ABSTRACT

This report contains accounts of the scale construction, reliability, and validity of an instrument used to collect parent survey data in a study of Catholic inner-city high schools. The survey was designed to ascertain parents' involvement in their children's schooling based on parental knowledge, reasons for school choice, expectations and personal background characteristis, and perceptions of the school chosen. These data are useful in determining the extent to which parents interact with a school of choice, which is thought to have a significant impact on the academic and social performance of their children. The report is introduced by a discussion of the conceptualization of the survey instrument, based on the research literature, the rationale for selecting the research methodology used, and an explanation of the researchers' approach to scals construction. The main analytic tools were factor analysis, followed by reliability analysis, to assess further the internal consistency of the resulting dimensions. The report also explains how the survey was administered, describes its parent population, and suggests how the instrument coulû be modified for future use. Appendixes include the questionnaire and a master key for analysis showing all variables and variable combinations. The report includes 32 tables. (AF)

TITLE: "Attitudes and Values of Inner-City Catholic School

Parents: Development and Analysis of a Survey"

ABSTRACT:

This report contains accounts of scale construction, reliability, and validity of an instrument used to collect parent survey data in a study of Catholic inner-city high schools. The report is introduced by a discussion on the conceptualization of the survey instrument, based on the research literature, the rationale for selecting the research methodology used, and an explanation of the researchers' approach to scale construction. The main analytic tools were factor analysis followed by reliability analysis to further assess the internal consistency of the resulting dimensions. The report also explains how the survey was administered, describes its parent population, and recommends how the instrument could be modified for future use. The appendix contains the questionnaire and a master key for analysis showing all variables and variable combinations.

Attitudes and Values of Inner-City Catholic Parents: Development and Analysis of a Survey

Introduction

Educational researchers at The Catholic University of America (CUA) completed the field study component of the National Catholic Educational Association (NCEA) study on the impact of inner-city Catholic secondary schooling on low-income students during Spring of 1985. Data for the larger study were gathered and analyzed by Search Institute, Minneapolis, Minnesota and were reported by NCEA (NCEA, 1986).

An integral part of the descriptive study, conducted by CUA, was the collection of information on parents' attitudes and behaviors at five inner-city ^-tholic high schools selected for special study based on selection criteria intended to identify "effective" schools serving lower-income students (Bauch, Blum, Taylor, Valli, 1985). While direct interviews with parents were conducted, the number was limited due to time constraints. Quantitative data, however, were collected via a Parent Survey (See Appendix A'. The survey was designed to ascertain parents' participation and involvement with their child's schooling based on parental knowledge, reasons for school choice, expectations and personal background characteristics (e.g., level of education), and perseptions of the school chosen. These data are useful in determining the extent to which parents interact with a school of choice that is thought to have a significant impact on the academic

. 8

and social performance of their student/child.

The data reported on the Parent Survey were analyzed using several statistical techniques. This paper serves as a technical reference on the construction, content, and statistical analyses of the survey. Statistical tests were selected based on generally acceptable procedures in analyzing data as well as to satisfy the research questions of the investigators. Subsequent analyses are included as addenda to this document.

Parent Survey Conceptualization

Research based on survey data collection currently dominates the social sciences. The most effective methodology for determining the relative incidence, distribution and interrelations of naturally occurring phenomena is survey research (Kerlinger, 1973, p. 410). Moreover, of the types of survey techniques available, questionnaires or written surveys are the most popular among social scientists (Gallup & Rogers, 1984). The survey is an efficient and generally effective way to collect data from a large population. Survey research is also ideally suited to meet the rigors and conditions of population sampling. A survey or questionnaire can be tailored to measure a specific phenomena within or across populations (Kerlinger, 1973). The flexibility and relative ease of administration and analysis makes the survey a desirable choice for data collection by social scientists.

The principle purpose of the survey developed and used by the

CUA field study team was to collect data on parent characteristics. as well as their perceptions, beliefs, expectations, and goals for their child's secondary schooling. There have been, to date, only imited number of data sets addressing these parent/schooling topics (See Greeley, 1982). Thus, a comprehensive parent/school data set would be an invaluable aid in understanding the conditions and circumstances for parents' interactions with schools of choice. Herein lies the primary mission of the Parent Survey.

The Parent Survey was constructed from three principle survey references (See Table 1):

- 1) The Parent Survey published and administered by the Institute for Development of Educational Activities, Inc. as a part of the Study of (Chooling (Goodlad, 1984).
- 2) The National Catholic Educational Association-A National Portrait of Catholic Secondary Schools Survey (NCEA, 1983).
- 3) Queries generated from the research questions formulated by the CUA field research team.

Sources one and two above provided the research team with a measure, or components of a measure, which were tested and standardized. The Parent Survey developed for the Study of Schooling was piloted on a sample of approximately 175 parents (77% white; 23% minority) of secondary students in California (Overman, 1979). This survey, in its final form was completed by 6,900 parents of secondary school students across the country² (Overman,

1979).

Elements of the NCEA Catholic Secondary School Sul/ey were also used in the conceptualization and development of the Parent Survey. During the fall of 1983, surveys were administered to Catholic secondary school principals, teachers, and students across the United States. Parents, however, were not directly surveyed. Nonetheless, the Principal Survey contained several sections akin to the research questions of the CUA research team. These sections were adapted (e.g., re-worded) to suit the needs of the research questions and the Parent Survey. The NCEA survey was completed by principals at 910 Catholic secondary schools (NCEA. Approximately seventeen percent of the student population of these schools surveyed are minority. The minority status of the student or parent samples in these studies is highlighted since the study of inner-city, low-income (which translates for the most part into a minority status) was under study.

The third source contributing to the conceptualization and development of the Parent Survey was the research agenda and the subsequent research queries that evolved. The global purpose of the high school study as expressed by NCEA was:

- 1) To create a national portrait of Catholic secondary schools. In addition to describing the characteristics of Catholic high schools in general, this study compared and contrasted the programs, resources, facilities, and personnel and policies of schools that serve students from low-income families with those that enroll students with other economic characteristics.
- 2) To assess how effectively Catholic secondary schools serve students from low-income families. Student outcomes to be addressed included academic achievement, life-skills, values, and religion. By assessing these

four areas, the study evaluated how well the Catholic secondary school achieves its dual mission—to deliver a quality academic experience and to stimulate growth in values and faith consistent with the Catholic tradition (Bauch, et al, 1985).

The specific objectives of the CUA field study team, then, included:

- --determining what Catholic secondary schools do to promote growth and learn:.ng among students from low-income families; and
- --determining what characterizes Catholic secondary schools that seems effective in fostering growth and learning among students from low-income families (Bauch, et al, 1985).

The purpose of the Parent Survey was to gather data from an important constituency of the high schools—parents—from whom no data had thus far been gathered. Such data would provide a more comprehensive database from which the study's goals and objectives can be addressed. This demanding research assignment, which focused on five inner-city high schools, presented many logistical complications. Time constraints posed the largest research obstacle to the field study team. The research agenda, however, presented an excellent opportunity to collect data on a myriad of events or conditions that may be present in the types of schools studied. Thus, there was a need to collect a significant amount of data within a relatively short period. The most efficient, and perhaps effective, solution to this troblem rested with the development of a survey to query the schooling triad of teachers, stude ts and

parents. The field study team devoted a significant amount of time to the planning and development of survey instruments, especially a parent survey. The remainder of this document shall be devoted to discussion on the evolution, construction and analysis of the Parent Survey.

Parent Survey - Theoretical Construction and Design

The design and, in some cases, the format of the Parent Survey was patterned after the survey instruments that served as the original models (See discussion above). Since the survey's target population was low-income families, special attention was given to the wording of directions and survey items to maximize an understanding of the requirements in completing the task. Historically, the surveying of low-income, inner-city families has not met with great success. A typical survey return rate for this population is usually below eight percent, while the national avarage household response rate is approximately thirty percent (Gallup, 1983). The length of surveys and the non-comprehension of procedures and questions are often cited as the primary reasons for the low return rate for low-income, inner-city families. Conciseness and clar... are especially important when designing an instrument to survey this population.

