IDENTIFIERS Counties; *Illinois

ABSTRACT

Rapid economic and population growth characterized the 1970s in much of rural America. Unfortunately, this "Rural Renaissance" was short-lived. Although some rural areas grew or remained stable during the 1980s, many others experienced stagnation and decline, evidenced by a variety of indicators. This document consists of graphic maps and statistical charts profiling and comparing socioeconomic conditions in Illinois. The data collected by federal and state agencies are broken down by county, identified by the standard of the Office of Management and Budget as "metropolitan," "non-metropolitan adjacent," or "remote." Profile data pertains to population, income, employment, economic base, human and financial resources, local government finance, and public health and safety (crime). Like the rest of the nation, Illinois experienced a widening gap between rural and metropolitan economic conditions. Poverty, measured in assistance recipients, was higher in remote counties. Rural counties suffered from out-migration. Per-capita income grew more rapidly in remote counties than adjacent counties, partly due to retirement income. Short-term employment became more favorable in rural areas, but long-term employment growth was far below that of metro counties. Non-metro counties increasingly depended on manufacturing, compared to natural resources (farming or mining). While higher levels of technology created a demand for better-educated workers, rural areas showed lagging educational levels. (TES)

Table of Contents

PREFACE

This handbook is intended as a general reference for those interested in conditions and trends in rural Illinois. The objective of the handbook is to profile trends in selected demographic, economic, and social conditions. Although the emphasis is on conditions in rural areas, data for metropolitan counties are included to facilitate comparison. Only Cook County is excluded from the information. Throughout the handbook, the terms non-metropolitan and rural are used interchangeably.

The handbook includes variables in the following categories; population, income, employment, economic base, human and financial resources, local government finance, and health and safety. A listing of the specific variables is in the Table of Contents.

This profile depicts county conditions in map form. The information is presented in a format that can be copied for further distribution and use in presentations. Readers should feel free to use the information as needed.

Rural counties in Illinois lag metropolitan areas in many key indicators of development, such as population change, income and employment growth, education and health access. However, rural areas are not all alike. As the handbook illustrates, rural counties in Illinois have social and economic characteristics that differ from one another. Documentation of these differences makes clear that policies and programs are likely to affect some rural areas differently than others. Hopefully, this profile will serve as a departure point for discussions of rural development policy and programs.

This is the second printing of the handbook. Some revisions of the original have been made. In particular, two variables and maps have been updated, some graphs have been omitted, and some corrections made. We await 1990 Census information which will allow a clearer portrait of rural Illinois.

Thanks to Dan Walker for early work on the project and to Poh P'ng and Nancy Baird for organization of the document. Nancy Baird updated the original handbook and coordinated the second printing. The project would not have been possible without the financial support of the Office of the Lt. Governor Bob Kustra.

OVERVIEW

In the 1970's, there was rapid economic and population growth in much of rural America. Unfortunately, the "Rural Renaissance" was short-lived. The 1980's were a time of stagnation and decline in many rural areas. However, some rural areas were stable or grew during the decade.

Many factors have contributed to economic changes in rural areas. Local rural economies tend to specialize in particular sectors, namely agriculture, mining, and manufacturing. When these industries falter, as they did in the 1980's, rural communities suffer. Structural changes in the economy have impacted rural areas. The movement to an information-based economy has created service and high-tech jobs in a few rural areas, but has reduced traditional manufacturing jobs in others. The growth in average farm size has meant that many people continue to leave agriculture. Deregulation of the airlines has reduced the competitiveness of rural areas, since the cost of flying to and from smaller communities has risen. International competition has hurt rural manufacturing, particularly durable goods manufacturing.

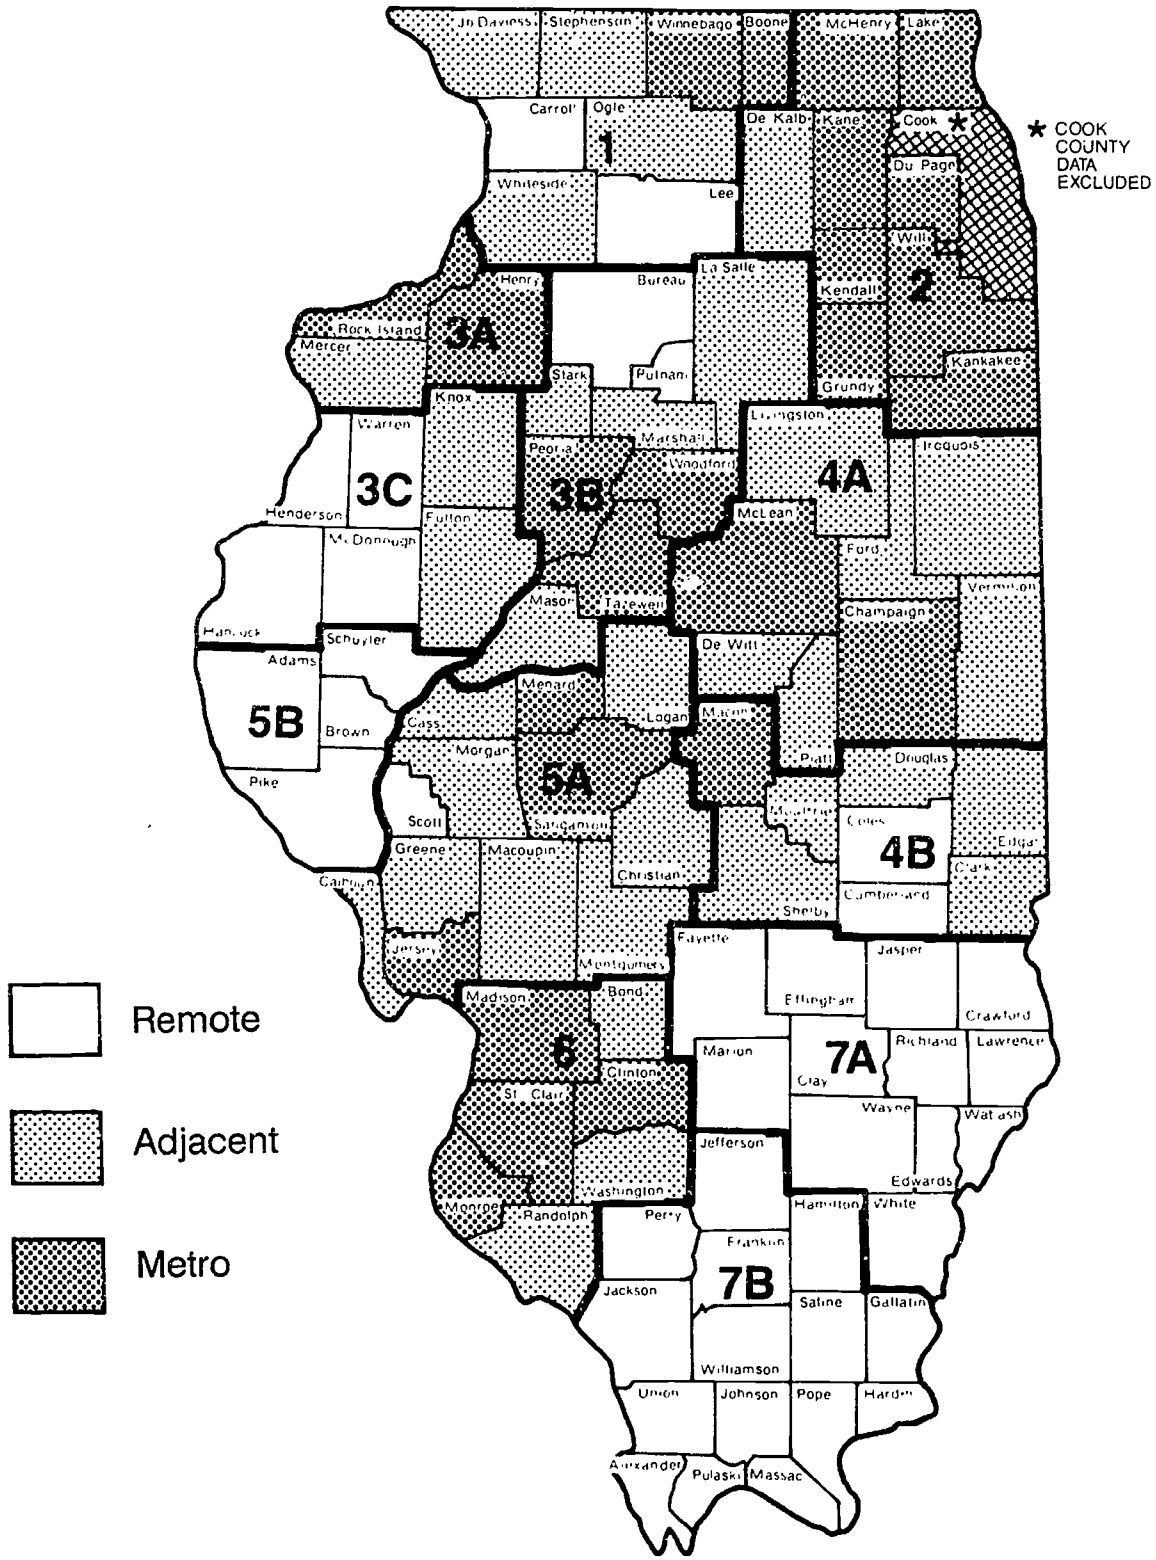
Rural Illinois has not escaped these national trends. The gap between rural and metro economic conditions widened during the 1980's. Although some rural areas in Illinois did well, others did poorly. This handbook profiles trends in selected economic and social conditions in rural Illinois and shows comparisons with metropolitan areas. Since rural areas have wide variations among themselves, comparisons are also made by region.

Graphical presentations of the data are emphasized. The county unit is selected for analysis because Federal and state agencies collect and report data for individual counties on a regular and timely basis. Except for the decennial census, little information is available on political or geographic units below the county level.

Using counties to define rural and metro areas is limiting. In fact, very small communities that are "rural" in nature exist within metropolitan counties. Conversely, some larger communities located in non-metropolitan areas have characteristics more in common with cities than with small places.

The county-level data are aggregated into the types of metropolitan (**metro**), non-metropolitan **adjacent**, and non-metropolitan **remote**. Metro counties are those designated by the Office of Management and Budget as being in a Metropolitan Statistical Area (MSA) as of 1983. A MSA contains a central city or twin cities having a population of 50,000 or more. Nonmetropolitan (non-metro) counties, or rural counties, the terms are used interchangeably in this report, are those outside of MSA's. An adjacent non-metro county is defined as both touching a

REGIONS IN ILLINOIS



MSA at more than one point and having at least 2 percent of its labor force commuting into the central county of the MSA for work.[1]

The data are also presented on a regional basis, by the twelve component areas designated by the Department of Commerce and Community Affairs and used in the state's five-year plan. The component areas, 1 to 7B, are shown in the map on the facing page. The metropolitan, adjacent non-metro, and remote non-metro county designations are also shown on the map.

As the map shows, area 2 is almost entirely metro Chicago. However, "downstate" Illinois has other metro areas. Area 3A is dominated by Moline/Rock Island. Area 3B contains Peoria, 4A includes Champaign, and 5A contains Springfield. Area 6 is dominated by the St. Louis metro area. The more remote parts of the state are those in the far west (areas 3C and 5B) and southern portions of the state (areas 7A and 7B).

The profile includes the categories of population, income, employment, economic base, human and financial resources, local government finance, and health and safety. An overview of the findings follows. For more detail and presentation of graphs and maps, please see the corresponding chapter in the handbook.

POPULATION

Illinois population growth from 1980-90 was concentrated in the collar counties of Chicago. Most rural counties lost population, although there are exceptions, primarily in southern Illinois. The loss of population was partly due to net out-migration. Loss of population through out-migration is of concern because migrants are younger and better educated than the general population. Western Illinois has the highest rate of out-migration.

Rural counties also have a lower percentage of working age residents and a higher percentage of elderly. This implies greater demands for certain services, such as health care and nursing homes. However, elderly contribute significant income to a community and can bolster the local economy. High percentages of elderly are found in western and southern Illinois.

INCOME

Per capita income actually grew more rapidly in the remote counties than in the adjacent counties. This is partly due to retirement income and the location of major universities in remote counties. Also, some adjacent counties may have been hurt by the economic performance of some "downstate" cities such as Decatur, Peoria, the Quad-Cities, and Rockford. The economies of these cities are manufacturing based and fared poorly during the 1980-82 recession. Per capita incomes are particularly low in southern Illinois.

[1] This definition follows that of the U.S. Department of Agriculture, Economic Research Service.

Poverty, as indicated by the number of general assistance recipients, is higher in remote counties especially those in southern Illinois. Earnings growth greatly favored metro counties. Changes in earnings result in part from varying fortunes of the major industries of the counties. Counties with strong service sectors did better. Counties specializing in durable manufacturing did poorly. Western Illinois did poorly, both in metro and rural areas. Average earnings per worker are highest in the collar counties and lowest in remote counties.

EMPLOYMENT

Long-term (1979-89) employment growth in rural areas was dramatically below that of metro areas. Metro counties gained about 20 percent, with the collar counties again leading the way with nearly a 40 percent gain. Rural counties (both adjacent and remote) had a decline of about 7 percent in number of jobs. Employment losses were especially severe in western Illinois, which was injured by the recession of the early 1980's. A decline in job opportunities is critical in explaining the loss of population in rural counties. In some remote communities, the industrial base has declined so severely that education and health care have become major employers.

The short-term (1987-89) employment trends are more favorable for rural areas, suggesting that employment is at least stabilizing in rural Illinois. High unemployment rates are found in the southern portion of the state. Remote counties have a decidedly higher unemployment rate than other county types.

ECONOMIC BASE

Local rural economies tend to specialize in one major industry. The industry of specialization is termed the county's economic base. Manufacturing is the economic base of many counties in the northern tier of the state. Mining and government are important in the southern counties. Farming is the base of some counties across the central portion of the state. Counties with services as an economic base are widely scattered.

Farming is the economic base of relatively few counties. More non-metro counties depend on manufacturing than natural resources (farming or mining) for their economic base. Manufacturing is important in rural areas; in fact, manufacturing and construction earnings are a larger fraction of total earnings in adjacent than in metro counties. The government sector is acting as a buffer for non-metro counties, partly due to the location of several major universities in these counties. Metro areas have larger service sectors than do non-metro areas. Non-metro areas need to capture more service sector jobs, since most future employment growth in the U.S. will be in the service sector.

HUMAN AND FINANCIAL RESOURCES

Businesses are demanding better educated workers because of the application of higher levels of technology. The lagging educational levels of rural communities are apparent when high school and college attainment are considered. Metro areas have sizeable advantage in college attainment. Remote areas are slightly behind adjacent areas in this measure of human resources. A vast portion of southern Illinois has low education levels.

There is no evidence that rural areas are at a disadvantage in the level of bank deposits per capita. On the contrary, levels are higher in non-metro than metro areas. This measure of capital availability may be inadequate because of the proliferation of other financial instruments.

LOCAL GOVERNMENT FINANCE

Assessed valuation is a measure of the local tax base; it suggests the capacity of local governments to provide services supported by local property taxes. In general, assessed valuation per capita is highest in the north and declines as one moves south. If two counties with large power plants are excluded, assessed valuation per capita is lower in rural areas and is declining.

There is less variation among counties in local government spending than in tax base. There seems to be little correlation between assessed valuation per capita and the level of local government spending. The regional pattern of property taxes is similar to that of assessed valuation. Metro counties have higher property taxes than non-metro on a per capita basis. However, this gives no indication of the tax burden, since it does not relate taxes to ability to pay.

HEALTH AND SAFETY

Infant mortality rates are slightly higher in rural compared to metro counties. It is surprising that adjacent counties have a higher rate than remote counties. Remote counties have higher poverty rates and less access to health care. The metro/rural comparisons of infant mortality rates would be affected if Cook County was included.

Metro areas have many more medical doctors, even after adjusting for population. Access to health care is becoming a major concern in rural areas. Along with fewer doctors, rural areas also face nursing shortages and local hospital closings. The crime rate is about twice as high in metro areas, compared with rural areas. This "quality of life" indicator strongly favors rural areas.

Chapter 1 POPULATION

Population Change, 1980-90

Net Migration, 1980-86

Dependency Ratio, 1980

Percentage of Elderly, 1980

Population Trends, by County

Sources:

U.S. Department of Commerce, Bureau of the Census, ***County and City Data Book***, Washington, D.C.; U.S. Government Printing Office, 1983 and 1988.

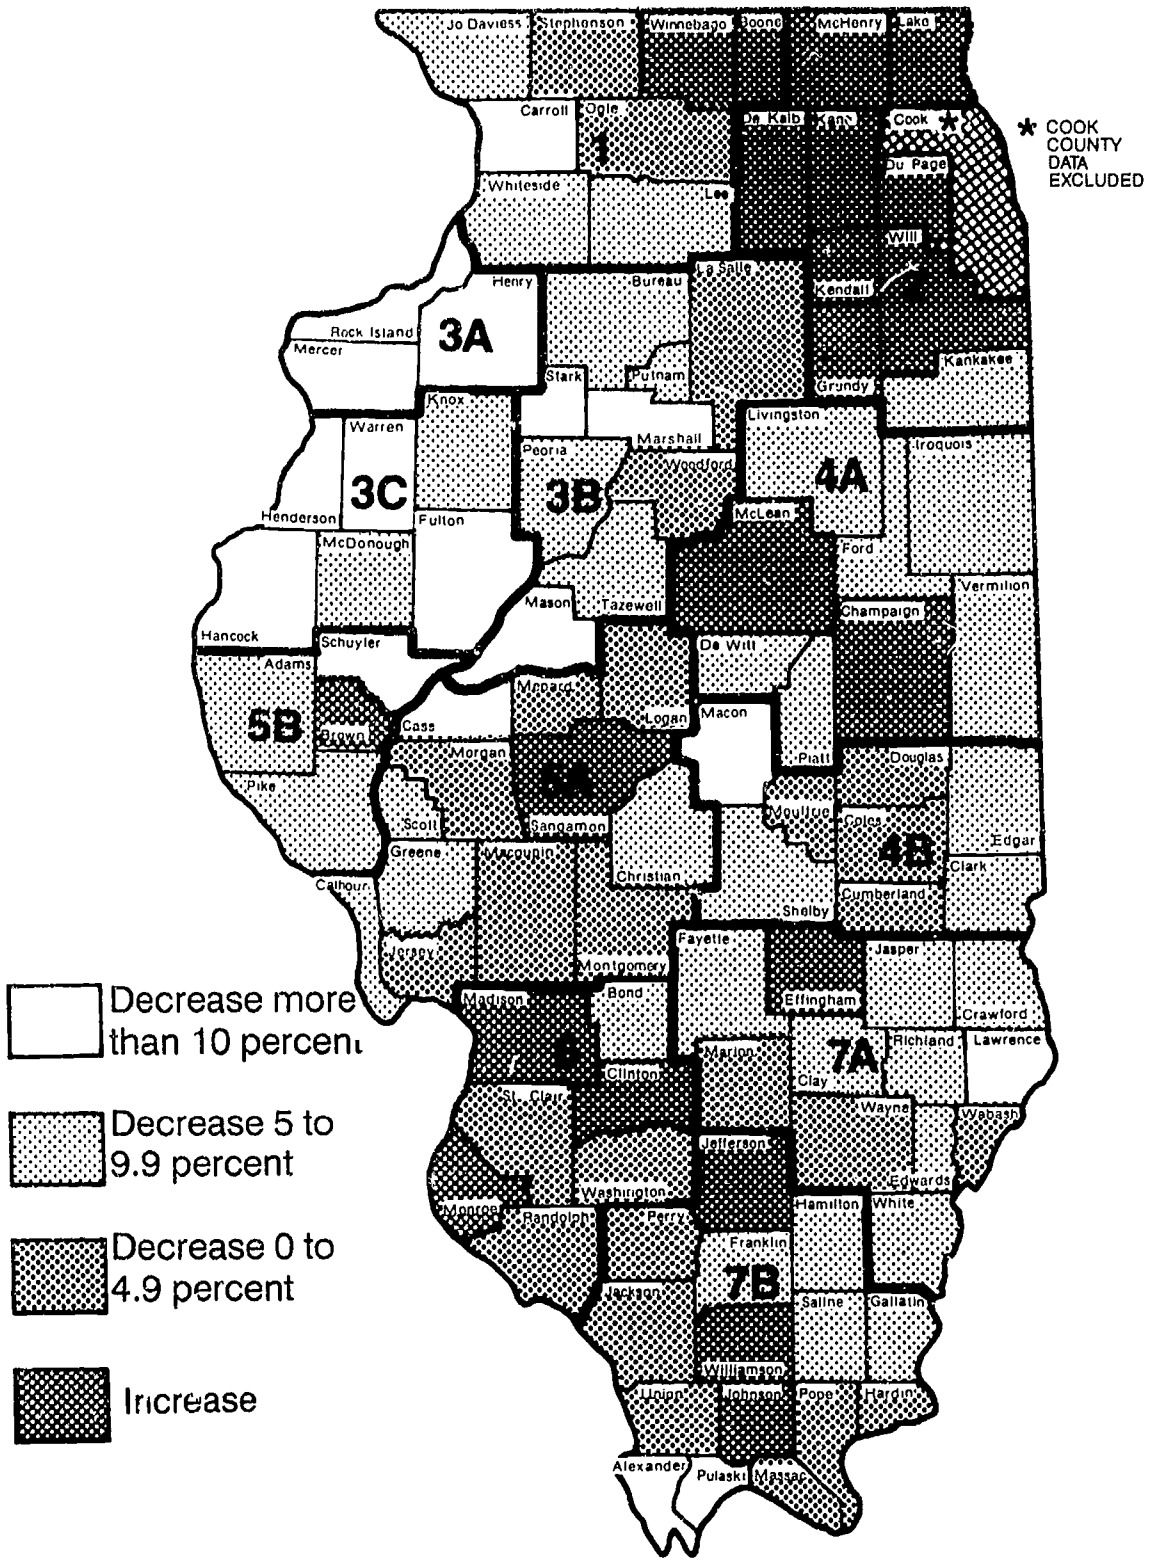
U.S. Department of Commerce, Bureau of the Census, ***1990 Illinois Census Counts by County***, 1991.

