4 points |
| n =1000: | 5 points | 4 points | 3 points |
| n =5000: | 3 points | 2 points | 1.5 points |

Thus any eight point difference between 1982 and 1985 would be significant for a group if that group's sample size were larger than 500 respondents; but an eight point difference would only be statistically significant, for a sample size of around 250 respondents if the population estimate were much less than 25% of those surveyed.

Further methodological details on the 1982 and 1985 Survey of Public Participation in the Arts can be found in the final reports on these surveys prepared by the Survey Research Center at the University of Maryland.

Chapter 1

CORE QUESTIONS ON ARTS PARTICIPATION

1. CORE QUESTIONS ON ARTS PARTICIPATION

The data shown in Table 1 compare the 1985 results for arts attendance with those obtained in the 1982 survey. In general, the 1985 results are very close to those obtained in the 1982 survey, with only one difference greater than a percentage point. That one change is for the decline in attending musical theatre performances.

Although none of the other differences in Table 1 is statistically significant, it is interesting to see that only ballet attendance showed <u>increases</u> between 1982 and 1985, and that was only from 4.2% to 4.3%.

| | Percentage | Attending | * | Assessment of Percentage Difference Found | | | | |

| Reading | 55.8 | 56.9 | - 0.6 | 1.3 | Not Significant | | | |

 $[\]mbox{*}$ Statistically significant at the 95% confidence level

This general impression of an overall decline in arts participation becomes more apparent if one restricts the 1985 comparison to data collected during the identical six-month period (January through June) during 1982. These comparisons are shown in Table 1a, which is presented in the same format as Table 1 but presents data from the sample for only the first half of the 1982 study (n=9263). Not only does this comparison show more of an overall decline (including for ballet), but two additional activities (opera and classical music) also show a statistically significant decline despite the smaller sample size. The decline in attending museums and galleries is not significant.

On the other hand, a much more stable picture emerges if one examines the month-by-month comparisons in Table 1b. Here it can be seen that there are only two month-to-month comparisons in the entire table that are statistically significant -- and even these involve only a three percentage point difference. These concern the declines found for March and for June in attending musical theatre and operettas.

The one clear and consistent difference emerging from these three tables then, is that reported attendance at musical stage plays and operettas has declined significantly between 1982 and 1985. This is the largest of several declines in arts attendance and participation found in the tables; the Table la sub-analyses indicate statistically significant declines as well in attending classical music and opera performances. No evidence is found to suggest that there has been any significant change in the proportions of people reporting that they had attended performances of jrzz, non-musical stage plays or ballet, or that they had visited museums, or had read literature such as novels or short stories.

Demographic Differences: Table 1c reviews these overall 1982-85 changes within particular demographic groups to examine whether some groups show greater changes than others, or the changes are found across the board. Each in the table represents the proportion of each group reporting participation in 1985 subtracted from the proportion of that group reporting participation in 1982. Thus, the -4 entry for 18-24 year olds for jazz in Table 1c was obtained by subtracting the 18% of the age group who reported participation in 1982 from the 14% who participated in 1985. (These percentage entries for demographic groups can be found in Appendix A and in Table 3.3 of the University of Maryland L in reports for the SPPA'82 and SPPA'85 studies).

Listed below are some of the major patterns of demographic differences in arts participation:

- o AGE. The age differences in Table 1c generally tend to show declines for the 18-34 year old group and increases for the 65 and over age group. Nonetheless only three differences are beyond the 95% confidence namely the four point declines in attending jazz performances among 18-24 year olds and in attending musical theater by 25-34 year olds, and the increase (from 41% to 48%) in the proportion of the age group 75 and older in reading literature.
- o SEX. Men and women tend to share the same patterns of participation, and changes in participation, between 1982 and 1985. The only significant change for both is the decline in attending musical theatre performances.
- o EDUCATION. In general, arts participation rates declined more in middleeducation categor'es (high school graduates, some college, and college graduates) than in the highest and lowest education groups. The most significant declines were found in the some college group--for attending classical musicals and art museums/galleries; both college graduate and graduate school groups also reported rates at musicals that were well below 1982 levels.
- o INCOME. Greater declines in general were found among upper-income groups--particularly for attending musicals and plays. The lowest income group (under \$5,000 family income per year) showed a modest increase in attendance.
- Whites reported a significant decrease of 2 percentage points in attending musicals. Otherwise, no significant differences were found racial group.
- AREA. Much the same pattern was for i for the factor of urbanicity. Residents of SMSA central cities reported a significant decline of percentage prints (from 21% to 18%) in attending musicals. Otherwise no ERIC significant differences were found -- although in general SMSA non-city (mainly suburban) residents showed less decline than either urban or

Personal Performance: No significant changes were found in rates of reported personal appearance in arts performances. As can be seen in Table 1d, virtually the same proportions reported such participation in 1985 as in 1982, although of ly one activity -- acting in plays -- shows an increase.

