ABSTRACT

In 1990, the National Assessment of Educational Progress (NAEP) included a Trial State Assessment (TSA); for the first time in the NAEP's history, voluntary state-by-state assessments were made. The sample was designed to represent the 8th grade public school population in a state or territory. In 1996, 44 states, the District of Columbia, Guam, and the Department of Defense schools, took part in the NAEP state science assessment program. The NAEP 1996 state science assessment was at grade 8 only, although grades 4, 8, and 12 were assessed at the national level as usual. The 1996 state science assessment covered three major fields: earth, physical, and life sciences. In Oregon, 2,275 students in 100 public schools were assessed. This report describes the science proficiency of Oregon eighth-graders, compares their overall performance to students in the West region of the United States and the entire United States (using data from the NAEP national assessment), presents the average proficiency for the three major fields, and summarizes the performance of subpopulations (gender, race/ethnicity, parents' educational level, Title I participation, and free/reduced lunch program eligibility). To provide a context for the assessment data, participating students, their science teachers, and principals completed questionnaires which focused on: instructional content (curriculum coverage, amount of homework); delivery of science instruction (availability of resources, type); use of computers in science instruction; educational background of teachers; and conditions facilitating science learning (e.g.,

+++++ ED413228 Has Multi-page SFR---Level=1 +++++

hours of television watched, absenteeism). On the NAEP fields of science scales that range from 0 to 300, Oregon students had an average proficiency of 155 compared to 148 throughout the United States. The average science scale score of males did not differ significantly from that of females in either Oregon or the nation. At the eighth grade, White students in Oregon had an average science scale score that was higher than those of Hispanic students but was not significantly different from that of Asian/Pacific islander or American Indian students. What is The Nation's Report Card?

THE NATION'S REPORT CARD, the National Assessment of Educational Progress (NAEP), is the only nationally representative and continuing assessment of what America's students know and can do in various subject areas. Since 1969, assessments have been conducted periodically in reading, mathematics, science, writing, history/geography, and other fields. By making objective information on student performance available to policymakers at the national, state, and local levels, NAEP is an integral part of our nation's evaluation of the condition and progress of education. Only information related to academic achievement is collected under this program. NAEP guarantees the privacy of individual students and their families.

NAEP is a congressionally mandated project of the National Center for Education Statistics, the U.S. Department of Education. The Commissioner of Education Statistics is responsible, by law, for carrying out the NAEP project through competitive awards to qualified organizations. NAEP reports directly to the Commissioner, who is also responsible for providing continuing reviews, including validation studies and solicitation of public comment, on NAEP's conduct and usefulness.

In 1988, Congress established the National Assessment Governing Board (NAGB) to formulate policy guidelines for NAEP. The Board is responsible for selecting the subject areas to be assessed from among those included in the National Education Goals; for setting appropriate student performance levels; for developing assessment objectives and test specifications through a national consensus approach; for designing the assessment methodology; for developing guidelines for reporting and disseminating NAEP results; for developing standards and procedures for interstate, regional, and national comparisons; for determining the appropriateness of test items and ensuring they are free from bias; and for taking actions to improve the form and use of the National Assessment.

HIGHLIGHTS

Monitoring the performance of students in subjects such as science is a key concern of the citizens, policy makers, and educators who direct educational reform efforts. The 1996 National Assessment of Educational Progress (NAEP) in science assesses the current level of science performance as a mechanism for informing education reform. This science assessment is the first to be constructed on a new framework, and it is also the first to be given at the state level. This report contains results for public school students at grade 8.

What Is NAEP?

The National Assessment of Educational Progress (NAEP), the “Nation’s Report Card,” is the only ongoing nationally representative assessment of what America’s students know and can do in various academic subjects. Since 1969, NAEP assessments have been conducted with national samples of students in the areas of reading, mathematics, science, writing, and other fields. By making information on student performance available to policy makers, educators, and the general public, NAEP is an integral part of our nation’s evaluation of the conditions and progress of education.

NAEP is a congressionally mandated project of the National Center for Education Statistics, U.S. Department of Education. Results are provided only for group performance. NAEP is forbidden by law to report results at an individual or school level.

In 1990 Congress authorized a voluntary state-by-state NAEP assessment. The 1990 Trial State Assessment in mathematics at grade 8 was the first state-level NAEP assessment. Since then, state-level assessments have taken place in 1992 and 1994 in reading (grade 4), in 1992 and 1996 in mathematics (grades 4 and 8), and in 1996 in science (grade 8). In 1996, 44 states, the District of Columbia, Guam, and the Department of Defense Schools took part in the NAEP state assessment program. The NAEP 1996 state science assessment was at grade 8 only, although grades 4, 8, and 12 were assessed at the national level as usual.

NAEP 1996 Science Assessment

The NAEP 1996 science assessment was developed using a new framework. This framework was produced by educators, administrators, assessment experts, and curriculum specialists using a national consensus process. The framework was designed to reflect current practices in science teaching. It called for the use of multiple-choice questions and constructed-response questions that required both short and extended responses. The constructed-response questions served as indicators of students' ability to know and integrate facts and scientific concepts, their ability to reason, and their ability to communicate scientific information. In the 1996 assessment, these constructed-response questions constituted nearly 80 percent of the total student response time. The NAEP 1996 assessment in science also included hands-on tasks that enabled students to demonstrate directly their knowledge and skills related to scientific investigation.

The 1996 science framework was structured according to a matrix that consisted of the three traditional fields of science (earth, physical, and life) crossed with three processes of knowing and doing science (conceptual understanding, scientific investigation, and practical reasoning). A central category encompassing the nature of science and the nature of technology was woven throughout the assessment, as was a themes category representing major ideas or key concepts that transcend scientific disciplines.¹

Students' science performance is summarized on the NAEP science scales, which range from 0 to 300 at each grade. While the scale score ranges are identical for grades 4, 8, and 12, the scales were derived independently at each grade. For example, scale scores on the grade 8 scale cannot imply anything about performance at grade 12 in the national assessment. The science scale is discussed in Appendix C of this report, the *NAEP 1996 Science State Report for Oregon* (see C.9). Note that the national average for the combined public and nonpublic school population is 150; the average for public schools only (appropriate for most tables in this report) is 148.

Comparison of Oregon to the Nation

Table H.1 shows the distribution of science scale scores for eighth-grade students attending public schools in Oregon, the West region, and the nation in 1996.

- The average science scale score for eighth graders in public schools in Oregon was 155. This average was higher than that for public school students across the nation (148).²

¹ More details about the NAEP 1996 science assessment can be found in Appendix B of this report, the *NAEP 1996 Science State Report for Oregon*.

² Differences reported as significant are statistically different at the 95 percent confidence level. This means that with 95 percent confidence there is a real difference in the average science scale score between the two populations of interest.

	TABLE H.1
	<i>Distribution of Science Scale Scores for Public School Students at Grade 8</i>

	Average Scale Score	10th Percentile	25th Percentile	50th Percentile	75th Percentile	90th Percentile
Oregon	155 (1.6)	115 (3.3)	136 (2.3)	157 (1.4)	176 (1.2)	192 (1.4)
West	148 (2.2)	101 (3.3)	127 (3.1)	151 (2.0)	172 (1.7)	190 (3.7)
Nation	148 (0.9)	102 (1.6)	126 (1.3)	151 (0.9)	172 (1.1)	191 (1.3)

The NAEP science scale ranges from 0 to 300. The standard errors of the statistics appear in parentheses. It can be said with about 95 percent confidence that, for each population of interest, the value for the entire population is within ± 2 standard errors of the estimate for the sample. In comparing two estimates, one must use the standard error of the difference (see Appendix A for details).

SOURCE: National Center for Education Statistics, National Assessment of Educational Progress (NAEP), 1996 Science Assessment.

Major Findings for Student Subpopulations

The preceding section provided a view of the overall science performance of eighth-grade students in Oregon. It is also important to examine the average science scale scores of subgroups within the population. Typically, NAEP presents results for demographic subgroups defined by gender, race/ethnicity, and parental education. In addition, in 1996 NAEP collected information on student participation in two federally funded programs: Title I programs and the free/reduced-price lunch component of the National School Lunch Program.

The reader is cautioned against using NAEP results to make simple or causal inferences related to subgroup membership. Differences among groups of students are almost certainly associated with a broad range of socioeconomic and educational factors not discussed in NAEP reports and possibly not addressed by the NAEP assessment program.

Results related to gender and race/ethnicity for public school students are highlighted below. More complete results for the various demographic subgroups examined by the NAEP science assessment can be found in Chapter 2 of this report, the *NAEP 1996 Science State Report for Oregon*.

- The average science scale score of males did not differ significantly from that of females in either Oregon or the nation.
- At the eighth grade, White students in Oregon had an average science scale score that was higher than that of Hispanic students but was not significantly different from that of Asian/Pacific Islander or American Indian students.

Finding a Context for Understanding Students' Science Performance in Public Schools

The science performance of students in Oregon may be better understood when viewed in the context of the environment in which students are learning. This educational environment is largely determined by school policies and practices, by characteristics of science instruction in the school, by home support for academics and other home influences, and by students' own views about science. Information about this environment is gathered by means of questionnaires completed by principals and teachers as well as questions answered by students as part of the assessment.

Because NAEP is administered to a sample of students that is representative of all eighth-grade students in Oregon schools, NAEP results provide a view of the educational practices in Oregon that may be useful for improving instruction and setting policy. However, despite the richness of context provided by the NAEP results, it is very important to note that NAEP data cannot establish a cause-and-effect relationship between educational environment and students' scores on the NAEP science assessment.

The following results are for public school students:

School Science Education Policies and Practices³

- In Oregon, the percentage of eighth-grade students attending public schools that reported science was a priority (36 percent) was not significantly different from* the percentage of eighth-grade students nationwide (43 percent).
- The percentage of eighth-grade students in Oregon who attended schools that were expected to follow a district or state curriculum (93 percent) was not significantly different from the national percentage (94 percent).
- In Oregon, 83 percent of eighth graders attended schools that reported providing instruction in science every day. This percentage did not differ significantly from* that of eighth graders across the nation (92 percent).
- A small percentage of the students in Oregon had teachers who reported receiving all of the resources they needed for classroom instruction (5 percent). This was not significantly different from the corresponding percentage of eighth-grade students nationwide (11 percent).
- In Oregon, 23 percent of the eighth-grade students were taught by teachers who reported that there was a curriculum specialist available to help or advise them in science. This figure was smaller than that of students across the nation (43 percent).

Science Classroom Practices⁴

- About half of the eighth-grade students in Oregon had science teachers who reported spending a lot of time on earth science (49 percent), about one third reported spending a lot of time on physical science (36 percent), and about one quarter reported spending a lot of time on life science (25 percent).
- About one fifth of the students in Oregon (22 percent) had teachers who reported they planned to place moderate emphasis on the understanding of key science concepts by their students. This percentage was smaller than that of students whose teachers planned heavy emphasis on conceptual understanding (78 percent).

* Although the difference may appear large, recall that "significance" here refers to "statistical significance."

³ More detailed results related to school policies and practices can be found in Chapter 3 of this report, the *NAEP 1996 Science State Report for Oregon*.

⁴ More detailed results related to classroom practices can be found in Chapter 4 of this report, the *NAEP 1996 Science State Report for Oregon*.

- In Oregon, the percentage of eighth-grade students whose teachers reported they planned to give moderate emphasis to developing science problem-solving skills (37 percent) was smaller than that of students whose teachers planned heavy emphasis on this topic (63 percent).
- Teachers of 60 percent of the students in Oregon reported that they planned to place moderate emphasis on knowing how to communicate ideas in science effectively, greater than the percentage of students whose teachers reported giving this topic heavy emphasis (27 percent).
- In Oregon, 25 percent of eighth graders reported not spending any time on science homework in a typical week while 32 percent spent one hour or more on their science homework each week.

Scientific Investigations⁵

- Of the eighth-grade students in Oregon, 81 percent had teachers who reported giving moderate to heavy emphasis on the development of data analysis skills. This percentage was not significantly different from* that of students nationwide (89 percent).
- A large majority of the eighth graders in Oregon had teachers who reported their students performed hands-on activities or investigations in science once a week or more (82 percent).

Influences Beyond School That Facilitate Learning Science⁶

- The percentage of eighth graders in Oregon who reported watching six or more hours of television a day (12 percent) was smaller than the percentage for the nation (17 percent).
- In Oregon, 38 percent of eighth graders agreed that science is useful for solving everyday problems.

* Although the difference may appear large, recall that "significance" here refers to "statistical significance."

⁵ More detailed results related to scientific investigations can be found in Chapter 5 of this report, the *NAEP 1996 Science State Report for Oregon*.

⁶ More detailed results related to influences beyond school that facilitate learning science can be found in Chapter 6 of this report, the *NAEP 1996 Science State Report for Oregon*.

INTRODUCTION

Improving education is often seen as an important first step as the United States attempts to remain competitive in an increasingly technical global economy. At the 1996 Governors' Summit in Palisades, New Jersey, the President and the Governors reaffirmed the need to strengthen our schools and strive for world-class standards. Furthermore, in his 1997 State of the Union Address, President Clinton placed education center stage and called for states to commit to national standards that represent what all students must know to succeed in the knowledge-based economy of the twenty-first century.

In 1983, the National Commission on Excellence in Education issued a report entitled *A Nation at Risk: The Imperative for Educational Reform* that was critical of education in the United States.⁷ Interest in reform was also fueled by the publication of other reports and analyses that pointed out the deficiencies of the educational system and noted how these could be rectified.⁸ Since then, organizations from the public and private sectors have assumed pivotal roles in providing support to state and local educational establishments as they seek to reform their educational systems in areas such as the development of standards, revision of curricula, development of appropriate assessment techniques, and professional development.⁹ In addition to these activities, organizations such as the National Science Teachers Association and the American Association for the Advancement of Science have worked closely with the National Research Council to produce documents that help teachers interpret the National Science Education Standards that were published in 1995.¹⁰ As the new century approaches, commitment to science reform continues.