Definitions:

Net migration represents the difference between the number of persons moving into the county and the number of persons moving away from the county. Net migration includes net immigration from abroad, net interstate migration, and movement of persons within the armed forces. The rate of net migration is the number of net migrants during 1980-86 as a percentage of 1980 population.

The dependency ratio is the percentage of the population under age 18 or over age 64.

MAP 1. POPULATION CHANGE, 1980 - 90



Source: 1980 and 1990 Census of Population, U.S. Bureau of the Census

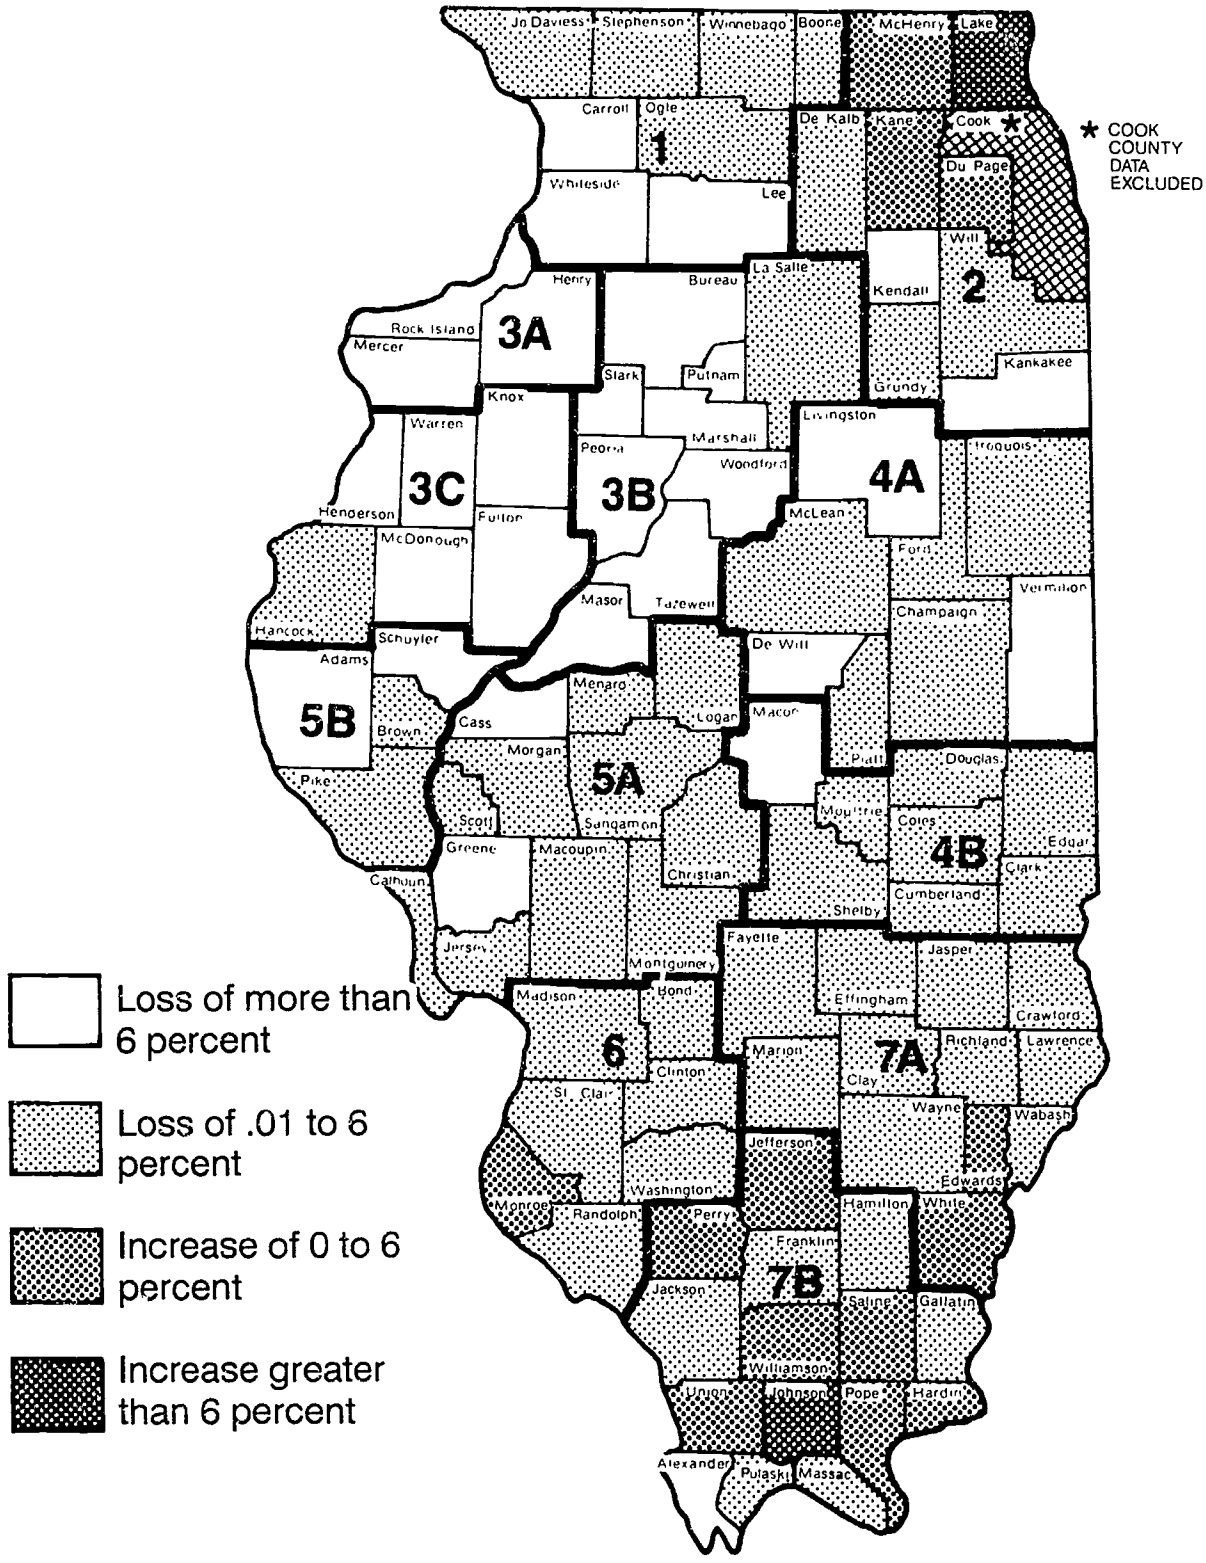
POPULATION CHANGE, 1980-90

During the past decade, most U.S. population growth has taken place in the southern and western states. Like its midwestern neighbors, Illinois has had a stable population. In the period 1980-90, the population of Illinois was virtually unchanged, growing by 0.03 percent. Slow population growth is expected to continue in Illinois for the next decade.

Although the overall population of Illinois was stable in the 1980's, there was considerable variation among the counties. As Map 1 shows, growth was concentrated in the collar counties of Chicago (area 2). Much of western Illinois lost heavily; including the metro areas of Rock Island/Moline and Peoria (areas 3A and 3B) and the remote areas (areas 3C and 5B). Most of the rural counties lost population, the exceptions are mainly in southern Illinois. As Chapters 2, 3 and 4 show, population changes are closely associated with economic changes. Counties with weak economies generally lost population.

Individual counties with the largest increases in population include Du Page, Kane, Lake, Will, and McHenry, all collar counties of Chicago. Those experiencing the largest decreases are Marshall, Mason, Stark (in area 3B) Fulton, Warren, Henderson, and Hancock (in area 3C).

MAP 2. NET MIGRATION, 1980 - 86



Source: *County and City Data Book*, U.S. Department of Commerce, 1988

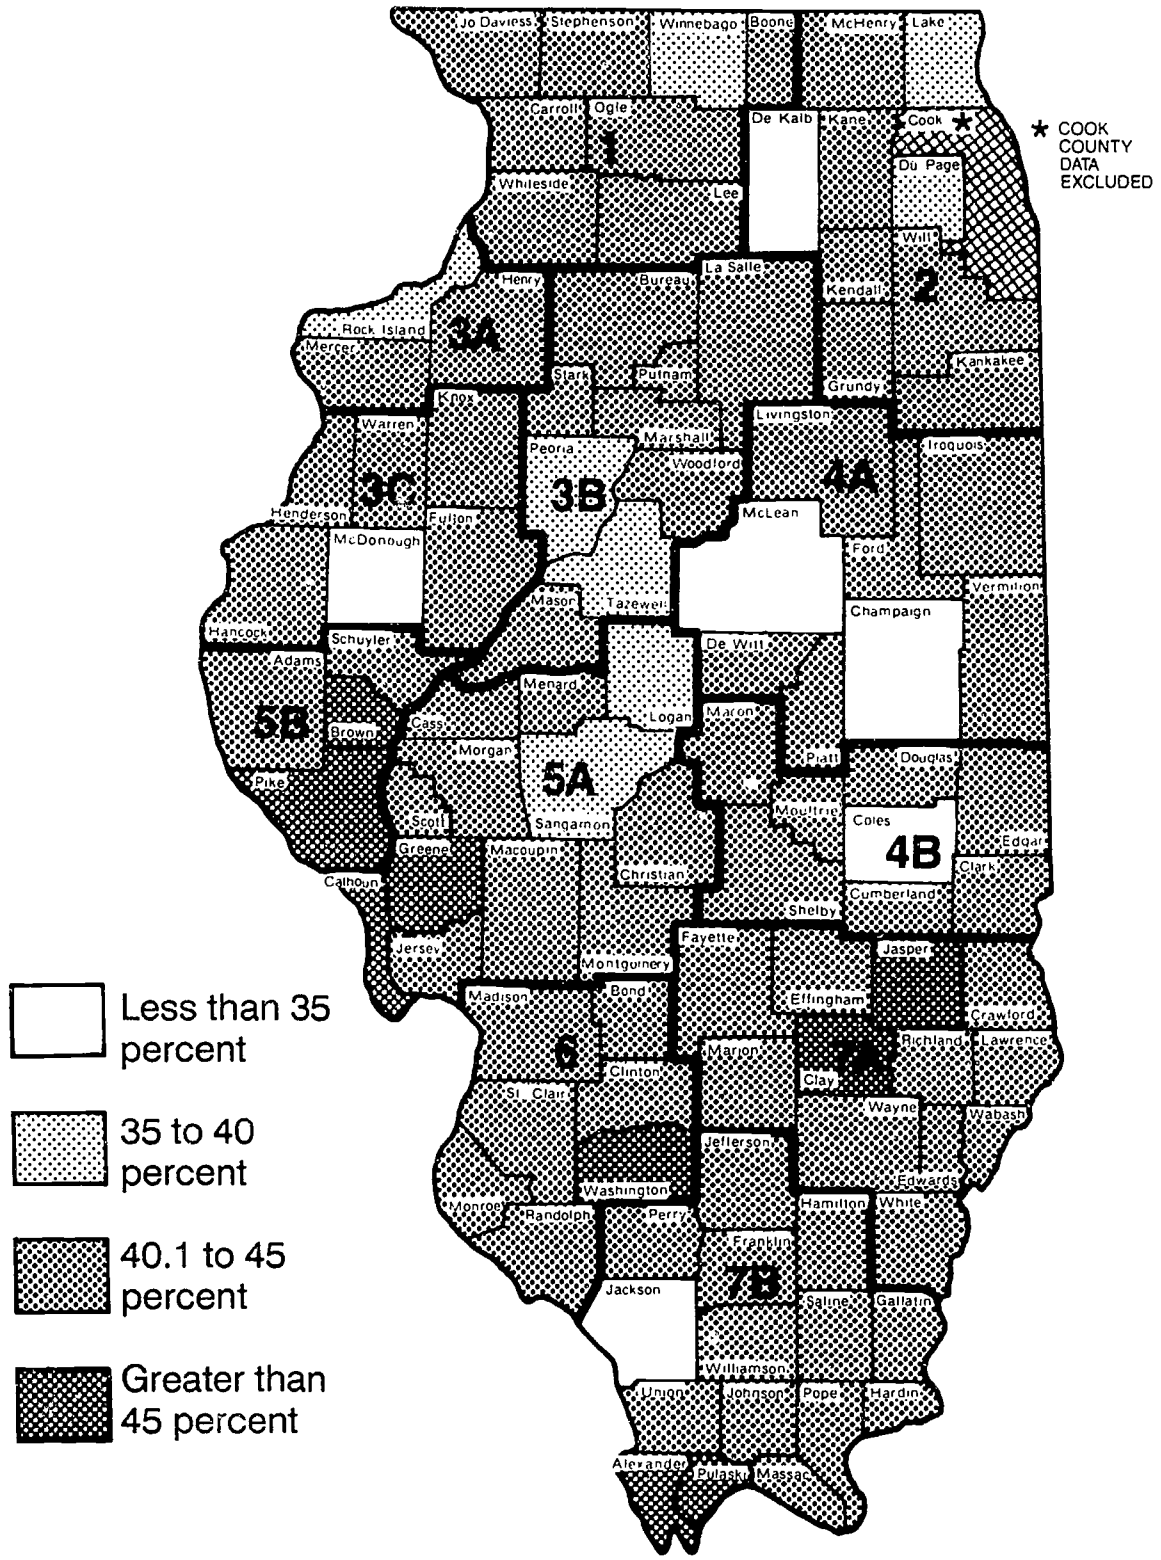
NET MIGRATION, 1980-86

The slow growth rate in Illinois was partly the result of high net out-migration; the net outflow of people from Illinois from 1980 to 1986 was about 377,000 persons.

Loss of population through out-migration is of special concern because migrants are younger and better educated than the general population. As Map 2 shows, western Illinois has the highest rate of out-migration, including both the mixed metro/non-metro areas 3A and 3B (which include Peoria and Rock Island/Moline) and the remote regions 3C and 5B. The collar counties of Chicago are experiencing net in-migration, as are scattered counties in southern Illinois (Map 2).

Counties with the highest rates of out-migration (greater than 10 percent over the 1980-86 period) are Marshall, Mason, Peoria, Tazewell (area 3B) Fulton, and Knox (area 3C). Those gaining population from in-migrants include the collar counties of Chicago, Monroe (area 6), Edwards (area 7A), Johnson, Saline, Williamson, and Union (area 7B).

MAP 3. DEPENDENCY RATIO, 1980



Source: *County and City Data Book*, U.S. Department of Commerce, 1988

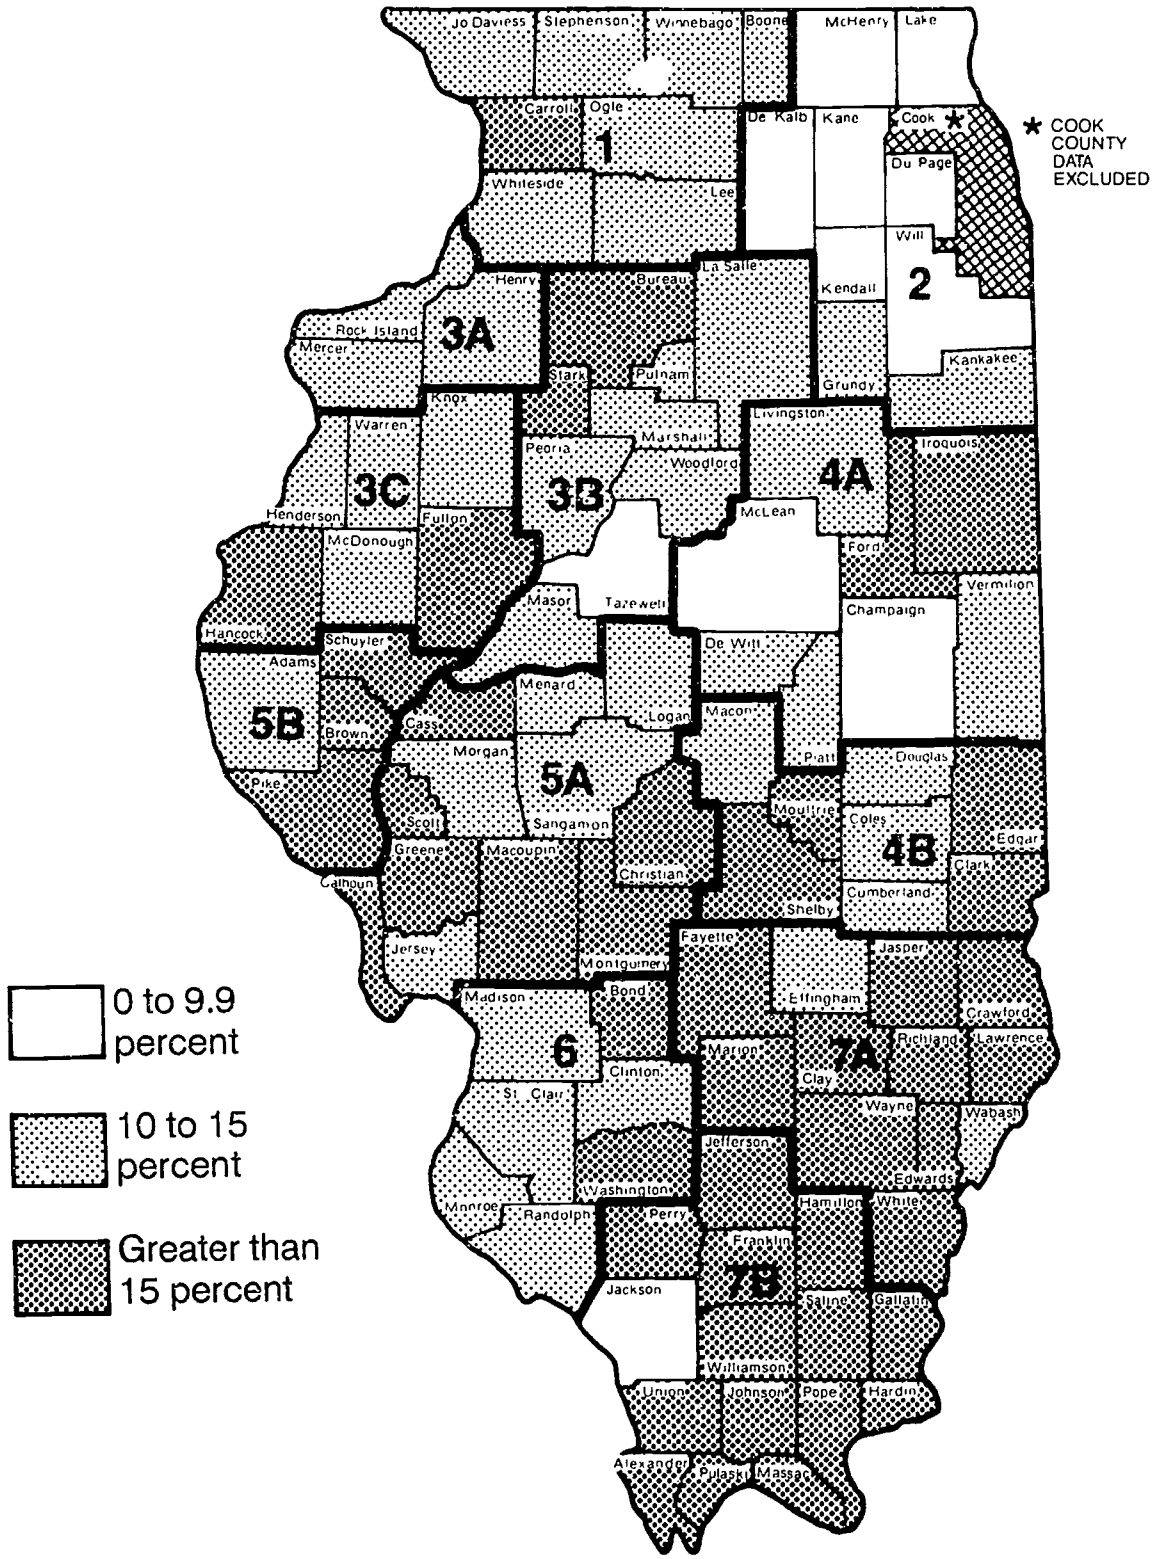
DEPENDENCY RATIO, 1980

The age distribution of the population provides useful information about the potential work force and the need for specific services. The dependency ratio is one measure of age distribution. The dependency ratio is defined as the percentage of the population under age 18 or over age 64; ages when people generally are not in the labor force.

