ABSTRACT

This study examines the magnitude of the difference between estimates from the 1990-91 Schools and Staffing Survey (SASS) using a Common Core of Data (CCD) definition of a school and a Quality Education Data (QED) definition of a school. The 1990-91 SASS sample design allows for the development of school and administrator estimates using either the QED definition or the definition from the CCD. The first section of the report explains the background and purpose of the study and describes the variables of interest chosen for the study. The second section describes the steps involved in converting the 1990-91 SASS to a QED-defined survey, identifies the file variables that indicate which CCD schools map to a QED school, and describes the use of those variables in mapping from the CCD definition to the QED definition. The third section presents selected tables based on the QED definition of a school to allow comparisons, and the fourth section analyzes the estimates from both definitions and makes recommendations based on the magnitude of the difference in school characteristics between the two estimates. An appendix contains a sample of the Statistical Analysis System programs used in this study. (Contains 25 tables.) (SLD)

Foreword

Each year a large number of written documents are generated by NCES staff and individuals commissioned by NCES which provide preliminary analyses of survey results and address technical, methodological, and evaluation issues. Even though they are not formally published, these documents reflect a tremendous amount of unique expertise, knowledge, and experience.

The *Working Paper Series* was created in order to preserve the valuable information contained in these documents and to promote the sharing of valuable work experience and knowledge. However, these documents were prepared under different formats and did not undergo vigorous NCES publication review and editing prior to their inclusion in the series. Consequently, we encourage users of the series to consult the individual authors for citations.

To receive information about submitting manuscripts or obtaining copies of the series, please contact Suellen Mauchamer at (202) 219-1828 or U.S. Department of Education, Office of Educational Research and Improvement, National Center for Education Statistics, 555 New Jersey Ave., N.W., Room 400, Washington, D.C. 20208-5652.

Preface

This report compares derived QED estimates and the original estimates of the same or similar variables from the 1990-91 Schools and Staffing Survey (SASS). It was prepared by Synectics for Management Decision Inc., a contractor to the National Center for Education Statistics, as Task 20B.1 under Contract No. RN-91-0600.01.

This report was prepared by Albert Holt, a research analyst for Synectics. Additional assistance from the Synectics staff was provided by Sameena Salvucci, Fan Zhang, Mehrdad Saba, and Brian R. Scanlon, all working under the direction of Wray Smith, Research Director.

Several key people from National Center for Education Statistics are also worth mentioning. Daniel Kasprzyk, Kerry Gruber, and Steve Kaufman were instrumental in reviewing and providing helpful comments on all drafts. This report would not have been possible without their valuable support.

1. INTRODUCTION

1.1 - Overview

This study examines the magnitude of the difference between estimates from the 1990-91 Schools and Staffing Survey (SASS) using a Common Core of Data (CCD) definition of a school and a Quality Education Data (QED) definition of a school.¹ The 1990-91 SASS sample design allows for the development of school and administrator estimates using either the QED definition of a school or the CCD definition of a school.

This report will develop and compare QED-defined school and administrator estimates for the 1990-91 SASS, then compare them to existing CCD-defined estimates from the same survey. For the purposes of comparing these two estimates, specific tables have been selected from "Schools and Staffing in the United States: A Statistical Profile, 1990-91."²

A comparison of newly generated QED-defined tables and existing CCD-defined tables from the 1990-91 SASS will indicate the differences in estimates of the same survey using separate criteria for defining the sample.

The four sections of this report will:

- (1) Explain the background and purpose of this study and describe the variables of interest chosen for this study.
- (2) Describe the necessary steps involved in converting the 1990-91 SASS to a QED-defined survey. Identify the file variable(s) that indicate which CCD schools map to a QED school, and describe the use of those variable(s) in mapping from the CCD definition to the QED definition of a school.
- (3) Produce a set of selected tables from the 1990-91 SASS Statistical Profile based upon the QED definition of school for comparing to CCD-defined survey estimates.
- (4) Analyze the estimates from both a QED-defined survey and the 1990-91 SASS, a CCD-defined survey, and make recommendations based upon the magnitude of the difference in school characteristics between the two estimates.