Public Arts Related Performance

Regional Differences: Differences in participation levels across 24 regions specially constructed for the SPPA analyses are shown in Table 1e. In general, relatively few significant differences can be found in the table.

The three regional differences which stand out most clearly are the decline in participation among residents of New York City (especially for musical and non-musical stage plays, for art museums and for reading), the increased participation in the city of Philadelphia and its suburbs, and the several increases in the San Francisco Bay area.

In general, however, these differences also tend to reflect a larger and more familiar pattern, the statistical phenomenon known as regression toward the mean. This refers to the tendency of groups or individuals who are very high or very low in one statistical reading to return to more normal levels on a second statistical reading (as when parents who are very tall or very short tend to have children who are not as tall or as short as they are).

In the same way, most of the significant differences in Table le refer to estimates for regions that were well above or below the national average. Thus the -10 entry for reading for New York City residents is based on a 65% estimate in 1982 subtracted from the 55% estimate in 1985. In 1982, the 65% estimate was 9 percentage points above the national average of 56%. The 55% estimate in 1985, then, represents a return to a rate more consistent with the rest of the country.

Among the differences that do not fit this "regression-to-the-mean" pattern are the above average readings in both surveys for attending art museums and galleries in the San Francisco (Bay) area, for reading literature in the Baltimore-Washington area and for attending opera in the Florida-Georgia cities.

Number of Participants: The percentage declines noted above need to be put into the context of the six million person increase in the number of adults living in the U.S. in 1982 and in 1985. Thus while smaller percentages of adults may be attending, it is possible with six million more adults that the actual number of participants involved is larger. This aspect of the data is examined in Table 1f, using the full (12-month) 1982 sample.

The top of Table 1f shows that the number of participants has increased or stayed the same between 1982 and 1985 for all art forms except musical theatre. The increase for reading literature is close to statistical significance, as is the decrease in attending musicals. The 1982 numbers in Table 1f are still very close to those for 1985.

The same is true for personal self-performance in arts activities, shown at the bottom of Table 1f. The population estimates are quite close for the two years, which is surprising given the minuscule proportions of the sample who report performing in arts events.

Table 1f: 1985-82 Differences in Estimated Numbers of Past Year Attendees and Performers for Core Arts Questions (in millions)

Chapter 2

OTHER LEISURE ACTIVITIES

2. OTHER LEISURE ACTIVITIES

As shown at the top of Table 2, several of the changes in participation in general recreation questions are significant in the 1985 data. More activities (8) show increases in 1985 participation than show decreases (5), but most of these changes are not statistically significant. However, the six percentage point increase in exercise activities (jogging, lifting weights, etc.), and the two point increase in reading books and magazines, were significant at the 95% level of statistical confidence. The two point increases in sports activities and in volunteer/charity work were almost large enough to achieve statistical significance.

Of the five activities that showed declines, on the other hand, there were significant declines in indoor/outdoor gardening (5 points), in attending movies (4 points) and in visiting amusement parks and related areas (4 points). All three were significantly lower than in 1982, while the declines in domestic repair activities and visiting zoos were not.

In contrast to the relatively large amount of change in general leisure activities, only one significant change is found in the bottom half of Table 2 for arts-related recreation activities. That is the four percentage point decline for needlecraft activities, such as sewing and knitting. At the same time, very small (one point) declines are found for seven other arts-related activities, while only two activities (visiting arts/crafts fairs and theater backstage work) show any increase.

In analyzing these results relative to Table 1, it must be remembered that the sample sizes involved in Table 2 are only about one sixth as large. Thus, it requires a much larger percentage difference to be significant in Table 2 than it did in Table 1.

