ABSTRACT

The 1990 National Household Survey on Drug Abuse is the 10th study in a series of national surveys to measure the prevalence of drug use among the American household population aged 12 and over. This report, which presents estimates of drug use prevalence for the civilian and noninstitutionalized population of the United States, is intended as a companion piece to the other reports generated for the 1990 National Household Survey. Population estimates are presented separately for the total population and for Whites, Hispanics, and Blacks. For each drug there are eight tables which are arranged to facilitate group comparisons. The data for the total population are presented by sex for each of the four age groups. Data in the remaining seven tables for each racial or regional category are presented first by age, then by sex, and finally for the total population in that racial or regional category. A prevalence section presents data for the illicit or nonmedical use of any drug, and for prevalence of the individual licit and illicit drugs, with separate data for the prevalence of phenocyclidine (PCP), heroin, cocaine and amphetamine use. The frequency and regularity of drug use during the past year are reported. Information is provided on the frequency of use in the past year for marijuana, cocaine, and alcohol. (LLL)

INTRODUCTION

The 1990 National Household Survey on Drug Abuse is the tenth study in a series of national surveys to measure the prevalence of drug use among the American household population aged 12 and over. The first two studies (1971 and 1972) were sponsored by the National Commission on Marijuana and Dangerous Drugs. The National Institute on Drug Abuse (NIDA) has sponsored the eight most recent surveys, with additional support for the 1985 and 1988 surveys from the National Institute on Alcohol Abuse and Alcoholism, and support in 1988 from the Department of Education.

This Population Estimates report, which presents population estimates of drug use prevalence for the civilian and noninstitutionalized population of the United States, is intended as a companion piece to the other reports generated for the 1990 National Household Survey. The Main Findings report provides details of the National Household Survey methodology as well as information on prevalence, trends, and correlates of drug use. The Highlights report summarizes principal findings. Also, special analytic reports based on the National Household Survey will be produced later on a variety of topics.

SURVEY METHODOLOGY

Essentially the same methodology was used for the 1990 survey as was used for each of the nine previous National Household Surveys. A national probability sample of households in the coterminous United States was selected from 100 primary sampling units. The household sample excluded persons living in group quarters or institutions; such as military installations, college dormitories, hotels, hospitals, and jails; and transient populations such as the homeless. Alaska and Hawaii have not been included in the sample since the first National Household Survey because of logistic and cost considerations.

In each selected household, a roster recording the age, race/ethnicity, and sex of all household members aged 12 and older was completed. Using a random sampling procedure, either two, one, or no respondents were selected to be interviewed. (In general, selection probabilities were based on the race/ethnicity of the head of household and the ages of household members.) The procedure was designed to control the sample sizes for age and race/ethnicity groups of interest. After selection, respondents were interviewed in person in their homes by trained interviewers. The interview process included use of self-administered answer sheets and other procedures designed to assure respondents that their responses to sensitive questions would be kept confidential and anonymous.

For the 1990 National Household Survey, data were collected from March 12, 1990 to June 30, 1990, resulting in a total of 9,259 interviews with a 96.4% completion rate for screening sample households and 82.0% for interviewing sample individuals. The median completion date for the survey was April 29, 1990.

Age and race/ethnicity were the two primary correlates of drug use on which the 1990 sample was stratified. The sample design ensured adequate sample sizes for four age groups (12-17, 18-25, 26-34, and 35+) and three race/ethnicity groups. In addition, for the 1990 NHSDA, sample sizes in the Washington, DC Metropolitan Statistical Area (MSA) were designed to be large enough to support particular special interest estimation. Based on the respondents' self-classifications, the race/ethnicity groups were classified as: (1) Hispanic in origin, regardless of race; (2) White, not of Hispanic origin; and (3) Black, not of Hispanic origin. As defined, these groups are mutually exclusive. Those who did not identify themselves as Hispanic, non-Hispanic White, or non-Hispanic Black are included in the population totals, but separate population estimates are not presented for this "Other" race/ethnicity group because of their small sample size.