⁷ *A Nation at Risk: The Imperative for Educational Reform*. (Washington, DC: National Commission on Excellence in Education, 1983).

⁸ *Educating Americans for the 21st Century: A Report to the American People and the National Science Board*. (Washington, DC: National Science Board, Commission on Precollege Education in Mathematics, Science, and Technology, 1983).

⁹ *Statewide Systemic Initiatives in Science, Mathematics, and Engineering*. (Arlington, VA: The National Science Foundation, 1995-1996); *Scope, Sequence, and Coordination of Secondary School Science. Volume I: The Content Core; Volume II: Relevant Research*. (Washington, DC: National Science Teachers Association, 1992); *Benchmarks for Science Literacy*. (Washington, DC: Project 2061, American Association for the Advancement of Science, 1993); *New Standards Project*. (Washington, DC: National Research Council, 1995).

¹⁰ *National Science Education Standards*. (Washington, DC: National Research Council, 1996).

Monitoring the performance of students in science is a key concern of the state and national policy makers and educators who direct educational reform efforts. To this end, the 1996 National Assessment of Educational Progress (NAEP) is an important source of information on what the nation's students know and can do in science.

What Was Assessed?

The science assessment was crafted to measure the content and skills specified in the science framework for the 1996 NAEP. Two organizing concepts underlie the science framework. First, scientific knowledge should be structured so as to make factual information meaningful. The way in which knowledge is structured should be influenced by the context in which the knowledge is being presented. Second, science performance depends on knowledge of facts, the ability to integrate this knowledge into larger constructs, and the capacity to use the tools, procedures, and reasoning processes of science to develop an increased understanding of the natural world. Thus, the framework called for the NAEP 1996 science assessment to include the following:

- Multiple-choice questions that assess students' knowledge of important facts and concepts and that probe their analytical reasoning skills;
- Constructed-response questions that explore students' abilities to explain, integrate, apply, reason about, plan, design, evaluate, and communicate scientific information; and
- Hands-on tasks that probe students' abilities to use materials to make observations, perform investigations, evaluate experimental results, and apply problem-solving skills.

The core of the science framework is organized along two dimensions. The first dimension divides science into three major fields: earth, physical, and life sciences. The second dimension defines characteristic elements of knowing and doing science: conceptual understanding, scientific investigation, and practical reasoning. Each question in the assessment is categorized as measuring one of the elements of knowing and doing within one of the fields of science (e.g., scientific investigation in the context of earth science). The framework also contains two overarching domains — the nature of science and the organizing themes of science. The nature of science encompasses the historical development of science and technology, the habits of mind that characterize science, and the methods of inquiry and problem solving. It also includes the nature of technology — specifically, design issues involving the application of science to real-world problems and associated trade-offs or compromises. The themes of science include the notions of systems and their application in the scientific disciplines, models and their functioning in the development of scientific understanding, and patterns of change as they are exemplified in natural phenomena. A fuller description of the framework is provided in Appendix B.

Who Was Assessed?

School and Student Characteristics

Table I.1 provides demographic profiles of the eighth-grade students in Oregon, the West region, and the nation. These profiles are based on data collected from the students and schools participating in the 1996 state and national science assessments at grade 8. As described in Appendix A, the state data and the regional and national data are drawn from separate samples.

To ensure comparability across jurisdictions, NCES has established guidelines for school and student participation rates. Appendix A highlights these guidelines, and jurisdictions failing to meet these guidelines are noted in tables and figures in NAEP reports containing state-by-state results. For jurisdictions failing to meet the initial school participation rate of 70 percent, results are not reported.

Schools and Students Assessed

Table I.2 summarizes participation data for schools and students sampled in Oregon for the 1996 state assessment program in science.¹¹

In Oregon, 100 public schools participated in the 1996 eighth-grade science assessment. These numbers include participating substitute schools that were selected to replace some of the nonparticipating schools from the original sample. The weighted school participation rate after substitution in 1996 was 92 percent for public schools, which means that the eighth-grade students in this sample were directly representative of 92 percent of all the eighth-grade public school students in Oregon.

In each school, a random sample of students was selected to participate in the assessment. In Oregon in 1996, on the basis of sample estimates, 3 percent of the eighth-grade public school population were classified as students with limited English proficiency (LEP). In addition, 9 percent of eighth graders in public schools had an Individual Education Plan (IEP). An IEP is a plan written for a student who has been determined to be eligible for special education. The IEP typically sets forth goals and objectives for the student and describes a program of activities and/or related services necessary to achieve the goals and objectives.

¹¹ For a detailed discussion of the NCES guidelines for sample participation, see Appendix A of this report or the *Technical Report of the NAEP 1996 State Assessment Program in Science*. (Washington, DC: National Center for Education Statistics, 1997).

Nation	Eligible	29 (1.6)
	Not eligible	51 (3.6)
	Information not available	20 (4.4)

The standard errors of the statistics appear in parentheses. It can be said with about 95 percent confidence that, for each population of interest, the value for the entire population is within ± 2 standard errors of the estimate for the sample. In comparing two estimates, one must use the standard error of the difference (see Appendix A for details). The percentages for Race/Ethnicity may not add to 100 percent because some students categorized themselves as "Other." ***** Standard error estimates cannot be accurately determined.

SOURCE: National Center for Education Statistics, National Assessment of Educational Progress (NAEP), 1996 Science Assessment.

Schools were permitted to exclude certain students from the assessment, provided that the following criteria were met. To be excluded, a student had to be categorized as LEP or had to have an IEP *and* (in either case) be judged incapable of participating in the assessment. The intent was to assess all selected students; therefore, all selected students who were capable of participating in the assessment should have been assessed. However, schools were allowed to exclude those students who, in the judgment of school staff, could not meaningfully participate. The NAEP guidelines for inclusion are intended to assure uniformity of inclusion criteria from school to school. Note that some students classified as LEP and some students having an IEP were deemed eligible to participate and were included in the assessment. In Oregon, the students who were excluded from the assessment because they were categorized as LEP or had an IEP represented 6 percent of the public school population in grade 8.

In Oregon, 2,275 public school eighth-grade students were assessed in 1996. The weighted student participation rate was 89 percent for public schools. This means that the sample of eighth-grade students who took part in the assessment was directly representative of 89 percent of the eligible public school student population in participating schools in Oregon (that is, all students from the population represented by the participating schools, minus those students excluded from the assessment). The overall weighted response rate (school rate times student rate) was 82 percent for public schools. This means that the sample of students who participated in the assessment was directly representative of 82 percent of the eligible eighth-grade public school population in Oregon.

In accordance with standard practice in survey research, the results presented in this report were based on calculations that incorporate adjustments for the nonparticipating schools and students. Hence, the final results derived from the sample provide estimates of the science performance for the full population of eligible public school eighth-grade students in Oregon. However, in instances where nonparticipation rates are large, these nonparticipation adjustments may not adequately compensate for the missing sample schools and students.

In order to guard against potential nonparticipation bias in published results, the National Center for Education Statistics (NCES) has established minimum participation levels as a condition for the publication of 1996 state assessment program results. NCES also established additional guidelines addressing four ways in which nonparticipation bias could be introduced into a jurisdiction's published results (see Appendix A). In 1996 Oregon met minimum participation levels for public schools at grade 8 but failed to meet minimum participation levels for nonpublic schools. Hence, results are included in this report only for public schools. Oregon met all other established NCES participation guidelines.

In the analysis of student data and reporting of results, nonresponse weighting adjustments have been made at both the school and student level, with the aim of making the sample of participating students as representative as possible of the entire eligible eighth-grade population. For details of the nonresponse weighting adjustment procedures, see the *Technical Report of the NAEP 1996 State Assessment Program in Science*.

 <p>THE NATION'S REPORT CARD 1996 State Assessment</p>	TABLE I.2
	<i>School and Student Participation at Grade 8 in Oregon</i>

	Public	Nonpublic
SCHOOL PARTICIPATION		
Weighted school participation rate before substitution	86%	26%
Weighted school participation rate after substitution	92%	26%
Number of schools originally sampled	111	17
Number of schools not eligible	3	4
Number of schools in original sample participating	94	4
Number of substitute schools provided	12	8
Number of substitute schools participating	6	0
Total number of participating schools	100	4
STUDENT PARTICIPATION		
Weighted student participation rate after makeups	89%	86%
Number of students selected to participate in the assessment	2,802	64
Number of students withdrawn from the assessment	160	2
Percentage of students who were of Limited English Proficiency	3%	0%
Percentage of students excluded from the assessment due to Limited English Proficiency	2%	0%
Percentage of students who had an Individualized Education Plan	9%	0%
Percentage of students excluded from the assessment due to Individualized Education Plan status	4%	0%
Number of students to be assessed	2,555	62
Number of students assessed	2,275	54
Overall weighted response rate	82%	22%

Oregon's nonpublic school weighted participation rate for the initial sample was less than 70%. See Appendix A for details. In Oregon, the materials from one public and one nonpublic school that conducted an assessment were lost in shipping. The schools are included in the counts of participating schools, both before and after substitution. However, in the weighted results, the schools are treated in the same manner as nonparticipating schools because no student responses were available for analysis and reporting.

Reporting NAEP Science Results

The NAEP Science Scale

The NAEP 1996 science assessment spans the broad field of science in each of the grades assessed. Because of the survey nature of the assessment and the breadth of the domain, each student participating cannot be expected to answer all the questions in the assessment since this would impose an unreasonable burden on students and their schools. Thus, each student was administered a portion of the assessment, and data were combined across students to report on the achievement of eighth graders and on the achievement of subgroups of students (e.g., subgroups defined by gender or parental education).

Student responses to the assessment questions were analyzed to determine the percentage of students responding correctly to each multiple-choice question and the percentage of students achieving each of the score categories for constructed-response questions. Item response theory (IRT) methods were used to produce scales that summarized results for each of the three fields of science (i.e., earth, physical, and life) at each grade level. An overall composite scale also was developed at each of grades 4, 8, and 12 by weighting the separate scales based on the relative importance of each field of science in the NAEP science framework. Results presented in this report are based on this overall composite scale, which ranges from 0 to 300.

The use of separate grade-specific reporting scales for the science assessment is consistent with the National Assessment Governing Board's 1993 policy that future NAEP assessments be developed using within-grade frameworks and that scaling be carried out within grade. Because this science assessment was based on a new framework, and no comparisons with previous NAEP science assessments were possible, a new scale was developed. The ranges of the science scales (from 0 to 300) differ by design from the 0-to-500 reporting scales used in other NAEP subject areas and were chosen to minimize confusion with other common test scales and to discourage inappropriate cross-grade comparisons.

The national average on the science scale is 150, including both public and nonpublic school students. The average for the nation's public school students appears most frequently in this report, and it is slightly lower. (Additional details of the scaling procedures can be found in Appendix C of this report, in the *NAEP 1996 Technical Report*, and in the *Technical Report of the NAEP 1996 State Assessment Program in Science*.)

Science Achievement Levels

A companion report, being issued by the National Assessment Governing Board, will present the NAEP 1996 science results in terms of achievement levels. As authorized by the NAEP legislation and adopted by the National Assessment Governing Board, the achievement levels are based on the Board's judgments about what are reasonable performance expectations for students on the NAEP 1996 science assessment. The achievement levels for the NAEP 1996 science assessment were adopted on an interim basis, indicating that they may be revised when other information becomes available, such as the fourth- and twelfth-grade results from the Third International Mathematics and Science Study (TIMSS).

Interpreting NAEP Results

This report describes science performance for eighth graders and compares the results for various groups of students within that population — for example, those who have certain demographic characteristics or who responded to a specific background question in a particular way. The report examines the results for individual demographic groups and for individual background questions. It does not include an analysis of the relationships among combinations of these subpopulations or background questions.

Because the percentages of students in these subpopulations and their average science scale scores are based on samples, rather than on the entire population of eighth graders in a jurisdiction, the numbers reported are necessarily *estimates*. As such, they are subject to a measure of uncertainty, reflected in the *standard error* of the estimate. When the percentages or average scale scores of certain groups are compared, it is essential to take the standard error into account, rather than to rely solely on observed similarities or differences. Therefore, the comparisons discussed in this report are based on *statistical tests* that consider both the magnitude of the difference between the means or percentages and the standard errors of those statistics.

The statistical tests determine whether the evidence, based on the data from the groups in the *sample*, is strong enough to conclude that the averages or percentages are really different for those groups in the *population*. If the evidence is strong (i.e., the difference is statistically significant), the report describes the group averages or percentages as being different (e.g., one group performed *higher than* or *lower than* another group) — regardless of whether the sample averages or sample percentages appear to be about the same or not. If the evidence is not sufficiently strong (i.e., the difference is not significant), the averages or percentages are described as being *not significantly different* — again, regardless of whether the sample averages or sample percentages appear to be about the same or widely discrepant. Rather than relying on the apparent magnitude of the difference between sample averages or percentages, the reader is cautioned to rely on the results of the statistical tests to determine whether those sample differences are likely to represent actual differences between the groups in the population. The statistical tests and the Bonferroni procedure, which is used when more than two groups are being compared, are discussed in greater detail in Appendix A.

In addition, some of the percentages reported in the text of the report are given qualitative descriptions (e.g., relatively few, about half, etc.). The descriptive phrases used and the rules used to select them are also described in Appendix A.

The tables in the Highlights and in Part 1 (Chapters 1 and 2) show not only the average scale scores for students but also the distribution of their scores at five selected percentiles. The distribution of the scores through these percentiles encourages the reader to consider the performance of the students in the various groupings (whether by state, region, gender, participation in federal programs, etc.) as overlapping ranges of heterogeneous performance, rather than as a simple monolithic average. As an example, consider Table 2.5 which shows that, for the nation, the 75th percentile for students eligible for free or reduced-price lunch is 157 while the average scale score for students who were not eligible for this service is 155. This means that at least 25 percent of the students eligible for free or reduced-price lunch performed above the average for students who were not eligible.

How Is This Report Organized?