<u>Demographic</u> <u>Differences</u>: There are some significant demographic differentials in changes in participation in addition to the total sample differences found in Table 2. Table 2a shows these demographic differentials for the general recreation activities, while Table 2b shows the differentials for the arts-related recreation activities. Some of the major patterns for several activities are as follows:

- o AGE. There is a general trend for activities to be engaged in less frequently by younger people (under age 35) and, to a lesser extent, more frequently by older people. This is most clear for reading books and magazines, but is also evident for the out-of-home activities of attending amusement parks, visiting zoos and for the at-home activities of collecting, home-auto improvements and gardening. In general, the most consistent or pronounced increases are found for the 35-44 age group (especially for exercising and collecting) and for the over age 75 group (especially for playing games, reading books and magazines and for exercise activities).
- o SEX. Some gender differences are found as well. Men report significant increases in exercising and playing sports, and significant decreases in attending movies, visiting amusement parks and the like, and gardening. The only significant difference for women is the increase in exercising. In general, then, men show somewhat greater declines in participation than do women.
- o EDUCATION. Relatively fewer subgroup differences are found overall. High school graduates report significant decreases in movie attendance, going to amusement parks, and gardening; the some college group decreased in gardening; the "some college group" also decreased their preparation of gourmet meals; and gardening; and the college grad and graduate school groups decreased their visits to zoos and their gardening activities.
- o INCOME. It is the middle-income groups who show the most decline in recreational participation. Thus, the \$10,000-14,999 income group shows significant decreases in attending movies, sports events, zoos, and amusement parks.
- c RACE. Among racial groups, blacks generally show lower participation-particularly in gardening, while the "other" race category shows a significant increase in outdoor activities. Whites show an increase in exercise and volunteer work and a decrease in movie attendance.
- o SMSA. Finally, there seems to be some general trend for recreation activities to decrease in urban areas (with the exception of exercise activities) and to increase in suburban areas. We find significant decreases in attending amusement parks in more urban areas, and in attending movies in rural areas, in contrast to a significant increase in playing games in suburban areas.

^{*} Statistically significant at the 95% confidence level

In comparison with Table 2a, fewer significant differences are found in Table 2b for arts-related recreation activities:

- o AGE. The same age pattern found in data on general recreation activities also holds for arts-related activities, as it did to a lesser extent for the cole arts activities shown in Table 1c. Once again there is more decline among younger age groups (under the age of 35) than for o der age groups. Once again there is more decline among younger age groups (under the age of 35) than for o der age groups. Only a handful of these differences are statistically significant.
- o SEX. The only significant gender differences are the increased backstage theatre help for men and the decreased needlecraft activities for women.
- o EDUCATION. Outside of the significant decreases in poetry-related and photography-related activities among those with graduate school education, few consistent differences are found by education. Those with highest levels of education show declines in other activities as well.
- o INCOME. More significant differences are found by income, although no consistent pattern is evident. Thus the lowest income groups (under \$5,000 income) report significant decreases in poetry-related activities, craft activities and backstage music concert help; and the second highest income group reports decreases in attending arts classes, doing needlecrafts and in photography-related activities. On the other hand, the highest income group (over \$50,000 per year) reports significant increases in non arts museums etc. and arts/crafts fairs and in painting and related visual arts.
- o RACE. Both Blacks and other racial groups report greater decreases in arts-related activities than do Whites, but none of these racial differences is statistically significant (except for the decline in needlecrafts among Whites).
- o SMSA. Only one rural-urlan difference is found to be significant--and that is for the greater decline in needlecrafts activities in rural areas.

 $^{^{3}}$ 1985-82 Differences statistically significant at the 95 level

28

Estimated Number of Participants: Because of the overall growth of the adult population between 1982 and 1985, the general decreases in participation rates in Table 2 may not be reflected in the actual number of participants. With six million more adults in 1985, many activities that show a percentage decrease could show an increased number of participants.

That is, in fact, reflected in the entries in Table 2c. Of the six significant differences in numbers of participants in Table 2c, five are increases. Four of the increases are for general recreation activities (exercise, books and magazines, sports and volunteer activities). Other activities with four to five million more participants (e.g., attending sports events, playing games, outdoor activities and preparing gourmet meals) are very close to statistically significant. Only gardening and visiting amusement parks and zoos etc. show a decrease.