PROCEDURES FOR DERIVING POPULATION ESTIMATES

For the reader's convenience, both the population estimates and corresponding percentages are included in each table. Population estimates

are given in thousands, that is, an estimate of 430 shown in the population estimates section of a table represents 430,000 persons. The "observed estimates" are given first, followed by the confidence interval in parentheses. Estimates are presented separately for the following drug-use prevalence categories: (1) any lifetime use, (2) use in the past year, and (3) use in the past month. These estimates were obtained by weighting the National Household Survey data to reflect population totals for various populations groups.

Development of Weights

Sampling weights were calculated to reflect selection probabilities and to compensate for nonresponse and undercoverage. Each weight can be viewed as the number of population members that the responding sample member represents. A post-stratification adjustment was made to force respondent weight totals to reflect population totals for age, sex, and race/ethnicity population groups.

Tables 1a, 1b and 1c present the sample and population sizes on which the population estimates of drug use are based. The population sizes are population projections prepared for the Current Population Survey (CPS) conducted by the U.S. Census Bureau; they reflect the noninstitutionalized population of the United States on May 1, 1990.^{1, 2} As in previous National Household Surveys on Drug Abuse, the counts reflect the total noninstitutionalized population of the entire United States, not just that of the 48 coterminous states.

1"Estimates of the Civilian Noninstitutional Population of the United States by Age, Color and Sex, as of May 1, 1990." In house document prepared for the Current Population Survey. Washington, D.C.: U.S. Census Bureau.

2"Estimates of the Civilian Noninstitutional Population of the United States of Hispanic Origin by Age and Sex, as of May 1, 1990." In house document prepared for the Current Population Survey. Washington, D.C.: U.S. Census Bureau.

The CPS counts are estimates of persons residing in housing units and in noninstitutional group quarters such as college dormitories, rooming houses, shelters, convents, and group homes. Civilians on military bases are also included in the estimates.

Adjusting for Nonresponse Through Imputation

The population estimates presented in this report are based on the total sample or all cases in a subgroup, including some cases for which missing data for some recency-of-use and frequency-of-use variables were replaced with logically or statistically imputed values. Prior to determining the completeness of a case, an editing procedure was implemented to check for inconsistencies and to determine if missing information was retrievable by using other information in the questionnaire. Logical imputation was then done to replace inconsistent, missing, or invalid data. Determination of completeness of a case was then made. To be classified as minimally complete interviews, and therefore included in the data base, data on the recency of use of alcohol, marijuana, and cocaine had to have been provided by the respondent or logically imputed from other answers supplied by the respondent.

Missing data for recency-of-use questions (for drugs other than alcohol, cocaine, and marijuana) and for the frequency-of-use-in-the-past-12-months variables were statistically imputed (that is, replaced) by using a technique known as hot deck imputation. The first step in this procedure involved sorting the data file with a progressive series of subsorts using data on recency-of-use of alcohol, marijuana, cocaine, age, sex, Hispanic origin and race. This sorting produced an ordered data file in which adjacent data records represent individuals with similar characteristics. Missing values for particular items were then replaced by the last encountered non-missing response in the sorted data base. A hot deck imputation procedure was appropriate for use because the level of item nonresponse was low.

The use of imputation can potentially reduce the bias caused by missing data and substantially improve estimates. In this survey, however, the potential impact of bias due to item nonresponse and the impact of imputation on the estimates themselves is quite small because item nonresponse was less than 5% for drug use questions. The main advantage of such imputation for this survey was that it simplified calculation of the estimates.

Sampling Error and Confidence Intervals

In the National Household Survey on Drug Abuse, as in every sample survey, there is some degree of statistical uncertainty or error. The estimates provided in this report are subject to uncertainties of two types: nonsampling and sampling errors. Nonsampling errors are attributed to such sources as recording mistakes, coding errors, missing data, and differences in respondents' interpretation of questions. Nonsampling errors cannot be quantified; however, rigorous attempts were made to minimize them through pretesting, interviewer training and evaluation, interview verification, coder training, coding checks and other quality control measures.