The *NAEP 1996 Science State Report for Oregon* is a computer-generated report that describes the science performance of eighth-grade students in Oregon, the West region, and the nation. The system to generate the state reports was developed because reports customized with each jurisdiction's data would otherwise have been impossible to produce in a timely fashion. Because the process is automated, the variables reported were chosen as those most likely to be of interest to most jurisdictions. Unfortunately, this means that some variables of particular interest may not be reported here; however, each jurisdiction will receive all reportable data on CD ROM, and all data will be available on the NCES Web site (<http://www.ed.gov/NCES/naep>). Also because of the process, the language in the bullets and in parts of the text sometimes seem awkward. It is hoped that understanding the reason for these awkwardnesses will enable the reader to overlook them.

A separate report describes additional eighth-grade science assessment results for the nation and the states, as well as the national results for grades 4 and 12.¹² This *State Report* consists of four sections:

- This **Introduction** provides background information about what was assessed, who was sampled, and how the results are reported.
- **Part One** shows the distribution of science scale score results for eighth-grade students in Oregon, the West region, and the nation.
- **Part Two** relates eighth-grade public school students' science scale scores to contextual information about school characteristics, instruction, and home support for science in Oregon, the West region, and the nation. In addition, Chapter 5 discusses student results of the hands-on tasks.

¹² O'Sullivan, C.Y., C.M. Reese, and J. Mazzeo. *NAEP 1996 Science Report Card for the Nation and the States*. (Washington, DC: National Center for Education Statistics, 1997).

- Several **Appendices** are presented to support the results discussed in the report:

Appendix A Reporting NAEP 1996 Science Results
Appendix B The NAEP 1996 Science Assessment
Appendix C Technical Appendix
Appendix D Teacher Preparation

Other Reports of NAEP 1996 Science Results

Related reports may be of interest to the reader:

- *Cross-State Data Compendium for the 1996 Grade 8 Science Assessment*
- *Technical Report of the NAEP 1996 State Assessment Program in Science*
- *NAEP 1996 Science Report Card for the Nation and the States*

As presently planned, there will be three additional reports appearing in late 1997 and early 1998. One report will contain sample items and examples of student work on these questions. A second report will cover policy and practices in the schools and classrooms in the United States. A third report will cover special components of the NAEP science assessment, including the advanced science assessment and the hands-on exercises.

PART ONE

Science Scale Score Results

The following chapters describe the average science scale scores of eighth-grade students in Oregon. As described in the Introduction, the NAEP science scale is a composite of the three major fields of science: earth, physical, and life. Student performance is generally reported on this composite scale and so reflects average student scores across the three fields. Student performance may also be summarized on separate NAEP fields of science scales that range from 0 to 300.

This part of the report contains two chapters. Chapter 1 compares the overall science performance of public school students in Oregon to the nation. (Results for the West region are also presented.) It also contains a U.S. map comparing the average scale scores in Oregon with other states, and a table showing students' scale score distributions for the three fields of science. Chapter 2 summarizes science performance for subpopulations of public school students as defined by gender, race/ethnicity, parental education, participation in Title I services and programs, and eligibility for the free/reduced-price lunch component of the National School Lunch Program (NSLP).

The NAEP 1996 assessment in science is the first developed using a new framework, described in Appendix B. The scale developed to report results from the 1996 science assessment is a within-grade scale comprised of three fields of science scales. Appendix A describes reporting on the scale, and Appendix C describes the construction of the scale.

Item Maps

Students' performance is summarized on the NAEP science scale which ranges from 0 to 300. Nationally, public school students' scale scores ranged from about 102 for those scoring at the 10th percentile to about 191 for those performing at the 90th percentile. Sample questions are shown in Figure 1.1 illustrating the range of performance on the NAEP science scale for grade 8. Each question is one that is likely to be answered correctly by a student whose score is at or near the given percentile.

To illustrate the range of performance in more detail, questions from the assessment were "mapped" onto a 0 to 300 scale, as in Figure 1.2. The item map is a visual representation of the scale showing selected questions in positions corresponding to their difficulty. The item map shows which questions a student of any particular ability is likely to answer correctly. The position of the question on the scale represents a dividing line. Students who attained scores greater than the score corresponding to the question's difficulty are likely to answer it correctly, while students with scores below that degree of difficulty are less likely to answer it correctly.

More specifically, students who scored below the scale score associated with a particular question had less than a 65 percent probability of earning a given amount of credit on a constructed-response question or less than a 74 percent probability of correctly answering a multiple-choice question. A small proportion of these students — those near but below the question's position on the scale — may be more likely than not to answer the question correctly (between 50 and 65 or 74 percent). Such students are not considered "able" to answer the question, since they have not achieved sufficient consistency in their responses.

This discussion and the item map illustrations refer to eighth-grade students in the national assessment, whose scores may not resemble those of eighth-grade students in Oregon.

FIGURE 1.1	
<i>Sample Questions Likely to Be Answered Correctly by Grade 8 Students At or Near Selected Percentiles</i>	
Percentile	Question
10th	Find typical yearly rainfall from a graph. (104)
25th	<i>Explain the impact of fish death on an ecosystem.</i> (127)
50th	Identify the effect of acid rain. (150)
75th	Understand where earthquakes occur. (172)
90th	<i>Explain why lightning is seen before thunder is heard.</i> (194)

The value in parentheses represents the scale score attained by students who had a 65 percent probability of reaching a given level on a constructed-response question (in italic type) or a 74 percent probability of correctly answering a 4-option multiple-choice question (in regular type).

SOURCE: National Center for Education Statistics, National Assessment of Educational Progress (NAEP), 1996 Science Assessment.

Figure 1.2 is an item map for grade 8.¹³ Multiple-choice questions are shown in regular type; constructed-response questions are in italic type.¹⁴ An example of how to interpret the item map may be helpful. In this figure, a multiple-choice question involving interpreting a graph maps at the 136 point on the scale. This means that eighth-grade students with science scale scores at or above 136 are likely to answer this question correctly — that is, they have at least a 74 percent chance of doing so.¹⁵ Put slightly differently, this question is answered correctly by at least 74 of every 100 students scoring at or above the 136 scale-score level. Note that this does not mean that students at or above the 136 scale score always answer the question correctly or that students below the 136 scale score always answer it incorrectly.

As another example, consider the constructed-response question that maps at a scale score of 194. This question concerns the differing speeds of light and sound. Scoring of responses to this question allows for partial credit by using a three-level scoring guide. Mapping a question at the 194 scale score indicates that at least 65 percent of the students performing at or above this point achieved a score of 3 (“Complete”) on the question. Among students with lower scores, less than 65 percent gave complete responses to the question.

¹³ Details on the procedures used to develop the item map are provided in the forthcoming *NAEP 1996 Technical Report*. The procedures are similar to those used in past NAEP assessments.

¹⁴ The placement of constructed-response questions is based on (1) the “mapping” of a score of 3 on a 3-point scoring guide for short constructed-response questions and (2) the “mapping” of a score of at least 3 on a 4-point scoring guide and a score of at least 4 on a 5-point scoring guide for extended constructed-response questions.

¹⁵ For constructed-response questions, a criterion of 65 percent was used. For multiple-choice questions, the criterion was 74 percent. The use of a higher criterion for multiple-choice questions reflected the students’ ability to “guess” the correct answer from among the alternatives.

CHAPTER 1**Science Scale Score Results for Eighth-Grade Students**

To remain competitive in the global economy, a technologically and scientifically literate citizenry is required. As a result, reform in science and mathematics education in the United States has gained increasing attention. The 1983 publication *A Nation At Risk: The Imperative for Educational Reform* called for overall reform of the United States educational system, with heavy emphasis placed on mathematics and science.¹⁶ The National Goals Panel was convened in 1989 to further focus attention on education reform. In 1991 the National Science Foundation's Statewide Systemic Initiative began awarding grants to support state reform in K-12 mathematics and science instruction.¹⁷ During the 1990s many states have been developing standards for science curriculum, teaching, and assessment using guidance from reform efforts such as the American Association for the Advancement of Science's *Project 2061*, the National Science Teachers Association's *Scope, Sequence, and Coordination of High School Science*, and the recently published National Research Council's *National Science Education Standards*.¹⁸ A reaffirmation of the goal for world-class standards in education was made at the 1996 Governors' Summit in Palisades, NJ. All these efforts address ways to produce innovative science curricula aimed at improving national scientific literacy. As a means of informing the progress of such reform, the U.S. Department of Education supports programs geared toward assessing the current level of science knowledge and skills including the Third International Mathematics and Science Study (TIMSS),¹⁹ administered in 1995, and the 1996 National Assessment of Educational Progress (NAEP) in science.

¹⁶ *A Nation at Risk: The Imperative for Educational Reform*. (Washington, DC: National Commission on Excellence in Education, 1983).

¹⁷ *Statewide Systemic Initiative*. (Washington, DC: National Science Foundation, 1990).

¹⁸ *Science for All Americans: A Project 2061 Report on Literacy Goals in Science, Mathematics and Technology*. (Washington, DC: American Association for the Advancement of Science, 1989); *Scope, Sequence, and Coordination of High School Science*. (Washington, DC: National Science Teachers Association, 1995); *National Science Education Standards*. (Washington DC: National Research Council, 1996).

¹⁹ The Third International Mathematics and Science Study was conducted in 1994 in the Southern Hemisphere and in 1995 in the Northern Hemisphere.

The NAEP 1996 state science assessment at grade 8 was the first time science has been assessed at the state level. It continues the state-level component begun in 1990 with the NAEP Trial State Assessment (TSA). The NAEP 1996 assessment in science had 47 participating jurisdictions.²⁰ Results for 46 jurisdictions were reported for the science assessment.²¹

The science framework for the 1996 National Assessment of Educational Progress²² was developed through a consensus process involving educators, policy makers, business people, assessment experts and curriculum specialists. The 1996 NAEP science assessment included multiple-choice questions, constructed-response exercises, and (for the first time) hands-on tasks. Because the 1996 assessment was based on an essentially new framework, it is not possible to compare results from the 1996 assessment with those from the previous NAEP science assessment in 1990.

Table 1.1 shows the distribution of science scale scores for eighth-grade students attending public schools in Oregon, the West region, and the nation.

- The average science scale score for eighth-grade public school students in Oregon was 155. This average was higher than that for public school students across the nation (148).²³

	TABLE 1.1
	<i>Distribution of Science Scale Scores for Public School Students</i>

	Average Scale Score	10th Percentile	25th Percentile	50th Percentile	75th Percentile	90th Percentile
Oregon	155 (1.6)	115 (3.3)	136 (2.3)	157 (1.4)	176 (1.2)	192 (1.4)
West	148 (2.2)	101 (3.3)	127 (3.1)	151 (2.0)	172 (1.7)	190 (3.7)
Nation	148 (0.9)	102 (1.6)	126 (1.3)	151 (0.9)	172 (1.1)	191 (1.3)

The NAEP science scale ranges from 0 to 300. The standard errors of the statistics appear in parentheses. It can be said with about 95 percent confidence that, for each population of interest, the value for the entire population is within ± 2 standard errors of the estimate for the sample. In comparing two estimates, one must use the standard error of the difference (see Appendix A for details).

SOURCE: National Center for Education Statistics, National Assessment of Educational Progress (NAEP), 1996 Science Assessment.

²⁰ *Jurisdiction* refers to states, territories, the District of Columbia, and the Department of Defense Education Activities (DoDEA) domestic and international schools. The DoDEA schools also made special arrangements to assess their fourth-grade students in science.

²¹ One jurisdiction did not meet minimum participation levels for public or nonpublic schools and did not have any results reported.

²² *Science Framework for the 1996 National Assessment of Educational Progress*. (Washington, DC: National Assessment Governing Board, 1993).

²³ Differences reported as significant are statistically different at the 95 percent confidence level. This means that with 95 percent confidence there is a real difference in the average science scale score between the two populations of interest.