Among the irts-related recreation activities, the only two significant differences are the decreases for needlecraft activities (from 53 to 48 million participants) and the increase in backstage theatre help (from 5 to 7 million participants). The 3 million increase in attending arts and crafts fairs is also relatively close to significance.

Chapter 3

MASS MEDIA EXPOSURE

3. MASS MEDIA EXPOSURE

As shown on Table 3, fourteen of the sixteen 1985 questions dealing with exposure to arts content in the mass media are within two percentage points of the 1982 figures and are therefore not significant. Both of the questions that show statistically significant declines involve exposure to television-related content. The largest is the five percentage point decline in viewing a TV stage play (from 26% to 21%), and, the next largest is a three point decline in viewing TV musicals/operettas (from 21% to 18%).

Among these fourteen non-significant question differences, six show a decrease, three an increase and five no change. The six decreases involve jazz and classical music on TV and on recordings, and ballet on TV. The three increases are found for listening to classical music and to musicals/show tunes on radio and for watching visual art programs on television. The last (visual arts) difference is close to statistical significance, showing a two percentage point increase, but that an increase represents about five million adults (see Table 3b.

These general declines in usage of the media particularly for television for arts-related content may be small, but they might also signal an important shift away from less direct arts experiences. The reasons for such a shift are not presently clear, although we can see there has been a small decline in reported TV viewing in general (from 3.0 to 2.8 hours per day) in the SPPA'85 results. This could be due to several factors: less free time in general, the use of TV for cable or cassette viewing (which respondents may not consider as regular TV viewing in answering the quistion) or the trend toward certain more active forms of leisure, as identified in Chapter 2.

<u>Demographic</u> <u>Differences</u>: Differences in percent participation rates for various demographic groups are shown in Table 3a. It can be seen that, as is the case for the entire sample, relatively few significant 1982-85 differences are found within demographic groups in arts exposure via the mass media.

- o AGE. The major differences by age are found for the 75 and older group, especially for the increases in watching ballet, classical music and visual arts presentations on television. In general, it is the middle-aged groups (aged 45-64) rather than the youngest age groups which show most decline in using the media for arts content.
- o SEX. The only significant difference for gender is found for both men and women in watching non-musical stage plays on television. Both show a four-five percentage point decline between 1982 and 1985.
- o EDUCATION. The largest educational difference is found for those with graduate school education, who report much higher media use for arts content, especially for opera and ballet on television, and for plays, musicals and opera on radio.
- o INCOME. Differences are mainly limited to those in the middle-to-high (\$25,000-49,999) income categories, and those for whom no income information was reported; this latter group reports much less use of recordings for classical music and opera on both recordings and radio.
- o RACE. Both blacks and other race groups report greater use of the media for arts content. The other race group reports markedly higher use of television for musicals and for ballet.
- o SMSA. The only SMSA differences occur for watching TV stage plays and even this does not occur for residents of SMSA non-city (suburban) residents.

Finally with regard to TV viewing in general, no significant or consistent differentials in viewing are found across demographic groups, although less educated respondents tend to report a slightly lower decline in viewing hours on an average day than middle-to-higher educated respondents.

Estimated Number of Participants: Differences in the estimated numbers of American adults using the mass media for arts content are shown in Table 3b. As in Table 3, few significant differences are found.

The ones that are found to be significant both involve television: the decrease in the number who have seen a TV play and the increase in the number who have seen a visual arts presentation, such as a program on an art gallery or museum.

The only other notable, but non-significant, changes are found for watching TV musicals (a decline) and for listening to classical music on the radio (an increase). Both estimates involve about three million adults.

Chapter 4

INTEREST IN INCREASED ARTS PARTICIPATION

4. INTEREST IN INCREASED ARTS PARTICIPATION

Table 4 shows that the proportions of the sample saying that they want to attend various arts events more often have changed very little from 1982 levels. Only one of the differences is statistically significant at the 95% level of confidence, and that is the 4 percentage point decrease in interest in attending musicals more often. The 2 percentage point decreases in interest in plays and in classical music performances are both close to statistical significance. The small (one point) increases in interest in attending jazz and performances are also not significant.