¹The QED defined a school as a physical location, while the CCD defined it as an administrative unit. When the CCD and QED frames are matched, multiple CCD schools can map to one QED school.

²"Schools and Staffing in the United States: A Statistical Profile, 1990-91." U.S. Department of Education, Office of Education Research and Improvement." NCES 93-146.

1.2 - Background

The Schools and Staffing Survey (SASS) was first conducted during the 1987-88 school year. The public school sampling frame for the initial SASS was constructed by Quality Education Data, Inc. (QED). In this frame, a public school was defined as a physical unit or location. In the 1990-91 SASS, the public school frame was based on the 1988-89 Common Core of Data (CCD). The information in the CCD database is collected by the National Center for Education Statistics (NCES) annually, and is believed to be the most comprehensive list of public schools available. The CCD-defined school is not a physical location, but an administrative unit. This difference in definition presented some concerns; some (CCD-defined) schools have two or more administrative units within one (QED-defined) physical location. In some cases, multiple CCD-defined schools map to a single QED-defined school. This suggests that the estimates for the number of schools would be higher based on the CCD definition. The 1990-91 SASS sample design has a flexibility (for researchers using the NCES Restricted Use Datasets) in that it facilitates the production of school, administrator, and teacher estimates using either the QED or the CCD definition of a school.

1.3 - Purpose

The purpose of this report is to measure the magnitude of the differences in estimates due to the difference in the CCD and QED definitions of a public school using the flexibility that has been built into the 1990-91 SASS sample design. A major component of such a measurement will be the number of schools that are affected by this difference in definition. This effort will investigate the proportion of schools which are affected with respect to the total number of schools, and will look at the characteristics of the affected schools. Examining the characteristics of affected schools may help to determine whether or not there are common traits in those schools which do not map from a CCD-defined school to a QED-defined school, such as community type. In the broadest sense, a determination will be made regarding the statistical significance of the difference in CCD and QED estimates based on the difference in definitions of a school.

2. TECHNICAL APPROACH

2.1 - Identification of Variables of Interest

Several tables in the "Schools and Staffing in the United States: A Statistical Profile, 1990-91" (July 1993)³ are reasonable to use for comparison of estimates based on the CCD and QED definitions. The generation of these tables included use of variables in the SASS, and constructed variables where necessary to produce estimates or groups of estimates.

Variables from the School, Administrator, and Teacher surveys are used to provide estimates for comparing CCD to QED defined totals and to create guidelines for grouping into SASS tables. Tables 1 through 3 on pages 4,5, and 6 list the constructed variables, and the variables of interest for schools and school administrators.

³"Schools and Staffing in the United States: A Statistical Profile, 1990-91." U.S. Department of Education, Office of Education Research and Improvement." NCES 93-146.

2.2 - Definitions and Descriptions for Stratification Variables

COMMUNITY TYPE. For the 1990-91 SASS Statistical Profile, "Community Type" was derived from a locale code based on the school's mailing address matched to Bureau of the Census data files containing population density data, Standard Metropolitan Statistical Area (SMSA) codes, and a Census code defining Urban and Rural areas.⁴ The locale codes were aggregated into three community types: Central City, Urban Fringe/Large Town, and Rural/Small City. The seven categories for the Census locale code are as follows:

- locale 1 Large Central City (Central city of SMSA with population of greater than or equal to 400,000 or population density of greater than or equal to 6,000 persons per square mile)
- locale 2 Mid-Size Central City (Central City of SMSA but not designated Large Central City)
- locale 3 Urban Fringe of Large City (Place within an SMSA of Large Central City and defined as Urban by U.S. Bureau of Census)
- locale 4 Urban Fringe of Mid-Size City (Place within an SMSA OF Mid-Size Central City and defined as Urban by U.S. Bureau of Census)
- locale 5 Large Town (Place not within an SMSA, but with population greater than or equal to 25,000 and defined as Urban by U.S. Bureau of Census)
- locale 6 Small Town (Place not within an SMSA, with population less than 25,000 but greater than or equal to 2,500 and defined as Urban by U.S. Bureau of Census)
- locale 7 Rural (Place with population less than 2,500 and defined as Rural by U.S. Bureau of Census)

⁴Johnson, Frank. (1989). *Assigning Type of Locale Codes to the 1987-88 CCD Public School Universe*. NCES Technical Report CS 89-194. Washington: Office of Educational Research and Improvement.