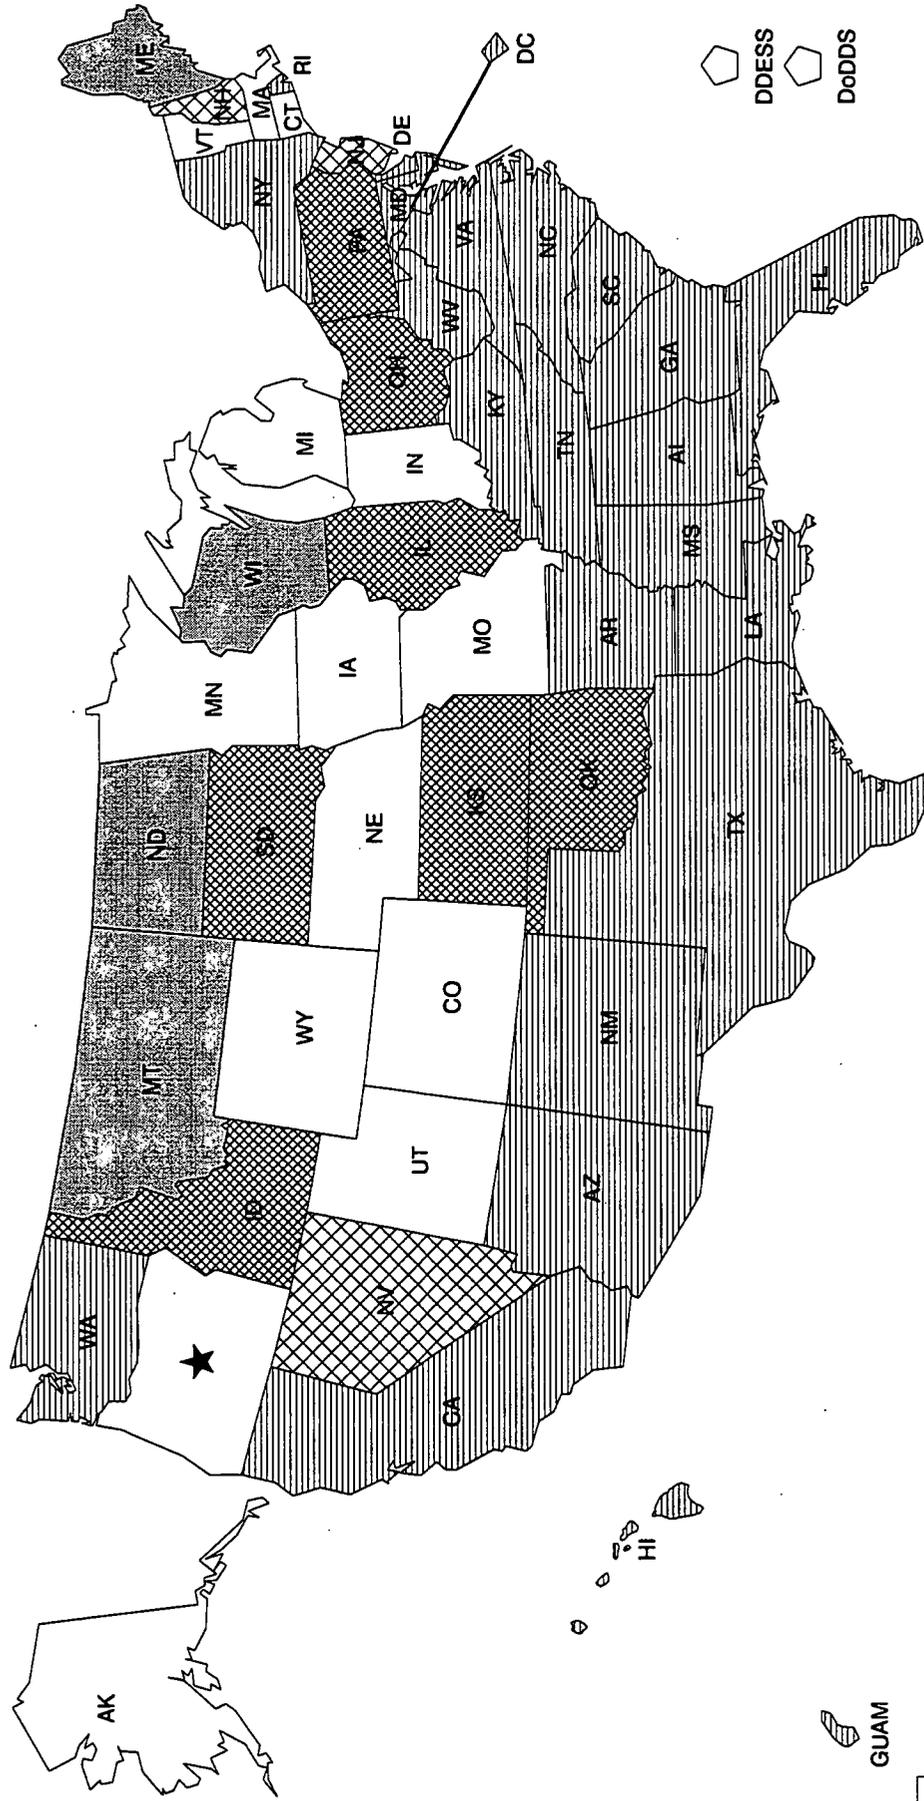

Comparisons Between Oregon and Other Participating Jurisdictions

The map on the following page shows how the average science scale score for eighth-grade public school students in Oregon compares with those of other jurisdictions participating in the NAEP 1996 science assessment. The different shadings on the map indicate whether or not the average scale scores of public school students in the other jurisdictions were statistically different from that of public school students in Oregon (“Target State”). States with horizontal lines have a significantly lower average science scale score than Oregon while states with gray shading have a significantly higher average scale score. Unshaded states have average scale scores that did not differ significantly from the average for Oregon. States with large crosshatching did not meet minimum participation rate guidelines established by NCES for the NAEP assessments. A description of the statistical procedures used to produce this map is contained in Appendix A.

The NAEP 1996 State Assessment

Comparisons of Overall Science Scale Scores at Grade 8

Oregon Public School Students

- ★ Target state
- [Stippled] State has statistically significantly higher average scale score than target state.
- [White] State shows no statistically significant difference in average scale score from target state.
- [Horizontal lines] State has statistically significantly lower average scale score than target state.
- [Vertical lines] State did not meet minimum participation rate guidelines.
- [Cross-hatched] State did not participate.

GUAM

State has statistically significantly higher average scale score than target state.
 State shows no statistically significant difference in average scale score from target state.
 State has statistically significantly lower average scale score than target state.
 State did not meet minimum participation rate guidelines.
 State did not participate.

 State Assessment

CHAPTER 2

Science Scale Score Results for Eighth-Grade Students by Subpopulations

The previous chapter provided a view of the overall science performance of eighth-grade students in Oregon and the nation. It is also important to examine the average performance of subgroups since past NAEP assessments in science, as well as in other academic subjects, have shown substantial differences among groups defined by gender, racial/ethnic background, parental education, and other demographic characteristics.²⁴ A key contribution of NAEP to the ongoing conversations concerning education reform is the ability to monitor the performance of subgroups of students in academic achievement.

The NAEP 1996 state assessment in science provides performance information for subgroups of eighth graders in Oregon, the West region, and the nation. In addition to the more typical demographic subgroups defined by gender, race/ethnicity, and parental education, the 1996 assessment also collected information on two federally funded programs — student participation in Title I programs and services, and student eligibility for the free/reduced-price school lunch program.

²⁴ Jones, L.R., I.V.S. Mullis, S.A. Raizen, I.R. Weiss, and E.A. Weston. *The 1990 Science Report Card: NAEP's Assessment of Fourth, Eighth, and Twelfth Graders*. (Washington, DC: National Center for Education Statistics, 1992); Campbell, J.R., C.M. Reese, C. O'Sullivan, and J.A. Dossey. *NAEP 1994 Trends in Academic Progress*. (Washington, DC: National Center for Education Statistics, 1996).

Students' Reports of Parents' Highest Education Level

Students were asked to indicate the highest level of education completed by each parent. Four levels of education were identified: did not finish high school, graduated from high school, some education after high school, and graduated from college. A choice of "I don't know" was also available. For this analysis, the highest education level reported for either parent was used.

In general, results show that increasing parental education is associated with increases in student performance. In reviewing these results, it is important to note that, nationally, approximately 10 percent of eighth graders did not know the level of education that either of their parents had completed. For public school students in Oregon, this percentage was 9 percent. Despite the fact that some research has questioned the accuracy of student-reported data from similar groups of students,²⁹ past NAEP assessments in science, as well as other subject areas, have found that student-reported level of parental education exhibits a consistent positive relationship with student performance on the assessments.³⁰ Other research has corroborated NAEP findings.³¹

Table 2.3 shows the results for eighth-grade public school students reporting that neither parent graduated from high school, at least one parent graduated from high school, at least one parent received some education after high school, at least one parent graduated from college, or that they did not know their parents' highest education level. The following pertains to those students who reported knowing the educational level of one or both parents.

- The average science scale score of students in Oregon who reported that neither parent graduated from high school did not differ significantly from that of students who reported that at least one parent graduated from high school but was lower than that of students who reported that at least one parent received some education after high school or at least one parent graduated from college.

Title I Participation

The Improving America's Schools Act of 1994 (P.L. 103-382) reauthorized the Elementary and Secondary Education Act of 1965 (ESEA). Title I Part A of the ESEA provides financial assistance to local educational agencies to meet the educational needs of children who are failing or most at risk of failing.³² Title I programs are designed to help disadvantaged students meet challenging academic performance standards. Through Title I, schools are assisted in improving teaching and learning and in providing students with opportunities to acquire the knowledge and skills outlined in their state's content and performance standards. For high poverty Title I schools, all children in the school may benefit through participation in schoolwide programs. Title I funding supports state and local education reform efforts and promotes coordinating of resources to improve education for all students.

NAEP first collected student-level information on participation in Title I programs in 1994. The NAEP program will continue to monitor the performance of Title I program participants in future assessments. The Title I information collected by NAEP refers to current participation in Title I services. Students who participated in such services in the past but do not currently receive services are not identified as Title I participants. Differences between students who receive Title I services and those who do not should not be viewed as an evaluation of Title I programs. Typically, Title I services are intended for students who score poorly on assessments. To properly evaluate Title I programs, the performance of students participating in such programs must be monitored over time and their progress must be assessed.³³

Table 2.4 presents results for eighth-grade students by Title I participation.

- For students receiving Title I services, the average science scale score of students in Oregon (128) was not significantly different from that of students nationwide (127). The average scale score of Oregon students who were not receiving Title I services (156) was higher than that of their national counterparts (152).
- The average scale score of Oregon students who were receiving Title I services was lower than that of students who were not.

(Washington, DC: U.S. Department of Education, 1995).

PART TWO

Finding a Context for Understanding Students' Science Performance in Public Schools

The science performance of public school students in Oregon can be better understood when viewed in the context of the environment in which the students are learning. This educational environment is largely determined by school characteristics, by characteristics of science instruction in the school, by home support for academics and other home influences, and by the students' own views about science. NAEP gathers information about this environment by means of the questionnaires administered to principals, teachers, and students.

Because NAEP is administered to a sample of students that is representative of the eighth-grade student population in the schools of Oregon, NAEP results provide a view of the educational practices in Oregon, useful for improving instruction and setting policy. However, despite the richness of the NAEP results, it is very important to note that NAEP data cannot establish a cause-and-effect relationship between educational environment and student scores on the NAEP science assessment.

The variables contained in Part Two are from the school characteristics and policies questionnaire, teacher questionnaires, and student background questionnaires. Part Two consists of four chapters: Chapter 3 discusses school characteristics related to science instruction;³⁵ Chapter 4 describes classroom practices related to science instruction, including curriculum, instructional emphases, coursework, and computer use; Chapter 5 describes portions of a hands-on task and explores student exposure to these experiences; and Chapter 6 covers some potential influences from the home and from the students' own views about science.

To provide additional information, the bullets below sometimes contain combined results from one or more categories (i.e., collapsed categories). When this is the case, the summed numbers reported in the bullets may be slightly different from the sums of the rounded numbers presented in the tables for each of the categories.

³⁵ Information on teacher preparation is included in Appendix D of this report.

CHAPTER 3

School Science Education Policies and Practices

School programs and conditions, instructional practices, and resource availability vary from state to state and even among schools within a locality. The information in this chapter is intended to give insight into those policies or practices that are associated with students' success in science.

The variables reported here reflect information from the questionnaires completed by principals and teachers of the public school students in the NAEP 1996 science assessment. In all cases, analyses are done at the student level. School and teacher-reported results are given in terms of the percentage of students who attend schools or who have teachers reporting particular practices.³⁶

Emphasis on Science in the School

In the school characteristics and policies questionnaire, principals or other head administrators were asked several questions relating to the priority placed on science within their schools. Table 3.1 presents their responses.

- The percentage of eighth-grade students in Oregon who attended schools with a special focus on science (3 percent) was not significantly different from the national percentage (8 percent).
- The percentage of eighth-grade students in Oregon attending schools that reported science was a priority (36 percent) was not significantly different from* the national percentage (43 percent). The average scale score for students in these schools (161) was higher than that of students in schools nationwide reporting that science was a priority (147).
- The average scale score of students in Oregon schools that reported that science was a priority (161) was higher than that of students in schools where science was not a priority (150).
- The percentage of eighth-grade students in Oregon who attended schools that reported having a district or state curriculum that the school was expected to follow (93 percent) was not significantly different from the national percentage (94 percent).

* Although the difference may appear large, recall that "significance" here refers to "statistical significance."

³⁶ Appendix A provides more details on the units of analysis used to derive the results presented in this report.

Teachers whose students participated in the NAEP 1996 science assessment were asked to categorize how well their school systems provided them with the classroom instructional materials they needed. The results are shown in Table 3.3.

- A small percentage of the students in Oregon had teachers who reported receiving all the resources they needed (5 percent). This percentage was not significantly different from that of students across the nation (11 percent).
- The average science scale score of students in Oregon whose teachers reported receiving all the resources they needed (157) was not significantly different from that of students whose teachers received some or none of the resources they needed (155).

	TABLE 3.3 <i>Public School Teachers' Reports on Resource Availability</i>		
	Oregon	West	Nation
Which of the following statements is true about how well your school system provides you with the instructional materials and other resources you need to teach your class?	Percentage and Average Scale Score		
I get some or none of the resources I need.	48 (4.7) 155 (2.2)	39 (7.0) 146 (3.0)	37 (4.1) 144 (2.0)
I get most of the resources I need.	47 (4.2) 157 (2.0)	54 (7.1) 152 (3.8)!	52 (4.1) 153 (2.1)
I get all the resources I need.	5 (1.7) 157 (4.7)!	7 (3.0) *** (**.*)	11 (3.1) 154 (5.4)!

The NAEP science scale ranges from 0 to 300. The standard errors of the statistics appear in parentheses. It can be said with about 95 percent confidence that, for each population of interest, the value for the entire population is within ± 2 standard errors of the estimate for the sample. In comparing two estimates, one must use the standard error of the difference (see Appendix A for details). ! Interpret with caution — the nature of the sample does not allow accurate determination of the variability of this statistic. *** Sample size is insufficient to permit a reliable estimate. SOURCE: National Center for Education Statistics, National Assessment of Educational Progress (NAEP), 1996 Science Assessment.

Availability of Curriculum Specialist in the School

Table 3.4 shows the percentages and average scale scores of eighth-grade students in public schools whose teachers indicated they had a curriculum specialist available to help or advise them in science.

- In Oregon, about one quarter of the students were taught by teachers who reported that there was a curriculum specialist available to help or advise them in science (23 percent). This figure was smaller than that of students across the nation (43 percent).