In general, then, the absence of statistically significant differences between 1982 and 1985 data supports the stability or reliability of the 1982 survey findings. The decline in interest levels in musical theatre is consistent with the decline in attendance data for that art form in Table 1 and suggests that future declines might also be in the offing.

Table 4: 1985-82 Differences in Rates of Interest in More Attendance at Core Arts Activities

Block William Straffer Later Colonia Colonia

<u>Demographic</u> <u>Differences</u>: Differences in interest levels between 1982 and 1983 for various demographic groups are shown in Table 4a. In general there are very few significant differences or trends by groups that can be detected, as the following highlights suggest:

- o AGE. The most consistent declines for age were found for the 45-54 year old group, with the nine point decline for interest in attending classical music performances being statistically significant. The 25-44 year old group showed a statistically significant increase in interest in attending more jazz performances.
- o SEX. The main differential by gender is for the significant decline in interest in musical theatre among women. Women also report greater decreases than men in their interest in attending more classical music performances, plays and art museums.
- o EDUCATION. For none of the art forms do any education subgroups show significant changes over time; both the graduate school educated and the college educated do show increased interest in at least three arts activities.
- o INCOME. There are few consistent differences by income, but the highest income group (\$50,000+) generally reports more increases in interest than those with less income including a significantly higher gain in interest in more jazz performances.
- o RACE. Outside of the significant decline in interest in attending musical theatre among Whites, no differentials by race are evident in the table.
- o SMSA. While there are no significant differences by the urbanicity factor, urban residents report lower decreases and smaller increases in their level of interest than do suburban or rural respondents, especially for attending musicals.

<u>Population</u> <u>Estimates</u>: As in Table 4, the only arts activity for which there was a significant change in the <u>numbers</u> of people interested in increased participation was musicals—which showed a decline from an estimated 54 million to 49 million who expressed an interest. The data are shown in Table 4b.

Otherwise, there were four activities for which there were more people interested in increased participation (representing from one to two million dults) compared to only one art form (classical music) for which there was a decline in interest. The increased numbers were found for jazz, for opera, for ballet and for art museums/galleries.

ARTS SOCIALIZATION

5. ARTS SOCIALIZATION

Only one of the arts socialization questions in Table 5 shows a significant change between the 1985 and the 1982 results. This is what would be expected since these questions deal with lifetime rather than prior year experiences.

The one significant increase in the 1985 proportions was for those who had had arts/crafts lessons, but even this 3 point difference was barely significant. There was also a one point increase in those who reported that their parents had listened to classical or opera music while they were growing up. But there was a corresponding one point decrease in the proportion reporting their parents had taken them to museums or encouraged them to do independent reading while growing up. Again neither of these differences was statistically significant.

Once again, these results indicate the 1982 findings are very stable, with one item suggesting a change in socialization arts exposure, and that being barely significant and involving only a three point shift.

 $^{^{*}}$ Statistically significant at 95% to sidence level

<u>Demographic Differences</u>: With only one (barely) significant difference in Table 5, it is not surprising to find few significant differences by demographic factors in Table 5a. None of them involves the socialization item that was significant in Table 5, namely taking lessons in one of the craft arts.

Even the significant differences that are found tend to be offsetting or contradictory in the direction of results. For example, we find a significant (nine point) decline in the proportion of college graduates reporting they had ever taken creative writing classes. This is offset by the increases among the college-graduate group saying their parents listened to classical music or had taken them to plays or dance events.

Put another way, we would expect with the 336 comparisons in Table 5a for 5% of them (or 16) would be significant by chance alone. In fact, in Table 5a only 4 of them are significant.

nces by Demographic Group

^{**} Deviations are given for the category "often."

Population Estimates: With only one significant difference in Table 5b, it is also not surprising to find most of the SPPA socialization questions showing no significant difference in the numbers exposed between 1982 and 1985. However, it is interesting to see that not one socialization experience shows a decline in the number of those exposed.

In addition to the significant six million person increase in the number of adults who had ever taken arts/crafts lessons, significantly more adults also now report having taken acting lessons.

Chapter 6

MUSIC PREFERENCES

6. MUSIC PREFERENCES

As shown in Table 6, there were several music preference items that showed significant differences between 1982 and 1985. The largest are the 7 percentage point increases that occur for scul/blues music, for jazz and for rock. For mood music, there was a 4 point increase that was significant, as there was for hymns/gospel music. Three other music forms showed an increase as well: classical music, show tunes and opezettas and "other" kinds of music; however, the differences for the first two of these music types were not stat.stically significant.