COMTYPE represents Community Type.

The 7 value variable LOCALE was collapsed the following way:

If the community was defined as a large or mid-size central city (locale codes 1 and 2), it was designated as a central city. If the community was defined as being an urban fringe of a large or mid-size city, or a large town (locale codes 3, 4, and 5) it was designated as an urban fringe/large town. If the community was defined as a small town, or rural (locale codes 6 and 7), it was designated as rural/small town.

MINORITY ENROLLMENT. For many of the tables included in the 1990-91 SASS Statistical Profile, a stratification was created for percentage of minority enrollment at less than 20 percent / greater than or equal to 20 percent. This percentage was determined by taking the sum of the enrollment of students by ethnicity for all but white students over the sum of enrollment by ethnicity for all students.

aminstu represents American Indian student, *asianstu* represents Asian/Pacific Islander student, *hispnstu* represents Hispanic student, and *blackstu* represents black student.

MIN_STAT represents Minority Enrollment, calculated the following way:

percent minority=100*(sum(aminstu,asianstu,hispnstu,blackstu) /
sum(aminstu,asianstu,hispnstu,blackstu,whitestu));

MIN_STAT=1 Minority Enrollment Less Than 20 percent

MIN_STAT=2 Minority Enrollment Greater Than or equal to 20 percent

SCHOOL SIZE. In the 1990-91 SASS Statistical Profile, a four-category variable was constructed based on the total enrollment of a school. The categories are:

1. < 150 students
2. 150-499 students
3. 500-749 students
4. 750 + students

SCH_SIZE represents School Size (Enrollment); totenrll represents Total Enrollment. It was defined as the sum of grades K through 12 plus ungraded. Enrollment is categorized the following way:

```
if 0 le totenrll lt 150 then sch_size=1;  
else if 150 le totenrll lt 500 then sch_size=2;  
else if 500 le totenrll lt 750 then sch_size=3;  
else if 750 le totenrll then sch_size=4;
```

SCHOOL LEVEL. The school level variable "SCHLEVEL" is available in the SASS files. It consists of the following three categories:

1. elementary school
2. secondary school
3. combined elementary and secondary school

A school is defined as elementary if the school has only grades below 8th grade. A school defined as secondary has grades between 7th and 12th. A school is considered to be combined elementary and secondary if the school has any other combination of grades. Two examples of a combined school level are 4-8 and 5-12. Secondary schools can have any combination of grades between 7th and 12th grade.

2.3 - Constructed Variables of Interest

The following is a list of some of the formulas used to construct variables of interest for comparison of QED and CCD estimates. This is not a complete list of all the variables that were constructed, but it does demonstrate the formulas and method for computing constructed variables from the 1990-91 SASS.

STUDENT-TEACHER RATIO. To determine the student-teacher ratio, it is necessary to include both full-time teachers and some measurement of part-time teachers. Using as a guide the approach taken in construction of "Schools and Staffing in the United States: A Statistical Profile, 1990-91," a full-time teacher equivalent was determined by totalling the number of full-time teachers and one-half the number of part-time teachers. To ascertain the student-teacher ratio, the total number of students was divided by the number of full-time teacher equivalents.

AVGSTD represents Average number of Students per Full-time Equivalent Teacher. *Totenrll* represents total enrollment, *fulteach* represents full-time teacher, and *parteach* represents part-time teacher. This variable is calculated as:

$$\text{Avgstd} = \text{totenrll} / (\text{fulteach} + (.5 * \text{parteach}))$$

AVERAGE SCHOOL SIZE. For any particular subgroup of analysis, average school size was determined by dividing the total number of students by the weighted number of schools.