	TABLE 3.4 <i>Public School Teachers' Reports on Curriculum Specialists</i>		
	Oregon	West	Nation
Is there a curriculum specialist available to help or advise you in science?	Percentage and Average Scale Score		
Yes	23 (3.7) 155 (2.5)	35 (6.3) 151 (7.6)	43 (3.9) 148 (2.7)
No	77 (3.7) 156 (2.0)	65 (6.3) 149 (2.0)	57 (3.9) 152 (1.5)

The NAEP science scale ranges from 0 to 300. The standard errors of the statistics appear in parentheses. It can be said with about 95 percent confidence that, for each population of interest, the value for the entire population is within ± 2 standard errors of the estimate for the sample. In comparing two estimates, one must use the standard error of the difference (see Appendix A for details). ! Interpret with caution — the nature of the sample does not allow accurate determination of the variability of this statistic.

Parents as Classroom Aides

When school personnel and parents develop a positive line of communication, they strengthen the learning environment for the students both at school and at home. One of the most frequent reasons cited by school personnel for contacting parents is to request parent volunteer time at school.⁴⁰ The principals of the participating public schools were asked if parents were used as classroom aides. As shown in Table 3.5, principals for eighth graders reported the following:

- About one third of the students in Oregon (31 percent) were in schools that reported routinely using parents as aides in classrooms while 10 percent of students in Oregon attended schools where parents were not used as classroom aides.

Does your school use parents as aides in classrooms?	Oregon	West	Nation
	Percentage and Average Scale Score		
No	10 (3.3) 148 (5.7)!	30 (6.1) 141 (2.4)!	43 (6.0) 146 (2.4)
Yes, occasionally	59 (5.3) 153 (2.3)	65 (7.0) 151 (3.4)	46 (6.3) 150 (2.7)
Yes, routinely	31 (4.6) 160 (1.9)	5 (****) *** (**.)	11 (3.6) 152 (6.9)!

The NAEP science scale ranges from 0 to 300. The standard errors of the statistics appear in parentheses. It can be said with about 95 percent confidence that, for each population of interest, the value for the entire population is within ± 2 standard errors of the estimate for the sample. In comparing two estimates, one must use the standard error of the difference (see Appendix A for details). ! Interpret with caution — the nature of the sample does not allow accurate determination of the variability of this statistic. *** Sample size is insufficient to permit a reliable estimate. **** Standard error estimates cannot be accurately determined.

Student Absenteeism

School principals were asked if student absenteeism was a serious, moderate, or minor problem, or not a problem. Table 3.6 shows results for eighth graders based on principals' reports.

- In Oregon, 40 percent of the eighth-grade public school students attended schools that reported that absenteeism was a moderate to serious problem. This percentage was greater than that for the nation (22 percent).
- The average scale score of students in Oregon attending schools that reported that absenteeism was not a problem (160) was higher than that of students in schools where absenteeism was a moderate to serious problem (149).

	TABLE 3.6		
	<i>Public Schools' Reports on Student Absenteeism</i>		
To what degree is student absenteeism a problem in your school?	Oregon	West	Nation
	Percentage and Average Scale Score		
Not a problem	16 (3.8) 160 (2.5)!	16 (8.5) 164 (10.4)!	28 (4.8) 156 (3.1)
Minor	45 (5.2) 158 (2.0)	65 (8.5) 149 (1.7)	50 (4.9) 149 (1.5)
Moderate to serious	40 (4.6) 149 (2.8)	19 (5.7) 138 (7.9)!	22 (3.7) 140 (3.0)

The NAEP science scale ranges from 0 to 300. The standard errors of the statistics appear in parentheses. It can be said with about 95 percent confidence that, for each population of interest, the value for the entire population is within ± 2 standard errors of the estimate for the sample. In comparing two estimates, one must use the standard error of the difference (see Appendix A for details). ! Interpret with caution — the nature of the sample does not allow accurate determination of the variability of this statistic.

SOURCE: National Center for Education Statistics, National Assessment of Educational Progress (NAEP), 1996 Science Assessment.

Curriculum Coverage

The NAEP 1996 science assessment examines three fields of science: earth, physical, and life. In grades 4 and 12, the 1996 NAEP framework emphasized the three fields of science more or less equally; however, the framework specified a heavier emphasis on life science at grade 8, consistent with the increasingly recognized importance of human biology for this age group.⁴⁵ Eighth-grade public school teachers were asked how much time was spent on the three traditional fields of science in their classes and the results are presented in Table 4.1.

- In Oregon, 49 percent of the eighth-grade public school students had teachers who reported spending a lot of time on earth science. This percentage was not significantly different* than that for the nation (41 percent). Students in Oregon in classrooms where a lot of time was spent on earth science had an average scale score (154) that did not differ significantly from that of similar students nationwide (149).
- In Oregon, 36 percent of the public school students had teachers who reported spending a lot of time on physical science. This figure was smaller than that of their national counterparts (49 percent). The average science scale score in classrooms where physical sciences was covered a lot was higher in Oregon (158) than nationwide (151).
- In Oregon, 25 percent of the students had teachers who reported spending a lot of time on life science. This was not significantly different from the percentage nationwide (19 percent). The average scale score for students in these classrooms (157) was higher than that of students across the nation spending a lot of time on life science (147).

* Although the difference may appear large, recall that "significance" here refers to "statistical significance."

⁴⁵ National Research Council. *National Science Education Standards*. (Washington, DC: National Academy Press, 1996).

Eighth-Grade Students' Course Taking

Exposure to science and the opportunity to learn science have a positive effect on the science performance of students.⁴⁶ To investigate whether there is a relationship between science performance of students on the 1996 NAEP assessment and their study of science in school, information on the types of science classes in which eighth-grade students were enrolled and the amount of time spent each week on science instruction was collected. As noted for Table 3.2, in which school principals answered a similar question concerning the frequency of science instruction, students in schools with block scheduling were not identified separately. Consequently, students under block scheduling who receive science instruction two or three times weekly may be receiving as much instruction as students in traditional settings who have science every day.

Based on students' responses shown in Table 4.2:

- In eighth grade, 4 percent of the students in Oregon reported not taking a science course this year. This did not differ significantly from the national percentage (3 percent).
- In Oregon, the average scale score for students taking life science (150) was lower than that of students taking physical science (159).
- The average scale score for Oregon students taking life science (150) was not significantly different from* that of students taking earth science (158).
- In Oregon, 86 percent of the students reported studying science three or more times a week. The average scale score for students who reported studying science three or more times a week in Oregon (156) was higher than that of students studying at this level nationwide (152).

* Although the difference may appear large, recall that "significance" here refers to "statistical significance."

⁴⁶ Council of Chief State School Officers. *State Indicators of Science and Mathematics Education*. (Washington, DC: CCSSO, 1995).

Computer Use in Science Instruction

The use of computers in the collection of data, interpretation of results, and communication of findings is part of the *Benchmarks for Science Literacy* and the recently published *National Science Education Standards*.⁵¹ Recommendations for facilitating science instruction in the nation's schools often include more use of computers. Computers can be used to demonstrate scientific concepts, simulate scientific phenomena, deliver instruction, and collect and analyze data. Of course, effective computer use may depend on many factors other than availability, such as teachers' training or whether computers have been incorporated into the curriculum effectively.

Computers are increasingly important in students' homes, where they are used for homework as well as for other pursuits. Since 1984 the percentage of students in grades 7 through 12 who use a computer at school or at home has increased over two-fold, to approximately 60 percent of students using a computer at school and 30 percent using one at home.⁵²

Given the potential role of computers in science instruction, NAEP asked teachers in Oregon about the availability and use of computers in science instruction. As presented in Table 4.8, when eighth-grade science teachers in Oregon were asked about the availability of computers, their responses indicated the following:

- In Oregon, 10 percent of the students were in science classes where computers were not available. This percentage was not significantly different from* that for the nation (17 percent).
- The average scale score of Oregon students whose teachers reported not having any computers available (156) was not significantly different from that of students whose teachers reported having one computer in the classroom (155).

* Although the difference may appear large, recall that "significance" here refers to "statistical significance."

⁵¹ American Association for the Advancement of Science. *Benchmarks for Science Literacy*. (New York: Oxford University Press, 1993); National Research Council. *National Science Education Standards*. (Washington, DC: National Academy Press, 1996).

⁵² U.S. Department of Education. *Digest of Education Statistics 1995*. (Washington, DC: National Center for Education Statistics, 1995).

The availability of computers varies from school to school, and the uses for computers can vary widely from class to class. Computers can be used in many ways to help students learn science, including simulating scientific phenomena or illustrating models. Also, the frequency of use can vary, regardless of the primary use in the classroom. Teachers in Oregon were asked how they used computers and how often they were used in their science classrooms. Also, students were asked how often they used computers when doing science in school. The responses of eighth-grade public school teachers to the purpose of use for science instruction, as shown in Table 4.9, indicate the following:

- The percentage of Oregon students whose teachers reported that they used computers for simulations and modeling (23 percent) was not significantly different from the corresponding national percentage (26 percent).
- The percentage of students in Oregon whose teachers reported that their use of computers for instruction in science was for data analysis and other applications (26 percent) was not significantly different from that of students nationwide (20 percent).
- About one third of the eighth graders had teachers who reported not using a computer for science instruction (36 percent). This percentage did not differ significantly from* the percentage for the nation (46 percent).

Table 4.10 presents teacher and student reports on the frequency of use of computers for science.

- In Oregon, 56 percent of the students had teachers who reported never or hardly ever using a computer with their classes, while relatively few reported doing so almost every day (3 percent) or once or twice a week (9 percent).
- In Oregon, 68 percent of the students reported never or hardly ever using computers to do science in school. Furthermore, 3 percent of the students reported using computers almost every day and 10 percent used them once or twice a week.

* Although the difference may appear large, recall that "significance" here refers to "statistical significance."

NAEP included assessments of higher-order thinking skills in science and mathematics as early as 1986 through a pilot assessment that required students to work on various hands-on tasks. Although the NAEP 1990 science assessment measured skills that were integral to scientific investigation,⁵⁷ hands-on tasks were not included. When the 1996 science framework⁵⁸ was developed in the early 1990s, it took into account the current reforms in science education by specifying three question types that probed understanding of conceptual and reasoning skills: performance exercises, constructed-response questions, and multiple-choice questions. It was envisaged that in the performance exercises, students would manipulate selected physical objects and try to solve a scientific problem using the objects before them. Hands-on tasks that met these criteria were developed for the 1996 science assessment, and each student who participated in the assessment was given an opportunity to conduct one of them.

NAEP Hands-On Science Tasks

Four different hands-on tasks were administered in the NAEP 1996 science assessment. Each task was designed to use materials to perform an investigation, make observations, evaluate experimental results, and apply problem-solving skills. In addition, tasks shared the following characteristics:

- Diagrams were included to guide students through the procedures;
- Multiple-choice and constructed-response questions were embedded throughout the tasks; and
- Scientific investigation was integrated with conceptual understanding and practical reasoning.

The creation of the hands-on tasks presented special challenges. Since the assessment was administered in a variety of settings, ranging from laboratories to cafeterias, all of the required equipment necessary to conduct each task had to be provided in a self-contained kit produced according to standard specifications to ensure uniformity. There were some limitations on materials and equipment. For example, live materials (with the exception of seeds) and equipment that required an electric outlet were not used. Safety was also an important concern and was addressed in a number of ways. The state's safety regulations were considered; no toxic or corrosive chemicals were used; assessment administrators were trained in appropriate laboratory safety; and students were provided with goggles for some tasks.

A brief summary of one of the four hands-on tasks is described in this chapter. Several questions from the hands-on task are also shown with their scoring criteria.

⁵⁷ *Science Objectives: 1990 Assessment*. (Princeton, NJ: The National Assessment of Educational Progress, 1989).

⁵⁸ *Science Framework for the 1996 National Assessment of Educational Progress*. (Washington, DC: National Assessment Governing Board, 1993).

Sample Questions from a Task

A brief summary of one of the four tasks given to grade 8 students in Oregon is presented below with sample questions in Figures 5.1 and 5.2.

Salt Solutions: Estimating the Salt Concentration of an Unknown Salt Solution Using the “Floating Pencil Test”

An instrument constructed from a pencil and thumbtack served as a hydrometer in this task. Students were asked to observe, measure, and compare the lengths of a portion of the pencil, marked with calibrations for ease of measurement, that floated above the surface in distilled water and in a 25 percent salt solution. Based on these observations, students were asked to predict how the addition of more salt to the salt solution would affect the floating pencil. Students then measured the length of the pencil that floated above the surface of a solution of unknown salt concentration and used the results of their previous observations to estimate the salt concentration of the unknown solution. The task assessed students' ability to make simple observations, measure length using a ruler, apply observations to an unknown, draw a graph, interpolate from graphical data, and make a generalized inference from observations. The task also assessed students' understanding of the value of performing multiple trials of the same procedure.

Figure 5.1 shows a data table that was presented in the first stage of the task. Questions 3, 4, and 5 are also presented in this figure. Students were asked to measure the length of pencil floating above the surface in three solutions: distilled water, a 25 percent salt solution, and a solution containing an unknown concentration of salt. The students recorded two measurements for each of the 3 solutions in Table 1 and calculated the average of each pair of readings. The scoring rubrics for **Complete** responses are shown in Figure 5.1.

CHAPTER 6

Influences Beyond School that Facilitate Learning Science

The home environment can be an important support for the school environment. To examine the relationship between science scale scores and home factors, data regarding students' responses to questions about home factors and principals' responses to questions about parental involvement in the school were examined. The student questionnaires also asked students how often they had changed schools because of household moves to examine the impact of student mobility on academic achievement.

Students' attitudes toward science can influence their performance in the assessment. For example, in a recent large scale science assessment, students who agreed that science learning is useful for the future and that science should be required in school performed better than those who disagreed with these statements.⁶⁰ These attitudes toward science may be attributed to factors within the school and external influences. The beliefs and general impressions that secondary school students form about science can affect not only their performance in assessments but also their decisions about pursuing scientific careers in the future.⁶¹

Guideline 10 — Notation for Strata-Specific Student Participation Rates in Public Schools

A jurisdiction that is not already receiving a notation under guideline 8 will receive a notation if the sampled students within participating public schools included a class of students with similar characteristics that had a weighted student response rate of below 80 percent, and from which the nonresponding students together accounted for more than five percent of the jurisdiction's weighted assessable public school student sample. Student groups from which a jurisdiction needed minimum levels of participation were determined by the age of the student, whether or not the student was classified as a student with a disability (SD) or of limited English proficiency (LEP), and the type of assessment session (monitored or unmonitored), as well as school level of urbanization, minority enrollment, and median household income of the area in which the school is located.