The only significant decrease, on the other hand, occurred for countrywestern music and involved a five percentage point decline. Small decreases in the proportion saying they liked big band or bluegrass music were also found.

The 1982 results do prove stable overall in terms of the general rankings of music types liked. Nonetheless, seven types of music preferences show a statistically significant change, indicating that music preferences have shown more real changes recently than arts participation behavior. In the case of the increases for jazz, blues, and rock, and the decrease in liking country-western music, the apparent changes could signal an important shift in America's music tastes.

These results suggest that two main predictors of the music preferences that changed need to be considered in these national averages -- race and education. There is the possibility that the results in Table 6 may be due to disproportionately higher numbers of blacks and higher educe and people, or other characteristics in the April 1985 sample. This possible ty is examined in Table 6c.

<u>Demographic Differences</u>: Table 6a shows the differences in 1982 and 1985 music preference responses by various demographic factors. Because of the overall larger number of significant differences in music preferences compared to other SPPA questions, there are many more significant differences by demographic variables as well. That does not mean, however, that these will form more consistent or more meaningful patterns in responses across these demographic factors.

o AGE. Age may show the most consistent pattern of results in Table 6a. Here, it can be seen that younger people do show more overall shift than older age groups. In the case of increased preferences for jazz, blues and rock, those age 18-34 show significantly higher appreciation levels in contrast to the lack of significant increases for older age groups. However, there is more positive response to these three music types among older age groups as well.

To some extent, this is also true for other increases in music types that have become more popular, such as classical music (where the increase is significantly only in the 18-24 age group), hymns/gospel (where the only significant increase is found among 25-34 year olds) and mood music (where few significant age-group differences are found).

In the case of country-western music, the only music form to show a significant overall decrease in popularity, much the same pattern can be observed: the largest and only significant drop (nine points) occurs among the 18-24 age group, while notable but non-significant drops (of five points) occur for the 25-54 age groups as well. Here again, however, general declines are also found among older age groups.

- o SEX. In the case of gender differences, significant changes are found among men but not among women, as the table shows is true for jazz, blues and rock music. Non-significant shifts in a positive direction are found among women for jazz, for soul and for hymns/ gospel music.
- o EDUCATION. Few consistent educational trends can be observed. The increased preference for jazz music is clearly and significantly concentrated among those with at least some college education. But that is not generally true for other music forms. Only sporadic significant differences are found, as among the same college group for rock or among the high school graduate group for hymns/gospel music.
- o INCOME. In general, most significant differences by income are concentrated among those at the extremes. Those earning less than \$5,000 a year show increased preference for classical, jazz and rock music and significant decreases in preference for country-western and hymns/gospel music. Those in the next lowest income category (\$5,000-\$9,999) also show increases in blues and rock music -- but a significant decrease in listaning to classical music.

 $^{^{\}circ}$ Stat stically significant at the 95% confidence level

- At the other end of the income scale, the \$25,000-\$49,000 group shows significant increases in liking jazz, blues and hymns/gospel music; and those ir the \$50,000 and over group show a significant and very large (23 percentage point) decrease in liking mood music.
- o RACE. There are some interesting differential patterns by <u>race</u>. While Whites show the same significant increase in preference for jazz, blues, rock and hymns/gospel music, among Blacks the only significant increases are for jazz and for blues (and not for rock or hymns/gospel music). The only other significant increase for Blacks is found for mood music.
- o SMSA. Relatively few consistent patterns by urbanicity can be found as well. Urban SMSA residents expressed a significantly higher preference in 1985 for blues, rock and mood music, while among non-city SMSA (mainly suburban) residents, significant increases are found for blues, jazz and hymns/gospel music. Non-SMSA (rural) residents, on the other hand, show significantly higher preferences only for rock music, along with the only significant decline for jazz and for country-western music.

Population Estimates: Again, because of the increased number of American adults between 1982 and 1985, the percentage figures in Table 6b do not tell the entire story in terms of how the American public is responding to these forms of music. Table 6b therefore provides differences in terms of these estimated numbers of American adults.