The Parent Survey is eight pages long (See Appendix A). The cover page introduces the nature and purpose of the survey. Basic

directions in completing the survey are also included. Parents are reassured that all responses are confidential and shall be protected by the research team.

The Parent Survey is divided into three parts. Part One examines the respondent (e.g., mother) and obtains household and family composition. These data are used to classify single-parent families. The sociological research literature is replete with case studies of single parents and their importance performance3. The first section also reveals information about family composition and size. Family composition and size, coupled with family income, are long-standing indices of the United States Government Bureau of Census in determining the poverty level statistics4. Also, states (e.g., Pennsylvania) use family size and composition as a standard for issuing welfare monies ar ? government subsidized rood aid programs, such as Food Stamps⁵. Thus, family size and composition are co-determinants of a family's socioeconomic status. Questions in Part 1 are designed to ascertain the number of children attending the school under study and, also, any siblings who may have previously attended this school. Patterns in parental selection of a school for their children can be studied with the aid of these data.

Section 2 examines parental involvement at the school, reasons for school choice, the amount of parental knowledge of the curriculum, and goals for the school. Each of these topics have received research attention, although some less than others. Studies have shown that parent expectations directly impact on

academic performance indices of students (Woelfel & Haller, 1971; St. John, 1972; Gigliotti & Brookover, 1975; Entwisle & Hayduk, 1978). In general, the research suggests that parental expectations influence school achievement. The dynamic interplay between parental expectations and childrens' academic achievement is continuing to receive educational and sociological research attention (Boocock, 1985).

Parent involvement has been shown to have a positive impact not only on the child's academic performance but on other child7. Researchers schooling experiences of the Marjoribanks, 1979) indicate that parent involvement of almost any form or type enables the child/student to do better academically. Thus, a primary interest of the CUA field research team was the degree and manner in which lower-income, inner-city parents involve themselves in the educational processes of their child. The Parent Survey examines involvement by querying parents on the importance and frequency of participation in school activities, making decisions related to the school and the interaction with teachers or school officials to monitor their child's schooling. Coleman, et al (1982) contends that low-income inner-city families fail to provide the appropriate stimulation for their children's academic achievement. Further, Greeley (1982) found a differential effect on the degree and types of involvement between low-income, innercity public and Catholic school parents. In both previously cited studies, the researchers conclude that parental involvement, especially direct involvement in monitoring academic performance

(e.g., homework), yields fruitful results for the parents and the child/student.

Parents' reason(~) for choosing a particular school is beginning to receive research attention, in light of the issue of school vouchers. Limited research has been devoted to this copic, especially to issues involving choice in public versus private education. Greeley (1982) reviewed reasons for school choice using the High School and Beyond data (Coleman, et al, 1966). But, the "forced-choice" five restricted to reasons was classifications. Cibulka, et al (1982), in their study of innercity private schools, concluded that parents choose private schools based on their perceptions or beliefs that private schools offer a "better" education. Academic reputation is the paramount reason for choosing a school⁸. The Parent Survey corrects the limited "forced-choice" format by providing parents with a comprehensive listing of reasons for school choice. The list was compiled from the survey models (discussed above) as well as a review of the research literature (e.g., Cibulka, et al, 1982). Thus, the reason(s) why parents choose the schools under study was an important research question for the CUA field study team.

The research team was also interested in examining parents' knowledge about the school and their child's schooling experiences. Once again, limited research has been devoted to perceptions of parental knowledge about a school. Parental knowledge of school is closely allied to interactions and involvement with the school and has an influence on parents' survey responses. It stands to reason

that parents who are involved with the schooling process will acquire knowledge about the school, either directly or vicariously. These assumptions prompted the development of questions designed to ascertain the degree of parental knowledge about the schools under study.

Similarly, the relationship between parents' goals for school and the perceived school goals provides an interesting study. The congruence between parents' desires and perceptions was addressed in the mega-study on schooling conducted by Goodlad (1984). The results indicate, however, a weak association between the perceived school goals and the school goals desired by parents. Further, there reportedly was an even greater disparity between parental and states' goals for . hooling. A study of school goals is important since goals may serve to stimulate involvement and be related to school choice. Parents who perceive their goals for schooling to be aligned with actual school goals, may be more inclined to participate in the schooling process. This assumption may be studied since the Parent Survey examines the congruence between desired and perceived parental goals for schooling.

Part Three of the Parent Survey is designed to investigate parent, child and family socio-economic, political and religious status. A plethora of research exists on the effects of socio-economic (SES) factors on family life and school achievement. Coleman, et al (1966), Jencks, et al (1972), Coleman, Hoffer and Kilgore (1982) and Greeley (1982) cited the effects of SES on the quality of school experiences and academic performance. These

researchers causally link SES factors to school attendance, performance and outcomes (e.g., college entrance). Thus, the effects of SES cannot be overlooked or even minimized when studying parent/school interactions. The Parent Survey does not deviate from this research norm. The third section of the survey questions parents on educational attainment, income, sousing, race, financial assistance for school and religio-political affiliations or beliefs. This data is useful in salidating differences, which have been documented by the aforementioned researchers, between high and low SES parents and families. Also, the contribution of the child/student to the family's income is investigated. The survey designers were most interested in the effect of a child/student working outside the home and homework monitoring. Student employment, homework and academic achievement suggest a potentially interesting correlational study.

In summary, the purpose of this section was to outline the theoretical conceptualization of the Parent Survey. A review of the theoretical foundations and the evolution of this instrument is necessary to aid in utilization and interpretation. The forthcoming section shall describe the design and the administration and subsequent statistical analyses of the Parent Survey.

Parent Survey - Initial Administration and Design Analysis

The Parent Survey (See Appendix A) is an eight page survey, containing thirty-seven (37) questions. Several of these questions are comprised of multiple items, which expands the actual number of items requiring responses to 192. There are 545 response options (e.g., Not a Problem, Minor Problem, Major Problem). There are six questions with both multiple response items and two or more response parts (Questions- 9-13,15). For example, Question 9 is a two-step question requiring a response for each of 26 items on the first part and a single selection of one of the twenty-six items to complete the second part. The instructions to complete this and other like questions are provided.

The Parent Survey did not have the benefit of a pilot administration. Severe time constraints prevented the piloting of this survey instrument on a sample parent population. Nonetheless, the Parent Survey is a derivative of several surveys that were, in fact, field tested and determined to be statistically reliable measures (See Table 1). Those sections of the model instruments used to create the Parent Survey possessed significant scale reliability coefficients (alphas) (See Table 2). Thus, these components continue to be individually reliable and contribute to the overall reliability of the survey (Nunnally, 1978). There is of course statistical phenomena that result when using this type of process in survey development (e.g., inflated error-terms). However, the developers of the Parent Survey consider the various

sections (or even questions) of the instrument to be more useful than attempting to survey, generate or analyze a single outcome. Those sections of the Parent Survey that were not modeled after an existing document were developed based upon findings reviewed in the research literature. Thus, each section is unique for purposes of statistical analysis and interpretation. Most survey instrument designs are oriented in this direction as opposed to developing a single-purpose measure (Kerlinger, 1973).

The Parent Survey was administered to parents at five inner-city Catholic high schools in five geographic regions of the country. Table 3 provides a demographic overview of the five schools. There particular schools were selected from a nine school sample. The nine school sample was determined by the Search Institute based on services provided to low-income students that were assessed as "reflective" responses by the surveying of secondary school teachers. Geographic location, the number (percentage) of minority and low-income students served, the gender of the student population, and other organizational features were the primary criteria used to select the five schools for field study.

The field research was conducted during February and March of 1985. A team of two researchers spent approximately one week in each school conducting interviews, observing classrooms, and administering surveys. A comprehensive analysis on each school was submitted to the NCEA for inclusion in their report on the servicing of low-income students in Catholic secondary schools

(NCEA, 1986).

The research team decided to administer the survey to all parents of students in each school. The purpose was to ensure a respectable return rate for analysis. One school, however, was not included in this plan. A selected random sampling methodology was utilized since parents at this school participated earlier in a school-generated survey, similar to the Parent Survey, near the time of the visit by the field research team. School officials wanted to avoid a duplication of survey tasks. The sampling plan consisted of the selection of every sixth student, who was determined to reside in a low-income family, of grade 9 through 12. Thus, low-income students were oversampled at this school to compensate for the small sample size and to ensure that low-income families would be adequately represented in the school sample. Farents of the students selected were asked to complete the survey.