Sampling errors denote the random fluctuations that occur in estimates based on samples drawn from the population; such variations can be eliminated only by conducting a complete census. Different samples drawn using the same procedures from the same population would be expected to result in different estimates. Many of these observed estimates would differ to some degree from the "true" population value and these differences are due to sampling error. Sampling errors are quantified in this report by way of confidence intervals.

Methods based on a logit transformation were used to calculate asymmetrical 95% confidence intervals for all estimated proportions and corresponding population estimates. To describe this method, let:

p = the estimated proportion

Var(p) = the variance of p, calculated from a complex survey design³

q = 1-p

L = the log odds of p = log [p/(1-p)]

Then, the variance of L is $\text{Var}(L) = \text{Var}(p)/(pq)^2$, as approximated via a Taylor series expansion.

An approximate 95% confidence interval for L is as follows:

$$L \pm 1.96 \left(\frac{\sqrt{\text{Var}(p)}}{pq} \right) = (A, B)$$

Applying the inverse logistic transformation to A and B yields a 95% confidence interval for P as follows:

$$\left(\frac{1}{1 + \exp(-A)}, \frac{1}{1 + \exp(-B)} \right) = (P_{\text{lower}}, P_{\text{upper}})$$

where "exp" denotes the inverse log transformation. The lower and upper limits of the percentage estimates are obtained by multiplying the lower and upper estimates of p by 100.

The confidence interval for the corresponding population estimate is obtained by multiplying the lower and upper limits of the proportion confidence interval by the estimated number of individuals in the population subgroup constituting the base or denominator of the associated proportion.

The precise interpretation of the 95 percent confidence interval is as follows: if repeated samples of identical design were drawn from the population, and the sample estimate and corresponding upper and lower confidence limits were calculated for each sample, then the true population value would be included in the confidence intervals of 95 of every 100 samples. Logit techniques provide a direct and efficient method for

³ Since the effects of clustering and unequal weighting should cause NHSDA estimates to be less precise than their simple random sample analogs, when the design-based variance estimate was less than the associated simple random sampling variance estimate, the simple random sample estimate was used.

computing confidence intervals (bounded by 0 and 100%) for complex survey data; they are commonly employed in many statistical applications to analyze proportions.^{4, 5, 6}

In the tables presented here, each population estimate as well as its corresponding percentage is accompanied by an upper and lower confidence limit. For example, in the lower portion of Table 3-A, the "observed estimate" of the total number of people who have ever tried marijuana is 66,507,000. The "lower limit" is 63,057,000 and the "upper limit" is 70,050,000. The interpretation of these estimates is that the total number of people who have ever tried marijuana at least once in their lifetime lies between 63,057,000 and 70,050,000 with the best estimate being 66,507,000. The corresponding percentage estimates for the lower and upper confidence limits are 31.3 and 34.8, respectively, with the best estimate being 33.1 percent.

As in other publications in this series, percentages with low precision are not reported, and no population estimates are made for such percentages. The criterion used for suppressing cell percentages and population estimates was based on the statistical ratio known as the relative standard error (RSE). Specifically, the RSE is a ratio of the variability of the estimate (as measured by the standard error) vs. the estimate itself. When this ratio was equal to or larger than 0.5 (or 50%), estimated percentages are considered to have low precision and are suppressed. In this report, because of the relatively large sample sizes for the population subgroups, low precision generally occurs only for prevalence rates of less than 1 percent.