Guideline 11 — Notation for Strata-Specific Student Participation Rates in Nonpublic Schools

A jurisdiction that is not already receiving a notation under guideline 9 will receive a notation if the sampled students within participating nonpublic schools included a class of students with similar characteristics that had a weighted student response rate of below 80 percent, and from which the nonresponding students together accounted for more than five percent of the jurisdiction's weighted assessable nonpublic school student sample. Student groups from which a jurisdiction needed minimum levels of participation were determined by the age of the student, whether or not the student was classified as a student with a disability (SD) or of limited English proficiency (LEP), and the type of assessment session (monitored or unmonitored), as well as type and location of school.

Minimum Subgroup Sample Sizes

Results for science performance and background variables were tabulated and reported for groups defined by gender, race/ethnicity, parental education, type of school, and participation in federally funded Title I programs and the free/reduced-price school lunch component of the National School Lunch Program. NAEP collects data for five racial/ethnic subgroups (White, Black, Hispanic, Asian/Pacific Islander, and American Indian/Alaskan Native) and four levels of parents' education (Graduated From College, Some Education After High School, Graduated From High School, and Did Not Finish High School) plus the category "I Don't Know."

In many jurisdictions, and for some regions of the country, the number of students in some of these groups was not sufficiently high to permit accurate estimation of performance and/or background variable results. As a result, data are not provided for the subgroups with students from very few schools or for the subgroups with very small sample sizes. For results to be reported for any state assessment subgroup, public school results must represent at least 5 primary sampling units (PSUs) and nonpublic school results must represent at least 6 schools. For results to be reported for any national assessment subgroup, at least 5 PSUs must be represented in the subgroup. In addition, a minimum sample of 62 students per subgroup is required. For statistical tests pertaining to subgroups, the sample size for both groups has to meet the minimum sample size requirements.

The minimum sample size of 62 was determined by computing the sample size required to detect an effect size of 0.5 total-group standard deviation units with a probability of 0.8 or greater. The effect size of 0.5 pertains to the *true* difference between the average scale score of the subgroup in question and the average scale score for the total eighth-grade public school population in the jurisdiction, divided by the standard deviation of the scale score in the total population. If the *true* difference between subgroup and total group mean is 0.5 total-group standard deviation units, then a sample size of at least 62 is required to detect such a difference with a probability of 0.8. Further details about the procedure for determining minimum sample size appear in the *Technical Report of the NAEP 1996 State Assessment Program in Science*.

APPENDIX B

The NAEP 1996 Science Assessment

The science framework for the 1996 National Assessment of Educational Progress was produced under the auspices of the National Assessment Governing Board through a consensus process. The consensus process, managed by the Council of Chief State School Officers, with the National Center for Improving Science Education and the American Institutes for Research, developed the framework over a ten-month period between October 1990 and August 1991. The following factors guided the process for developing consensus on the science framework:¹

- The active participation of individuals such as curriculum specialists, science teachers, science supervisors, state supervisors, administrators, individuals from business and industry, government officials, and parents;
- The representation of what is considered essential learning in science, and the recommendation of innovative assessment techniques to probe the critical abilities and content areas;
- The recognition of the lack of agreement on such things as common scope of instruction and sequence, components of scientific literacy, important outcomes of learning, and the nature of overarching themes in science.

While maintaining some conceptual continuity with the 1990 NAEP Science Assessment, the 1996 framework takes into account the current reforms in science education, as well as documents such as the science framework used for the 1991 International Assessment of Educational Progress. In addition, the Framework Steering Committee recommended that a variety of strategies, including the following, be used for assessing students' performance.²

¹ *Science Framework for the 1996 National Assessment of Educational Progress*. (Washington, DC: National Assessment Governing Board, 1993).

² *Ibid.*

- Performance tasks that allow students to manipulate physical objects and draw scientific understanding from the materials before them
- Constructed-response questions that provide insights into students' levels of understanding and ability to communicate in the sciences as well as their ability to generate, rather than simply recognize, information related to scientific concepts and their interconnections
- Multiple-choice items that probe students' conceptual understanding and ability to connect ideas in a scientifically sound way

B.1 Percentage of Assessment Time by Domain

The framework for the 1996 science assessment can be described as a two-dimensional matrix. The three fields of science (earth, physical, and life) make up the first dimension and ways of knowing and doing science (conceptual understanding, scientific investigation, and practical reasoning) make up the second dimension. Every question or task in the assessment is classified according to the two major dimensions. There are also two overarching domains — nature of science (that includes nature of technology) and themes (systems, models, and patterns of change).

In addition to describing the content of the assessment, the framework also recommends what percentage of time should be devoted to each field of science, each way of knowing and doing science, the nature of science, and themes.

In this section, each figure describes an element of the framework, and is followed by a table showing the *actual* distribution of assessment time as well as the distribution *recommended* by the framework. Care was taken to ensure congruence between the proportions actually used in the assessment and those recommended in the assessment specifications. Note that the tables represent all three grades assessed nationally; only grade 8 was assessed at the state level.

Figure B.1 describes the fields of science and Table B.1 shows the actual and recommended distribution of assessment time across each field. The ways of knowing and doing science are outlined in Figure B.2. The distribution of assessment time for this dimension, both actual and recommended, is depicted in Table B.2.

Other features were built into the blocks of cognitive questions. Four of the blocks were hands-on tasks in which students were given a set of equipment and asked to conduct an investigation and answer questions relating to the investigation. Every student was assessed on one of these four blocks. A second feature was the inclusion of three theme blocks — one assessing systems, one assessing models, and one assessing patterns of change. For example, students were shown a simplified model of part of the Solar System with a brief description, and then asked a number of questions based on this scenario. Theme blocks were randomly placed in booklets, but not in all booklets. No student received more than one theme block.

Each booklet in the assessment also included three sets of student background questions. The first, consisting of general background questions, asked students about such things as mother's and father's level of education, reading materials in the home, homework, and school attendance. The second, consisting of science background questions, asked students questions about their classroom learning activities such as hands-on exercises, courses taken, use of specialized resources such as computers, and views on the utility and value of science. Students were given five minutes to complete each of these questionnaires. The third set contained five questions about students' motivation to do well on the assessment, their perception of the difficulty of the assessment, and their familiarity with the types of cognitive questions asked. This section took three minutes or less to complete.

Using information gathered from the field test, the booklets were carefully constructed to balance time requirements for the question types in each block. For more information on the design of the assessment, the reader is referred to Appendix C.

APPENDIX C

Technical Appendix: The Design, Implementation, and Analysis of the 1996 State Assessment Program in Science

C.1 Overview

The purpose of this appendix is to provide technical information about the 1996 state assessment program in science. It describes the design of the assessment and gives an overview of the steps used to implement the program, from the planning stages through the analysis of the data.

This appendix is one of several documents that provide technical information about the 1996 state assessment program. Readers interested in more details are referred to the *Technical Report of the NAEP 1996 State Assessment Program in Science*. Theoretical information about the models and procedures used in NAEP can be found in the special NAEP-related issue of the *Journal of Educational Statistics* (Summer 1992/Volume 17, Number 2) as well as previous national technical reports.

Educational Testing Service (ETS) was awarded the cooperative agreement for the 1996 NAEP programs, including the state assessment program. ETS was responsible for overall management of the programs as well as for development of the overall design, the cognitive questions and questionnaires, data analysis, and reporting. National Computer Systems (NCS) was a subcontractor to ETS on both the national and state NAEP programs. NCS was responsible for printing, distributing, and receiving all assessment materials, and for scanning and scoring the assessments. The National Center for Education Statistics (NCES) awarded a separate cooperative agreement to Westat, Inc., for handling all aspects of sampling and field operations for the national and state assessments for 1996.

Organization of the Technical Appendix

This appendix has the following organization:

- Section C.2 provides an overview of the design of the 1996 state assessment program in science.
- Section C.3 discusses the partially-balanced incomplete block (PBIB) spiral design used to assign cognitive questions to assessment booklets and assessment booklets to students.
- Section C.4 outlines the sampling design used for the 1996 state assessment program.
- Section C.5 summarizes Westat's field administration procedures.
- Section C.6 describes the flow of the data from receipt at NCS through data entry and professional scoring.
- Section C.7 summarizes the procedures used to weight the assessment data and to obtain estimates of the sampling variability of subpopulation estimates.
- Section C.8 describes the initial analyses performed to verify the quality of the data.
- Section C.9 describes the item response theory scales and the overall science composite scale created for the final analyses of the state assessment program data.
- Section C.10 provides an overview of the linking of the scaled results from the state assessment program in science to those from the national assessment.

C.2 Design of the NAEP 1996 State Assessment Program in Science

The design for the state assessment program in science included the following major aspects:

- Participation at the jurisdiction level was voluntary, except for a few jurisdictions for which NAEP has been mandated by the state legislature.
- Students from public and nonpublic schools were assessed. Nonpublic schools included Catholic schools, other religious schools, and private schools. Separate representative samples of public and nonpublic schools were selected in each participating jurisdiction and students were randomly sampled within schools. The size of a jurisdiction's nonpublic school samples was proportional to the percentage of students in that jurisdiction attending such schools.

- The eighth-grade science assessment instruments used for the state assessment program and the national assessment consisted of 15 blocks of questions, of which 4 were hands-on tasks. Each block could contain a mixture of question types — constructed-response or multiple-choice — that was determined by the nature of the task. In addition, the constructed-response questions were of two types: *short constructed-response* questions required students to respond to a question with a few words or a few sentences, while *extended constructed-response* questions required students to respond to a question with a paragraph or more, sometimes including graphs or calculations. The hands-on tasks were similar to laboratory exercises. Each student was given 2 of the 11 cognitive blocks of questions, and one of the four hands-on blocks.
- A complex form of matrix sampling called a partially balanced incomplete block (PBIB) spiraling design was used. With PBIB spiraling, students in an assessment session received different booklets containing 3 of the 15 blocks. This provided for greater science content coverage without imposing an undue testing burden by administering an identical set of questions to each student.
- Sets of background questions given to the students, the students' science teachers, and the principals or other school administrators provided a variety of contextual information. The background questionnaires for the state assessment program were identical to those used in the national eighth-grade assessment.
- The total assessment time for each student was approximately two hours, including cleanup and collection of materials from hands-on tasks. Each assessed student was assigned a science booklet that contained 3 of the 15 blocks of science questions requiring 30 minutes each (including a hands-on task block in the last position), followed by a 5-minute general background questionnaire, a 5-minute science background questionnaire, and a 3-minute motivation questionnaire. Thirty-seven different booklets were assembled.
- The assessments were administered in the five-week period between January 29 and March 4, 1996. One-fourth of the schools in each jurisdiction were assessed each week throughout the first four weeks. Because of the severe weather throughout much of the country, the fifth week was used for regular testing as well as for makeup sessions.
- Data collection was, by law, the responsibility of each participating jurisdiction. Security and uniform assessment administration were high priorities. Extensive training of state assessment personnel was conducted to assure that the assessment would be administered under standard, uniform procedures. For jurisdictions that had participated in previous NAEP state assessments, 25 percent of both public and nonpublic school assessment sessions were monitored by Westat staff. For the jurisdictions new to NAEP, 50 percent of both public and nonpublic school sessions were monitored.

C.3 Assessment Instruments

The *student assessment booklets* contained six sections and included both cognitive and noncognitive questions. The assembly of cognitive questions into booklets and their subsequent assignment to assessed students were determined by a matrix sampling design using a variant of a balanced incomplete block design (BIB), with spiraled administration. Each assessed student received a booklet containing 3 of the 15 cognitive blocks according to a design that ensured that each block was administered to a representative sample of students within each jurisdiction. The third cognitive block was always one of the four hands-on blocks; this requirement meant that the BIB was partially balanced (PBIB).

In addition to two 30-minute sections of cognitive questions and the 30-minute performance task section, each booklet included two 5-minute sets of general and science background questions designed to gather contextual information about students, their experiences in science, and their attitudes toward the subject, and one 3-minute section of motivation questions designed to gather information about the student's level of motivation while taking the assessment.

In addition to the student assessment booklets, three other instruments provided data relating to the assessment: a science teacher questionnaire, a school characteristics and policies questionnaire, and an SD/LEP student questionnaire (for students categorized as students with disabilities or with limited English proficiency).

The *teacher questionnaire* was administered to the science teachers of the eighth-grade students participating in the assessment. The questionnaire consisted of three sections and took approximately 20 minutes to complete. The first section focused on the teacher's general background and experience; the second, on the teacher's background related to science; and the third, on classroom information about science instruction.

The *school characteristics and policies questionnaire* was given to the principal or other administrator in each participating school and took about 20 minutes to complete. The questions asked about the principal's background and experience, school policies, programs, and facilities, and the demographic composition and background of the students and teachers.

The *SD/LEP student questionnaire* was completed by the staff member most familiar with any student selected for the assessment who was classified in either of two ways: students with disabilities (SD) had an Individualized Education Plan (IEP) or equivalent special education plan (for reasons other than being gifted and talented); students with limited English proficiency were classified as LEP students. The questionnaire took approximately three minutes to complete and asked about the student and the special programs in which the student participated. It was completed for all selected SD or LEP students regardless of whether or not they participated in the assessment. Selected SD or LEP students participated in the assessment if they were determined by the school to be able to participate, considering the terms of their IEP and accommodations provided by the school or by NAEP.