The Parent Survey instruments were distributed at the beginning of the weeklong site visit. In all cases, distribution involved the students hand-carrying the surveys to their parents or legal guardians. Students were reminded daily by school personnel and field researchers to encourage their parents to complete and return the surveys within the same week. Most surveys were collected at the schools by the field study teams, however, a few schools did forward some late returning surveys to CUA several weeks after the site visit. The distribution and collection process was for the most part effective. The parent populations in each of five schools were very cooperative in completing the Parent

Survey. Much of the credit for the return rate rests with school personnel (e.g., teachers) who prompted students, and even parents, to complete and return the survey.

A total of 1,702 Parent Surveys were distributed at the five schools. Of this number, 1070 usable surveys were completed and returned by parents. The 63% return rate was acceptable for quantitative analyses. Table 4 examines the distribution and return rate among the five schools studied.

Parent Survey questions are essentially multiple choice. Likert-type and discrete response styles are utilized. respondent is given three or four gradient options to complete the items. Various headings employ the Likert format (See Appendix A). This response style is of benefit in those sections of the survey where parents' insights and attitudes toward the school are queried. The discreet response style is equally used in the Parent Survey. There are several questions where a definitive response is required (e.g., Do you participate in...?). With discrete response styles, the occurrence of compliance or non-compliance to an item is of interest, whereas the use of continuous scoring format allows the measurement of the degree of compliance or non-compliance (Nunnally, 1978). Both response scoring styles are equally "athome" on a survey. However, careful attention must be given to any comparative analyses of these response styles to ensure that the results are accurately reported.

The coding of the Parent Survey was straight-forward. Table 5 reveals the coding scheme for each question on the survey. The

concept the item measures and item response style dictated the assignment of codes. In all cases of continuous response style items, the most desirable of the response options received the highest value (Note: Part II; 30-31 most desirable items are scored in reverse order—low to high). The coding assigned to a response option merely served for classification of responses. The codes did not serve as weights for any of the subsequent statistical analysic. Discretely scored items were assigned values of 2 for "Yes" and 1 for "No." Again, the assignment of these values were only for categorizing responses to the survey items. Several questions required the respondent to list an actual number (e.g., How many adults live in home?). These answers were classified by the actual numbers provided by the respondents. Missing responses or illegible entries were coded with the survey—wide missing value designation of 9.

Missing responses often pose a problem during analyses of survey data (Nunnally, 1978). This is often cited as the primary limitation to survey research (Anoble, 1983). The Parent Survey, with 1070 respondents, required 190,102 responses for a one hundred percent completion rate, no missing responses. This is a most unrealistic expectation. Nonetheless, only five (5) percent, or 10,110, responses were missing or unscorable. As is the case with the overall return rate by parents, the Parent Survey achieved remarkable success in completeness. In the large-scale longitudinal study on schooling, Coleman, et al (1982) reported a missing response rate of over ten percent in parent responses to the survey

instruments used in this study. Table 6 provides an analysis of the missing responses for each question on the Parent Survey. The data suggest that multiple step questions, those with two or more steps for completion, resulted in the largest number of missing values. This directly reflects the difficulty experienced by the respondents in understanding and acting on the survey instructions. The length of the survey and a declining lack of interest by the respondents probably contributed to the missing values 'r these types of questions.

Performed on an IBM-Personal Computer (AT)^c using The Statistical Package for the Social Sciences for the Personal Computer Plus (SPSS+) (Norusis, 1986). SPSSPC+ is comparable to the SPSSX (Nie, et al., 1985), offered on many university mainframe systems. CUA subscribes to SPSSX. Like its mainframe cousin, SPSSPC+ is able to perform all univariate and many bi- or multivariate statistical techniques. Also, the size of the statistical request is only limited by the amount of the processing and storage capabilities of the PC-hardware. No significant difficulties were encountered in completing the statistical studies requested by the field study team. Table 7 lists all the statistical measures used in the initial analysis of the Parent Survey data. This list is not final since research interest in this data set continues to grow.

Parent Survey- Preliminary Statistical Analyses 10

The survey data were manually read into a log file. Each survey was assigned an alphanumeric code (e.g., X001). The alpha code designated the school and the three digit number identified the parent surveyed. Surveys that were incomplete (e.g., missing pages) or incomprehensible were excluded from the data entry process. A total of 1,070 cases were accepted for data entry; 13 were discarded for the aforementioned reasons.

The first step in data analysis was the determination of the descriptive statistics. The <u>Frequency</u> program module of SPSSPC+ was used. This data "run" aided the research team in analyzing trends or oddities in the data while serving as a check for data entry errors. The <u>Frequency</u> program provided the following statistics:

- 1) Distribution of responses by item response categories
- 2) Measures of central tendencies (e.g., mean)
- 3) Missing data information

Since the frequency data represented the entire sample, a primary research interest was the examination of differences in response styles among the schools. Thus, the data were classified by item response category across the four schools using the Crosstabs program. A two-way crosstabs analysis was performed for each question on the Parent Survey. The intersection of an item response category and a school creates a "cell" containing the classification of responses unique to that particular variable combination. The Crosstabs program yields the following analyses:

- 1) Row, Column, Total cell frequencies and variances
- 2) Tests of significance between the cells (e.g., Chi-square)
- 3) Missing data information

The <u>Crosstabs</u> application is useful in examining the distribution and associatio, of responses across two or more variables. This statistical application yields several tests of significance. The appropriate selection of the significance test for crosstabulation should be an apriori decision based on the hypotheses being posited (Glass & Stanley, 1970).

The results of the initial statistical procedures were analyzed by the research team. Since the data set was large, almost 200 questions/variables, survey constructs were generated to manage and prepare the data for more complex and revealing statistical procedures. The forthcoming section examines the evolution of the Parent Survey constructs and their analyses.

Parent Survey- Construct Development and Theoretical Analyses

The initial data analyses provided the research team with a baseline understanding of response patterns and tendencies. However, the data set was unwieldy and not particularly useful in developing an understanding of the theoretical and statistical implications of the findings. The second phase of data analysis was initiated with the development of constructs that would provide the theoretical framework for synthesizing the voluminous parent data set. The constructs would operationally serve as scales for the grouping of like survey items/questions.

The educational, sociological and psychological research literature served as the primary reference source for the formation of each construct. Limited research attention has been devoted to the collection and analysis of a comprehensive parent data set that addresses a multitude of parent/school issues, concerns and events (Greeley, 1982). Thus, the research team reviewed a plethora of literature that focused on specific parent/school effects.

Based on the research literature review, a conceptual framework evolved that housed eight constructs (See Table 8). The constructs represent a wide range of parent/school relations and events. Once the constructs were established, the items/questions on the Parent Survey were reviewed and categorized by educational researchers at CUA. Sometimes, survey items/questions were combined to represent one item or variable (See Table 9). This resulted in a more compact and manageable parent data set. To better understand the constructs, the conceptual basis and rationale for each shall be briefly reviewed.

The first construct was labelled Individual Factors. The item/variables included under this construct related to those survey questions that serve to identify the survey respondent and their political beliefs, religious beliefs, socio-economic status and personal schooling experiences. Several of these item/variables are research worthy, especially those cited in previous research, and shall be briefly highlighted. Included under this heading are item/variables related to the socio-economic conditions of the family, i.e., educational attainment, income, and housing

situation. The formation of this construct was not terribly difficult. The research literature is replete with studies related to factors of socio-economic status (SES) and student performance (Majoribanks, 1979; Wexler, 1976; Clark, 1983; Boocock, 1985). Since the purpose of the Parent Survey is to provide descriptive data on parents for the study of inner-city schools, SES factors are extremely important. The relationship of SES to the other items/variables is a significant focus of the overall research agenda, which is studying the effects of parental involvement in inner-city schooling.