FORMAT AND ORGANIZATION OF THE POPULATION ESTIMATES TABLES

Population estimates are presented separately for the total population and for Whites, Hispanics, and Blacks. These data are also presented separately for each of the four U.S. Census Bureau regions: Northeast, North Central, South, and West. For each drug there are eight tables which are arranged to facilitate group comparisons. The data for the total population are presented by sex for each of the four age groups. Data in the remaining seven tables for each racial or regional category are presented first by age, then by sex, and finally for the total population in that racial or regional category.

Categories of use are "ever used," "used in the past year," and "used in the past month." These categories are cumulative; those who have "used in the past month" are also included in the "used in the past year" and "ever used" categories. Likewise, those who have "used in the past year" are included in the "ever used" estimates.

The population estimate tables have been organized into two sections, each with a slightly different purpose:

Section III - Prevalence Estimates for Specific Drugs and Drug Classes

Section IV - Frequency of Drug Use Among Past Year Users.

Section III -- Prevalence Estimates for Specific Drugs

This section is useful when the reader needs estimates of the percentage or number of persons illicitly using drugs, or a particular drug. First, data are presented for the illicit or nonmedical use of ANY drug.

Data for the prevalence of the individual illicit drugs are presented immediately following the tables for any illicit use of any drug. The individual illicit drugs are presented in the same order as previous

reports, with the additional inclusion of crack. The order of presentation is: marijuana, cocaine (including crack), crack separately, inhalants, and hallucinogens (including PCP). These tables are followed by those for the nonmedical use of psychotherapeutic drugs: first, use of any psychotherapeutic drug, then stimulants, sedatives, tranquilizers, and analgesics. After this, data are presented for the licit drugs: alcohol, cigarettes, and smokeless tobacco. Finally data are presented separately (in a different format) for prevalence of PCP use, heroin use, and the use of needles with heroin, cocaine, or amphetamines. These tables show less detail than the other prevalence tables because precision for the detailed population subgroups of estimates of these behaviors is low.

Section IV -- Frequency of Drug Use Among Past Year Users

First introduced in 1985, this section is useful for those who want some indication of the regularity of drug use. In earlier surveys, the estimate of those who had tried a drug in the past month was cited by many readers as an estimate of the number of "regular users." This was not satisfactory since past month users include both those experimenting with the drug as well as regular users. Therefore, in 1985 and 1988, information was collected on the frequency of use in the past year for marijuana, cocaine, and alcohol. These particular drugs were selected because their use is the most prevalent. Frequency of drug use is classified into "at least once," "12 or more times," and "once a week or more." The categories are cumulative: those using "once a week or more" are also counted among the "12 or more times" users and the "at least once" users. Similarly, those using "12 or more times" are also counted among those who have used "at least once" in the past year.

CONSIDERATIONS IN INTERPRETING THE DATA

The estimates produced in this report should be viewed as approximations based on the best data available at this time. Readers are therefore cautioned to take the following points into account when using or interpreting the data provided in this report.

- The value of self-reports obviously depends upon the honesty and memory of sampled respondents. A number of studies have established the validity of self-report data in similar contexts⁷ and the National Household Survey procedures are designed to encourage truthfulness and recall. However, as is the case with all studies of this type, some under- or over-reporting may occur.
- Drug use prevalence estimates from the National Household Survey for specific subgroups are sometimes based on modest to small sample sizes, which may lead to substantial sampling error.
- The population projections prepared for the Current Population Survey and used in weighting the National Household Survey sample are subject to error as the time since the last census increases. Further, these population projections include the population of the entire United States while the National Household Survey included only the population of the coterminous states.
- The population surveyed is the noninstitutionalized population living in households, and therefore does not include some segments of the U.S. population which may contain a substantial proportion of drug users, such as college students living in dormitories, transients and those incarcerated.

Note: Needle Use is derived from specific questions about use of cocaine, heroin, or amphetamines with a needle, and from general questions about needle use with other drugs. 1990 estimates of needle use are not comparable to those published in the 1988 Population Estimates. The 1990 estimates are based upon a more extensive set of questions about needle use available in the 1990 NHSDA.
