ABSTRACT

To supplement previous reliability and validity studies concerning the Noncognitive Questionnaire (NCQ), new NCQ items were written and assessed in relation to the original eight NCQ scales. The NCQ measures eight non-traditional or non-cognitive variables that relate to minority student retention--positive self-concept, realistic self-appraisal, understanding and dealing with racism, preferring long-range goals to short-term or immediate needs, availability of strong support person, successful leadership experience, demonstrated community service, and knowledge acquired in a field. As it has been reported that the original eight variable3 could be related to particular aspects of academic success among minority and non-traditional students, it was determined that stress-coping abilities might be correlated with the NCQ. The construct validity and congruent validity of the NCO were further established by studying its correlation with the Perceived Stress Scale (PSS), a stress-coping measure, and correlating new and original NCQ items. The study involved administration of the NCQ and the PSS to 251 incoming 1987-88 freshmen attending summer orientation sessions at the University of Maryland (College Park). Data were analyzed via a principal components factor analysis, using squared multiple correlations as communality estimates, and varimax rotation of all factors with eigenvalues greater than one. Several original NCQ variables correlated highly with both new NCQ items and the stress questionnaire items. One table presents construct and congruent validity data for the NCQ and PSS. (TJH)

Construct and Congruent Validity of the Noncognitive Questionnaire (NCQ)

Paula A. Woods and William E. Sedlacek

Research Report #6 -88

SUMMARY'.

Although evidence of validity and reliability has been provided on the Noncognitive Questionnaire(NCQ), additional validation studies are needed. In order to further establish construct reliability and validity of the NCQ, new NCQ items were written to establish their relationships to the original 8 NCQ scales.

Stress-coping measures were also identified as another source which would be helpful in establishing congruent validity of the NCQ. As it has been reported that the original 8 noncognitive variables may be related to particular aspects of academic success among minority and non-traditional students, it was felt that stress-coping abilities might be correlated with the NCQ.

Construct and congruent validity of the NCQ was therefore further established by investigating its' correlation with the Perceived Stress Scale (PSS), a stress-coping measure, and correlation of new and original NCQ items.

Retention in higher education has become increasingly important in recent years "for both human value reasons and the continued existence of schools" (Tracey and Sedlacek; 1984). Retention of minority students, in particular, has become an especially vital issue in post secondary education. Research indicates that retention rates for minority students are lower than rates for majority students (Astín, 1982; Sedlacek & Pelham, 1976; Tracey & Sedlacek, 1987).

In order to examine areas that may be closely related to retention for minority students, and ultimately increase retention rates for this group, eight noncognitive variables have been identified (Sedlacek and Brooks, 1976; Sedlacek, 1977, Tracey and Sedlacek, 1984).

Unlike the traditional cognitive predictors of retention and academic success(e.g. G.P.A., SAT scores), the noncognitive variables relate to broader dimensions such as personality, attitudes, and values. The eight noncognitive variables are:

(a) Positive self-concept, (b) Realistic self- appraisal,

(c) Understanding and dealing with racism, (d) Preferring long-range goals to short term or immediate needs, (e) Aavailability of strong support person, (f) Successful leadership experience, (g) Demonstrated community service, and (h) Knowledge acquired in a field.

The eight noncognitive variables have been found to be related to persistence and grade point average, particularly for minority students (Sedlacek & Brooks, 1976; Sedlacek, 1977). In

order to better measure these eight variables, Tracey and Sedlacek (1984) designed The Noncognitive Questionnaire (NCQ). The NCQ has been shown to be predictive of continued enrollment for Black students and GPA for Black and White students (Tracey and Sedlacek, 1984, 1985). It has also been predictive of graduation for Black and White students (Tracey and Sedlacek, 1987). In addition, further research has indicated that the NCQ predicted academic success for specially admitted students (White and Sedlacek, 1986), counseling center usage by Black and White U. S. students (Arbona, Sedlacek, & Carstens, 1987), and international students (Boyer & Sedlacek, 1987).

While evidence of validity and reliability of the NCQ has been provided (Tracey & Sedlacek, 1984), the purpose of the present study is to provide additional construct validity and reliability on this instrument.

In order to further establish construct validity and reliability of the NCQ, 65 new NCQ items were written to establish their relationships to the NCQ scales.