A significant relationship exists between parents' educational attainment and the academic achievement of students according to several researchers (e.g., Woelfel & Haller, 1971; Pugh, 1976). These studies indicate that parents with a high school or beyond education had higher expectations for their children's educational advancements than those who failed to graduate from high school. Also, Coleman, et al (1982, and Greeley (1.82) found differential effects between Catholic and non-Catholic parents in relation to involvement with the school, aspirations for their children and time spent monitoring child's educational activities. Parental political ideologies or affiliations may impact on the reason for selecting a particular school for their child. This poses interesting research questions. In summary, there has been sufficient research attention devoted to the items/variables grouped under the first construct of Individual Factors to Warrant their inclusion and study.

The second construct is entitled Family Factors. This construct includes such items as identifying the number of children attending the same high school, home conditions (e.g., crowding), financial aid and parents' expectations for child's educational attainment. These items are useful in describing family conditions that may impact on a child's schooling experience. For example, Parent Expectations for Child's Educational Attainment is an important research topic. Therefore, there is sufficient research attention devoted to the study of parental expectations to justify this construct category. Seginer (1983), in a comprehensive review of the research literature concluded that parent expectations appear to be both a cause and an effect of academic achievement. There is, however, a need for continued research on parent expectations, especially those of inner-city parents and their effects on student achievement indices.

The third construct is Parent Expectations of School Parent Survey questions that addressed school goals and reasons for choosing the school under study were clustered under this construct. Goodlad (1984) examined parental goals for school in A Study of Schooling (ASOS). He found that parents wanted a diversity of goals for schooling. Intellectual, social, vocational and personal goals were identified as the categories most important to parents surveyed for ASOS. Similarly, there is diversity among parents on reasons for choosing a school for their children. While academic reputation and acrievement associated with the school are often the primary reasons parents select private schools over

public schools (Cibulka, et al., 1982; Greeley, 1982; Bryk & Holland, 1984; Bauch & Small, 1986), a variety of other reasons were also chosen. Nonetheless, it is important to investigate the multiple relationships that exist between reasons for school choice and other factors of parental SES, involvement, expectations and goals for schooling.

The fourth construct is labeled as Parent Perceptions of school. This construct is devoted to those items/variables that questioned parents on school problems, school goals most emphasized by the school and characteristics of the school curriculum. Parents' perceptions and, in turn, beliefs may play a critical role in the degree of involvement with their childrens' education and the school itsel. Perceptions may or may not be based on a true body of knowledge of the schooling experience. Also, there is research that suggests that a parent's previous schooling experience serves as the basis on which parents choose a school for their child and decide on the type and degree of involvement (Seginer, 1983). Thus, parents' perceptions about what is going on in their childrens' schools may play a direct role in determining the parents' interactions with the schools.

The fifth construct is entitled Parent Involvement in School Related Activities. This construct contains those items/variables that pertain to participation, decision making, communication and reasons for non-participation. Bauch (1985) provided ar overview of parent involvement concerning the roles of parents in curriculum and school improvement. The consensus of research on this topic is

that parental involvement is both an important and effective force in enhancing childrens' academic performance and improving the conditions of schooling. The item/variable categories used to create this construct are all related to parental roles as participators, decision makers and communicators outlined in the research literature (Bauch, 1985).

The sixth construct is Parent School and Curriculum Knowledge. This construct represents the parents' general school knowledge, knowledge of general characteristics of the curriculum and curriculum emphasized by the school. The question "How much do parents know about their children's school?" can be investicated by examining this construct. Parental knowledge can be skewed by previous schooling experiences and their perceptions of what goes on in a school. The degree of parental involvement and satisfaction will be affected by the parents' body of knowledge about the school. Thus, it is important to study how knowledgeable the parents are about their childrens' schools.

The seventh construct is Parent Attitudes toward School.

This construct represents two themes: 1) the parents' view on the importance of participation; and 2) the parents' need to be involved in the decision making process at their childrens' school. Attitudes often dictate actions (Kuklinski, 1984). Thus, it is necessary to explore those items/variables on the Farent Survey that are attitudinal probes. Since there are several questions of this design, a construct was developed based on a theoretical context for analysis and interpretation of these

items/variables.

The eighth, and final, construct addresses Parent

Satisfaction with School. Parent satisfaction with their child's school is the focus of this construct. Satisfaction is assessed by exploring the parent's attitudes toward the school's curriculum. The curriculum provides a common focus for parental satisfaction and concerns about schooling. Thus, the construct was developed to allow the grouping of items/variables on the Parent Survey that address parental satisfaction with aspects of the schools' curricula.

In summary, the purpose of this section was to outline the eight constructs and provide an overview of the theoretical origins of each. The research literature was used extensively, not only to provide the conceptual framework for each construct, but also as an aid in grouping and categorizing items/variables from the Parent Survey. The forthcoming section converts the constructs into item/variable scales and provides the statistical verification for the eight constructs.

Parent Survey- Construct/Scale Analysis of Internal Consistency

Each item on the Parent Survey serves as a variable. Hence, the term variable shall denote a particular question or item or grouping of questions/items. The variables were assigned to a construct based on the following criteria:

1) What does the variable directly measure?

- 2) What does the variable indirectly measure?
- 3) How does the variable relate to other variables measuring the same subject or topic?

Redundancy of items measuring the same concept is a frequent characteristic of survey designs (Kidder, 1981). During revisions of the survey instrument or statistical analyses, like-items can be removed or combined with similar items to form one unit of measure. The latter strategy was employed to manage the large parent data set. Items were also grouped based on theoretical considerations. The 192 original items were synthesized to 143 variables within the eight constructs. While this is a large number of variables for statistical manipulations, the management of the variables was not terribly cumbersome since analyses were performed either within or between construct/scales. Table 9 reveals the transformations that were performed on the original items/ questions. Combined items were taken from the same or similar questions on the Parent Survey. This facilitated the transformations since the items being combined were represented by the same coding scheme. The calculation of the new variable was straight-forward. The original items were averaged to create new values for each parent case. Values were rounded to the nearest whole integer to avoid decimal gradations. The missing response values (9,99,999) remained unchanged and unaffected by these transformations.

Once the items were appropriately cataloged under one of the eight constructs/scales, reliability analyses were performed to

determine the statistical effectiveness of each scale. Reliability, simply stated, refers to the extent to which a test or measure yields the same results on repeated administrations; in other words, a measurement of consistency of a survey or test instrument. There are several methods for determining the reliability (i.e., alternate forms, split-half, coefficient alpha and test-retest). The Parent Survey does not have an alternate form, nor can it serve as a measure against itself, as happens with split-half reliability techniques. Due to the nature of the survey task and the survey instrument design, the most appropriate test of reliability is coefficient alpha (Cronbach, 1951). The test for coefficient alpha determines the extent to which each variable is related to every other variable within a particular scale. It should be noted that the coefficient alpha for dichotomously scored items (e.g., yesno) is known as the Kuder-Richardson Formula 20 (Nunnally, 1978). Potential sources of error when using coefficient alpha are item sampling differences and the heterogeneity of the domain of parents' expectations, perceptions, knowledge, and so on, sampled by the question or item. Overall, coefficient alpha is the most widely used measure of reliability and the most appropriate for demonstrating the effectiveness of the internal consistency of the Parent Survey.

An item-correlation matrix and a reliability coefficient (alphas) were obtained for six of the eight scales (See Tables 10-32). The Individual and Family Factors scales were excluded from reliability analysis due to the diversity of topics addressed by

each construct. The inter-relationship of demographic variables do not always prove to be significant due to the similarities in what these items measure (e.g., socio-economic factors) (Rosenberg, 1968). Thus, indices that measure these relationships may not prove to be statistically fruitful. Demographic variables are usually mutually exclusive when compared to each other. The variables on the Individual Factors and Family Factors scale are most appropriately used to measure associations with other variables than with each other. These variables are often desirable independent variables for social science researchers (Robinson & Shaver, 1969).