Several of the collar counties of Chicago have a lower proportion of young and elderly residents, as Map 3 illustrates. Low dependency rates are also found in counties with major universities and in metro areas of Rock Island, Peoria, and Springfield. The highest ratios of dependency are found in the remote areas of southwestern (5B) and southern Illinois (7A and 7B). Metro areas may have an advantage in attracting business because of their concentration of working-age residents.

Counties with the highest dependency ratios include Alexander, Pulaski, Washington, Clay, and Jasper in the southern part of the state and Pike, Brown, Greene, and Calhoun in west central Illinois. Low dependency ratios are found in De Kalb, McDonough, McLean, Champaign, and Coles.

MAP 4. PERCENTAGE OF ELDERLY, 1980



Source: *County and City Data Book*, U.S. Department of Commerce, 1988

PERCENTAGE OF ELDERLY, 1980

The collar counties of Chicago, area 2, have a low percentage of elderly (8.6 percent). By comparison, some of the remote areas in western Illinois (5B) and southern Illinois (7A and 7B) have twice or nearly twice the relative number of elderly persons (Map 4).

Metro counties have a much lower percentage of elderly than non-metro counties. Remote counties have the relatively highest number of elderly, suggesting greater demands for certain services, such as hospitals and nursing homes.

Elderly sometimes are viewed as limiting economic potential; requiring public services while contributing little income. Recent research suggests that elderly contribute significant income, and bolster employment in a community. In part this is because elderly are more apt to spend their income locally. The aging of the U. S. population suggests a potential for the elderly as a source of economic opportunity for remote counties. Some remote areas, especially those with attractive resources such as lakes and forests, might become retirement centers.

Note: Net Migration consists of net immigration from abroad, net interstate migration, and movement of persons in the Armed Forces.

[1] Rate of Net Migration is the number of net migrants as a percentage of total population-1980.

[2] Dependency ratio is the percentage of a county's population under the age of 18 or over the age of 64.

[3] Age 65+ is the percentage of population 65 years or older.

[4] Percent change in population is calculated from totals.

Chapter 2 INCOME

Per Capita Income Change, 1979-87[1]

General Assistance Recipients, 1988[2]

Long-Term Earnings Growth, 1979-87[1]

Average Earnings per Worker, 1987[1]

Income Trends, by County

Sources:

[1] U.S. Department of Commerce, Bureau of Economic Analysis, ***Local Area Personal Income***, 1977-82 (Volume 4) and 1982-87 (Volume 2).

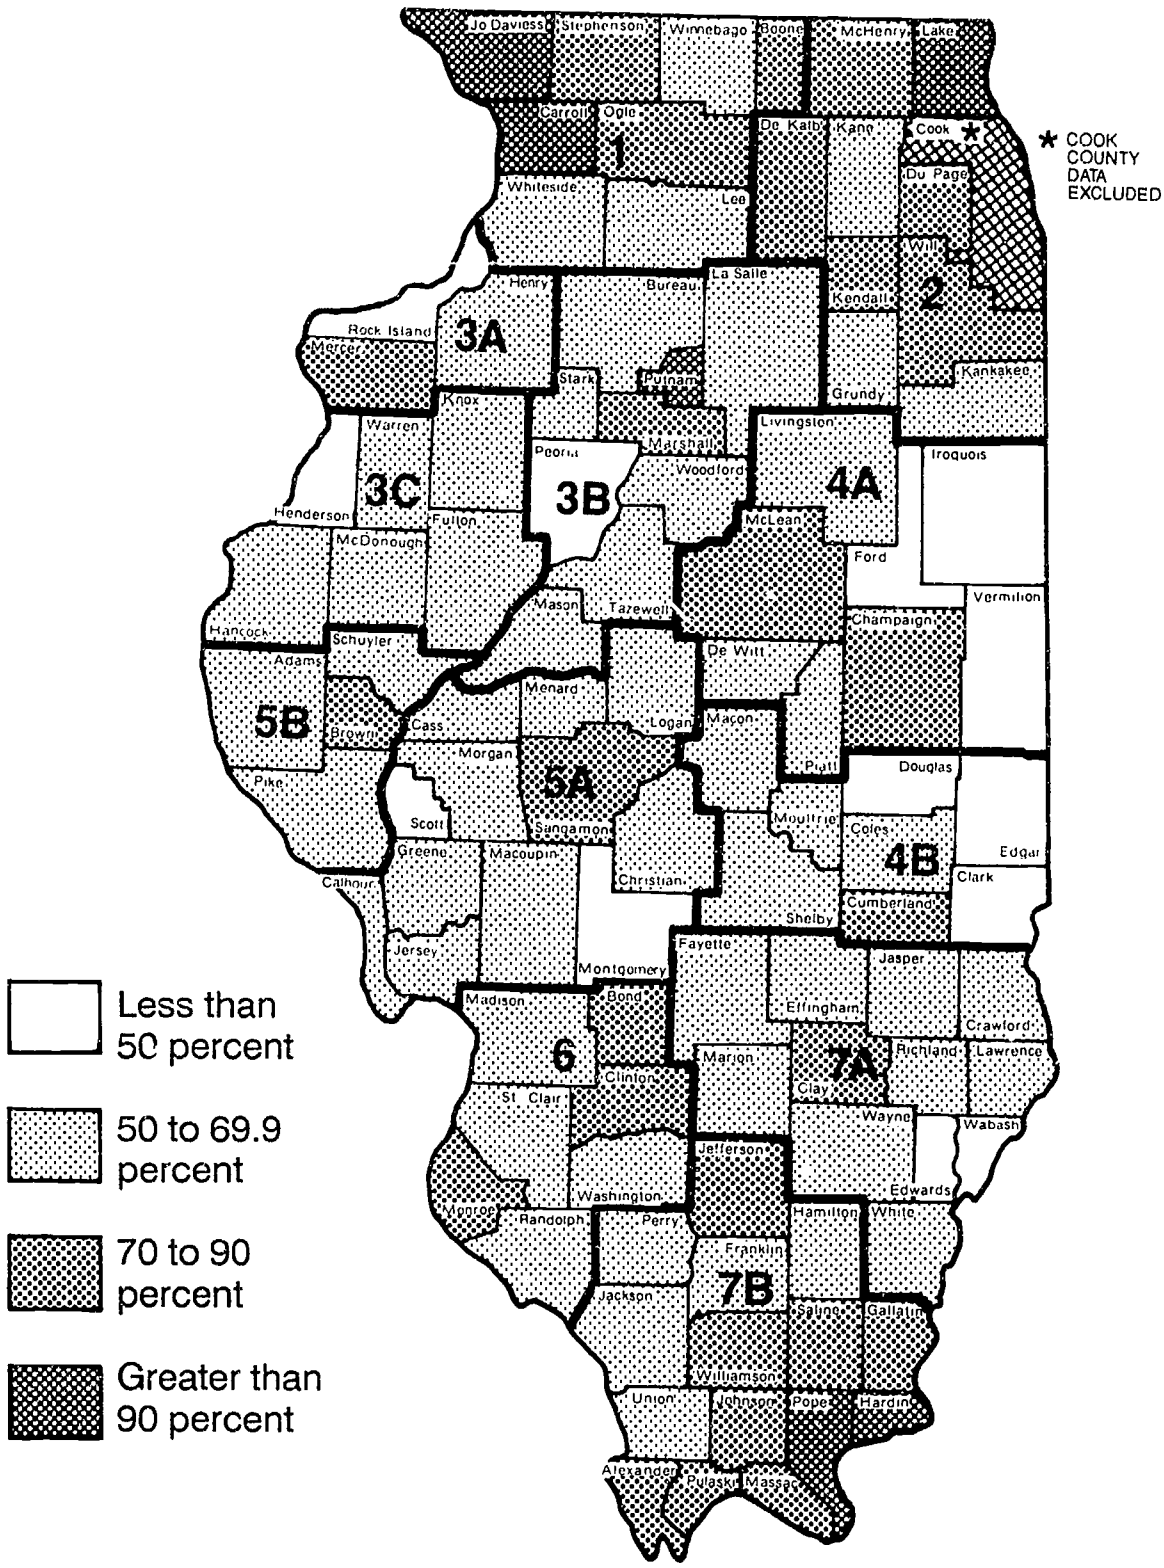
[2] Illinois Department of Public Aid, unpublished data.

Definitions:

Earnings are net earnings by place of residence and include wage and salary disbursements and proprietor's income. Total income is net earnings plus unearned income (dividends, interest, and rent and transfer payments).

Number of general assistance recipients is based on reports to the Illinois Department of Public Aid. Many local government units do not file reports.

MAP 5. PER CAPITA INCOME CHANGE, 1979 - 87



Source: *Local Area Personal Income,* U.S. Department of Commerce, 1977-82, 1982-87

PER CAPITA INCOME CHANGE, 1979-87

Per capita income is often used as an indicator of an area's economic well-being. If Cook County is included, the 1987 per capita income of Illinois ($16,421) is greater than the United States ($15,514).

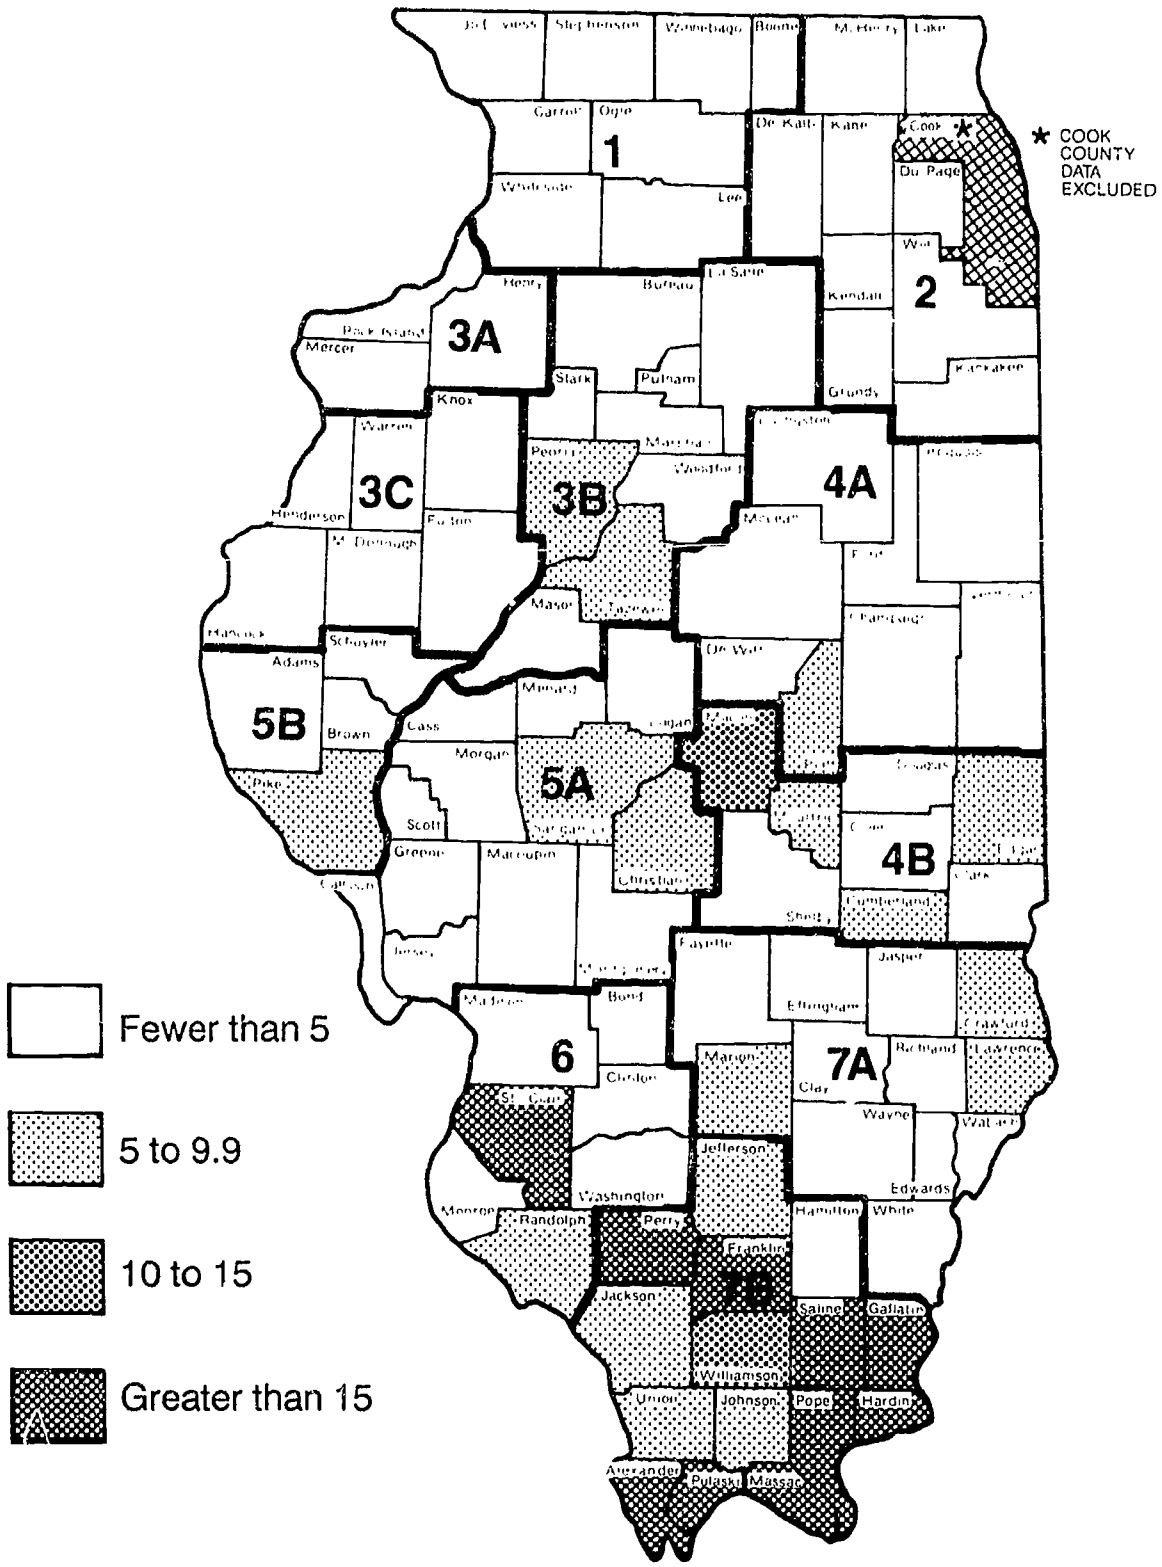
There is considerable variation in 1979-87 income changes among the counties (Map 5). The figures shown are not adjusted for inflation. The collar counties around Chicago (area 2) were again favored. Northwest Illinois (area 1) and southernmost Illinois (area 7B) also did well in per capita income growth. However, the gains in those areas were localized in several counties. Southwestern Illinois (area 6) which is mostly metro St. Louis did well. Western Illinois was mixed; with the remote area 5B doing quite well, while neighboring, mostly remote, 3C did poorly. The economies of western Illinois vary widely, in part because the cities of Quincy, Peoria, and Rock Island/Moline have differing impacts. Eastern Illinois was weak; both in rural 4B and mixed rural/urban 4A.

As might be expected, metropolitan counties have the highest per capita 1987 incomes of the three groups, $15,521, next are the adjacent counties, $13,504, followed by the remote counties, $12,315. Changes in per capita income in the 1980's follow a similar pattern as population change; income increases were largest among metro counties, followed by remote counties, with adjacent counties lagging. This is reasonable, since over time, population and economic activity tend to move together.

Unearned income (such as Social Security benefits, dividends, interest, and rent) and the location of major universities in remote counties have served as a stabilizing force. Adjacent counties may have been hurt by the performance of some "downstate" cities, such as Decatur, Peoria, Rock Island/Moline, and Rockford. The economies of these cities are manufacturing based and fared poorly during the 1980-82 recession.

Gains of 100 percent or more from 1979-87 were enjoyed by Jo Daviess (area 1), Putnam (area 3B), and Hardin and Pope (area 7B). These comparisons are slightly misleading because the counties are small and some have relatively low incomes. Thus, a small increase can appear to be a relatively large gain. Counties with the smallest gains (less than 40 percent) included Ford (area 4A), Douglas (area 4B), and Montgomery (area 5A).

MAP 6. GENERAL ASSISTANCE RECIPIENTS PER 1,000 RESIDENTS, 1988



Source: Illinois Department of Public Aid, unpublished data, 1988

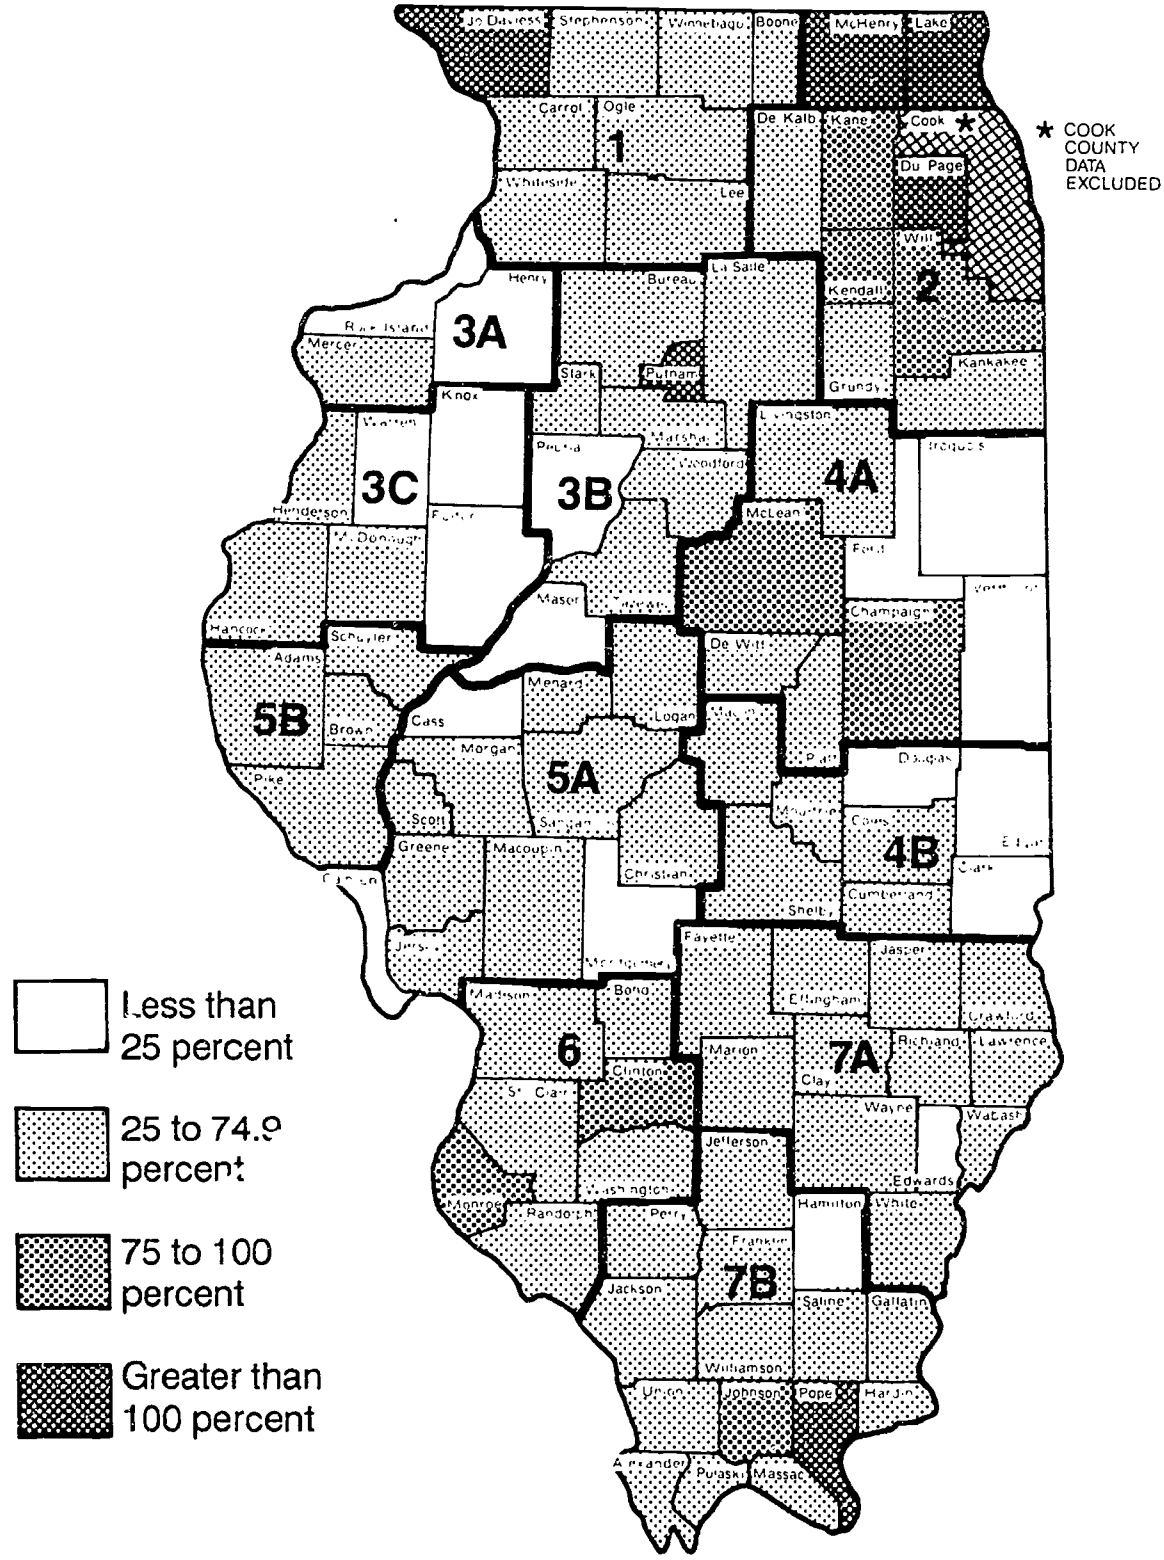
GENERAL ASSISTANCE RECIPIENTS, 1988

The number of general assistance recipients per 1,000 residents is used as an indicator of poverty, since recent poverty statistics are not available. The number of general assistance recipients is based on reports filed by local government units (townships or county governments) to the Illinois Department of Public Aid. Since many local governmental units do not file reports with the Department, the figures are incomplete. Before the numbers are used in a specific analysis, they should be checked for completeness.