Stress-coping measures are one source which may be helpful in establishing congruent validity of the NCQ. The college experience for minorities, particularly at predominantly White institutions, can certainly be a difficult and stressful one. Adaptability, and the ability to persevere and cope with continual stresses in a difficult, often culturally alienating environment is important. In addition, noncognitive variables such as a good degree of self-confidence, understanding of and

ability to deal with racism, and strong social support are a few stress-coping measures needed to get through successfully to graduation. Since it has been shown that noncognitive variables are predictive of certain aspects of academic success among minority and nontraditional students, stress-coping abilities and perception of stress might be correlated with the NCQ.

In order to measure the degree to which life situations are appraised as stressful, Cohen, Kamarck & Mermelstein (1983) designed the Perceived Stress Scale (PSS). The rationale for employing this scale is that the impact of objectively stressful events is determined in large extent by the perception of their stressfulness, not the objective occurrence of the events (Lazarus, 1966, 1977). High correlation of the PSS with certain variables on the NCQ, (e.g. self-confidence, understanding racism), suggests that these variables are related to the subjective experience of stress.

The purpose of the present study will therefore be to further establish construct and congruent validity of the NCQ by investigating its' correlation with the PSS, a stress-coping skills measure, and correlation of new and original NCQ items.

METHOD

Subjects

Subjects employed in this study consisted of 251 incoming freshmen (1987-1988) who attended summer orientation sessions at the University of Maryland, College Park.

Instruments

Moncognitive Questionnaire. (NCQ) The NCQ is an instrument which measures eight non-traditional or non-cognitive variables that have been found to relate to minority student retention. The eight non-cognitive variables on the NCQ are (1) Positive self-concept or self-confidence (2) Realistic self- appraisal (particularly academic), (3) Understands and deals with racism, (4) Prefers long-range goals to short term or immediate needs, (5) Availability of strong support person to turn to in time of crises, (6) Successful leadership experience in an area pertinent to background, (7) Demonstrated community service within ones' cultural community, and (8) Non-traditional or culturally related ways of acquiring knowledge within a field. The NCQ contains 23 items: 18 Likert format items, 2 multiple choice items, and 3 open-ended items pertaining to present goals and past accomplishments.

Test-retest reliability was found to range from .70 to .94 and inter-rater reliability was found to range from .83 to 1.00 for the open-ended items (Tracey and Sedlacek, 1984). Coefficient alpha ranged from .54 to .73 on a modified version of the questionnaire (Lockett, 1980). A principal components factor analysis also showed the NCQ variables to be relatively independent of one another (Tracey and Sedlacek, 1984).

Perceived Stress Scale. (PSS) The PSS is an instrument designed (Cohen, Karmarck, & Mermelstein, 1983) to measure the degree to

4

which life situations are appraised as stressful by an individual. The PSS consists of 14 items designed to measure the degree to which respondents found their lives unpredictable, uncontrollable, and overloading. Items contained information about perceptions such as feeling nervous and stressed, being upset, being overwhelmed by difficulties, and feeling one has control, or the lack of it, over life in general.

Predictive validity of the PSS is expected to decrease significantly after four to eight weeks given that appraised stress is presumed to be influenced by major life events, daily life hassles, and changes in coping resources over time. Testretest reliabilities were .85 over a two day interval when examined for college students. Given that the PSS is a state measure, test-retest correlations are expected to be higher for short retest intervals than for long retest intervals.

Analysis

A principal components factor analysis was conducted with the original NCQ items, the new NCQ items, and the PSS, using squared multiple correlations as communality estimates, and varimax rotation of all factors with eigenvalues greater than one.

RESULTS

A total of fifteen factors were identified which accounted for 62% of the common variance (See Table I). Factor I was

labeled "Internal-external locus of control" since items dealing with coping resources and perceived ability to control life difficulties loaded highest. Factor 2 was labeled "Achievement and self-improvement". Factor 3 appeared to load highest on items having to do with "Social responsibility and activism". Factor 4 focused on items concerning "Leadership and effectiveness". Factor 5 was labeled "Ethnocentricity". Factor 6 focused on "Professional relationships". Factor 7 appeared most closely related to "Self-awareness issues. Factor 8 concerned items relating to "Resourcefulness". Factor 9 was difficult to interpret and label, but most closely resembled "Community awareness and involvement". Factor 10 related to "Assertiveness and initiative issues". Factor 11 focused primarily on "Social relationships" with others. Factor 12 loaded highest on the "Introversion-extroversion" dimension while Factor 13 focused on items concerning "Social support". Factor 14, also difficult to label, contained items dealing with "Nontraditional learning styles". Lastly, Factor 15 primarily contained items relating to "Self-understanding".