Parent Expectations of School is the third scale to be created. This scale contains two subscales that address parents! goals for school and reasons for school choice. The reliability coefficient for the original thirteen item scale is .93 (See Table 10). Most of the original school goals survey items goals are significantly correlated with one another (See Table 10). Consequently, the coefficient alpha for the construct scale-School Goals is a highly meaningful .87 (See Table 11). A review of the cor. tion matrix finds all four variables to be significantly related. The alpha level would be unchanged with the deletion of any of the variables on this subscale. Intellectual gcals (XX) and Vocational/Survival goals (YY) form the most significant relationship on the subscale (r = .69) (See Table 11). Conversely, Intellectual goals (XX) and Personal/Religious goals (SS) generate the lowest correlation (r = .53). Parents perceive academic goals

to be allied with vocational/survival (aka: basic learning or living skills), with personal/religious goals being somewhat incongruent with intellectual goals for their childrens' school Respondents found, however, all the goals for school to be important.

The original twenty-five item school choice scale earned an alpha of .96 (See Table 12). A review of the correlation matrix of Table 12 reveals that most reasons for school choice are moderately to highly related. The construct scale Reasons for Choosing the School also earned a high reliability coefficient (.90) (See Table 13). This subscale proves to be an accurate measure of school choice. The highest correlational relationship among the schoo' choice variables is between Academic/Curriculum (Q) and Religion/ Values (V) and (r = .75). Parents who select Catholic schools for academic training also value the religious education and moral training of their children. Significant relationships are also found between the important choice reasons of Religion/Values (V) and Convenience/Safety (U) (r = .71) and Religion/Values (V) and Child's Choice (R) (r = .69). Religious, moral, and character development are as important in parents' selection criteria as factors of convenience and safety (i.e., school location and safe environment). The concept of structure and discipline are important facets of Catholic schooling and influence parents' school choice decisions (Greeley, 1982). Children also appear to find their parents' school of choice to be consonant with their own. Athletic programs offered by the five schools are also attractive to

children and their parents during the school selection process. Any of the variables in this subscale could be deleted with minimal impact on maintaining an acceptable alpha level. Thus, it can be concluded from the scale analysis that parents find academic, social and religious/moral factors to be equally important as school goals and reasons for choosing a school for their children.

The fourth scale, Parents Perceptions of School, contains two subscales: School Problems and School Curriculum Characteristics including the variable related to the parents' perceptions of the school goal most emphasized. Table 14 shows the reliability analysis for the 19 original school problems. The coefficient alpha (.98) and the correlation matrix present a highly sliable scale. Likewise, the seven item construct subscale of School Problems obtained an alpha of .96 (See Table 15). There are several significant correlations between subscale variables. A correlation coefficient of .96 exists between School Problems of Moral/Ethical Behavior (DX) and School Finances (EA). School Finances has also been linked (r= .81) to Curriculum/Teachers (DY). The financial conditions of each school studied were viewed as a significant problem. A possible explanation of these findings could be that parents consider teachers to be underpaid and the school lacking either the facilities or curriculum materials to provide students with additional educational and social structure they (parents) perceive as lacking at the five schools. Parents also may feer that teaching would concomitantly improve if teachers are adequately compensated. The problem of School Finances is also correlated (r

= .78) to the problem of Poor Attitude/Lack of Interest (EJ) at the schools. The lack of adequate monies is a major problem currently facing private schools. This issue probably impacts directly on parents faced with rising tuition costs. The variable Student Body Composition (EO) is also seen as a basic school problem. Four of the five school studied were single sex high schools. This variable was linked to problems of Curriculum/Teachers (DY) (r= .71). Finances (EA)(r= .69) and Poor Attitude/Lack of Interest (EJ)(r= .75). Several of these relationships are obvious, such as Student Body Composition and Poor Attitude/Lack of Interest. The others may be a result of the strong intra-scale statistical effect of this variable, much like the School Finances variable. The alpha value of the scale would not be severely affected if any of the variables would be dropped from the scale. Parents were unable to discern a single, predominant problem facing their childrens' schools.

The 14 original item scale-School Curriculum Charact istics generated a reliability coefficient of .97 (See Table 16). These items are significantly correlated. Consequently, the construct subscale-School Curriculum Characteristics yielded an alpha coeffi ient of .97 (See Table 17). Most correlations among the scale variables are high (r =.70-.87). However, there are several statistically noteworthy associations. There is a direct correlation (r = .81) between Liberal/Modern Beliefs (AH) and Conservative/Traditional Beliefs (AI). Parants, therefore, perceive their childrens' schools to be adequately representing liberal and conservative viewpoints in a nonpartisan manner. Parents also

perceive Homework (AM) and Discipline (AN) to be active components of the schools' curriculum (r = .86). Nomework has also been correlated with Religious Education (AP) emphasis in the curriculum (r = .87). Religious Education and Discipline (AN) are also significantly interrelated (r = .84); both are probably expected by most parents who place their child in a parochial school. In general, parents may perceive discipline and religion to be inherent in the curriculum while viewing homework as the manifestation of the structure of the schooling experience. A deletion of any of the subscale variables would not seriously change the obtained alpha level. In summary, parents perceive the ratholic secondary schools, studied here, to have a well-rounded and representative curriculum.

The fifth scale, Parent Involvement in School Related Activities, has four subscales: Participation, Decision-Making, Communication and Reasons for Non-Participation. The amount of parent Participation is measured by eleven items. The original scale earned an alpha coefficient of .96 (See Table 18). Since these highly correlated, the grouping of the original items into five variables produced alpha of .98 for the Participation construct subscale (See Table 19). All correlational relationships among the five variables are meaningful. The highest correlation was achieved between Teachers & Aides (DE) and Board Members (DG) (r = .93). This finding suggests that parents who serve as classroom teachers or aides also have a tendency to serve on school boards. This seems logical since both participation activities

requires parents to be highly involved with the school. Parents who serve as Teachers & Aides are also more apt to act as Helpers (DM) during school events or activities (r = .89). Homework Monitors (DO) and Attenders (DH) garnered the correlation coefficient of .89. Thus, parent responders who monitor their childrens' homework are also more likely to attend their childrens' activities at school. The alpha value would remain somewhat unchanged with the deletion of any one of the subscale variables.

The second scale is related to parents as Decision Makers. The significant relationship of the original fifteen items produced an alpha of .98 (See Table 20). The fifteen items were consolidation into six variables to form the Decision Makers construct subscale. The six item Decision Making subscale produced a .97 alpha coefficient (See Table 21). Based on this result, the scale provides an accurate measure of parents' involvement via decision also numerous significant inter-item making. There are correlations. The relationship with the most magnitude (r = .91)is parents' decision making on Home/School Relations (BS) and School Goals (BV). It can be inferred that parents who make decisions on home/school relations are also involved in decisions related to school goals. Deciding the goals for a school also may directly relate to curriculan and operational policies. Thus, the School Goal variable was significantly correlated with decisions on Curriculum (BM) (r = .82) and School Policy (BL) (r = .86). Apparently, if parents are providing input on decisions about one of the variable/categories, there are likely to be also involved

in other decisions making categories outlined by this subscale.

Parents as Communicators is the focus of the third subscale. The subscale contains seven variables that intend to define the type and degree of communication between parents and the schools. The alpha level derived for this scale was .76 (See Table 22). Nonetheless, there are very few significantly correlated variables on this subscale. Three variables, K- Setting for Talks (Telephone), L- Setting for Talks (Parent Meetings) and M- Setting for Talks (Parent-Teacher Conferences) are highly intercorrelated. These relationships are expected since the variables are sub-parts of the one question on the Parent Survey. An example of this phenomenon is the depressing effect on the alpha level if any of the three variables would be dropped from the subscale. But, there is a poor mix among the remaining subscale variables. The correlation coefficients are generally weak, thereby rendering this substale to be an ineffective measure of parent communication. A descriptive analysis of the data supports this notion since parents responded poorly to these survey items addressing communication with the school.

The fourth subscale measures the Reasons for Non-Participation of parents in schooling activities or events. The original six variable subscale netted a substantial reliability coefficient (alpha = .97) (See Table 23). The collapsing of two of the original items into one variable produced a highly reliable five item subscale for Reasons for Non-Participation (alpha = .96). Meaningful correlational relationships exist between Child Care

(DQ) and Attitude-Language Differences (DS) (r = .87), Transportation (DR) and Delegation (DU) (r = .84) and Child Care (DQ) and Transportation (DR) (r = .86). The results, inferentially, find parents who cite child care as a reason for non-participation also do not attend school events due to the attitude of school personnel or a language barrier. Also, parents with transportation difficulties are more likely to concede the responsibility of schooling of their children to the school. Child care and transportation appear to most often prevent parents from attending school functions and activities.