A poverty measure serves as a counter indicator to per capita income. As an average, per capita income does not provide information on the concentration of low-income persons. Use of a poverty indicator allows areas to be identified that, while experiencing increases in per capita income, may still have distressed segments of the population.

As Map 6 shows, the general assistance recipient rate suggests a concentration of poverty in southern Illinois (area 7B). Some of these counties have very low income levels even after relatively high rates of per capita income growth between 1979 and 1987. Moderate to high general assistance recipient rates are also found in southwestern Illinois (area 6, primarily metro St. Louis), scattered rural counties in eastern Illinois, and metro counties (Peoria and Springfield). The extent of poverty may be understated by this measure since some persons may be reluctant to file claims for assistance. The existence of poverty in the southern region will be confirmed later by the presence of high unemployment and the relatively low access to public services.

MAP 7. LONG-TERM EARNINGS GROWTH, 1979 - 87



Source: *Local Area Personal Income*, U.S. Department of Commerce, 1977-82, 1982-87

LONG-TERM EARNINGS GROWTH, 1979-87

Income is generated from two sources; earnings and unearned income. Earnings include wage and salary disbursements and proprietor's income. Unearned income includes dividends, interest, and rent and transfer payments.[1]

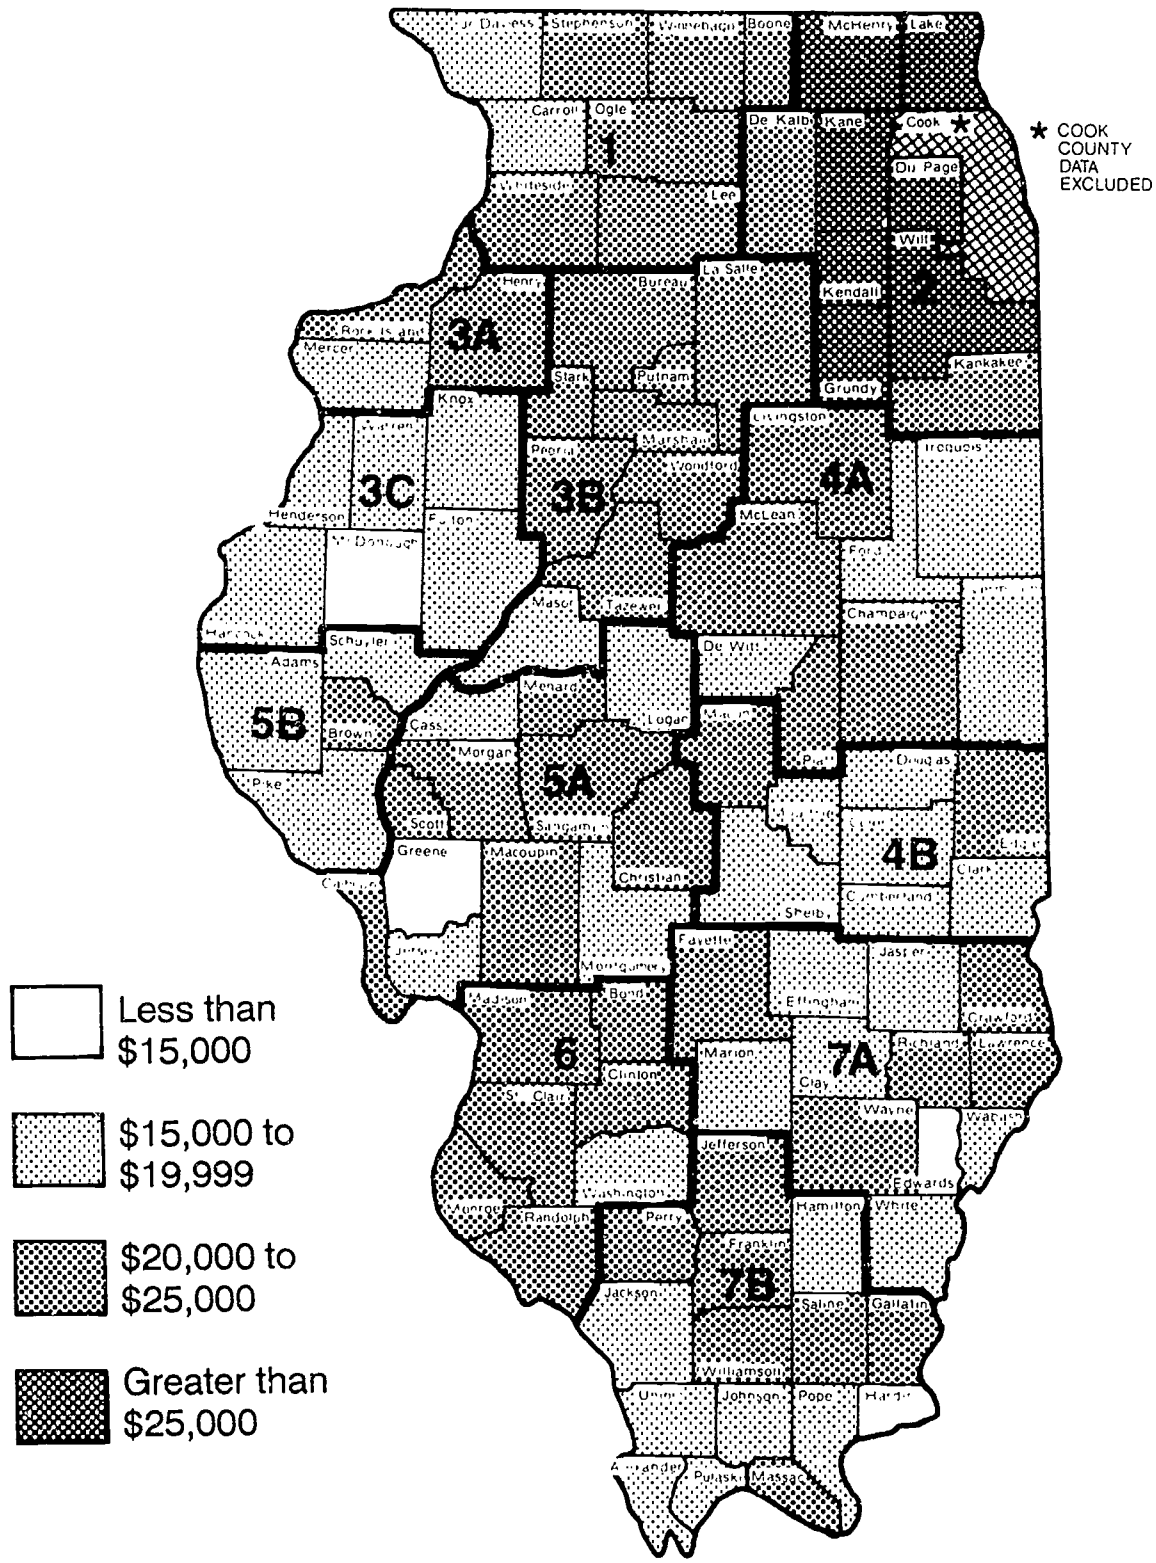
Not surprisingly, the collar counties of Chicago (area 2) dominate earnings growth (Map 7). Du Page County in particular has had strong growth and is providing a major stimulus for the surrounding region. Southern Illinois shows strength in earnings growth, both in remote area 7B and metro St. Louis (area 6). Western Illinois is weak, with metro areas Rock Island/Moline (area 3A) and Peoria (3B) and remote areas (3C and 5B) doing very poorly. Western and central Illinois were hurt by cutbacks in Caterpillar and the farm implement industry during the recession.

These changes result in part from varying fortunes of the major industries of the counties. Nationally, the economy is undergoing a transformation to a service economy. Counties with strong service sectors (especially business services) did better. Those counties specializing in durable manufacturing (especially farm machinery) generally did poorly. Farming and mining have been erratic, but show signs of stabilizing in recent years.

Metro counties had a distinct advantage in earnings growth. However, this is not uniform, as the weakness of Rock Island/Moline and Peoria attests. The growth of income was more even in metro and non-metro counties, suggesting the importance of unearned income to the economies of rural areas. Retirement income is relatively more important in non-metropolitan areas.

[1] Dividends, interest, and rent income includes payments made by corporations to stockholders, interest from all sources, and rent and royalties. Transfer payments are income payments to persons for which they do not render current services. These include retirement and insurance benefits, medicare and medicaid benefits, food stamps, and other kinds of benefits.

MAP 8. AVERAGE EARNINGS PER WORKER, 1987



Source: *Local Area Personal Income*, U.S. Department of Commerce, 1977-82, 1982-87

AVERAGE EARNINGS PER WORKER, 1987

There is a more than $10,000 range among counties in average earnings per worker. The highest earnings level is found in the collar counties of Chicago (area 2) and the lowest levels in the remote areas of western Illinois (area 3C and 5B). McDonough County may be a statistical aberration because of the inclusion of university students but there is no large economic stimulus in this region.

Earnings per worker are also low in the extreme southern counties (7B) and in some eastern counties (area 4B). The population is sparse with relatively little industry in these counties. Earnings per worker are moderately high in northern Illinois but, to some extent, these variations are compensated by cost of living differences, especially in the suburbs.

Outside of the collar counties, earnings per worker are greater than $24,000 in Putnam (area 3B), Monroe (area 6), and Perry (area 7B). Low earnings per worker (below $17,000) are found in McDonough (area 3C), Greene (area 5A), Schuyler (area 5B), Clay, Edwards, and Jasper (area 7A), and Hardin, and Johnson (area 7A).

Chapter 3 EMPLOYMENT

Long-Term Employment Growth, 1979-89

Short-Term Employment Growth, 1987-89

Unemployment Rate, 1989

Employment Trends, by County

Source:

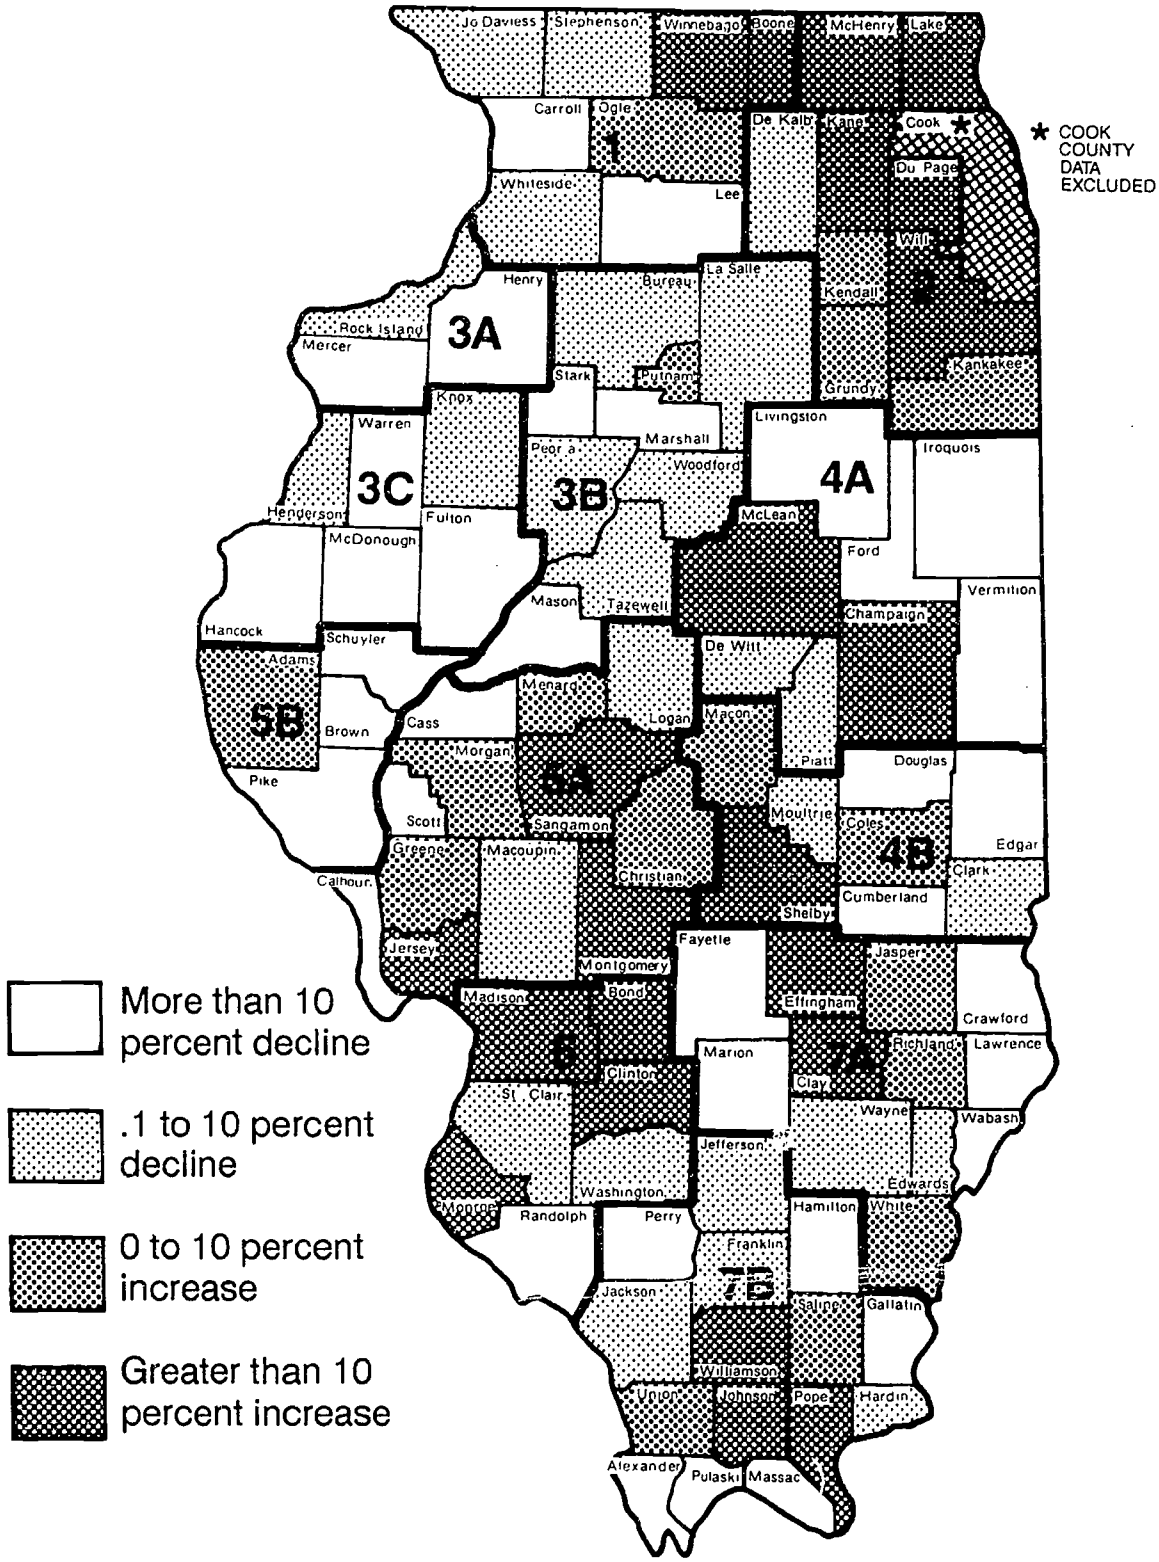
Illinois Department of Employment Security, ***Illinois Labor Force Report***, 1979, 1987, 1989.

Definitions:

Employment data is from unemployment compensation records. Employment figures are annual averages of monthly data.

Unemployment rate is the percentage of the labor force that is not employed.

MAP 9. LONG-TERM EMPLOYMENT GROWTH, 1979 - 89



Source: *Illinois Labor Force Report*, Illinois Department of Employment Security, 1979, 1989

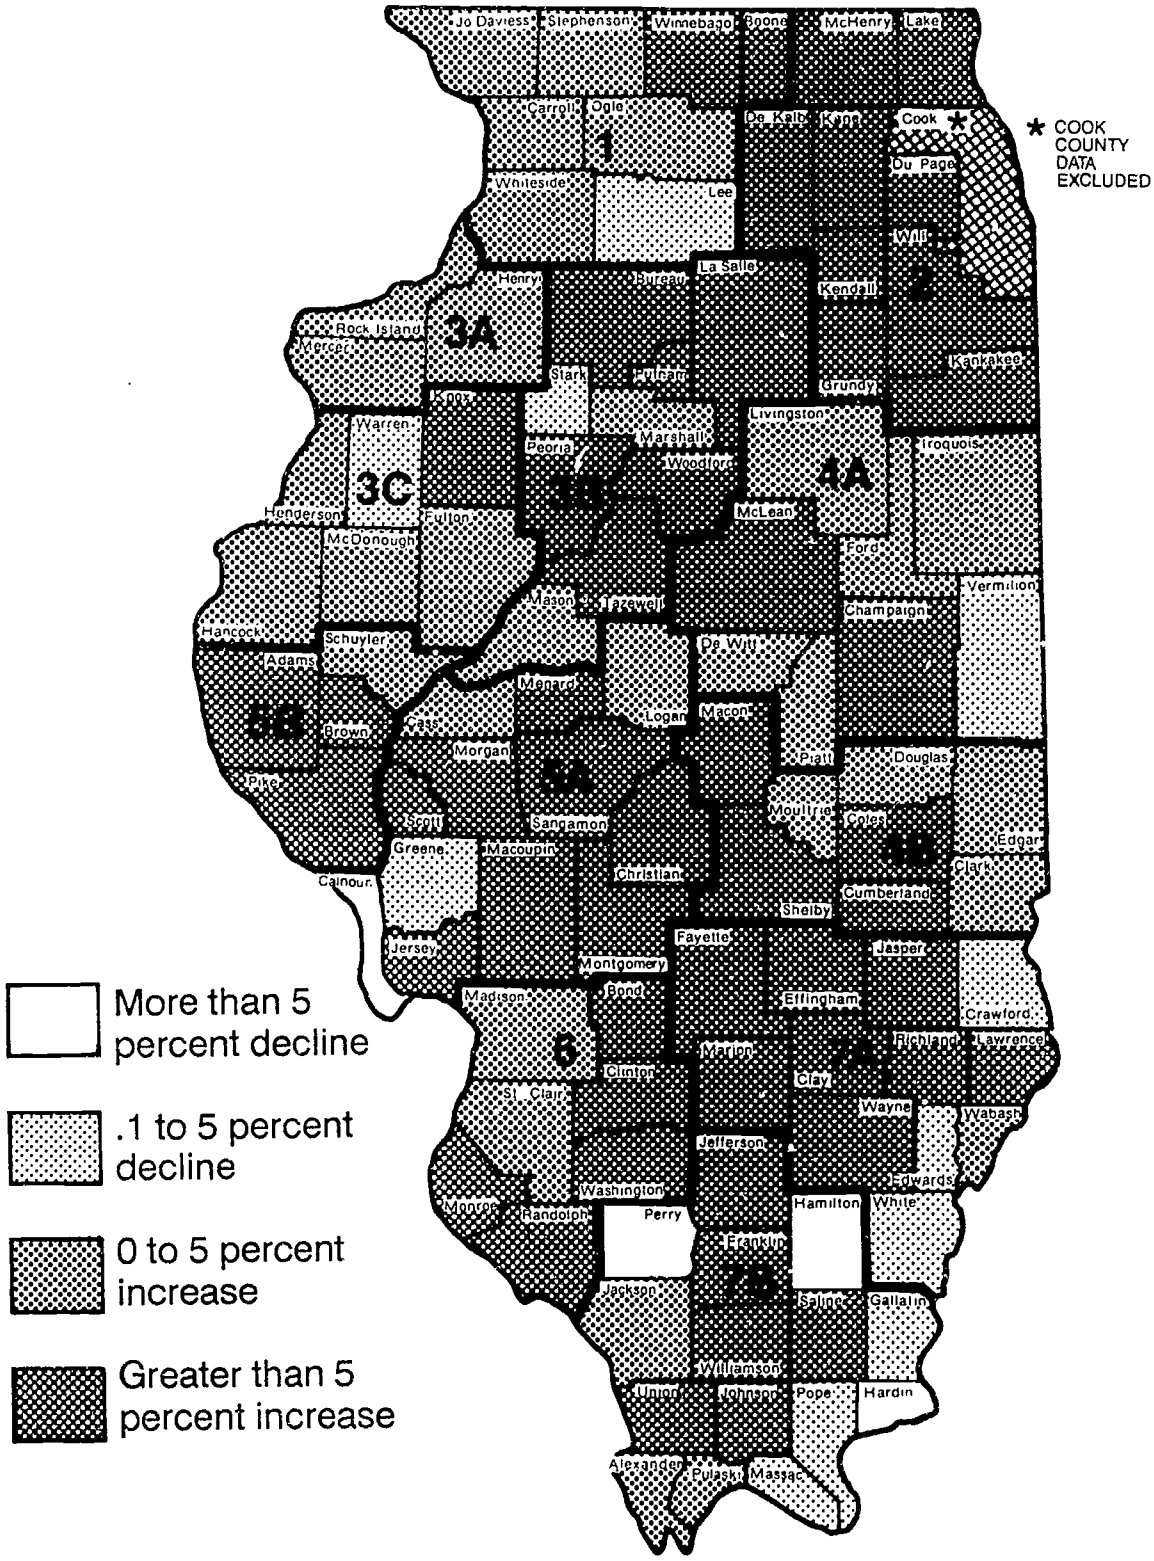
LONG-TERM EMPLOYMENT GROWTH, 1979-89

The Illinois economy has been producing jobs at a rate below the national average. Employment growth between 1979 and 1989 for Illinois was 12.3 percent compared to 18.3 percent for the nation. Since jobs are the primary source of income for most residents, Illinois communities are concerned about providing adequate job opportunities. There is particular concern in rural areas where there has been a decline in the employment base.