Factors 2, 3, 5, 6, 11, and 14 had their highest item loadings from the new NCQ items.

Construct Validity

Inspection of the factor loadings indicates that the 8 original NCQ scale variables differentiated into several scales and were spread out among 11 of the 15 factors identified in this

6

study (See Table 1). Three NCQ variables each loaded on Factor 7- "Self-awareness issues" and Factor 10 - "Assertiveness and initiative issues". Two NCQ variables each loaded on Factor 5, which was labeled "Ethnocentricity" and Factor 12, "Introversion-extroversion". The remaining 7 factor loadings each contained only one original NCQ scale variable.

The first NCQ variable of "Positive self-concept or confidence" developed into two different scales, revealing loadings on Factor 7 (Self-awareness issues) and Factor 15 (Self-understanding). On Factor 7, this variable had a high positive correlation with another original NCQ variable (Prefers long-range goals to short term needs) and a new NCQ item (Friends all exclusively the same race). On Factor 15, this NCQ variable had a high positive correlation (+.26, +.19) with the new NCQ item (Find I get more comfortable in a new place as soon as I make friends).

Realistic self-appraisal, the second NCQ variable, loaded on Factor 3 (Social responsibility and activism) and Factor 5 (Ethnocentricity). On Factor 3, this NCQ variable was highly positively correlated with 3 new NCQ items(If I encounter racism, it's up to me to point out and correct; Contact with faculty is important to academic success; and Everyone must work towards improving social conditions). "Realistic self-appraisal also positively correlated with three new NCQ items loading on Factor 5 (See Table 1).

The "Understands and deals with racism" variable did not load on any of the factors. The fourth NCQ variable, "Prefers

long term goals to short term or immediate needs" differentiated into two different scales, loading on Factor 7 (Self-awareness issues) and Factor 12 (Introversion-extroversion). This NCQ variable was positively correlated (*.44 and +.39) with new NCQ item #31(Friends all exclusively the same race) and negatively correlated (-.30) with new NCQ item #47 (Have learned more outside school than in school). On Factor 12, the original NCQ variable loaded with new NCQ item #30 (Enjoy working with others and #43(Know areas were weak and try to improve them).

The "Availability of a Strong support person" NCO variable loaded on three different factors: Factor 5, "Ethnocentricity", Fector 7, "Self-awareness issues" and Factor 13, "Social support". This original NCQ variable was highly negatively correlated (-.35 and -.30) with new NCQ item #47(Have learned more outside school than in school) on Factor 7. It was also positively correlated with 3 new NCQ scale items on Factor 5 (See Table 1). On Factor 13, this NCQ variable was both positively and negatively correlated with two new NCQ items.

The sixth NCQ variable of "Successful leadership experience" did not load on any of the 15 identified factors. The seventh NCQ variable of "Demonstrated community service" also loaded on three factors. The factors were Factor 4 (Leadership and effectiveness), Factor 9 (Community awareness and involvement), and Factor 10 (Assertiveness and initiative issues). On Factor 4, this variable was positively correlated with two new NCQ items: f45-Usually come up with ideas that friends end up doing and

#38-I think many people see racism where it doesn't exist. This variable was correlated with the same two new NCQ items on Factor 9.

The final NCQ variable, "Knowledge acquired in a field" was the most differentiated of all original NCQ variables. This variable loaded on four different factors: Factor 8 (Resourcefulness), Factor 10 (Assertiveness and initiative issues), Factor 12 (Introversion-extroversion) and Factor 14 (Non-traditional learning styles). On Factor 8, this variable was correlated with 3 new NCQ items. It further correlated with 2 new NCQ items on Factor 10, 2 new NCQ items on Factor 12, and 4 new NCQ items on Factor 14 (See Table 1).