C.4 The Sampling Design

The sampling design for NAEP is complex, in order to minimize burden on schools and students while maximizing the utility of the data. For further details see the *Technical Report for the NAEP 1996 State Assessment Program in Science*. The target populations for the state assessment program in science consisted of eighth-grade students enrolled in either public or nonpublic schools. The representative samples of public school eighth graders assessed in the state assessment program came from about 100 schools (per grade) in each jurisdiction. If a jurisdiction had fewer than 100 public schools with a particular grade, all or almost all schools were asked to participate. If a jurisdiction had smaller numbers of students in each school than expected, more than 100 schools were selected for participation. The nonpublic school samples differed in size across the jurisdictions, with the number of schools selected proportional to the nonpublic school enrollment within each jurisdiction. Typically, about 25 nonpublic schools were included for each jurisdiction. The school samples in each state were designed to produce aggregate estimates for the jurisdiction and for selected subpopulations (depending upon the size and distribution of the various subpopulations within the jurisdiction) and also to enable comparisons to be made, at the jurisdiction level, between administration of assessment tasks with monitoring and without monitoring. The public schools were stratified by urbanization, percentage of Black and Hispanic students enrolled, and median household income within the ZIP code area of the school. The nonpublic schools were stratified by type of control (Catholic, private/other religious, other nonpublic), metropolitan status, and enrollment size per grade.

The national and regional results are based on nationally representative samples of eighth-grade students. The samples were selected using a complex multistage sampling design involving the sampling of students from selected schools within selected geographic areas across the country. The sample design had the following stages:

- (1) selection of geographic areas (a county, group of counties, or a metropolitan statistical area);
- (2) selection of schools (public and nonpublic) within the selected areas; and
- (3) selection of students within selected schools.

Each selected school that participated in the assessment, and each student assessed, represent a portion of the population of interest. To make valid inferences from student samples to the respective populations from which they were drawn, sampling weights are needed. Discussions of sampling weights and how they are used in analyses are presented in sections C.7 and C.8.

The state results provided in this report are based on state-level samples of eighth-grade students. The samples of both public and nonpublic school students were selected based on a two-stage sample design that entailed selecting students within schools. The first-stage samples of schools were selected with a probability proportional to the eighth-grade enrollment in the schools. Special procedures were used for jurisdictions with many small schools and for jurisdictions with a small number of schools. As with the national samples, the state samples were weighted to allow for valid inferences about the populations of interest.

The results presented for a particular jurisdiction are based on the representative sample of students who participated in the 1996 state assessment program. The results for the nation and regions of the country are based on the nationally and regionally representative samples of students who were assessed as part of the national NAEP program. Using the national and regional results from the 1996 national assessment was necessary because of the voluntary nature of the state assessment program. Because not every state participated in the program, the aggregated data across states did not necessarily provide representative national or regional results.

In most jurisdictions, up to 30 students were selected from each school, with the aim of providing an initial sample size of approximately 3,000 public school students per jurisdiction for the eighth grade. The student sample size of 30 for each school was chosen to ensure that at least 2,000 public school students participated from each jurisdiction, allowing for school nonresponse, exclusion of students, inaccuracies in the measures of enrollment, and student absenteeism from the assessment. In jurisdictions with fewer schools, larger numbers of students per school were often required to ensure initial samples of roughly 3,000 students. In certain jurisdictions, all eligible eighth graders were targeted for assessment. Jurisdictions were given the option to reduce the expected student sample size in order to reduce testing burden and the number of multiple-testing sessions for participating schools. At grade 8, four jurisdictions (Alaska, Delaware, Hawaii, and Rhode Island) elected to exercise this option. Using this option can involve compromises such as higher standard errors and accompanying loss of precision.

In order to provide for wider inclusion of students with disabilities and limited English proficiency, the 1996 state assessments both in mathematics and science involved dividing the sample of students at each grade level into two subsamples, referred to as S1 and S2. S1 provided continuity with the 1992 mathematics assessment and thus allowed for the reporting of performance over time by using the same exclusion criteria for students with disabilities and limited English proficiency as was used in that assessment. S2 provided for wider inclusion of students with disabilities and limited English proficiency by incorporating new exclusion rules.

The NAEP 1996 science assessment was developed using a new framework, and therefore does not include reporting of performance over time. However, in order to make the sample design identical for both subjects at the state level, both S1 and S2 were included. For further discussion, see the *NAEP 1996 Science Report Card*.

The 1996 national assessment in science used only the more inclusive S2 guidelines for student participation. The national assessments in mathematics and science both involved an additional subsample, S3, in which accommodations were provided for certain students with disabilities or limited English proficiency, again in order to make NAEP more inclusive.

For the national science assessment, scaling and analysis procedures (discussed in sections C.8 through C.10) were applied to all assessed students from S2. For the state science assessment, scaling and analysis procedures were applied to a combination of all assessed students from S2 and students who were **not** identified as SD or LEP from S1. This combination of segments of the S1 and S2 subsamples maximized the usefulness of available data while allowing for comparisons to the student population in the national sample. This combination, referred to as the “reporting sample,” was the sample used to link the state science assessment to the national assessment (see Section C.10), as well as for scaling and reporting.

Additional analyses will be conducted on the national samples to study the effects of changing the exclusion rules and allowing the use of accommodations. Preliminary discussion can be found in the *NAEP 1996 Science Report Card* and the *NAEP 1996 Mathematics Report Card*; more detailed discussion will follow in future NAEP publications.

C.5 Field Administration

Administering the 1996 program required collaboration among staff in the participating jurisdictions and schools and the NAEP contractors, especially Westat, the field administration contractor.

Each jurisdiction volunteering to participate in the 1996 state assessment program appointed a state coordinator to serve as liaison between NAEP staff and the participating schools. In addition, Westat hired and trained a supervisor for each jurisdiction and six field managers who worked with groups of jurisdictions. The state supervisors worked with the state coordinators, overseeing assessment activities, training school district personnel to administer the assessment, and coordinating quality control monitoring efforts. Each field manager worked with the state coordinators from seven to eight jurisdictions and the state supervisors assigned to those jurisdictions. An assessment administrator prepared and conducted the assessment session in one or more schools. These individuals were usually school or district staff and were trained by Westat. Westat also hired and trained three to five quality control monitors in each jurisdiction. For jurisdictions that had previously participated in the state assessment program, 25 percent of the public and nonpublic school sessions were monitored. For jurisdictions new to the program, 50 percent of all sessions were monitored. The assessment sessions were conducted during a five-week period beginning in late January 1996.

C.6 Materials Processing, Professional Scoring, and Database Creation

Upon completion of each assessment session, school personnel shipped the assessment booklets and forms to NCS for professional scoring, entry into computer files, and checking. The files were then sent to ETS for creation of the database.

After NCS received all appropriate materials from a school, they were forwarded to the professional scoring area where the responses to the constructed-response question were evaluated by trained staff using guidelines prepared by ETS. Each constructed-response question had a unique scoring guide that defined the criteria to be used in evaluating students' responses. The extended constructed-response questions were evaluated with four- or five-level rubrics. Some of the short constructed-response questions were rated according to three-level rubrics that permit partial credit to be given; other short constructed-response questions were scored as either acceptable or unacceptable.

For the national science assessment and the state assessment program in science, over 4.1 million constructed responses were scored. This figure includes rescoring to monitor interrater reliability. The overall percentage of agreement between scorers for the reliability sample was 93 percent for the tasks in the cognitive blocks and 95 percent for the hands-on tasks.

Data transcription and editing procedures were used to generate the disk and tape files containing various assessment information, including the sampling weights required to make valid statistical inferences about the population from which the state assessment program sample was drawn. Prior to analysis, the data from these files underwent a quality control check at ETS. The files were then merged into a comprehensive, integrated database.

C.7 Weighting and Variance Estimation

A complex sample design was used to select the students who were assessed in each of the participating jurisdictions. The properties of a sample selected through a complex design are very different from those of a simple random sample in which every student in the target population has an equal chance of selection and in which the observations from different sampled students can be considered to be statistically independent of one another. Therefore, the properties of the sample for the complex state assessment program design were taken into account during the analysis of the assessment data.

One way that the properties of the sample design were addressed was by using sampling weights to account for the fact that the probabilities of selection were not identical for all students. All population and subpopulation characteristics based on the state assessment program data used sampling weights in their estimation. These weights included adjustments for school and student nonresponse.

Not only must appropriate estimates of population characteristics be derived, but appropriate measures of the degree of uncertainty must be obtained for those statistics. One component of uncertainty results from sampling variability, which is a measure of the dependence of the results on the particular sample of students actually assessed. Because of the effects of cluster selection (schools are selected first, then students are selected within those schools), observations made on different students cannot be assumed to be independent of each other (and, in fact, are generally positively correlated). As a result, classical variance estimation formulas will produce incorrect results. Thus, a jackknife variance estimation procedure that accounts for the characteristics of the sample was used for all analyses.

Jackknife variance estimation provides a reasonable measure of uncertainty for any statistic based on values observed without error. Statistics such as the percentage of students correctly answering a given question meet this requirement, but other statistics based on estimates of student science performance, such as the average science scale score of a subpopulation, do not. Because each student typically responds to relatively few questions from a particular field of science (e.g., physical or life science), a nontrivial amount of imprecision exists in the measurement of the scale score of a given student. This imprecision adds another component of variability to statistics based on estimates of individual performance.

C.8 Preliminary Data Analysis

After the computer files of student responses were received and merged into an integrated database, all cognitive and noncognitive questions were subjected to an extensive item analysis. For each cognitive question, this analysis yielded the number of respondents, the percentage of responses in each category, the percentage who omitted the question, the percentage who did not reach the question, and the correlation between the question score and the block score. In addition, the item analysis program provided summary statistics for each block of cognitive questions, including a reliability (internal consistency) coefficient. These analyses were used to check the scoring of the questions, to verify that the difficulty level of the questions was appropriate, and to ensure that students had received adequate time to complete the assessment. The results were reviewed by knowledgeable project staff in search of aberrations that might signal unusual results or errors in the database.

The question and block-level analyses were conducted using rescaled versions of the final sampling weights provided by Westat (see Section C.7). The rescaling was implemented for each jurisdiction. The sum of the sampling weights for the public school students within each jurisdiction was constrained to be equal. The same transformation was applied to the weights of the nonpublic school students in that jurisdiction. The sum of the weights for each of the Department of Defense (DoDEA) samples (i.e., DDESS and DoDDS) was constrained to equal the same value as the public school students in other jurisdictions. Using rescaled weights does not alter the value of statistics calculated separately within each jurisdiction. However, for statistics obtained from samples that combine students from different jurisdictions, using rescaled weights results in a roughly equal contribution of each jurisdiction's data to the final value of the estimate. Equal contribution of each jurisdiction's data to the results of the item response theory (IRT) scaling was viewed as a desirable outcome. The original final sampling weights provided by Westat were used in reporting.

Additional analyses that compared the data from the monitored sessions with those from the unmonitored sessions were conducted to determine the comparability of the assessment data from the two types of administrations. Differential item functioning (DIF) analyses were carried out using the national assessment data. DIF analyses identified questions that were differentially difficult for various subgroups, so that these questions could be re-examined for their fairness and their appropriateness for inclusion in the scaling process.

C.9 Scaling the Assessment Questions

The primary analysis and reporting of the results from the state assessment program used item response theory (IRT) scale-score models. Scaling models quantify a respondent's tendency to provide correct answers to the domain of questions that contribute to a scale as a function of a parameter called performance, estimated by a scale score. The scale scores can be viewed as a summary measure of performance across the domain of questions that make up the scale. Three distinct IRT models were used for scaling: three-parameter logistic models for multiple-choice questions; two-parameter logistic models for short constructed-response questions that were scored correct or incorrect; and generalized partial credit models for short and extended constructed-response questions that were scored on a multipoint scale (i.e., greater than two levels).

Three distinct scales were created for the state assessment program in science to summarize eighth-grade students' abilities according to the three defined fields of science (earth, physical, and life). These scales were defined identically to, but separately from, those used for the scaling of the national NAEP eighth-grade science data. Although the questions composing each scale were identical to those used in the national assessment program, the item parameters for the state assessment program scales were estimated from combined public school data from the jurisdictions participating in the state assessment program.¹ Item parameter estimation was carried out on an item calibration subsample. The calibration subsample consisted of a sample drawn from approximately 25 percent sample of all available public school data. To ensure equal representation in the scaling process, each jurisdiction contributed the same number of students to the item calibration sample. Within each jurisdiction, 25 percent of the calibration sample was taken from monitored administrations while the remaining 75 percent came from unmonitored administrations.

Within each scale, the estimates of the empirical item characteristic functions were compared with the theoretical curves to determine how well the IRT model fit the observed data. For correct-incorrect questions, nonmodel-based estimates of the expected proportions of correct responses to each question for students with various levels of scale proficiency were compared with the fitted item response curve. For the short and extended partial-credit constructed-response questions, the comparisons were based on the expected proportions of students with various levels of scale proficiency who achieved each score level. In general, the scaling models fit the question-level results well.

¹ For the creation of scales, schools from the DoDEA jurisdictions are considered nonpublic, so the responses from these students were not included in the item calibration sample.

Using the item parameter estimates, estimates of various population statistics were obtained for each jurisdiction. The NAEP methods use random draws (“plausible values”) from estimated proficiency distributions for each student to compute population statistics. Plausible values are not optimal estimates of individual student proficiencies; instead, they serve as intermediate values to be used in estimating population characteristics. Under the assumptions of the scaling models, these population estimates will be consistent, in the sense that the estimates approach the model-based population values as the sample size increases, which would not be the case for population estimates obtained by aggregating optimal estimates of individual performance.

The 1996 science assessment was developed using a new framework. Because it was not appropriate to compare results from the 1996 assessment to those of previous NAEP science assessments, no attempt was made to link or align scores on the new assessment to those of previous assessments. Therefore, it was necessary to establish a new scale for reporting. Earlier NAEP assessments (such as the current mathematics assessment and the 1994 reading assessment) were developed with a cross-grade framework, in which the trait being measured is conceptualized as cumulative across the grades of the assessment. This concept was reflected in the scaling. The score scales developed for these assessments were cross-grade scales on a single 0-500 scale for all three grades in the assessment.