The variation among counties in long-term employment growth is striking. The collar counties of Chicago (area 2) again dominate. Employment in those counties grew at nearly 40 percent. These counties have thriving high-tech industries and business services. There was also moderate growth (greater than 10 percent) in portions of southwest areas 6 and 5A, mainly metro St. Louis and Springfield (Map 9). Much of Illinois was characterized by employment decline. Declines were especially severe in western Illinois, both in remote area 3C and mostly metro 3A and 3B (Rock Island/Moline and Peoria). The recession of the early 1980's brought serious economic decline to this region. The metro areas of western Illinois suffered from weakness in durable manufacturing, particularly farm machinery. In some remote communities, the industrial base has declined so severely that education and health care have become major employers. Eastern and southern Illinois were mixed, with some counties having declines, while neighboring counties had increases. Some of these counties have small employment bases so that a moderate change in the number of jobs has a large percentage effect.

Rural counties were at a dramatic disadvantage to metro counties in job creation. Metro counties gained 20 percent in jobs compared to declines of about 7 percent in rural areas. This is partly a consequence of employment reductions in rural manufacturing and growth in service sector jobs in metro counties. A decline in job opportunities is critical in explaining the loss of population in rural counties. Faced with long-term population and employment declines, some rural residents are worried about the very survival of their communities.

MAP 10. SHORT-TERM EMPLOYMENT GROWTH, 1979 - 89



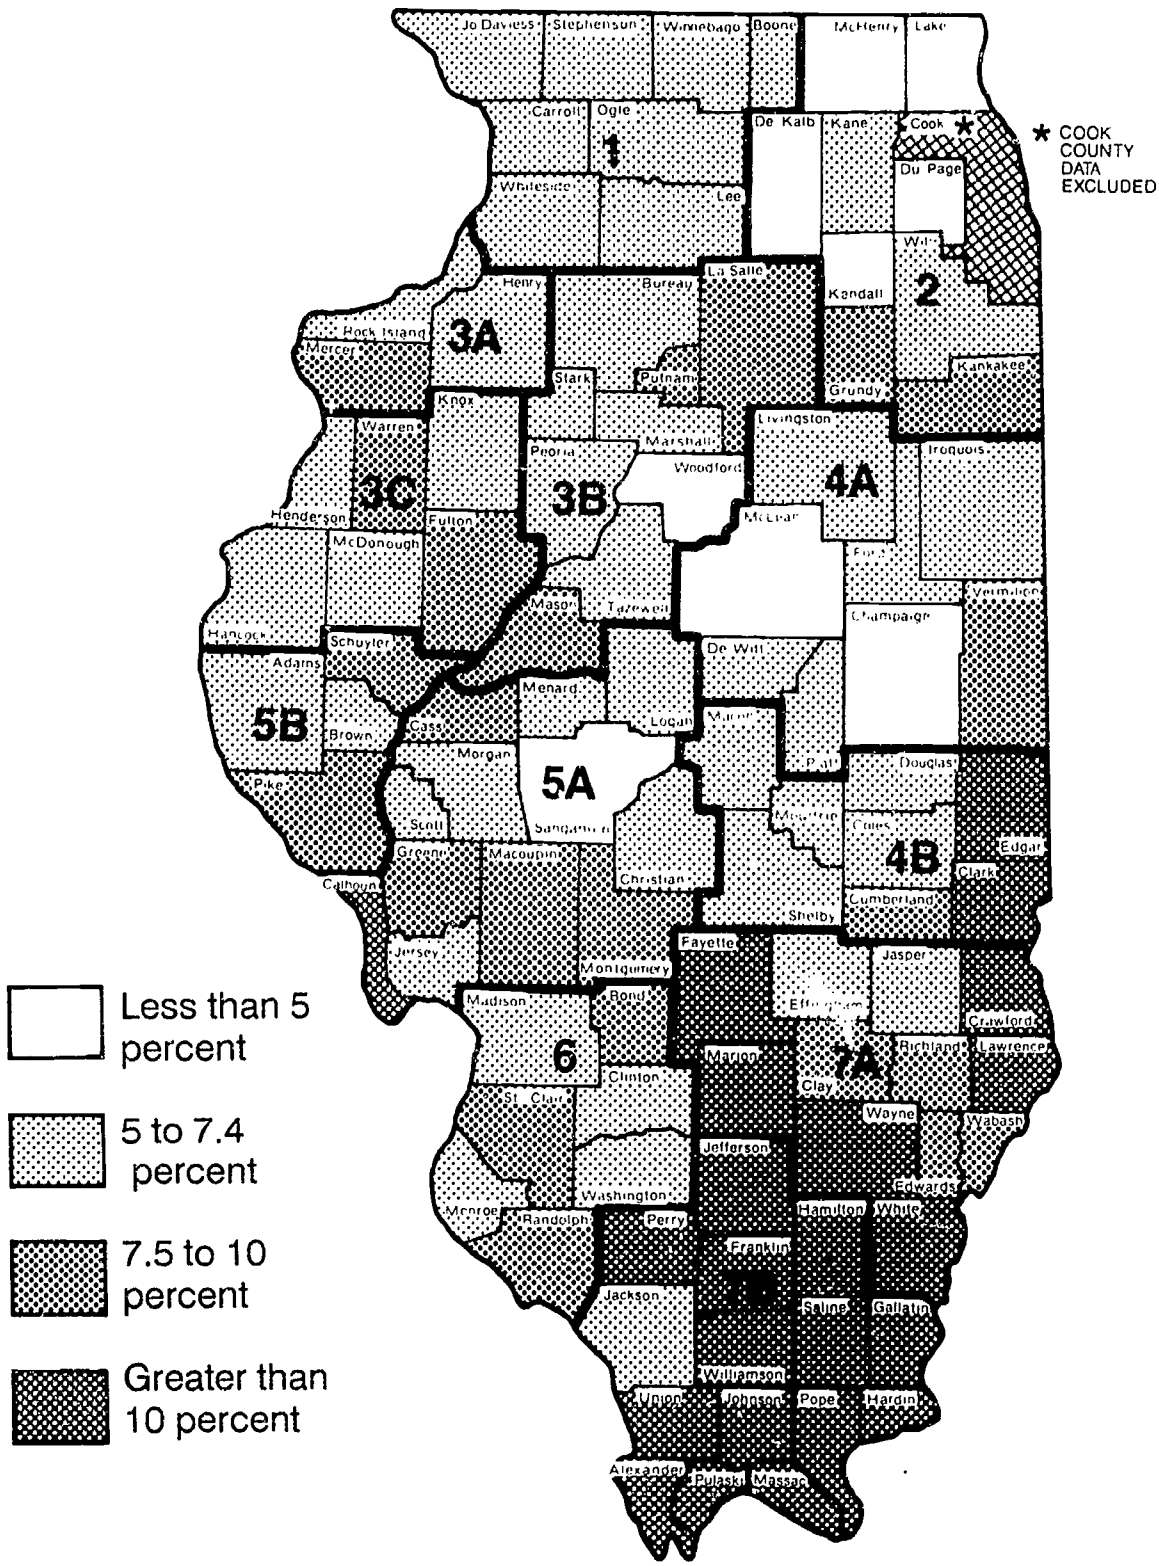
Source: *Illinois Labor Force Report*, Illinois Department of Employment Security, 1979, 1989

SHORT-TERM EMPLOYMENT GROWTH, 1987-89

During the 1987-89 period, the Illinois economy improved, evidenced by a 7.4 percent increase in jobs. As expected, the collar counties of Chicago have the highest rate of growth (Map 10). Some areas show a turnaround, with higher growth rates, on an annual basis, in the short-term. This includes the Peoria area (3B) and much of central and southern Illinois (areas 5A, 6, 7A, 7B). The growth of jobs in this wide area is a positive development. Statewide, only a few counties lost jobs during this time period.

The short-term trends suggest that employment is at least stabilizing in rural Illinois. The nearly 5 percent job increase in rural areas still lags metro areas, but may signal improved rural economic performance. Although job numbers have increased, there remains serious concern with the quality of jobs in rural areas.

MAP 11. UNEMPLOYMENT RATE, 1989



Source: *Illinois Labor Force Report*, Illinois Department of Employment Security, 1989

UNEMPLOYMENT RATE, 1989

The unemployment rate is a commonly used measure of economic distress. In 1989, Illinois had an unemployment rate of 6 percent, slightly higher than the national rate of 5.2 percent. Nationally, 1989 was a year of economic expansion. So counties with high unemployment rates in 1989 are not following the general business cycle, but rather are experiencing local difficulties.

As Map 11 shows, high unemployment rates are concentrated in the southern portion of the state (areas 7A and 7B). This area also has high rates of general assistance recipients (see Chapter 2). There are some areas of moderately high unemployment (7.5 to 10 percent) in southwestern Illinois (area 5A) and western Illinois. Most of the rest of Illinois has moderate to low levels. The collar counties of Chicago (area 2) have an average rate below 5 percent.

An attendant concern is the issue of underemployment, in which people are unable to find full-time jobs or jobs that are commensurate with their experience. It seems likely that underemployment is more acute in rural rather than in metro Illinois, although measures of the extent of underemployment are not readily available.

ECONOMIC BASE, 1987

Individual rural communities are small enough so they are unlikely to develop a broad, well diversified economy. Instead, communities tend to specialize in one, or several, economic activities. The economic health of a rural area is closely related to the performance of its key sector(s).

In this chapter, counties are classified into groups based on their degree of economic specialization. The industry of highest specialization is designated the county's economic base. The classification scheme is based on work by the U.S. Department of Agriculture, Economic Research Service.[1]

Map 12 shows the economic bases of Illinois counties. Manufacturing dominates the northern tier of the state. Mining and government are important in the southern counties. Farming is the base of some counties across the central portion of the state. Services are widely scattered.

Farming is the economic base of relatively few counties. More non-metro counties depend on manufacturing than natural resources (farming or mining) for their economic base. However, this analysis understates the importance of agriculture in that earnings from agricultural inputs (such as machinery purchases) or earnings by agricultural processing firms are not included in the farming category.

There are many ungrouped counties. Counties in this category are varied. Some may have well diversified economies, not easily classified. But for many, being ungrouped may be an indication of decline in their principal industry.

Definition of County Types

Farm Dependent - Annual average (over three-year period 1985-87) of farm income is 20 percent or more of total labor and proprietor's income in 1987.

Mining Dependent - Mining contributes 20 percent or more to total labor and proprietor's income in 1987.

Manufacturing Dependent - Manufacturing contributes 25 percent or more to total labor and proprietor's income in 1987.

Service Dependent - Service industries contribute 25 percent or more to total labor and proprietor's income in 1987.

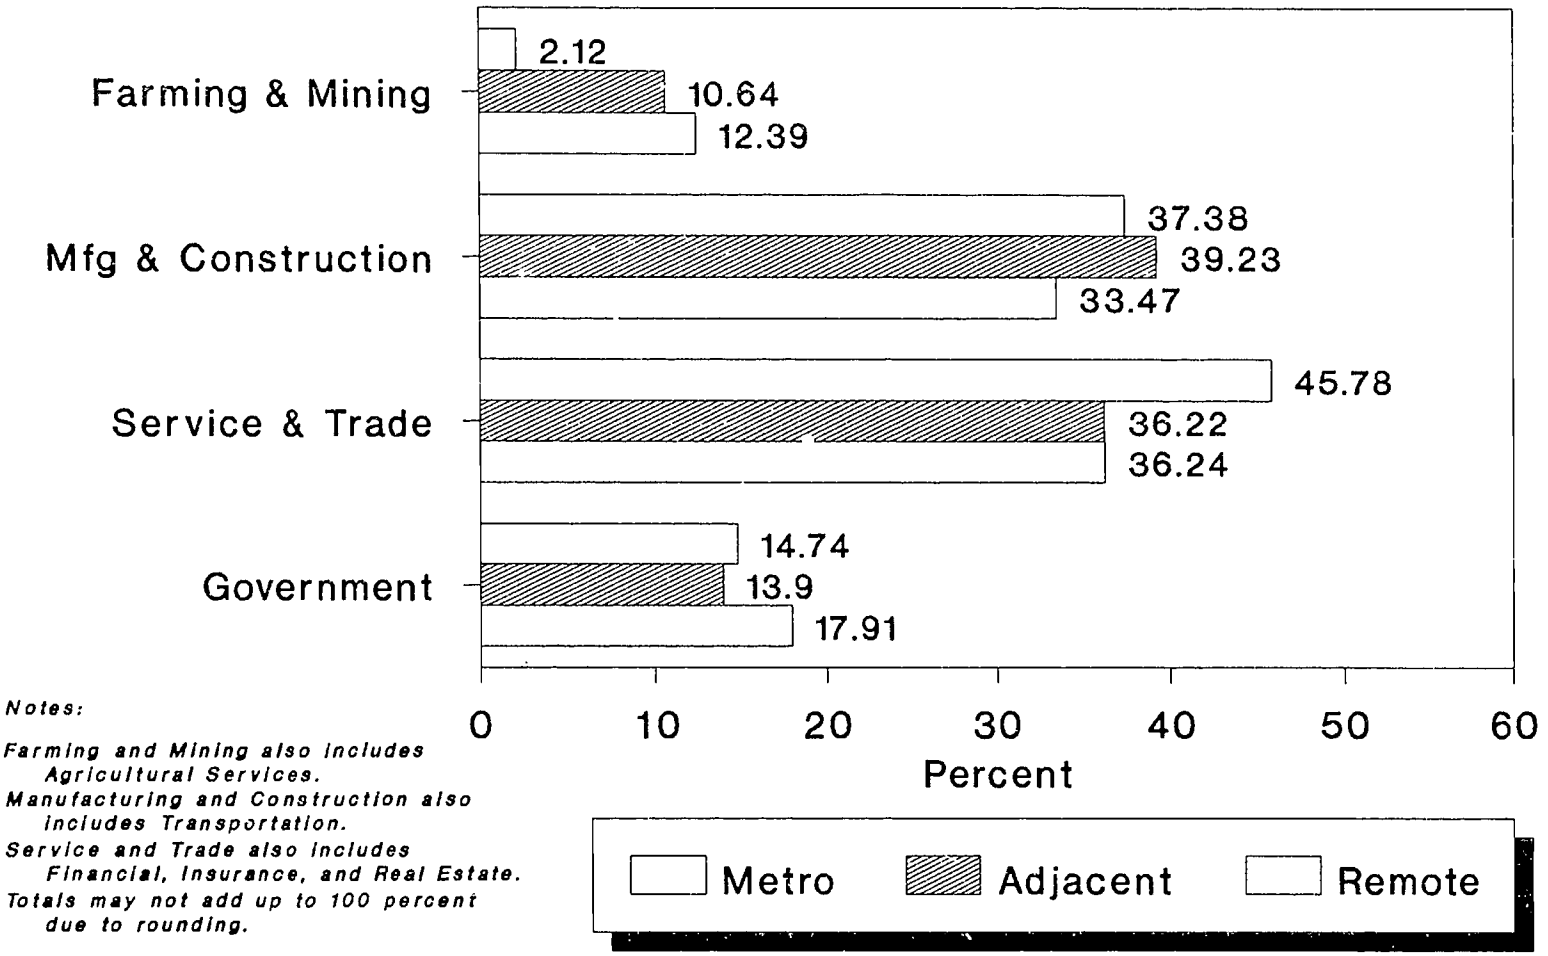
Government Dependent - Government contributes 25 percent or more to total labor and proprietor's income in 1987.

Ungrouped - The economy does not fit into any of the above categories.

Note: The only counties belonging to more than one category are Adams, Pulaski, and Sangamon. They are classified by the activity that contributes the most to total 1987 labor and proprietor's income.

[1] See Bender et. al. (1985). The major differences between their classification system and the one used in this report are: 1) the categories of federal lands, retirement, and poverty are not used here. Only Saline falls exclusively into one of these categories (retirement). 2) service is included as an additional category.

Figure 1. Industrial Structure, 1987
Percentage of Earnings by Major Sectors



Notes:

Farming and Mining also includes Agricultural Services.
Manufacturing and Construction also includes Transportation.
Service and Trade also includes Financial, Insurance, and Real Estate.
Totals may not add up to 100 percent due to rounding.

Source: Calculated from Local Area Personal Income, 1982-87, U.S. Dept. of Commerce.

INDUSTRIAL STRUCTURE, 1987

For generations the economy of rural Illinois was homogeneous, dependent on farming and other natural resource activities, such as mining. In the 1960's and 1970's, manufacturing and service industries expanded in rural Illinois and became critical to the economic health of many communities. Natural resource industries remained vitally important in many rural areas, but generally declined in importance.

Figure 1 compares the industrial structure of metro, adjacent, and remote counties in Illinois. Farming and mining are important in non-metro areas, but certainly are not dominant. In remote areas, most dependent on resource activities, farming and mining make up 12.39 percent of total earnings.

Manufacturing is important in rural areas; in fact, manufacturing and construction earnings are a larger fraction of total earnings in adjacent than in metro counties. Metro areas have larger service sectors than do non-metro areas. A broad definition of service is used in Figure 1 (included are wholesale trade, retail trade, and financial, insurance, and real estate). However, the major advantage of metro areas is in producer, personal, and professional services. The service sector is an area of growth in the economy. In fact, in the U.S. well over two-thirds of workers and self-employed are in service-producing industries. Rural counties must evaluate their potential to capture a larger share of this rapidly growing sector.

The government sector is acting as a buffer for non-metro counties. Remote counties have the highest percentage of earnings from the government. This is due, in part, to the location of universities and prisons in those counties.

Chapter 5 HUMAN AND FINANCIAL RESOURCES

High School Attainment, 1980

College Attainment, 1980

Bank Deposits per Capita, 1986

Human and Financial Resources, by County

Source:

U.S. Department of Commerce, Bureau of the Census, ***County and City Data Book***, Washington, D.C.; U.S. Government Printing Office, 1983 and 1988.