The sixth scale, Parent School and Curriculum Knowledge, is composed of two subscales. One subscale is devoted to analyzing parents' school and curriculum knowledge while the second subscale focuses on the type of curricular topics emphasized at their children's schools. The twelve item curriculum knowledge subscale from the fourteen original item scale--Curriculum derives Characteristics (See Table 16). The grouping of several original items, and the addition of the item related to school knowledge, produced a subscale alpha coefficient of .98 (See Table 25). This subscale can be considered a reliable measure of parents' general knowledge of school. Several significant variable combinations were found on the correlation matrix. Parents not only perceive (See narrative on Scale V), but know that Liberal/Modern Beliefs-Attitudes (AH) and Conservative/Traditional Beliefs-Attitudes (AI) are equally represented in the schools' curricula (r = .83). The significant relationship (r = .89) between Homework (AM) and

ı

Discipline (N) validates the parents' impressions that both variables are conjointly operative in their childrens' school. Discipline (AN) (r = .87) and Helping the Poor (AT) (r = .92) are also interrelated with Religion (AP). The combination of these variables produces a curriculum that reflects the mission of Catholic schools that is evident to the parents surveyed. Additionally, rents find the ideas of Vatican II (AR) related to the components of the school curriculum that address Social Justice Issues (AU) (r = .91). This evidence suggests that Vatican II doct ine had an effect on raising the consciousness of schools in addressing social justice issues. The thirteen variables would not alter the alpha if deleted from the subscale. Parents' knowledge about the curriculum is not related to their general knowledge about the school. While this subscale measures parents' knowledge of schooling, the second is directed at determining curriculum topics that are stressed by the schools.

The second subscale measure parents' perceptions of Curriculum Emphasis. While topics are identical with those in the first subscale, the response scoring style provides the basis for a differential application and analysis. The original scale, comprised of fourteen items, highly reliable measure (alpha = .97) of Curriculum Emphasis (See Table 26). A twelve item subscale on Curricul'm Emphasis was formed by combining items several items on the original scale. This construct subscale earned a reliability 'pha of .96 (See Table 27). Again, this can be considered an accurate measure of curriculum importance. Not surp isingly,

parents consider both Liberal/Modern Beliefs-Attitudes (AV) and Conservative/Traditional Beliefs-Attitudes (AW) to be stres. ed in the school curriculum (r = .86). This is a consistent relationship throughout all examinations of the schools' curricula. An interesting duo-variable correlation (r = .81) exists between Vatican II Ideas (BG) and Theory of Evolution (BH). The schools, according to parental observations, apparently stress theories of evolution as much as the ideologies of Vatican II. If this is so, the Catholic secondary school studied are providing students with unbiased educational experiences. This is an interesting topic for further exploration. Also, significant relationships exist between the curriculum emphasis of Vatican II ideas and the opportunity for Students to Express Personal Feelings (BF) (r = .79) and Social Justice Issues (BJ) (r = .77). The findings would suggest that the teachings of the Church incite Catholic educators to address the personal and social awareness of the students. However, parents also believe that theories of evolution will also sensitize students to social justice issues based on the statistical relationship between these two variables (r = .72). Homewor. (BA) and Discipline (BC) are also highly correlated (r = .80). Apparently the curricula of the schools studied, according to parents, include religiou, social and self-development experiences for the students.

Parent Attitudes toward School is the eighth scale to be constructed. Three separate parental attitudes are measured:

1) Importance of Participation at School; 2) Parents Want

to Make Decisions (on selected topics) and; 3) Importance of Knowing School. Two subscales (and a single item scale--Importance Knowing School) were formed to evaluate these attitude questions. The original Importance of Participation at School scale is comprised of twelve items. The items in this scale are significantly related evidenced by the coefficient alpha (.93) (See Table 28). The twelve items on the Importance of Participation at School scale were collapsed into a five item construct subscale. The coefficient alpha of .69 denotes this subscale to be a weak measure of this construct (See Table 29). However, a study of the correlation matrix finds several significant variable alliances. The combination with the greatest magnitude (r = .89) exists between Board Members (CT) and Teachers & Aides (CR). This would infer that parents who want to participate on school boards or committees also would volunteer their time as substitute teachers or classroom aides. Further, parents who would serve on boards or committees would attend (Attenders-CU) (r = .84) school functions and events. It is only worthy to note that parents find Homework Monitoring (DB) to be significant despite what other roles they would fulfill at the school (e.g., Board Member). The variable Helpers (CZ) is poorly correlated with the other variables in this small subscule. If this variable were deleted from the subscale, the alpha coefficient would rise to .94. A probable explanation for this effect is that parents did not respond positively (noting a need to participate in school tasks) to this variable since they see themselves as already acting as helpers for school activities

or events. Thus, the result would be a low or negative response to the question/item that related to this topic. This would account for the poor interaction of this variable with the others in the subscale.

The fifteen item Parents Want to Make Decision scale proved to be a highly reliable measure (alpha = .97) (See Table 30). Since most of these items are significantly related, the collapsing of the fifteen items into eight produced a significant subscale. An alpha coefficient .88 was obtained for the eight items (See Table 31). Parents who want to make decisions about Curriculum (CD) concomitantly want to be involved with school Finance (CE) (r = .83), School Policy (CB) (r = .89) and School Goals (CM) (r = .83) decisions. The variable that measures the parental attitude of the Importance of Knowing School (H) was not significantly correlated with the other seven items. Therefore, parents' desire to make school related decisions is not related to the importance of knowing the school.

The final scale measures Parent Satisfaction with School originated with the fourteen item Curriculum Emphasis scale (See Table 26). The twelve variable scale assesses the degree to which parents are satisfied with selected curriculum topics. The coefficienc alpha of .97 attests to the reliability of this scale (See Table 32). The findings of the correlation matrix show that parents are satisfied (r = .87) with the school's representation of Liberal (AV) and Conservative (AW) Beliefs-Attitudes in the curriculum. Vatican II ideas (BG) and Theory of Evolution (BH) are

also equally present in the curriculum to the satisfaction of the parents (r =.83). There are additional moderate correlational associations among the variables of this scale.

In summary, the scales that were formulated proved to be reliable measures for most of the eight constructs. The statistical anomalies often found with the scales that assess demographic characteristics can be rectified by considering demographic variable individually and not as a grouping or scale. Demographic variables can "stand-alone" during statistical analyses that exemplifies their utility as dependent variables (Kerlinger, 1973). Several recommendations for scale revisions or improvement shall be offered in the final section of this paper.

Once the constructs and scales were established, further statistical procedures were conducted. The forthcoming section describes the various purpose and utility of each statistical application employed.

Parent Survey- Construct/Scale Statistical Analyses

The creation of the eight construct/scales effectively streamlined data analysis. The combining or exclusion of variables from the original Parent Survey questions/items significantly reduced the data set from 192 to 143 variables. The grouping of variables by scales aided in managing the data evaluations. The purpose of this section is to outline the various statistical procedures that were used on the nine construct/scales (See Table

8). The actual results of the data analyses are not presented, since these findings are the subject of a series of investigative research studies on various parent/school topics currently in progress.

Initially, descriptive data were recollected using the Frequencies program of SPSSPC+. Measures of central tendencies were derived that aided the research team in determining the distribution and frequency of responses for each variable and, collectively, each of the eight scales. This data run also helped in uncovering data management problems, such as missing values and incompatible response coding among combined variables. Data presentations of demographic variables were mostly obtained from this statistical application.

The eight construct/scales were compared across the five schools under study using the Crosstabs procedure. The twoway crosstabs tables examined the distribution of variable responses within and across each secondary school. The accompanying tests of significance (e.g., Fisher's Chi-square analysis) provided evidence of variance in the frequency of responses for each variable/school interaction. Three-way crosstabs procedures were also performed. In one application, several construct/scales were compared across the four schools (as a two-way analysis), while controlling for parent demographic characteristics. The second construct/scales with demographic the procedure crossed characteristics controlling for the five high schools. The first application permits the study of the effects of each of the

demographic characteristics on the construct/scale variables. The second procedure investigates the effects of each of the schools on the construct/scale. Thus, the impact of parent vs. school effects on parental attitudes, involvement, and so on, toward the school can be probed. The three-way crosstabs analysis allows for the investigation of multiple variable interaction effects via joint frequency distributions (Glass & Hopkins, 1984). This procedure is useful in the simultaneous comparison of more than two variables or variable scales.