In 1993, the National Assessment Governing Board (NAGB) determined that future NAEP assessments should be developed using within-grade frameworks. This removes the constraint that the trait being measured is cumulative, and there is no need for overlap of questions across grades. Consistent with this view, NAGB also declared that scaling be performed within-grade. Any items which happened to be the same across grades in the assessment were scaled separately for each grade, thus allowing common items, potentially, to function differently in the separate grades. The 1994 NAEP history and geography assessments were developed and scaled within-grade. After scaling, the scales were aligned so that grade 8 had a higher mean than did grade 4, and grade 12 had a higher mean than grade 8. The results were reported on a final 0-500 scale that looked similar to those used in mathematics and reading, in spite of the differences in development and scaling. This definition of the reporting scale was a source of potential confusion and misinterpretation.

The 1996 science assessment was also developed and scaled using within-grade procedures. A new reporting metric was adopted to differ from the 0-to-500 reporting scales used in other NAEP subject areas in order to minimize confusion with other common test scales and to discourage cross-grade comparisons. For each grade in the national assessment, the mean for each field of science was set at 150 and the standard deviation was set at 35. First, the reporting metric was developed using data from the national assessment program; the results for the state assessment program were then linked to that scale using procedures described in Section C.10.

In addition to the plausible values for each scale, a composite of the three fields of science scales was created as a measure of overall science performance; as for the individual fields of science scales, the mean of the composite scale was set to 150 with a standard deviation of 35.² This composite was a weighted average of the plausible values for the three fields of science scales. The scales were weighted proportionally to the relative importance assigned to each field of science in the science framework (see Table B.1). The definition of the composite for the state assessment program was identical to that used for the national eighth-grade science assessments.

C.10 Linking the State Results to the National Results

A major purpose of the state assessment program was to allow each participating jurisdiction to compare its 1996 results with those for the nation as a whole and with those for the region of the country where it is located. For meaningful comparisons to be made between each jurisdiction and the relevant national sample, results from these two assessments had to be expressed in terms of a similar system of scale units.

The results from the state assessment program were linked to those from the national assessment through linking functions determined by comparing the results for the aggregate of all students assessed in the state assessment program with the results for eighth-grade students within the National Linking Sample of the national NAEP. The National Linking Sample of the national NAEP is a representative sample of the population of all grade-eligible public school students within the aggregate of 43 participating states and the District of Columbia. (Guam and the two DoDEA jurisdictions were not included in the National Linking Sample.) Specifically, the National Linking Sample for science consisted of all eighth-grade students in public schools in the states and the District of Columbia who were assessed in the national cross-sectional science assessment.

A linear equating within each field of science scale was used to link the results of the state assessment program to the national assessment. For each scale, the adequacy of the linear equating was evaluated by comparing the distribution of science scale scores based on the aggregation of all assessed students at each grade from the participating states and the District of Columbia with the equivalent distribution based on the students in the National Linking Sample. In the estimation of these distributions, the students were weighted to represent the target population of public school students in the specified grade in the aggregation of the states and the District of Columbia. If a linear equating were adequate, the distribution for the aggregate of states and the District of Columbia and that for the National Linking Sample would have, to a close approximation, the same shape in terms of the skewness, kurtosis, and higher moments of the distributions. The only differences in the distributions allowed by linear equating would be in the means and variances. Generally, this has been found to be the case.

Thus, each field of science scale was linked by matching the scale mean and standard deviation of the scale scores across all students in the state assessment (excluding Guam and the two DoDEA jurisdictions) to the corresponding mean and standard deviation across all students in the National Linking Sample.

² The national average of students in public and nonpublic schools combined is 150. The national average seen in the tables in this report is based on the average for public schools only (148).

APPENDIX D

Teacher Preparation

Because teachers are key to improving science education, their background and professional development should be examined. Eighth-grade science teachers completed questionnaires about their background and training, including their experience, certification, undergraduate and graduate course work in science, and involvement in pre-service education.

Consistent with procedures used throughout this report, the student was the unit of analysis. That is, the science teachers' responses were linked to their students, and the data reported are the percentages of *students taught by these teachers* rather than the percentages of *teachers*.

The tables in Appendix D represent only a few of the questions in the teacher questionnaire, and this small selection can give only a sketchy profile of the teachers.¹ A report scheduled to appear in early 1998 will explore more of the questions related to school and classroom policy and practices and should give a better picture of the nation's teachers.

¹ The interested reader can obtain additional information on teachers' characteristics and qualifications and the conditions under which they teach in *SASS by State* (NCES 96-312) from the 1993-94 Schools and Staffing Survey. URL: <http://www.ed.gov/NCES/pubs/96312.html>.

	TABLE D.3
	<i>Public School Teachers' Reports on Their Teaching Certification</i>

Oregon	West	Nation
Percentage		

<i>What type of teaching certification do you have in this state in your main assignment field?</i>			
I don't have a certificate in my main assignment field.	3 (1.3)	1 (****)	1 (0.5)
Certification by an accreditation body other than the state	0 (****)	0 (****)	0 (****)
Temporary, provisional, or emergency state certificate	0 (****)	5 (2.9)	4 (1.3)
Probationary state certificate (initial certificate)	7 (2.0)	1 (****)	3 (1.3)
Regular or standard state certificate	82 (3.0)	89 (4.7)	79 (3.5)
Advanced professional certificate	8 (2.2)	4 (****)	13 (3.0)
<i>Do you have teaching certification in any of the following areas that is recognized by the state in which you teach? (multiple responses possible)</i>			
Elementary or middle/junior high school education	56 (3.6)	77 (5.6)	66 (5.9)
Elementary science	21 (5.0)	45 (10.1)	25 (4.3)
Middle/junior high school or secondary science	85 (2.7)	97 (1.2)	95 (1.6)
Other	43 (5.3)	59 (9.6)	51 (6.3)

The standard errors of the statistics appear in parentheses. It can be said with about 95 percent confidence that, for each population of interest, the value for the entire population is within ± 2 standard errors of the estimate for the sample. In comparing two estimates, one must use the standard error of the difference (see Appendix A for details). **** Standard error estimates cannot be accurately determined.

11-24 years	45 (3.6)	37 (6.6)	36 (4.1)
25 years or more	16 (3.1)	10 (3.6)	24 (3.2)
<i>taught science?²</i>			
2 years or less	12 (2.4)	9 (2.7)	13 (2.4)
3-5 years	12 (2.8)	16 (4.6)	11 (2.2)
6-10 years	28 (4.2)	44 (7.1)	30 (3.2)
11-24 years	35 (4.2)	25 (4.8)	26 (3.4)
25 years or more	14 (3.4)	5 (3.2)	20 (3.0)

The standard errors of the statistics appear in parentheses. It can be said with about 95 percent confidence that, for each population of interest, the value for the entire population is within ± 2 standard errors of the estimate for the sample. In comparing two estimates, one must use the standard error of the difference (see Appendix A for details). ¹Teachers were instructed to include part-time teaching experience. ²Teachers were instructed to include full-time and part-time assignments, but not substitute assignments.

ACKNOWLEDGMENTS

This report is the culmination of the effort of many individuals who contributed their considerable knowledge, experience, and creativity to the NAEP 1996 science assessment. The NAEP 1996 science assessment was a collaborative effort among staff from the National Center for Education Statistics (NCES), the National Assessment Governing Board (NAGB), Educational Testing Service (ETS), Westat, Inc., and National Computer Systems (NCS). In addition, the program benefited from the contributions of hundreds of individuals at the state and local levels — governors, chief state school officers, state and district test directors, state coordinators, and district administrators — who tirelessly provided their wisdom, experience, and hard work. Most importantly, NAEP is grateful to the over 109,000 students and the teachers and administrators from 4,400 schools in 47 jurisdictions who made the science assessment possible.

The NAEP 1996 science assessment was funded through NCES, in the Office of Educational Research and Improvement of the U.S. Department of Education. The Commissioner of Education Statistics, Pascal D. Forgione, and the NCES staff — Sue Ahmed, Peggy Carr, Arnold Goldstein, Steven Gorman, Larry Ogle, Gary W. Phillips, Sharif Shakrani, Maureen Treacy — worked closely and collegially with the authors to produce this report. The authors were also provided guidance by the members of the National Assessment Governing Board and NAGB staff. In particular, the authors are indebted to Arnold Goldstein of NCES for his daily efforts to coordinate the activities of the many people who contributed to this report.

The NAEP project at ETS is housed in the Center for the Assessment of Educational Progress under the direction of Paul Williams. The NAEP 1996 assessments were directed by Stephen Lazer and John Mazzeo. Tom Corley, Lee Jones, Tim Liggett, Beth Nichols, Christine O'Sullivan, Amy Pearlmutter, Will Pfeifferberger, Mario Yepes-Baraya, and Ann Marie Zolandz worked with the Science Instrument Development committee to develop the assessment instrument. Sampling and data collection activities were conducted by Westat under the direction of Rene Slobasky, Nancy Caldwell, Keith Rust, and Dianne Walsh. Printing, distribution, scoring, and processing activities were conducted by NCS under the direction of Brad Thayer, Patrick Bourgeacq, Charles Brungardt, Jay Happel, Mathilde Kennel, Linda Reynolds, and Brent Studer.

The complex statistical and psychometric activities necessary to report results for the NAEP 1996 Science Assessment were directed by Nancy Allen, John Barone, James Carlson, and Juliet Shaffer. The analyses presented in this report were led by John Donoghue and Steven Isham with assistance from Spencer Swinton, Lois Worthington, Inge Novatkoski, Kate Pashley, David Freund, and Norma Norris.

Laura Jerry was responsible for the development and creation of the computer-generated reports, with assistance from Xiaohui Wang, Laura Jenkins, Phillip Leung, Inge Novatkoski, Bruce Kaplan, and Alfred Rogers. Two of the reports were skillfully produced by Karen Damiano. A large group of NAEP staff at ETS checked the data, text, and tables. Debbie Kline coordinated the technical appendices. The overall production efforts were completed by Carol Errickson, Barbetta Tardugno, Loretta Casalaina, Kelly Gibson (cover design), Sharon Davis-Johnson, and Alice Kass. Editorial assistance was provided by Walt Brower and by John Calderone of Aspen Systems. The World Wide Web version of the state reports was produced by Philip Leung and Pat O'Reilly with assistance from Debbie Kline, Craig Pizzuti, and Christine Zelenak.

Many thanks are due to the numerous reviewers, both internal and external to NCES and ETS. The comments and critical feedback of the following reviewers are reflected in this report: Sue Ahmed, Peggy Carr, Mary Frase, Arnold Goldstein, Andrew Kolstad, Michael Ross, and Shi-Chang Wu of NCES; Rolf Blank of CCSSO; Audrey Champagne of the State University of New York in Albany; Michelle Leon of the Connecticut Department of Education; Will Pfeiffenberger of ETS; Senta Raizen of the National Center for Improving Science Education; and Mistilina Sato of Stanford University.

NAEP 1996 Science Instrument Development Committee

An Instrument Development Committee was convened to oversee the development of items and scoring rubrics. Committee members wrote assessment exercises and ensured that the instrument adhered to the assessment framework and specifications. In addition, the committee made certain that the instrument was developmentally appropriate for each grade and that it was relevant to curricular and instructional goals. The members are to be commended for their diligence and dedication to the lengthy process of producing the instrument:

Gail Baxter, University of Michigan

Ron Bonnstetter, University of Nebraska

Audrey Champagne, State University of New York at Albany

Richard Clark, Minnetonka, Minnesota

Sally Crissman, Shady Hill School, Cambridge, Massachusetts

Pat Dung, Los Angeles Educational Partnership

Michael Johnson, Science Skills Center

Michael Jojola, Isleta, New Mexico

Clifton Poodry, University of California at Santa Cruz

Senta Raizen, National Center for Improving Science Education

Douglas Reynolds, Rensselaer, New York

Realista Rodriguez, Stuart High School, Falls Church, Virginia

Mistilina Sato, Stanford University

Gerald Weaver, University City High School, Philadelphia, Pennsylvania

Mary Louise Bellamy, National Association of Biology Teachers

ERRATA NOTICE

Date: December 29, 1997

To: Participants in the NAEP 1996 Science State Assessment

From: Nada Ballator

Re: Replacement pages attached for NAEP 1996 Science State Reports, correcting error in national and regional data in Table 6.2 and associated text

An error was recently discovered in the *national and regional* data presented in Table 6.2 of the 1996 science state reports. *For all states and jurisdictions, the data are correct*; however, incorrect national data made it necessary to recompute comparisons between state and national results. The error involved the student background item, "About how many books are in your home?" which is reported in the *NAEP 1996 Science State Report* in Table 6.2, as well as in the bullets comparing your jurisdiction with the nation.

Attached to this memo are the two corrected pages to insert into your printed reports. If you received camera-ready copy of the NAEP 1996 science state report, we have also enclosed pages for insertion there. The pages are for Chapter 6 in the section on "Literacy Materials in the Home" which includes Table 6.2; they contain revised comparisons to national data, and revised national and regional data in the table. We apologize for the publication of inaccurate data, and for the extra effort its correction will cause you.

DONE

The state science reports appear on the NCES web site (<http://nces.ed.gov/naep>). All affected reports on the web were corrected on December 17. There is now a **Revised** logo beside the reports on the Index of Results and Summary Data web page (<http://nces.ed.gov/naep/rsdindex.shtml>) and on the Current Assessment Results web page (<http://nces.ed.gov/naep/naep1996.html>), and an **Errata Notice** containing a brief description of the repair on the NAEP 1996 Science State Reports web page (<http://nces.ed.gov/naep/96state/97499.shtml>).

Also on the web site, the student data tables for national science results for public schools have been revised. On the web page for NAEP 1996 Summary Data Tables, Student Data (<http://nces.ed.gov/naep/tables96/index.shtml>), you will see an **Errata Notice** describing the repair. Please alert anyone who may be using national 1996 science student data to this revision concerning the raw variable, "How many books are in your home," and the derived variable HOMEEN3, "Home environment - Articles (of 4) in home."

We very much regret the extra work that this error may have necessitated in your jurisdiction; we will redouble our efforts to prevent such things happening again.