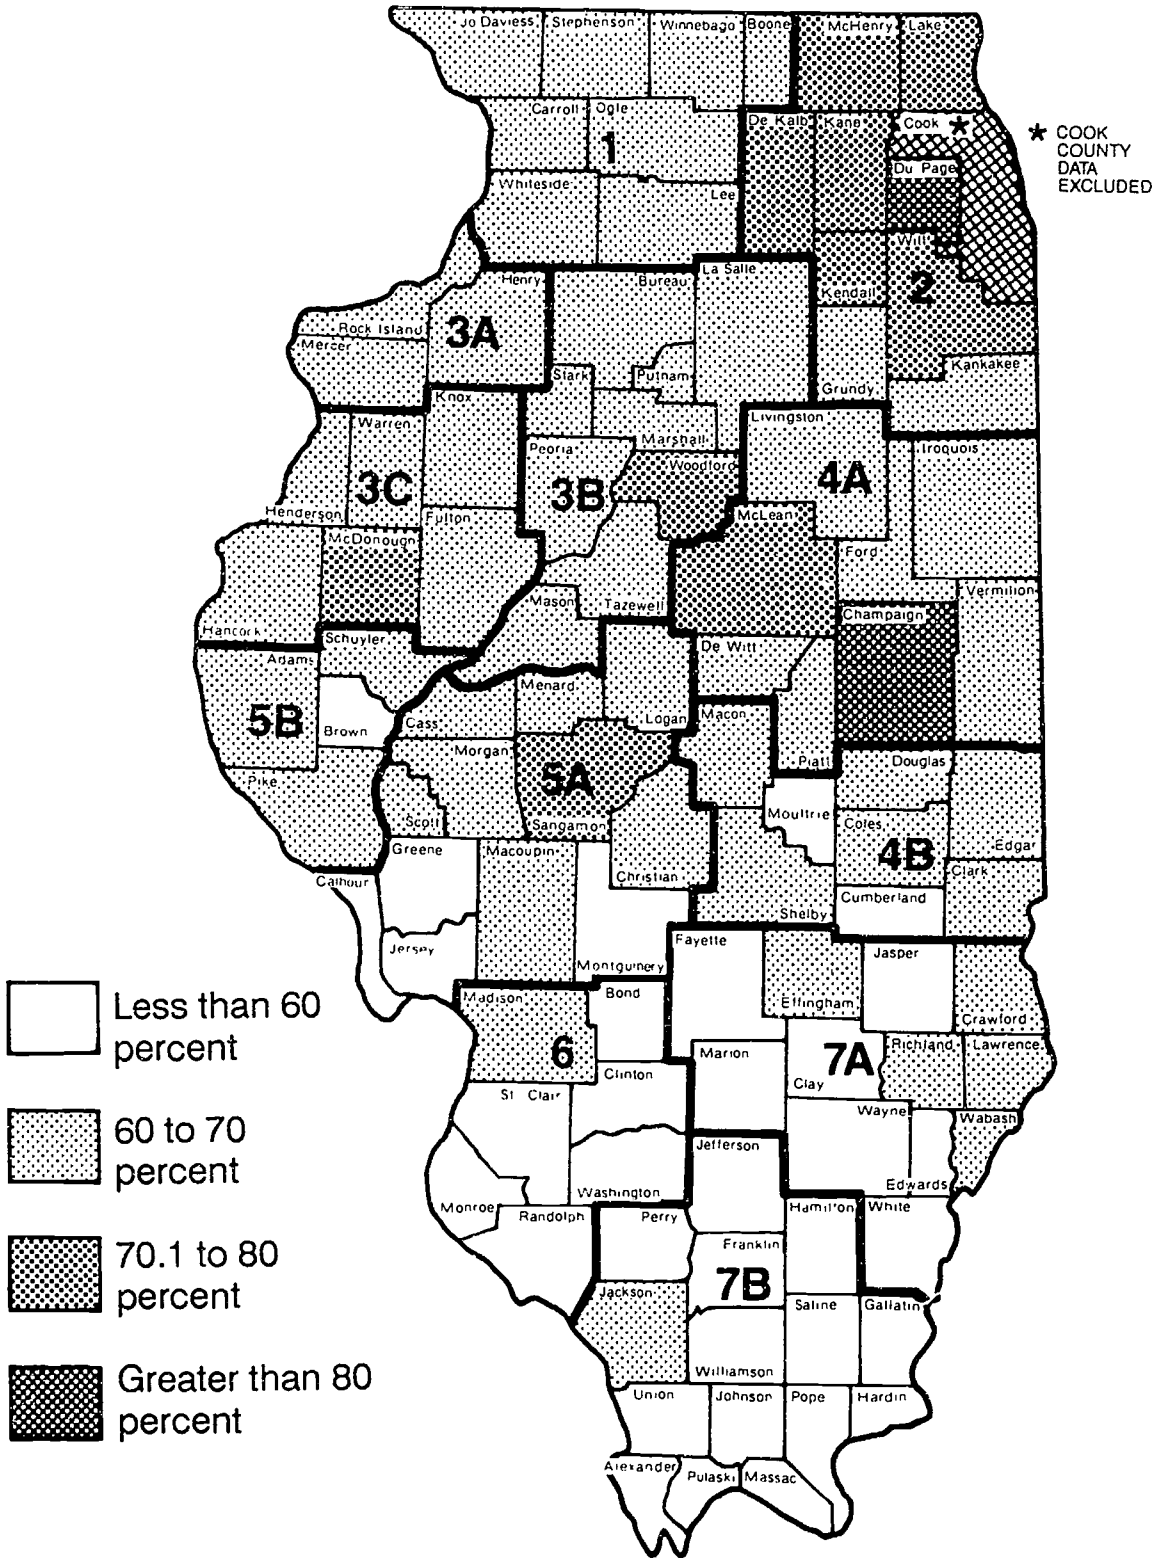
Definitions:

High school attainment is the percentage of persons 25 years of age or older who have completed at least 12 years of formal education.

College attainment is the percentage of persons 25 years of age or older who have completed at least 16 years of formal education.

Bank deposits includes deposits for all insured and reporting non-insured commercial and mutual savings banks.

MAP 13. HIGH SCHOOL ATTAINMENT, 1980



Source: *County and City Data Book*, U.S. Department of Commerce, 1983

HUMAN AND FINANCIAL RESOURCES

The availability of human and financial resources is critical to economic success in today's economy. Many rural areas are finding that natural resources alone do not make for economic development. Instead, businesses require a skilled and adaptable work force and capital for investment in business formation and expansion. The question faced by rural areas is whether they can compete on these terms with urban areas.

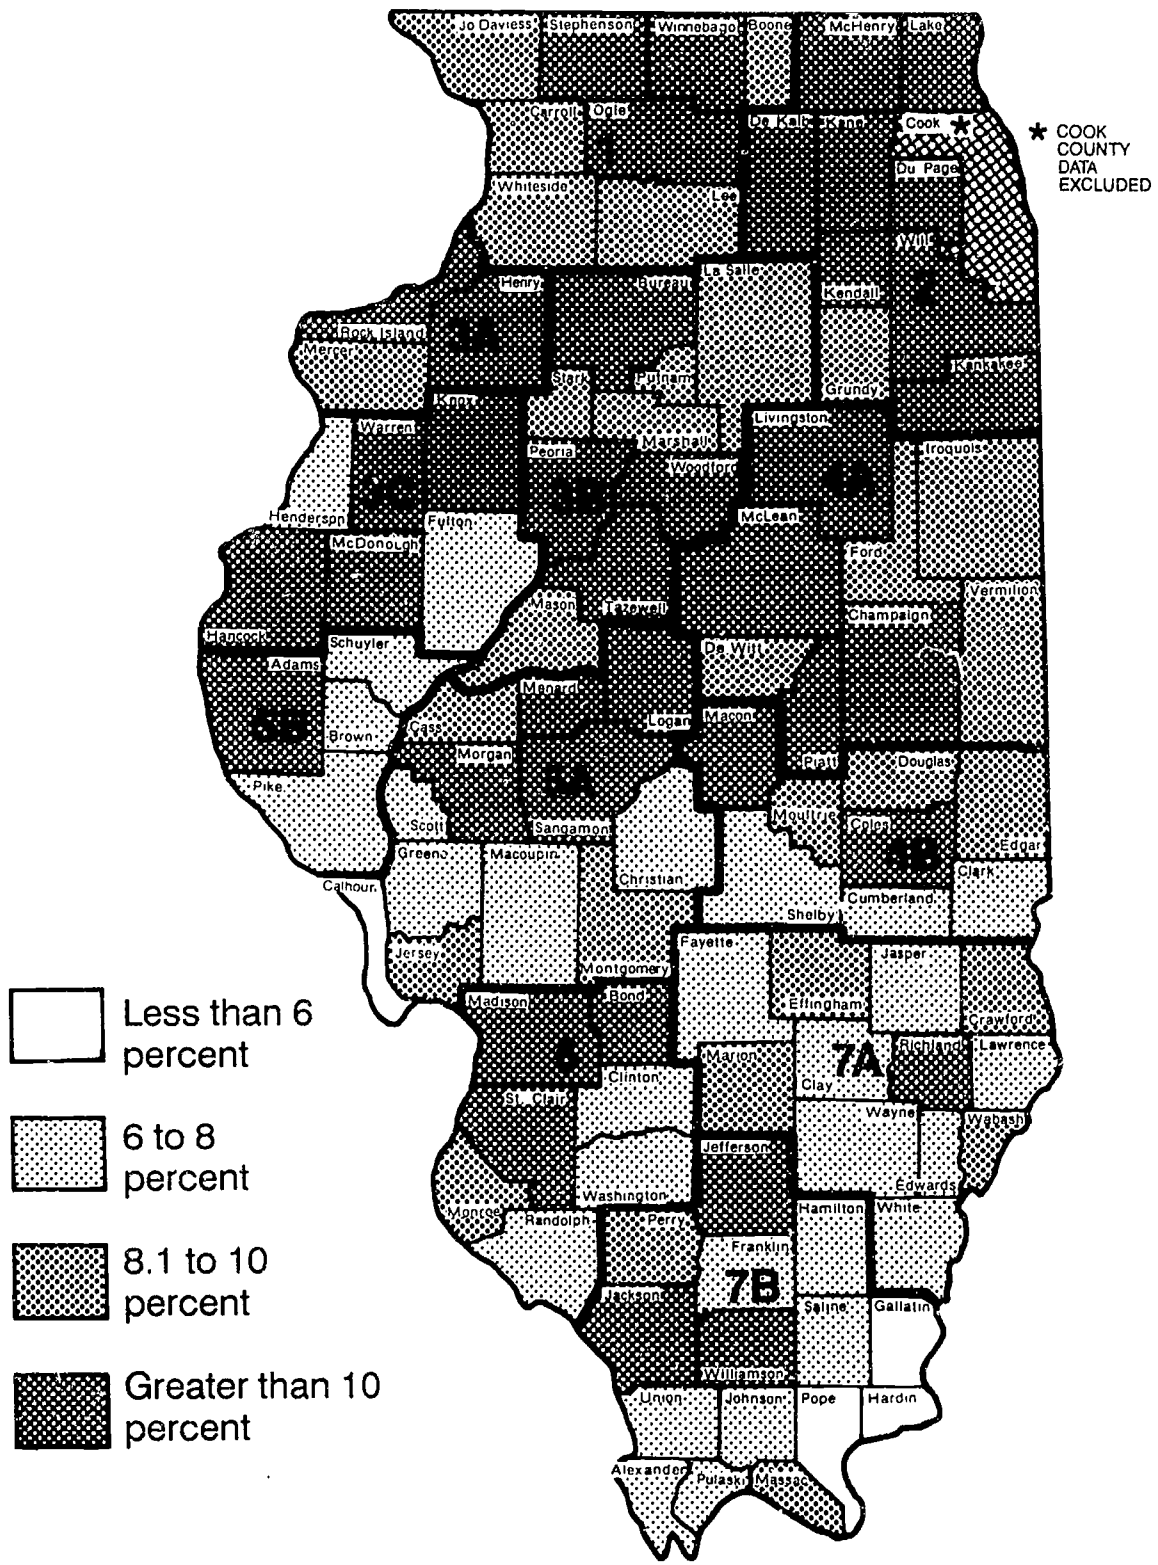
County-level measures of human and financial resources are limited. Two measures of educational attainment are presented, high school attainment and college attainment. The level of financial resources is measured by bank deposits per capita.

HIGH SCHOOL ATTAINMENT, 1980

High school attainment, the percentage of adults who have completed high school, is highest in the collar counties (area 2) and in several scattered counties, some of which are home to major universities (Map 13). A vast portion of southern Illinois (areas 6, 7A, and 7B) has low education levels, less than 60 percent of adults have a high school education. Certainly, this is a factor in limiting the attractiveness of the region for industry. The combination of low education, high unemployment, and low wages, all related, accounts for the poor incomes in the region.

Metro counties have a distinct advantage in high school attainment. This is partly due to migration of young persons from rural to metro areas. If the skill level of the labor force is essential to economic development, then investment in education and human capital is needed in rural areas. Unfortunately, the sparse population makes the cost of high quality educational programs relatively high.

MAP 14. COLLEGE ATTAINMENT, 1980



Source: *County and City Data Book*, U.S. Department of Commerce, 1983

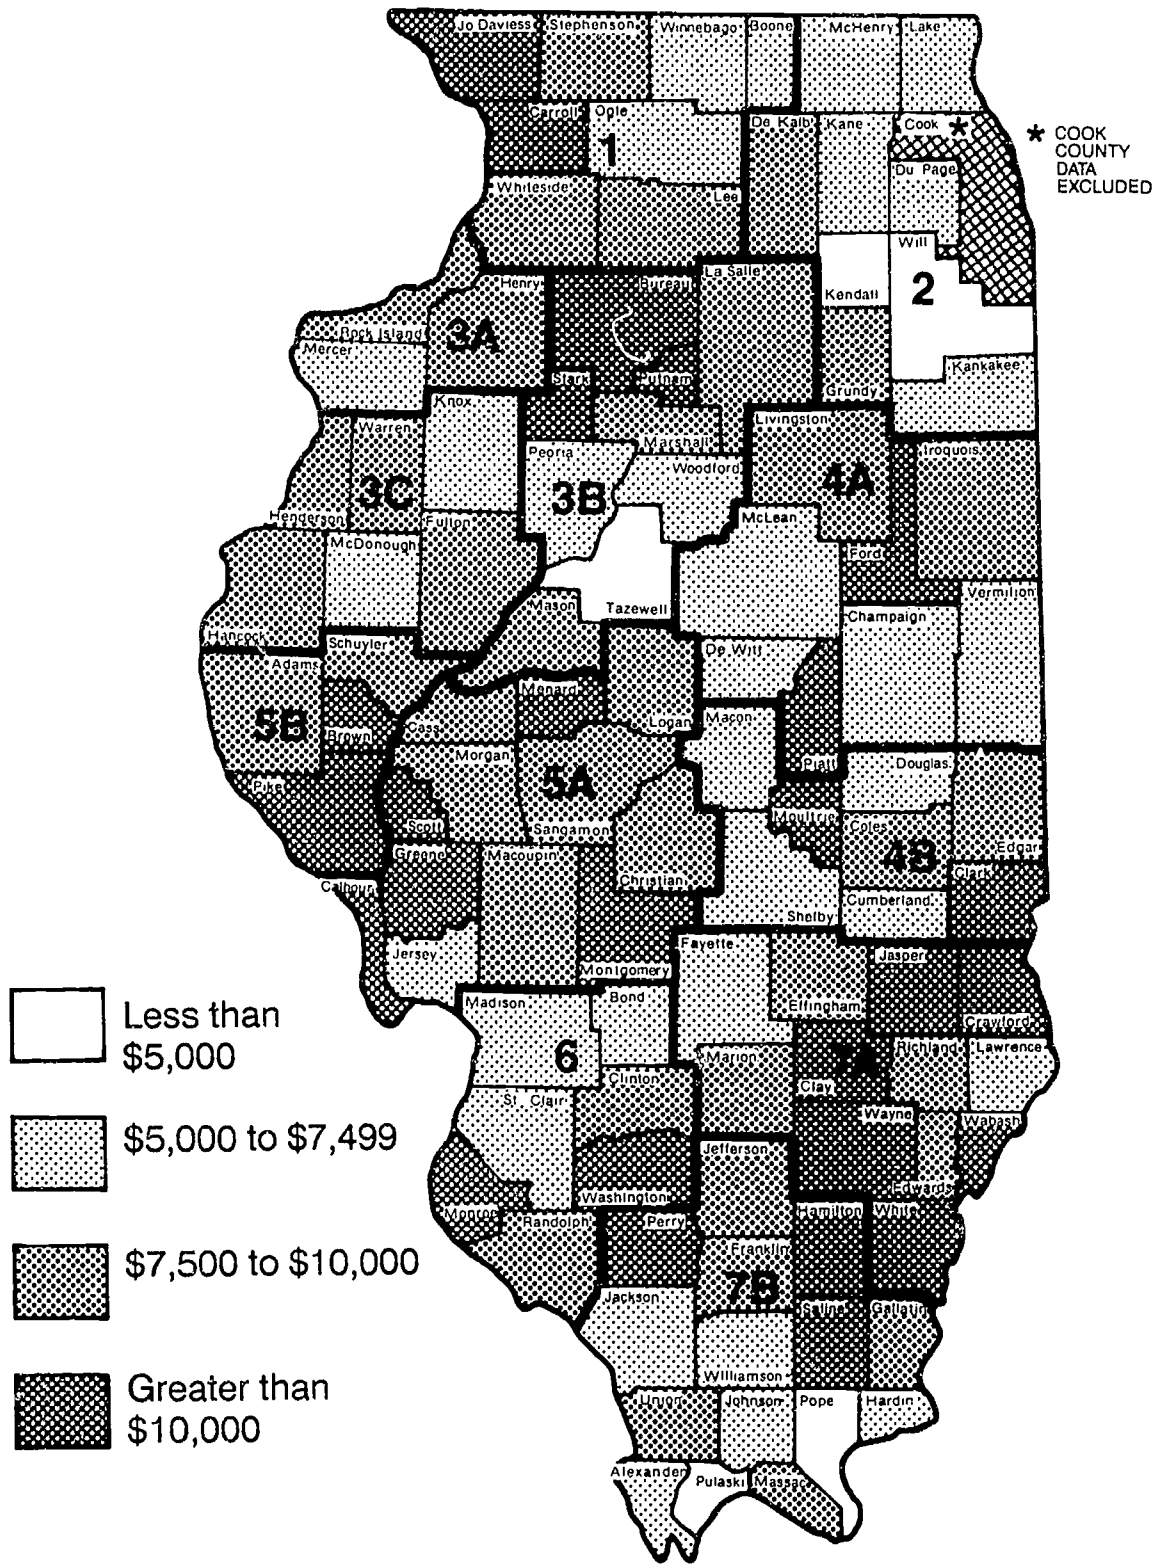
COLLEGE ATTAINMENT, 1980

College attainment, the percentage of residents who have completed college, is higher in northern and northeastern Illinois. Attainment is high in the collar counties of Chicago (area 2), areas near downstate cities, such as Rock Island/Moline, Peoria, Champaign-Urbana, and Springfield, and in counties near universities in western and southern Illinois (Map 14). Areas of low college attainment are found in some counties in southern Illinois.

The lagging educational levels of rural communities are apparent when college attainment is considered. Metro areas have about a 5 percent advantage in college attainment. Remote areas are slightly behind adjacent areas in this measure of human resources.

Part of this may have resulted from a "brain drain". Rural counties have high rates of out-migration (see Chapter 1). They lose some of their better educated residents to the metro areas. It is important not only that education be improved for rural residents, but that educated residents be retained in the community. To accomplish this requires attraction of industry and businesses that pay competitive wages. Unfortunately, however, these industries may require an educational level and population size not available in the relatively poorer counties.

MAP 15. BANK DEPOSITS PER CAPITA, 1986



Source: *County and City Data Book*, U.S. Department of Commerce, 1988

BANK DEPOSITS PER CAPITA, 1986

Capital for business investment is vital for the start-up and expansion of local businesses. Local banks are a primary source of loans for local businesses. The level of resources available for lending is measured by bank deposits per capita.

The results are unexpected. The collar counties of Chicago are found to have the lowest level of bank deposits per capita. Bank deposits are low in some areas of central and eastern Illinois. Some southern counties (in areas 7A and 7B) and southwestern counties (area 5B) show relatively high bank deposits per capita.

It seems unlikely that the collar counties are at a real disadvantage in capital availability. These puzzling findings suggest the inadequacy of this measure of financial resources. Since financial deregulation, there are many alternative instruments, such as money market funds, with similar features to bank deposits. It may be that urban residents and businesses make more use of these alternative instruments. Elderly people, who are more concentrated in southern Illinois, may prefer to hold their assets in more traditional form as bank deposits. Unfortunately, this explanation remains speculative without data on other financial instruments.

There is no evidence here that rural areas are at a disadvantage in the level of bank deposits per capita. On the contrary, levels are higher in non-metro than metro areas. The exclusion of Cook County likely is biasing the analysis. In any case, per capita deposits do not tell us how willing banks are to respond to credit needs of local businesses.

[2] U.S. Department of Commerce, Bureau of the Census, ***1987 Census of Governments***, Vol. 4, Government Finances, No. 5, Compendium of Government Finances, GC87(4)-5 Washington, D.C.: U.S. Government Printing Office, 1990, Table 51.

[3] Illinois Department of Revenue, calculations by Taxpayers Federation of Illinois, 1989.