Congruent Validity

The Perceived Stress Scale items (PSS) spread out among six different factors (See Table 1), loading highest on Factor 1, which was labeled Internal-External Locus of Control. It should be noted that the top five loadings on Factor 1 were all stress scale items. Two stress scale items, "How often dealt successfully with irritating life hassles", and "Effective coping with important life changes" loaded on Factor 4, which included items concerning leadership and effectiveness. These items loaded with one original NCQ scale item, "Demonstrated community service", and two new NCQ items. Two stress scale items, "How often have you been angered because of things that happened outside of your control" and "How often have you felt on top of

things" also loaded on Factor 13, which focused on items concerning social support. This loading was moderately correlated with the original NCQ scale item of "Availability of strong support person". Factor 15, most closely related to self-understanding, also loaded the two stress scale items, "Have been able to control the way time is spent" and "How often upset because of something that happened unexpectedly", which were both moderately correlated with the NCQ variable of "Positive self-concept or confidence". One PSS scale item each loaded on Factor 2, "Achievement and self-improvement" (PSS item: How often felt nervous and "stressed") and Factor 12, "Introversion-extroversion" (PSS item: "How often thought about things have to accomplish").

None of the 8 original NCQ scale variables clustered with the stress item leading on Factor 2. The two NCQ scale variables of "Knowledge acquired within a field" and "Prefers long-range goals to short term needs" revealed moderately negative correlations with the PSS item which loaded on Factor 12.

DISCUSSION

٠. . . .

Based on item loadings, results demonstrated that several of the original noncognitive variables correlated highly with both new NCQ items and the stress questionnaire scale items.

A number of NCQ variables correlated more highly with new items and stress scale items than did others. For example, the noncognitive variable of "Positive self- concept or confidence"

loaded on two factors (Factor 7 and Factor 15) concerning selfawareness or self-concept issues. In addition, it had a strong
positive correlation with stress items on one factor (Factor 15).

"Positive self-concept or confidence" also demonstrated a strong
positive correlation with the new NCQ items. "The Demonstrated
community service" variable correlated highly with item loadings
on factors having to do with Leadership and effectiveness (Factor
4), Community awareness and involvement (Factor 9), and
Assertiveness and initiative issues (Factor 10). "Demonstrated
community service" also correlated strongly with both n.c NCQ
items and stress scale items."

The NCQ variable of "Non-traditional knowledge" correlated primarily with the new NCQ items rather than stress scale items. This variable correlated most highly with items pertaining to initiative and openness to non-traditional learning experiences. "Realistic self-appraisal" had high positive correlations with new NCQ items loading under factors of social responsibility and ethnocentric issues. The NCQ variable of "Availability of strong support person" correlated highly with items regarding alienation and self-awareness. This variable correlated with both new NCQ items and stress-scale items.

Three of the 8 original NCQ variables (a) Positive self-concept or self-confidence, (b) Availability of strong support person and (c) Demonstrated community service in ones cultural community) correlated most highly with stress-scale items.

These variables all appear to be related to stress-coping

abilities and adaptability. For example, the high positive correlations found between "Positive self-concept" and stress items concerning self-understanding and self-control may imply that these constructs are closely related. It may further be reasonable to note that lack of self-confidence or positive self-concept may be presumed to be related to one's ability or the perception of that ability to handle stress situations.

In addition, "Demonstrated community service", which had strong positive correlations with stress scale items concerning effectiveness and leadership issues, and "Availability of strong support person" are both likely to be related to ones' coping resources, particularly for minority students in a culturally alienating environment. Further, "Availability of strong support person" had a strong negetive correlation with the stress scale item "How often been angered due to things happening outside control", indicating that the more support one has, the less angry or frustrated one might feel when events occur beyond his/her control. Based on these correlations, one could therefore surmise that the more support the student has, either through ongoing contact with his/her cultural community or one individual, the better will be his/her stress-coping abilities, feelings of effectiveness, and sense of control over the environment.

In total, six of the 8 original NCQ variables correlated with the new NCQ items and 3 of the original NCQ variables correlated with stress scale items.

12

Results imply that future validation studies need to be done on the original NCQ scales. However, additional research also needs to further investigate construct validity of two NCQ scales in particular, (a) Understands and deals with racism and (b) Successful leadership experience, as these did not load on any of the 15 factors, indicating no evident correlations with stress scale items or new NCQ items. Perhaps, these two NCQ items should be further explored and more clearly defined in terms of the specific constructs being measured. Excluding these two scales, the remainder of the original NCQ scales appear to be clearly related to the new NCQ item, indicating construct validity for the original instrument.

The fact that results indicated only 3 of the original NCQ scales (a) Positive self-concept or self-confidence, (b)

Availability of strong support person and (c) Demonstrated community service in ones cultural community were clearly related to stress scale items establishes congruent validity for these variables. Nowever, results also imply that further empirical investigation of the remaining 5 NCQ variables is needed in order to establish congruent validity with stress-coping measures or other instruments measuring similar or related constructs.