As in the case of Table 6b, there are significantly more Americans who say they like blues, rock, mood, jazz, hymns/gospel and other types of music. These involve between 5 and 13 million more adults. There are also significantly more Americans (7 million) who like classical music as well.

The five million decline in the numbers of those who say they like country-western music, from 96 million in 1982 to 91 million in 1985, is also statistically significant—although barely so. In other words, the decline in the numbers of country-western fans is not as large as the increase for the other seven types of music noted in the above paragraph.

Statistical controls. Because of the large number of statistically significant differences in the music questions relative to other SPPA questions, a more finely-tuned statistical analysis was applied to these responses. This consisted of a multivariate analysis (MCA) of the combined 1982-1985 data set with the year of study as a separate independent predictor variable in the analysis. The other independent predictor variables of music preference that were included in the analysis were the main predictors of music preference, namely age, education, race and urbanicity. imbalances in these proportions for a particular month could well account for the observed differences in music preference if there were overrepresentations of black or young respondents. [The other predictor in the MCA analysis was question context (or month of study). Since the November and December 1982 music preference data were part of a 20 minute questionnaire and not a fiveminute questionnaire, it might be that this question context have acted to lessen respondents' willingness to express positive responses.]

These MCA-adjusted difference figures are shown in the second column of Table 6c, alongside the unadjusted figures from Table 6. It can be seen that some of the adjusted 1982-85 differences are slightly lower after MCA control for these other factors, but not significantly so. The 1982-85 differences that were significant before control are also significant after control. In other words, the Table 3 differences do seem to represent genuine change, change that cannot be explained by peculiarities in sample composition or sampling error factors in the one sample month in 1985 in which the data were collected.

Chapter 7

64

FACILITIES FOR ARTS PERFORMANCES

7. FACILITIES FOR ARTS PERFORMANCES

As shown in Table 7, only one of the differences in types of arts facilities attended is statistically significant. Even this two point decline in attending an arts event at a concert hall or auditorium is barely significant. Otherwise the data from 1982 and 1985 are virtually identical. That same conclusion applies to the number of American adults attending arts events at these types of facilities. Not even the estimated 2 million person decline at concert halls and open air facilities is significant in terms of numbers of Americans attending.

Chapter 8

SOME GENERAL CONCLUSIONS

8. SOME GENERAL CONCLUSIONS

Comparison of data from SPPA'85 and data from SPPA'82 shows relatively little variation in most estimates of core activity participation, recreational activities, socialization experiences, or interest in attending arts events more often. The 18 SPPA questions that did show significant differences from the 100+ questions examined are summarized in Table 8. Only one difference in the core arts questions was statistically significant, despite the very large sample sizes involved. This was the two percentage point decline in attending musicals and in visiting art galleries or museums.

In contrast, five general recreational activities show significant differences: jogging/lifting weights/exercising showed a 6 point increase, and 4-5 point declines were found for movie going, attending amusement parks and the like, working with plants/gardening and doing needlework crafts. Roughly equivalent declines were found for watching plays and musical theatre on television.

However, the largest and most concentrated differences in Table 8 are found not for activity participation, but for music preferences. Increased proportions of American adults in 1985 said they liked jazz, blues, rock, mood and gospel music; these increases are found mainly, but not entirely among younger people. Greatest change for country/western music is also found among younger adults, country western being the only music form for which there was a significant decrease in the proportion saying they liked that type of music.

The close correspondence between certain 1982 and 1985 data supports the base reliability of SPPA measurement methods, and puts those few changes that are found in clearer perspective. It enhances our confidence that the increases and decreases that are found do reflect real changes in reported behavior and not some across-the-board shift due to some response set or other extraneous factor in responding. 68