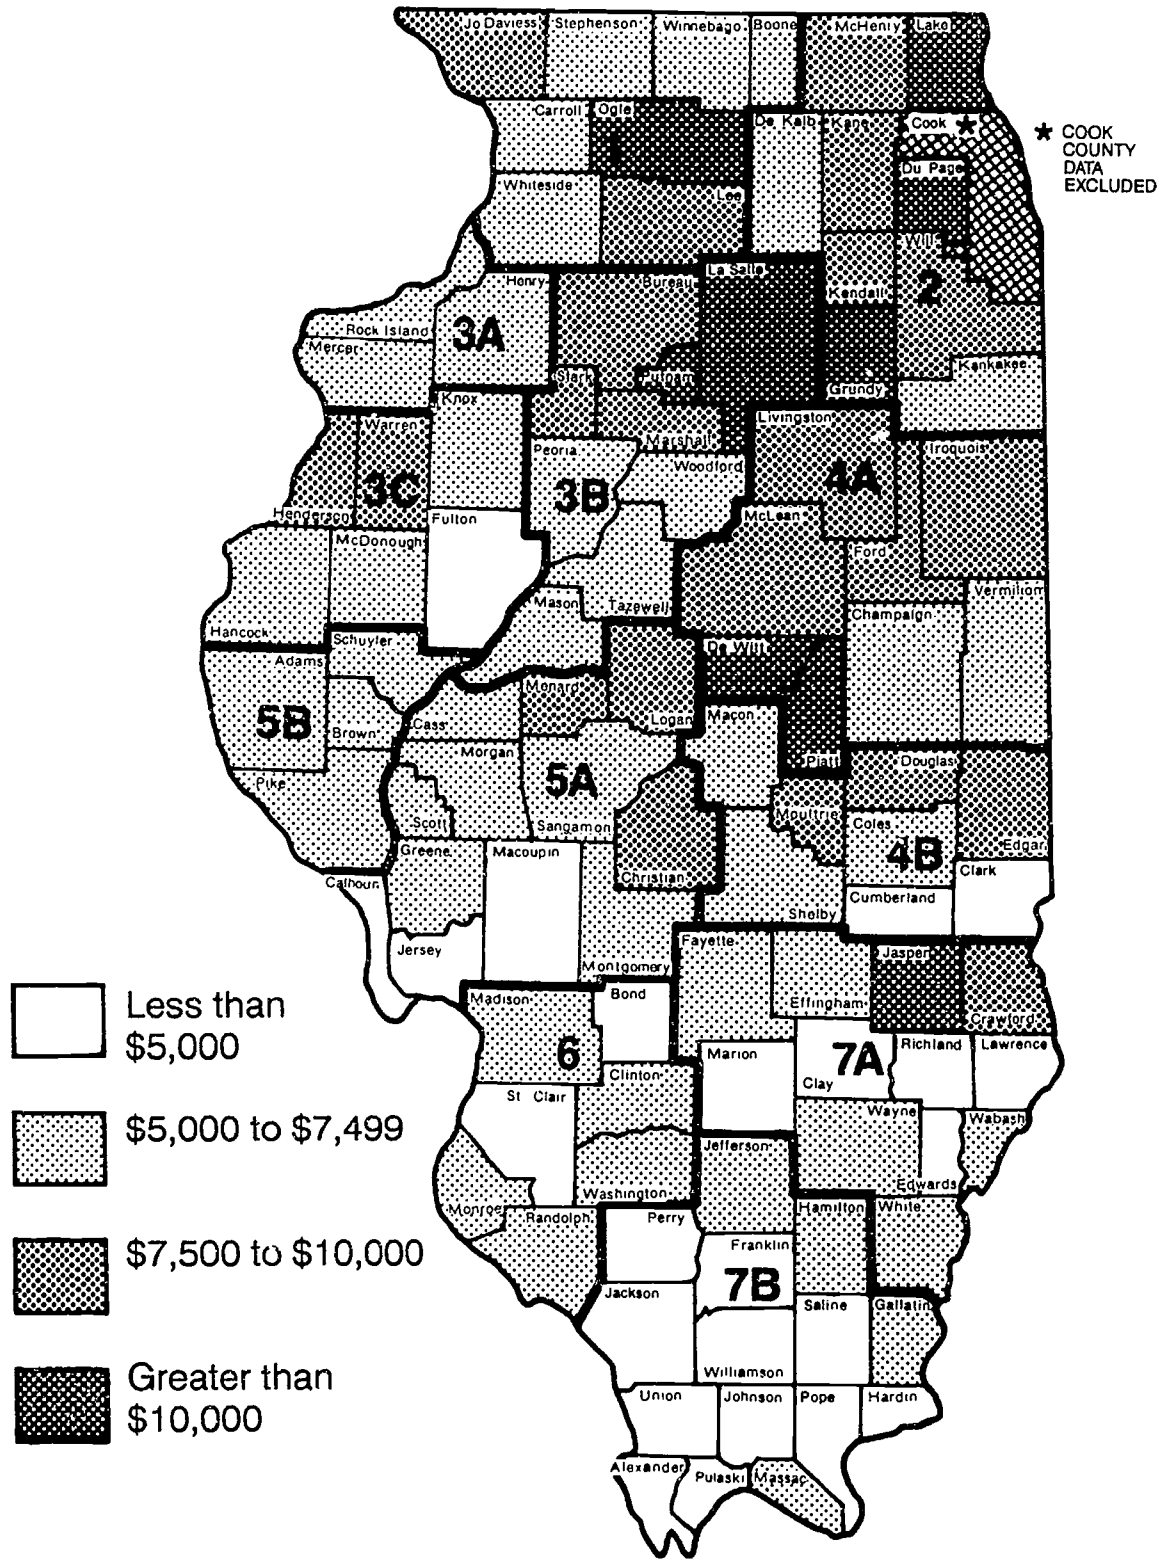
Definitions:

Assessed valuation is the value placed on property for tax purposes, after equalization.

Spending and tax data include amounts for all local governments, not only the county government but also any municipalities, townships, school districts, and special districts within the county.

57

MAP 16. ASSESSED VALUATION PER CAPITA, 1987



Source: Illinois Department of Revenue, Property Tax Tables, computer printout

LOCAL GOVERNMENT FINANCE

The system of local governments in Illinois is complicated. In 1987, there were 1,434 township governments in 87 counties. The remaining counties do not contain townships. In addition, 1,279 cities provide services independently from county governments. Special services are provided by 2,783 special districts including cemetery districts, mosquito abatement districts, and many created to meet special needs. Overlaying the entire system are 1,029 school districts.

This complex governmental structure complicates comparisons of local government finance. To simplify comparisons, several broad measures representing fiscal capacity (assessed valuation), spending, and revenues (property taxes) are used. The spending and tax measures are aggregated across all governmental units in the county.

ASSESSED VALUATION PER CAPITA, 1987

Assessed valuation is a measure of the local tax base; it suggests the capacity of local governments to provide services supported by local property taxes. Assessed valuation also serves as a comparative figure for the property wealth of a county. If assessed valuation is above average and increasing, it is an indication that the industrial and residential development in the county is healthy.

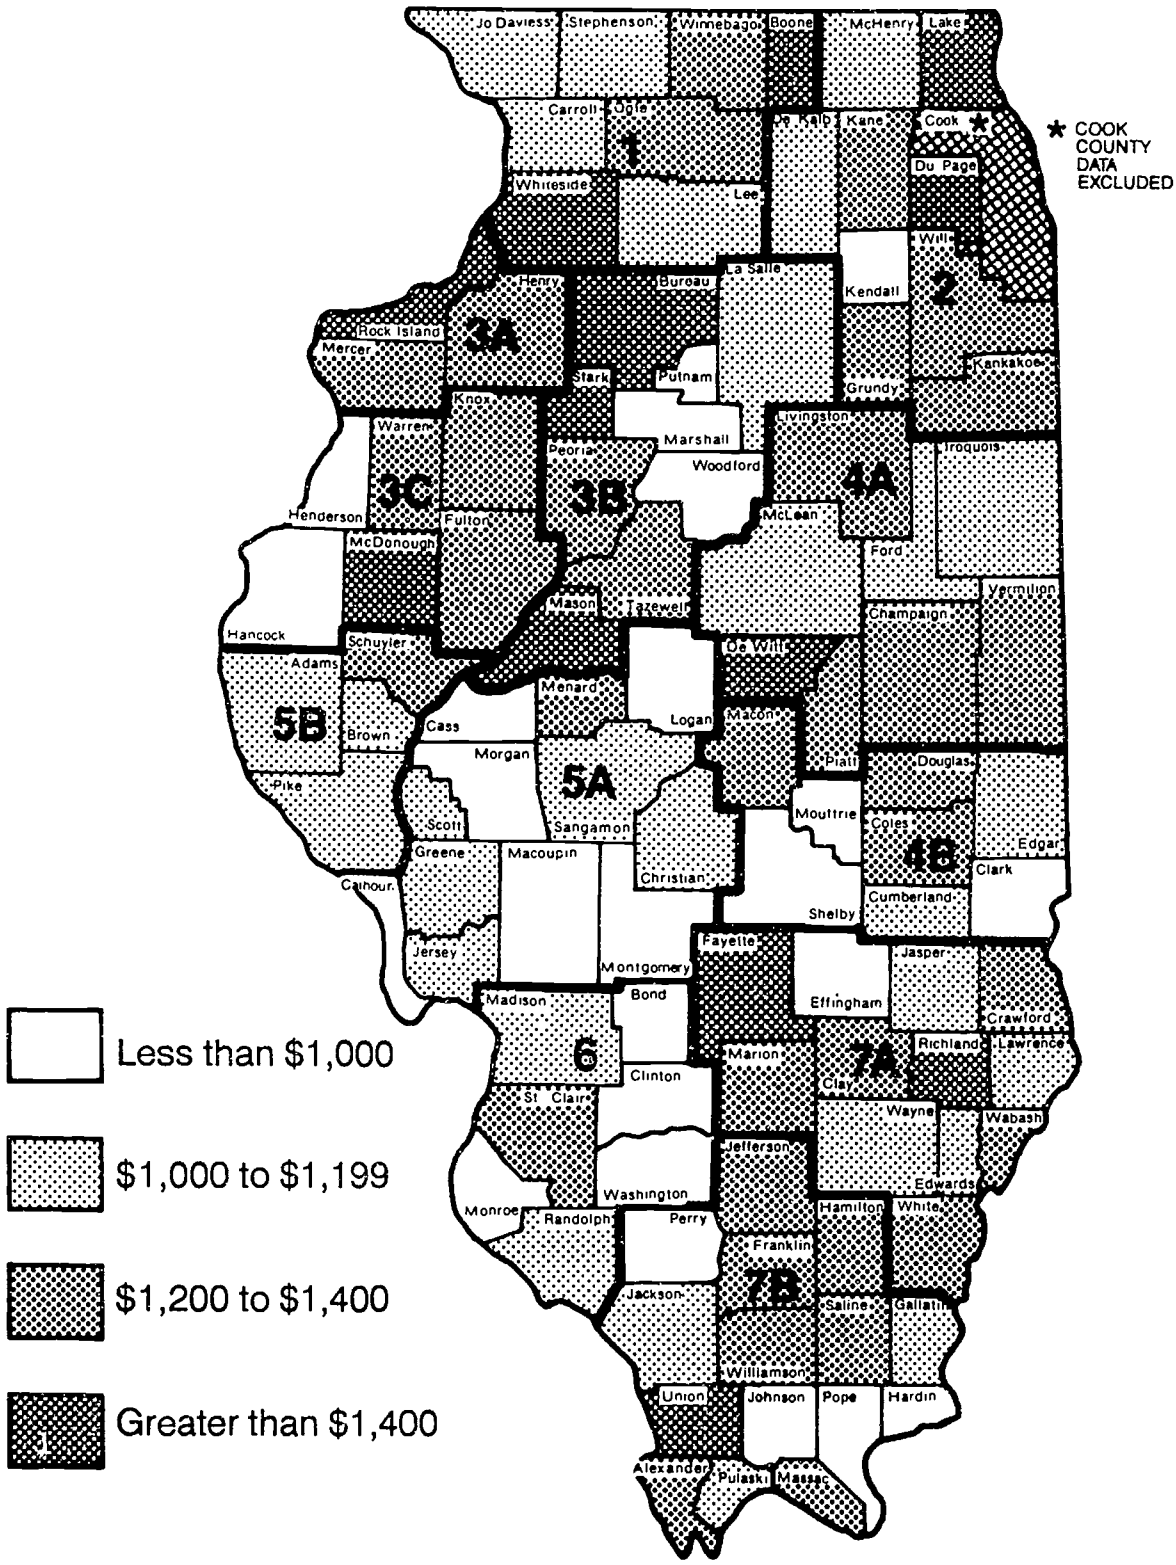
In general, assessed valuation per capita is highest in the north and declines as one moves south (Map 16). The highest levels are in the collar counties and other points in the northeast (area 2 and part of area 3B). However, not all metro areas have fared well. The industrial counties near Quad-Cities, Peoria, and Decatur have had assessed valuation decline in the 1980's. Those areas still have per capita assessed valuations higher than most southern counties (areas 7A and 7B).

The assessed valuations in the adjacent counties of Ogle and De Witt rose because of power plants. Including Ogle and De Witt counties, adjacent counties have a higher level of assessed valuation than metro counties. However, if Ogle and De Witt are excluded from the calculations, then metro counties value of $7,619 exceeds the value for adjacent counties of $6,881. The remote counties lag considerably, with an assessed valuation per capita of $5,452.

Not only are assessed values low in rural areas, but they are declining. A recent study by the Illinois Economic and Fiscal Commission found that, excluding Ogle and De Witt counties, assessed valuation declined by 12 percent between 1981 and 1987 in rural counties. This is due in part to out-migration from rural counties, the relatively poor performance of agriculture, changes in farmland assessment practices, and generally poor performance of rural economies.

59

MAP 17. LOCAL GOVERNMENT SPENDING PER CAPITA, 1987



Source: 1987 Census of Governments, U.S. Bureau of Census, 1991

LOCAL GOVERNMENT SPENDING PER CAPITA, 1987

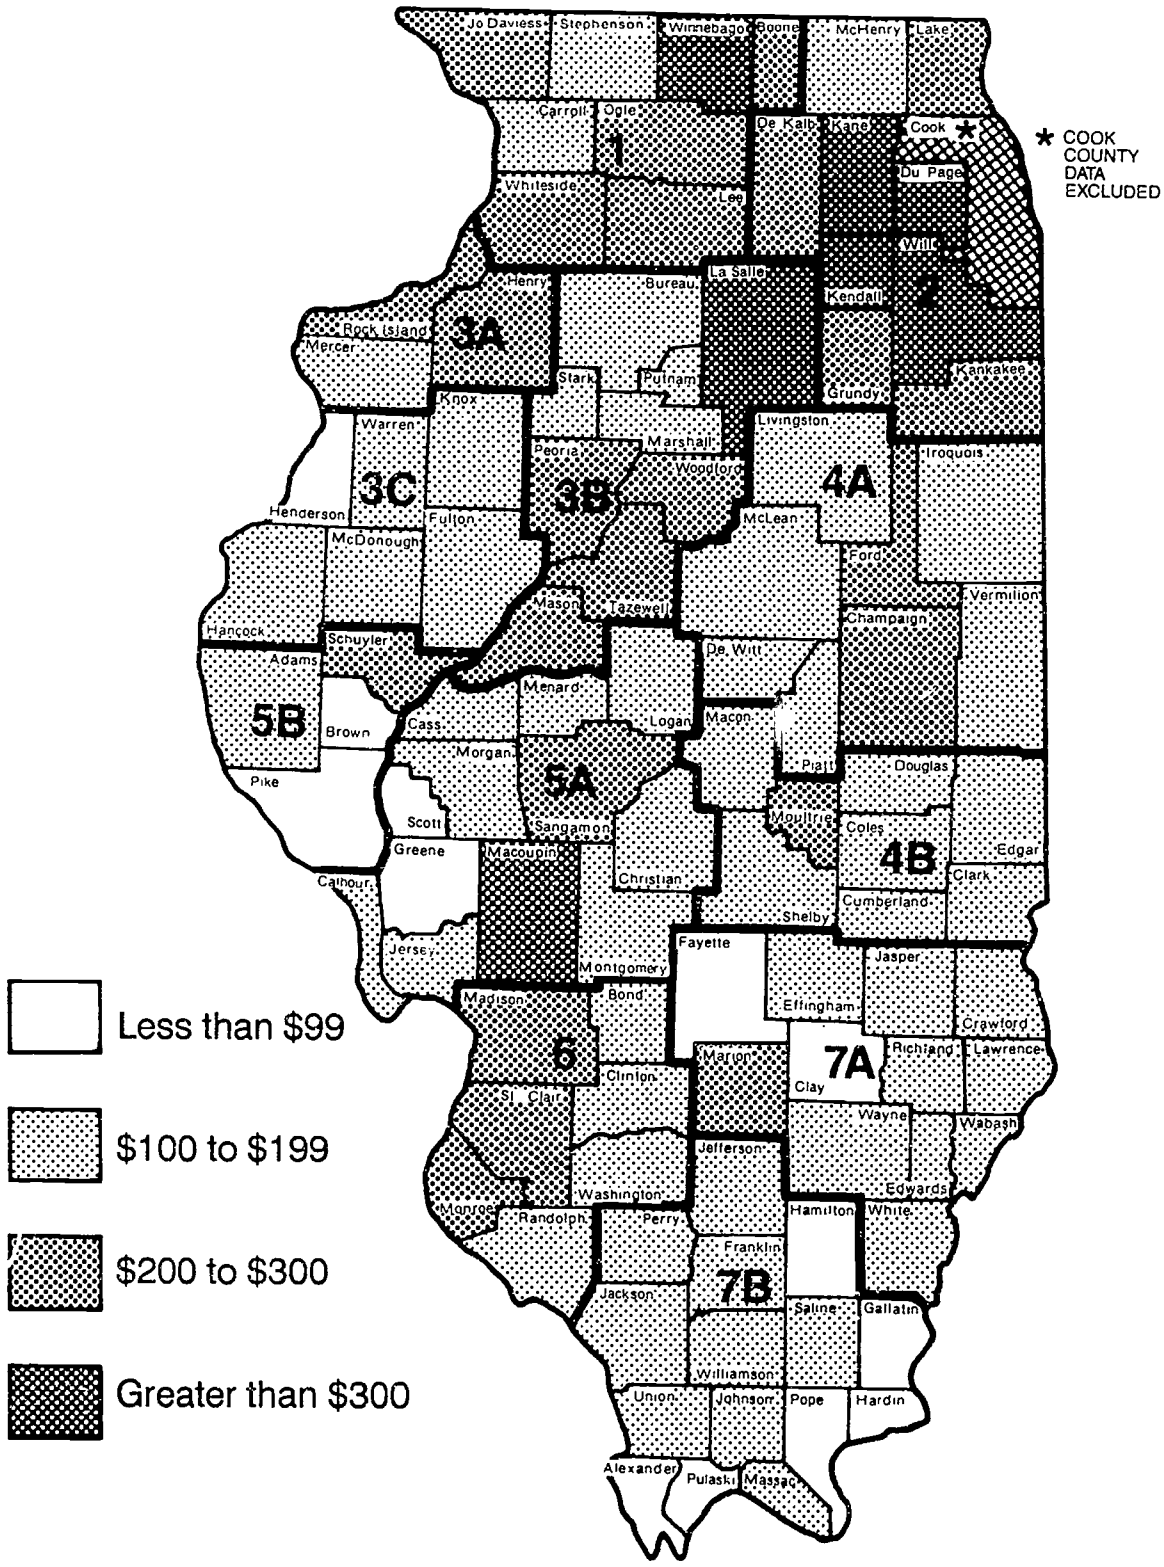
Local governments provide residents with services, such as road maintenance, general assistance, public safety, and recreation. The revenues to finance these services come from several sources, the largest source being the property tax.

There is less variation among counties in spending than in tax base. Also, as Map 17 suggests, there is no clear geographical pattern. Generally, combined local government spending is higher in some regions in northern (areas 1 and 2), western (areas 3A and 3C), and southern Illinois (areas 7A and 7B).

There seems to be little connection between tax base and level of spending. In fact, the southern counties generally have a low tax base and high levels of per capita spending. This implies that either the tax burden is high or that state and federal aid is substituting for local taxes. On the other hand, the collar counties have a high tax base, but expenditures only slightly above average. One explanation is that a certain level of government services must be provided, even for small populations. The smaller county population sizes in southern Illinois means that government expenditures are spread over a relatively small number of residents, yielding a higher per capita amount.

Total spending is not very different for rural versus metro counties. The type of spending may vary; for example, highway spending may be higher in metro counties, while public assistance is higher in rural counties.

MAP 18. PROPERTY TAXES PER CAPITA, 1987



Note: Property taxes are actually collected in the year following the tax year; e.g. 1987 taxes are paid in 1988

Source: Illinois Department of Revenue, calculations by Taxpayers Federation of Illinois

PROPERTY TAXES PER CAPITA, 1987

The main local revenue source in Illinois is a property tax on real estate. With recent changes in farmland assessments practices, rural counties experienced a substantial decline in the tax base against which property taxes are levied. Farmland is no longer assessed based on market value; rather the assessment is based on soil productivity. Only dwellings are based on market value. These revisions were requested by the agriculture community in response to relatively high property taxes compared with incomes during the early 1980's. The obvious outcome was restraint of property tax increases or, in some cases, declines. Even though some relief was spaced over several years, governments relying heavily on property taxes faced fiscal restrictions.