The field research team was most interested in parent response differences at each of the five schools studied. While the Crosstabs program provided some statistical insight into variable relationships, a more sophisticated and exacting measure, in which several variables could be examined simultaneously, was desired. The statistical method that fulfilled the research needs was Discriminant Analysis. The construct/scales were ideally suited for the discriminant study. Before presenting the procedures used, a brief overview of discriminant analysis is warranted.

Discriminant analysis is useful in the investigation of multivariate research problems. Tatsuoka and Tiedeman (1954) contend that discriminant analysis provides:

- the estab_ishment of significant group-differences;
- 2) the study and "explanation" of these differences, and
- 3) the utilization of multivariate information from the samples studied in classifying a future individual known to belong to one of the groups represented (pp. 413-414).

Discriminant analysis determines the best combination of

two or more variables that maximally differentiates existing groups cases or variable categories. The concept underlying discriminant analysis is simple. Linear combinations of independent, often called predictor, variables are statistically formed and serve as the basis for classifying subjects into a particular group being studied (Huberty, 1975). Discriminant analysis provides a measure of group variance or separation by determining the inter-group significant differences of group mean vectors (i.e., group determining the group separation, variables centroids). In (discriminators) are mathematically weighted and combined so that the groups are forced to be as statistically separate as possible from one another when interacting with two or more variables. Estimates of inter-group distances (between centroids) and the degree of the relationship between response variables and group membership can be examined (Huberty, 1975). These estimations are useful in setting up rules of assigning an individual from outside the sample, but within the group population, to one of the predetermined classification by predicting possible membership.

Discriminant analysis was used to determine the linear impa of the construct/scales on the five high schools. The latter served as the classification groups for the initial discriminant study. The primary use of discriminant analysis in this study was to determine how well the variable scales combined to distinguish the parent groups at the five schools. The research team acknowledges the limitations in the generalization of results from discriminant

analyses. 11 Nonetheless, <u>Discriminant Analysis</u> provided data on parent/school differences that supports the purpose and utility of the Parent Survey.

In summary, the statistical procedures performed on the nine construct/scales provide only the inertia for further statistical analyses of the Parent Survey data. As other research hypotheses and questions are posed, other techniques will hopefully be employed to further test the efficacy of the Parent Survey.

Parent Survey- Recommendations and Conclusions

Overall, the Parent Survey provides an extensive analysis of parents' demographics/characteristics and perceptions, attitudes, expectations, involvement and knowledge of their childrens' schools. There are strengths and weaknesses to this survey instrument. To aid prospective users of the Parent Survey, an outline of both bi-polar ratings shall be offered. Please be advised that this listing is neither conclusive nor exhaustive. The strengths and weaknesses of any test or measure should be scrutinized with each administration.

Strengths

1) The Parent Survey provides a comprehensive study of parents' interaction with their childrens' school. The questions/items on the survey are theoretically flexible to allow for alternate

Ţ,

groupings of questions/items for exploration of a particular concept or construct. The eight construct/scales were created, in part, based on the grouping and order of questions/items on the Parent Survey. Theoretically, variables could be combined within scales or scales could even be combined. Statistical studies would have to be conducted to prove the worth of reconstruction. Nonetheless, the Parent Survey contains a large item domain to measure many research queries about parent/school interaction.

- 2) The eight scales proved to be reliable measures of the related construct. Most of the reliability coefficients obtained were acceptable. Thus, abbreviated forms of the Parent Survey could be issued if only selected constructs are of interest. A researcher can examine the scales (and alpha levels) and select those that provide an accurate measure of intended survey topic. There is tremendous utility in being able to select scales to reduce costs of administration to the researcher and costs of time to potential respondents.
- 3) The administration and scoring of the Parent Survey is straight-forward. The survey can either be administered in proctered sessions or act as a mail-survey. The design of the survey lends itself to minimal response complications that are often found in narrative surveys or face-to-face interviews (Kerlinger, 1973). The use of dichotomous and continuous response options provide an uncomplicated reporting and scoring format. These response options are compatible with most

- statistical procedures that may be performed.
- 4) The Parent Survey is not restricted to the particular parent population. The survey will most likely produce similar results with a high-income, non-minority parent population. Thus, the Parent Survey has valuable research applications with any Catholic, and with minor modifications to certain questions, other private or public school parent population.
- 5) The Parent Survey provides a data set for a body of research knowledge that is virtually uncharted. Parents' involvement with their children's schools is an important research topic. The value of parent/school interaction must continue to be studied to stimulate parent interest and provide the schools with guidelines on parent/school interface. Therefore, data collected via the Parent Survey may aid in developing the promoting this type of research.

Limitations

- 1) The Parent Survey was released without the benefit of a pilot administration. This is usually a serious problem, however, the techniques used to construct the survey (as discussed in an earlier section of this document) salvaged the reliability and validity of this instrument. Nonetheless, pilot studies are valuable exercises to improve not only the survey design, but also administration and scoring procedures.
- 2) The Parent Survey is a lengthy measure. Even though the survey

return and the missing response rates were acceptable, the eight page, 202 questions/items is still a bit too long. The survey instrument needs to be closely examined to determine if any streamlining can occur. Also, a response style or bias effect may occur with lengthy survey instruments. Briefly, respondents may select or not select items based on criteria independent of the intent of the survey. For example, faking or lying on survey items distorts reportage; also responses using extreme scale points or choosing a random pattern of responses adversely effects survey data credibility (Rorer, 1965). These "sins" may be amplified with long or redundant surveys. Thus, survey designers should be attentive to these response phenomena.

- 3) The multiple step questions presented a certain degree of difficulty for respondents. The missing response rates are highest for the second and, sometimes, third parts of these questions. Perhaps these items would be better served if considered as single part questions. This may lengthen the survey, but would improve response rate to these items. The value of these items must be examined to determine the merit of this proposal.
- 4) The five parent samples differ in size which creates certain problems for purposes of statistical ana? sis. A stratified random sampling technique could have been used in the initial data collection. This would have ensured consistent samples sizes for all four schools. Due to the unequal parent samples,

the row percentages in <u>Crosstabs</u> procedures were uninterpretable. The unequal "n's" may also confound other statistical techniques that may be performed on this particular data set.

There are two versions of the Parent Survey. Each was administered at two schools. The second revision resulted mostly in a format change of the questions. However, the last item on Questions 12, 13, 14 were added to the second printing of the Parent Survey. These items provide useful classification data, but should be eliminated from the variable set when performing more advanced statistical analyses.

There are probably many more positive and negative aspects of the Parent Survey. However, the purpose of this document is to provide the "road-map" that was used to develop and implement the Parent Survey. Survey and data analyses are still on-going. However, there are several recommendations that can be offered at this stage of the evolution of the Parent Survey.

- The survey should be shortened to expedite completion time for respondents and reduce the amount of data entry services needed.
- 2) The multiple step questions should not be dropped. However, the instructions for these types of questions should be in different colors to elicit the attention of the respondent. For example, step one instructions could be printed in black, step two in red and step three in green. This would visually cue the respondent to acknowledge the instructions for the steps two or three. The missing response rate for this type of question

- should improve with this survey "gadget."
- 3) One form of the Parent Survey must be chosen and endorsed by the field research team. The items added to several the questions creates a multitude of statistical problems during analyses. For the sake of convenience, these items should be deleted from any analyses involving the current data set of the Parent Survey.
- 4) The Parent Survey should be re-administered to a similar parent population to establish the test-retest performance of the instrument. This would not only aid in legitimizing the reliability of the instrument, but also provide a measure of response comparison to ensure that deviations among variables is not due to measurement error.
- 5) The survey should be re-formatted to accommodate entry of data via light (or laser) reading techniques. The manual recording of surveys for a large sample (e.g., 1070 respondents) is tedious and a potential source of error. Either the survey directly needs to be revised or a separate score sheet for the survey needs to developed for automated data entry.