Table 8: A Summary of Statistically Significant Differences in SPPA Analysis

| Core Arts Questions Musicals | 1985 17% | 1982 19% | 1985-1982 Difference -2 points |
|---------------------------------|-------------|-------------|--------------------------------------|
| Other Recreational Activities | | | |
| Movies | 59% | 63% | -4 points |
| Amusement parks | 45% | 49% | -4 points |
| Exercise | 57 % | 51% | +6 points |
| Gardening | 55% | 60% | -5 points |
| Needle-crafts | 28% | 32% | -4 points |
| Mass Media Arts Exposure | | | |
| Musicals on TV | 18% | 21% | -3 points |
| lays on TV | 217 | 26% | -5 points |
| Interest in Attending Core Arts | | | |
| Musicals | 29% | 33% | -4 points |
| Arts Socialization | | | |
| Arts/crafts classes | 34% | 31% | +3 points |
| Music Preferences | | | |
| Jazz | 30% | 26% | +4 points |
| Soul, blues | 33% | 7.6% | +7 points |
| Country-western | 53 % | 58% | -5 points |
| Rock | 42% | 35% | +7 points |
| Mood/easy listening | 52 % | 48% | +4 points |
| Hymns/gospel | 40% | 36% | +4 points |
| Other | 5% | 2% | +3 points |
| Arts Facilities | | | |
| Concert hall/auditorium | 12% | 14% | -2 points |

More significant trends in arts participation patterns will be clearer when future SPPA surveys are undertaken in 1988 > '990. With even larger sample sizes to reduce sampling error estimates, we expect to be able to identify possible "trade off" patterns across activities -- as in the case of Table 1 and 2, which show increases in some leisure activities and declines in others.

With so few statistically significant changes in this preliminary comparison between the 1985 and 1982 results, the SPPA data collection method can be said to provide reliable cross-time measures of public participation in the arts, and no methodological adjustments are recommended in general field procedures in the near future. It will be necessary to add new questions to the SPPA questionnaire co gain more insight into some of the apparent anomalies in the present comparison--such as the greater number of activities that show declines rather than increases.

The large number of 1985-1982 comparisons which show no change or only small changes in arts participation, 'festyle recreation, socialization, facilities attended or music preferences supports the reliability of the 1982 survey methods. It also increases our confidence in the ability to identify those changes that have occurred in the public's arts participation.

Appendix A:

Appendix C:

Differences by Threa-Year Age Cohort Categories

The entries in Appendix C show a more fine-grained and appropriate analysis of differences across age groups. This is done on a three-year cohort basis, which coincides exactly with the time interval between SPPA'82 and SPPA'85. Thus, one can compare 18-20 year olds in 1982 with their same age group in 1985. One can also see what the 18-20 age cohort in 1982 now looks like three years later when they are 21-23 year olds.

It can be seen in Table C that the largest over 11 declines occur in two clusters of age groups, one cluster aged 24-32, the other cluster aged 51-65. In both clusters, greater declines are found both in comparison to other age clusters and in terms of other activity increases over time in the table. Thus, the 24-26 and 27-29 age groups in 1985 reported declines compared to their age counterparts in 1982 in all but attending non-musical stage plays (where the older group showed a small increase), and the 30-32 age group reported declines in all but jazz and opera. Among the larger declines for 24-26 year olds in 1985 were: jazz performances (down 5 percentage points), art museums (down 5 points) and reading (down 9 percentage points); for 27-29 year olds, the 1985 figure for classical music was 4 points lower and for musicals 6 points lower, while 30-32 year olds reported a five point decline in attending musicals.

Fewer sharp declines were found in the 51-65 year o'd age cluster, but far more declines than increases can be seen. The most profound decreases are found for the 57-59 year old group, with four to eight point declines found for classical music, musicals, plays, art museums and reading. Offsetting overall increases can be found in some younger age cohorts (mainly in ages 33-41) and in some older ones (mainly ages 60-62, 66-68 and 90+).

| 96-98 | +7.3 | r5.5 | 0 | +12.8 | +5.5 | 0 | +38.6 | +6.0 |

The impression of more decline among those in their mid-twenties and in their fifties is reinforced by a strict cohort analyses. This analysis compares participation of the same age group three years later, for example those who were 18-20 years old in 1982 and with those who were in the 21-23 year age bracket in 1985. This youngest age cohort actually shows more general participation in 1982 than in 1985, in contrast to the general decline for those who were 21-23, 24-26 or 27-29 in 1982, and in contrast to the general decline for those who were 21-23, 24-26 or 27-29 in 1982. Those aged 48-50, 51-53, 54-56 and 57-59 also show consistently lower participation as they became older in 1985.

The analyses suggest, then, that the declines in arts participation found in 1985 were more concentrated in, but not limited to, people in middle to late twenties and in their fifties. No monotonically linear trends were obvious in the data, that is in terms of older or younger adults showing a strict and consistent increase (or decrease) in responses compared to 1982.