The regional pattern of property taxes is similar to that of assessed values (Map 18). Taxes are at higher per capita levels in the northern counties, particularly the collar counties, and decline as one moves south. Counties near the downstate cities of Peoria, the Quad-Cities, Springfield, and East St. Louis have fairly high per capita taxes. Peoria and the Quad-Cities have had declining assessed values in recent years, so the tax burden is high. Pockets of low taxes are found in the southwestern (areas 5B and 5A) and far southern (area 7B) corners of the state. Considering the low assessed valuations is some southern counties, even moderate taxes may be a burden.

Metro counties have higher property taxes than non-metro on a per capita basis. However, this gives no indication of the tax load, since it does not relate taxes to ability to pay, either wealth or income.

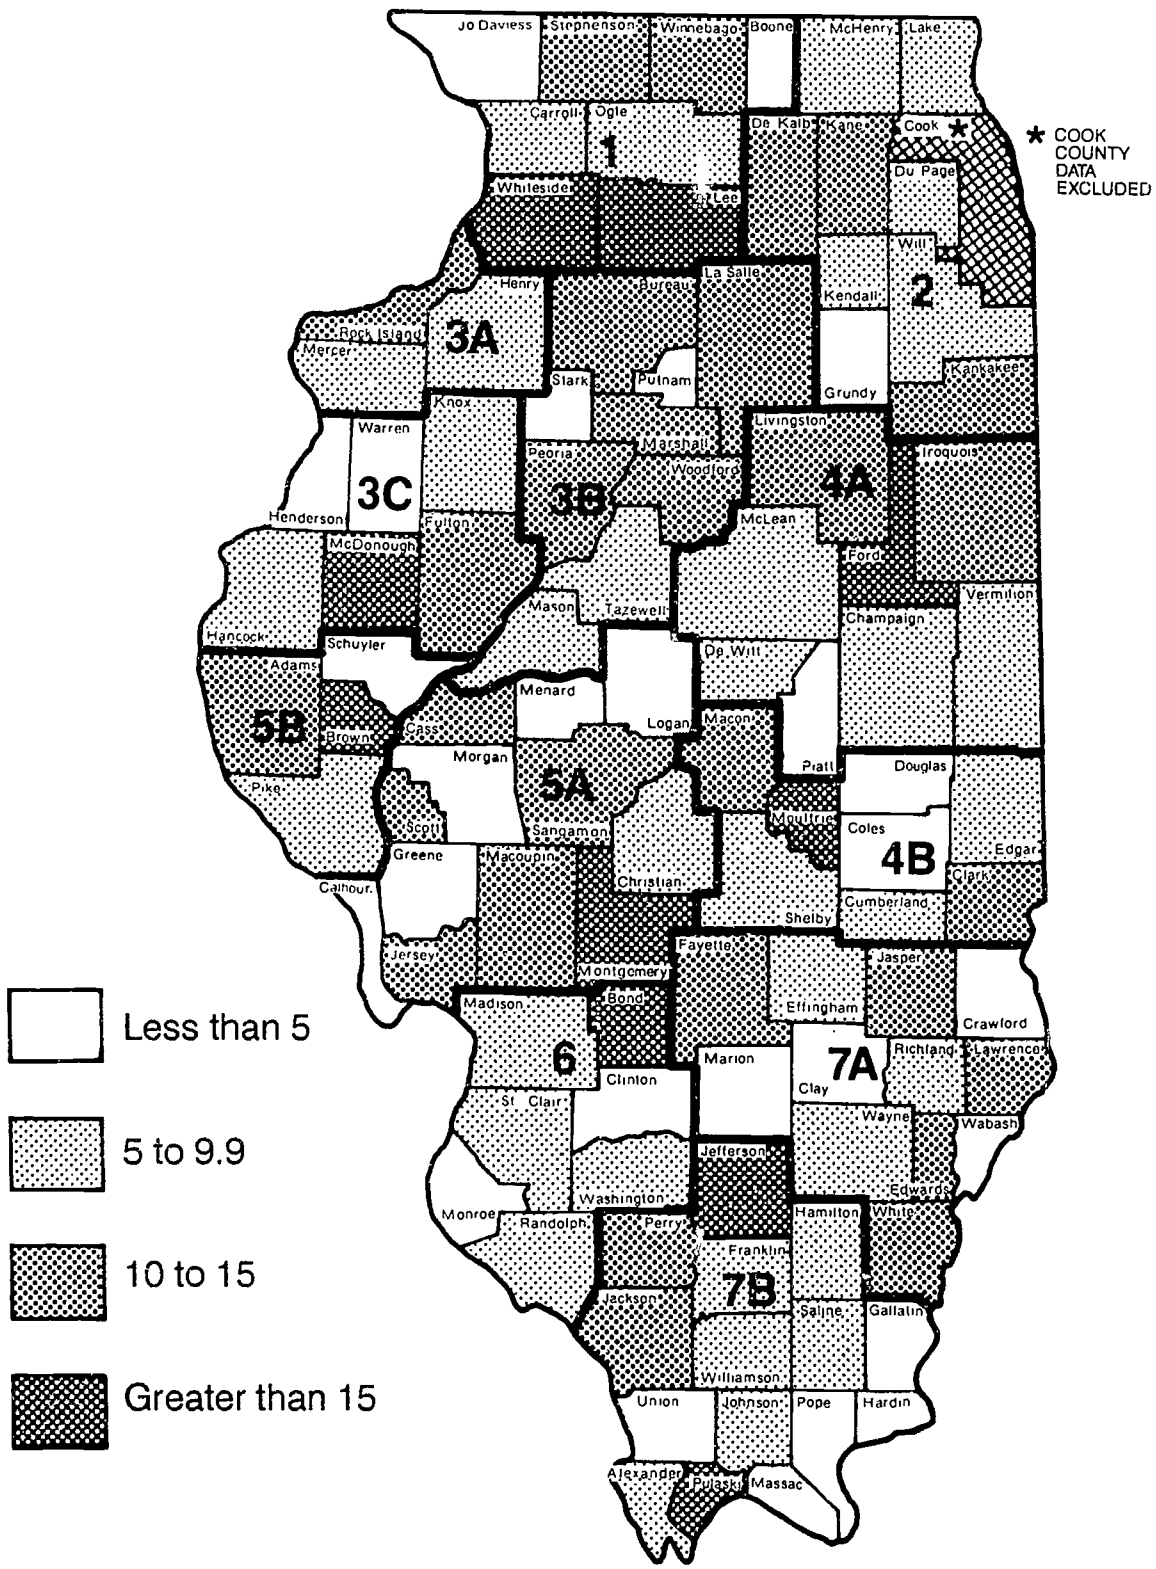
Definitions:

Infant mortality is the death of infants under one year of age.

The number of physicians represents the distribution of non-Federal physicians with known addresses who are professionally active.

Crimes include seven offenses which because of their seriousness, frequency of occurrence, pervasiveness in all geographic areas of the country, and likelihood of being reported to police, were initially selected to serve as a Crime Index.

MAP 19. INFANT MORTALITY PER 1,000 BIRTHS, 1987



Note: Infant mortality is death of infants under one year of age

HEALTH AND SAFETY

The well-being of rural residents is not described solely by economic measures. To provide for their residents, communities must develop an extensive infrastructure, which includes health care, education, and physical facilities such as roads, hospitals, and schools. The development of infrastructure, such as electrification and the interstate highway system, historically has broken the isolation of rural areas and facilitated economic development.

Measures of education were presented in Chapter 5. In this chapter, health and safety measures are presented.

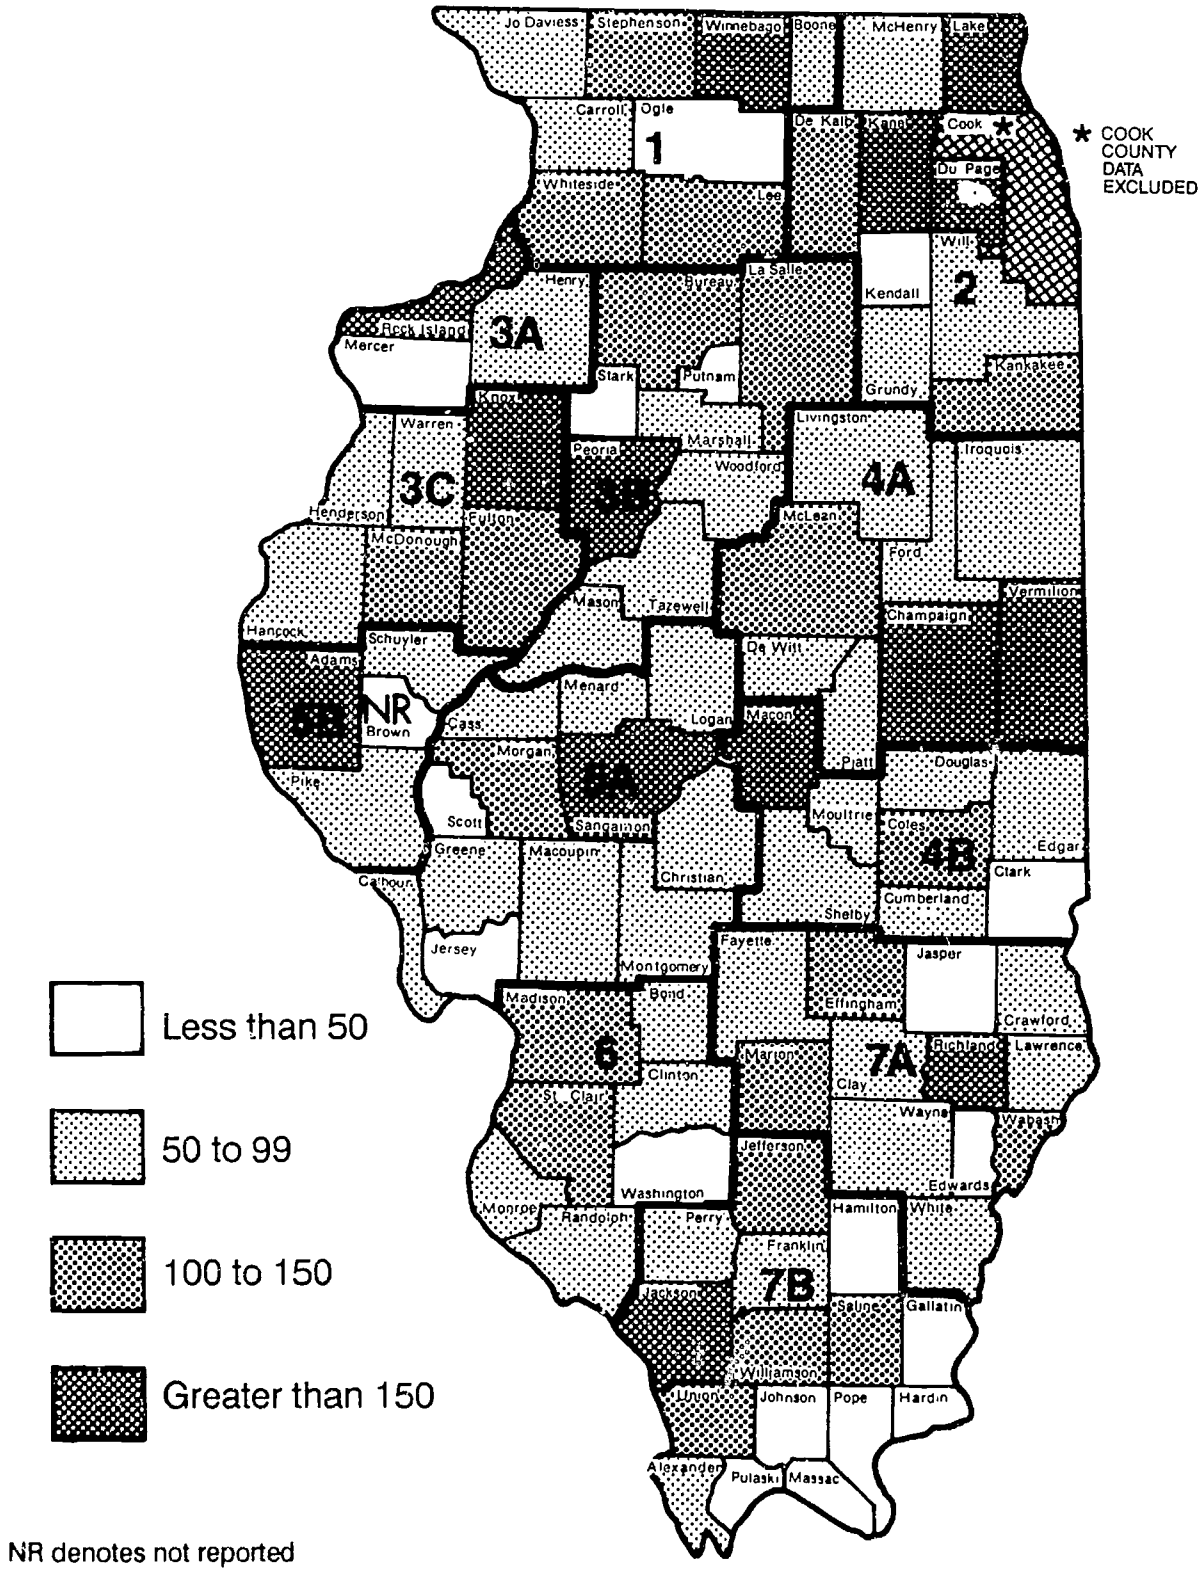
INFANT MORTALITY, 1987

Rising infant mortality rates have become a national concern. While medical technology advances during the 1970's lowered the infant mortality rate significantly, rates have increased in the 1980's. The lack of prenatal care and drug use by mothers are important reasons.

Relatively high rates of infant mortality (more than ten per 1,000 births) are found throughout the state (Map 19). In small counties, with few births, the infant mortality rate can fluctuate considerably from year to year. No clear geographic pattern emerges. High rates are found in remote counties (e.g., McDonough, area 3C, and Lee, area 1) as well as in metro counties (Peoria, area 3B, and Kane, area 2). Higher rates in poverty counties were expected, but that isn't the case.

Infant mortality rates are slightly higher in rural compared to metro counties. The metro/rural comparisons would be greatly affected if Cook County was included. The infant mortality rate was 22.2 in Cook County in 1987.

MAP 20. PHYSICIANS PER 100,000 POPULATION, 1987



NR denotes not reported

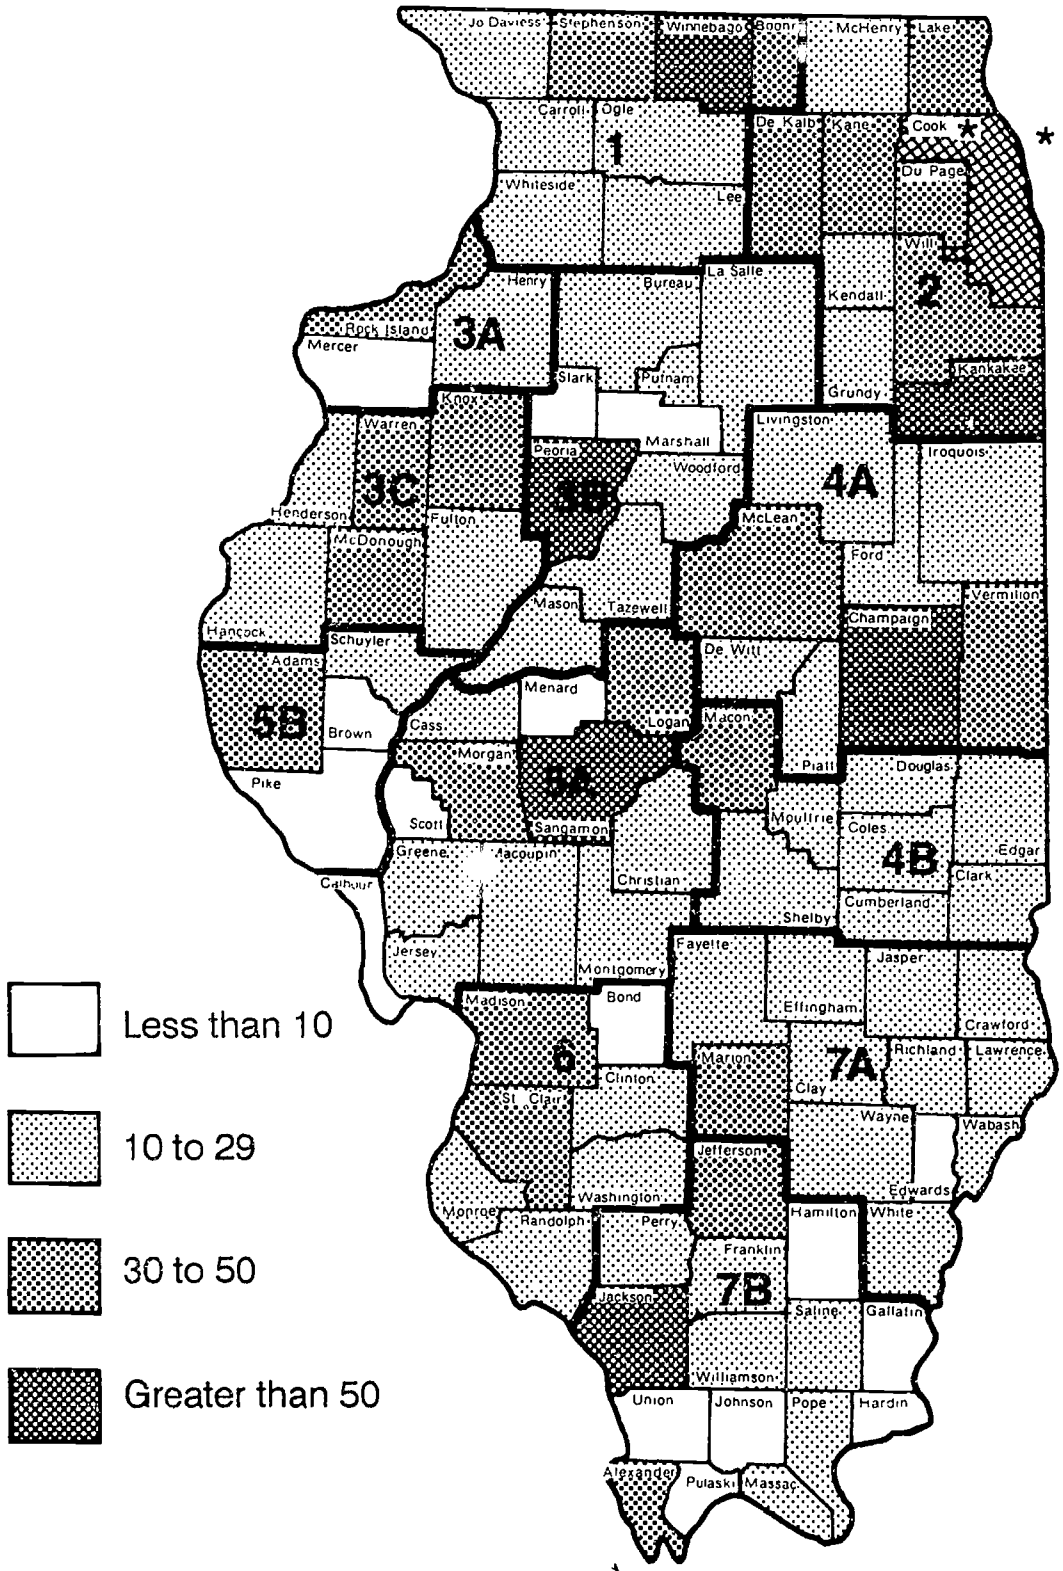
Source: *Physicians Characteristics and Distribution in the United States*, American Medical Association, 1987

PHYSICIANS, 1987

Physicians per 100,000 population are used as a measure of doctor availability. Counties near cities, including Chicago, the Quad cities, Peoria, Champaign-Urbana-Rantoul, Decatur, and Quincy are heavily favored (Map 20). Regionally, the southern half of the state is at a disadvantage.

Metro areas have many more medical doctors, even after adjusting for population. The numbers for remote and adjacent counties, when adjusted for population, are nearly equal. Access to health care is becoming a major concern in rural areas. Along with fewer doctors, rural areas also face nursing shortages and local hospital closings. Residents in remote counties have to travel a considerable distance for medical care.

MAP 21. CRIME RATES PER 1,000 POPULATION, 1985



Note: Crimes are defined as serious crimes known to police

Source: *County and City Data Book, U.S. Department of Commerce, 1988*

CRIME RATES, 1985

Crime rates are higher in metro counties, including the collar counties of Chicago, and those counties near Rockford, Peoria, the Quad cities, Springfield, and St. Louis (Map 21). Extremely low rates are more likely in the southern part of the state.

The crime rate is about twice as high in metro areas, compared with rural areas. Crime is associated with many urban problems, such as slums and drug trafficking. This is one "quality of life" indicator that strongly favors rural areas.