In closing, the Parent Survey is worthy of further investigation and improvement. The data collected by the instrument is of significant research value to not only educational researchers, but also to other social scientists. Thus, the final recommendation is to continue investing research time and efforts to improve the design, application and statistical performance of the Parent Survey.

Table 7

Chronology of Statistical Analyses for Parent Survey*

Statistical Applications	Unit of Measurement
Frequency Distributions 1) Measures of Central Tendencies	All 192 survey questions/items
Crosstabs Tables 1) Joint Frequency Distributions 2) Significance Tests Frequency Distributions	All 192 survey questions/items by the four secondary schools
 Measures of Central Tendencies Crosstabs Tables Joint Frequency Distributions Significance Tests 	The eight constructs/scales- 143 variables The nine constructs/scales- 143 variables by the four The constructs/scales of Individual Factors & Family Factors by: Parent Expectations for Child Parent Expectations for School Parent Perceptions of School
Discriminant Analysis 1) Discriminant Functions 2) Group Centroids (mean vectors) 3) Canonical Correlations 4) Additional Significance Tests	Parent Involvement at School Parent Knowledge of School The nine constructs/scales- 143 variables

Table 8

<u>Parent Survey Constructs and Scales</u>

Constructs/Scales	Subscales
I. Individual Factors	None
II. Family Factors	None
III. Parent Expectations of School	School Goals- Importance and Priority Goals
	Reason for Choosing School- Importance and Priority Reason
IV. Parent Perceptions of School	School Goals- Most Emphasized Goal
	School Problems- Biggest Problem
Characteristic	School Curriculum
V. Parent Involvement in School	Participation
	Decision Making
	Communication
	Reasons for Non-Participation
VI. Parent School and Curriculum Knowledge	General School Knowledge Curricu : Knowledge- General
	Characteristics
	Curriculum Emphasis

constructs/Scales	Subscales
VII. Parent Attitudes Towards School	Importance of Participation at School
	Parent Wants to Make Decisions
	Important to Know School
VIII. Parent Satisfaction with School	None

PARENTS OF STUDENTS IN CATHOLIC HIGH SCHOOLS: A NATIONAL STUDY

The National Catholic Educational Association is conducting a study of Catholic secondary schools here and in other communities in the United Status. We have developed this questionnaire for the parents of students in the schools we are studying.

We realize that this questionnaire is long, but we worked very hard to make it as short as possible. We are asking you these questions because we feel that parent opinions on a large number of issues are extremely important for the growth and improvement of Catholic schools. This information is essential for understanding and interpreting the rest of the information we collect in your child's school.

PLEASE TAKE THE TIME TO ANSWER EACH QUESTION IN THE QUESTIONNAIRE. We realize that you may find some questions difficult to answer or you may feel that some questions are personal or are about "sensitive" issues. We are asking you these questions only because we think the answers will give us meaningful information for our study of Catholic high schools. We hope you will cooperate with us in our effort.

Your answers will be kept completely confidential. All information will be immediately returned to our researchers for analysis, and the results will be presented in "averaged" form NOT IN TERMS OF INDIVIDUAL PARENTS.

Please help us in this study. We hope as a result of your cooperation we can see some useful ways of helping all Catholic schools offer the best education possible to their students.

We want you to answer the questions in this _uestionnaire only for

If you have any questions or concerns about this study, please contact the National Catholic Educational Association representative at your school.

Please return the questionnaire as soon as possible in the sealed envelope to the school.

THANK YOU FOR YOUR HELP

	6 -
DIX	112

PA!	RT I:
1)	How many of your children are currently enrolled in this school?
2)	How many of your other children attended this school?
	What is your relation to the oldest child now attending this high school?
	MotherFatherOther:
4)	Do both parents live in the home? Yes No
5)	How many adults (over age 18) live in your home? (Count yourself)
6)	How many children age 18 or under Live in your home?
PA	RT II:
Ev on	enthough you may have more than one child enrolled in this school, think ly of the <u>oldest</u> child now enrolled in answering the following questions.
1)	As things stand now, how far do you think your child will get? (Mark ONLY ONE)
	Dray out of school before getting Go to college for one or two years a high school diploma Get a college degree
	Graduate from high school and get no more education after thatGet past college and get a Master's degree
	Go to trade, business, or vocational school for a year or two after high school Get an advanced degree after college (Ph.D., M.D., or law degree)
2)	How important do you feel it is for parents to know what goes on in their child's school?
	Very Important Somewhat Important Not Important at All
3)	How much do you feel you know about what goes on in your child's school?
	A great deal A moderate amount Very little
4)	During the last year, <u>about</u> how many times have you talked to your child's teachers?
	None 1-2 3-5 6-10 10 or more times
5)	About how many times did these talks take place in the following settings? (Write the number beside each item as it applies)
	Over the phone In a group (back-to-school night, parents meetings)
	Individual meetings (parent-teacher conferences)
6)	About how many times in the last year did the teacher and/or principal come to your home?
	None 1-2 3-5 6-10 10 or more times
7)	Who usually asks for any personal contact you have with the school?
	Pareni(s) Teachers Guidance counselors Administrators
8)	When you make a request for contact with the school concerning your child, how quick! y does the school respond to your request?
	The school usually responds quickly The school usually doesn't
The cchool responds, but after respond at all	
,	some delay I never had to contact the school

9) As a parent, you have a variety of reasons for sending your child to a Catholic high school. Listed below are some reasons parents frequently give for choosing a Catholic school.

Making sure homework 1. Helping with school maintenance.....O······O······O·····O 14) Mark whether or not any of the following have prevented you from being involved in activities at this school during the past year. No Yes a. Baby sitting/c ild care..... b. Lack of transportation to get to the school....................... c. Principal's and teachers' attitudes...... d. Conflict with my working hours...... e. My belief that it is the job of the principal and the teachers to run the school...... f. Different language spoken by the school people.....

g. Other:

15) Below is a list of things that could be problems at any school.

FIRST: To what extent do you think each is a problem at this school?	SECOND: If you had to choose the one biggest problem at this school which one would it be? (Please mark ONLY ONE)
Not a Minor Major Problem Problem	Biggest Problem
O······O····a. St	udent misbehavior (fighting, ealing, etc.)
OOD. Po	oor curriculum
OOOc. Lo	ow teache. salaries
OOOd. Pr	ejudice/Racial conflict
OOe. Po	oor teachers or teaching
OOf. Sc	chool too small
OOg. Sc	chool too large
OOh. CI	Lasses are overcrowded
OOOi. Te	eachers don't discipline students
O·····O····O··i. Ir	nadequate resources (such as personnel, uildings, equipment, and materials)
O······O···k. Th	ne attitude of the principal and others no run this school
sı	ack of student interest (poor scholl pirit, students don't want to learn, tc.)
OO	oo many rules and regulations
OO La	ack of enough money to operate school dequately
OOOOO. La	ack of parent interest
O······O····p. L.	ack of staff interest in good arent/school relations
Oq. R	acial composition of student body
OOr. G	ender composition of student body
000s. L	ack of after school activities

(Please return to second question at top of page.)

16)	What is your highest level of educat	ion? (Please mark ONLY ONE)
	Completed eighth grade or less	Had some college, but didn't finish
	Had some high school, but	Graduated from a two-year college
	didn't finish Completed high school	Graduated from a 4-year college or university
	Completed technical, vocation, trade, or business school	Completed a post-graduate or professional degree
17)	How satisfied are you with your own	level of education? (Please mark ONLY ONE)
	Very satisfied	Somewhat dissatisfied
	Somewhat satisfied	Very dissatisfied
18)	How many years did you attend	
	Catholic elementary school?	Catholic high school?
19)	What kind of financial assistance do that comes from outside the home?	es your child receive for schooling
	. None	Sponsorship of a relative
	Partial school scholarship	Sponsorship of a patron not a relative
	Full school scholarship	
	-	Other:
20)	How many hours a week does your chil the home?	
20)		
20)	the home?	d earn money by working outside