AVGSIZE represents the Average Enrollment per School (in the schools being analyzed). It is calculated as:

$$\text{Avgsize} = \text{totenrll} / N; \text{ (where } N \text{ is the weighted number of schools for a given subgroup of analysis)}$$

WHITEP represents Percent Distribution of White Non-Hispanic Students. It is calculated as:

$$\text{Whitep} = \text{whitestu} / \text{sum}(\text{whitestu}, \text{blackstu}, \text{hispnstu}, \text{amindstu}, \text{asianstu}); \text{ (for any given subgroup of analysis)}$$

BLACKSTU represents Percent Distribution of Black Non-Hispanic Students. It is calculated as:

$$\text{blackp} = \text{blackstu} / \text{sum}(\text{whitestu}, \text{blackstu}, \text{hispnstu}, \text{amindstu}, \text{asianstu}); \text{ (for any given subgroup of analysis)}$$

HISPNP represents the Percent Distribution of Hispanic Students. It is calculated as:

$$\text{hisnp} = \text{hispnstu} / \text{sum}(\text{whitestu}, \text{blackstu}, \text{hispnstu}, \text{amindstu}, \text{asianstu}); \text{ (for any given subgroup of analysis)}$$

AMINDSTU represents the Percent Distribution of American Indian Students. It is calculated as:

$$\text{compute amindp} = \text{amindstu} / \text{sum}(\text{whitestu}, \text{blackstu}, \text{hispnstu}, \text{amindstu}, \text{asianstu}); \text{ (for any given subgroup of analysis)}$$

ASIANSTU represents Percent Distribution of Asian/Pacific Islander Students. It is calculated as:

$$\text{asianp} = \text{asianstu} / \text{sum}(\text{whitestu}, \text{blackstu}, \text{hispnstu}, \text{amindstu}, \text{asianstu}); \text{ (for any given subgroup of analysis)}$$

2.4 - Determination of CCD / QED Identifier

The 1990-91 SASS (Round 2) public school sampling frame, the 1988-89 CCD, differed from the 1987-88 SASS (Round 1) public school frame, a listing of schools obtained from the QED. The sample frame for the 1990-91 SASS (1988-89 CCD) defined a school as an administrative unit. The sample frame for the 1987-88 SASS (QED) defined a school as a physical location. The 1990-91 SASS has variables that contain QED and CCD identification numbers. For sample selection purposes, the school sample units in the Round 2 frame were either CCD schools or groups of CCD schools corresponding to a single QED school.

The variable for the CCD number is CCDIDSCH. The variable for the QED number is APIN. In the 1990-91 SASS public school survey, there are 681 records with missing APIN values. As instructed by NCES, these schools had the CCD identification number assigned to the variable APIN. It follows that the records which have a CCD number assigned to the

APIN variable will not be candidates for collapsing to the QED definition, since the input file is based on unique CCD numbers. At this stage, all public school records have both CCD and QED identifiers. Due to differences in the CCD and QED definitions, there are multiple CCD-defined schools that map to one QED-defined school. For this reason, there are more schools in the CCD-defined file than in the QED-defined file.

2.5 - Collapsing of CCD Schools to QED Definition

The 1990-91 SASS Public School Survey used the 1988-89 school year CCD as the frame for the sample of public schools', therefore, construction of CCD-defined tables (the original files) is accomplished using the SASS Public School file in its present form. Each record in the file contains a unique CCD identification number. Proc WESVAR (a SAS procedure developed by WESTAT, Inc.) generated CCD-defined estimates for comparison between the CCD and QED-defined files. Some schools must be collapsed together to accommodate the QED definition of a school. Collapsing is accomplished by executing several steps. First, the QED identification number in each record is examined. If no number is present, the CCD identification number is assigned the QED identification number. Second, records with matching CCD identification numbers are collected together. Third, variables of interest are summed, as is the school's final sample weight. Fourth, the final sample weight is averaged across the number of schools that have matching CCD numbers. Fifth, flags are then set to identify schools which can be collapsed from the CCD to QED-defined schools.

By design, the 1990-91 SASS can produce estimates using either the CCD or the QED definition of school. The variable APIN is used to identify CCD-defined schools which map to one school using the QED definition. CCD schools that map to one QED-defined school are collapsed, with the variables of interest summed, averaged, or quantified as a percentage.

2.6 - Adjustment of Weights for the QED Definition

School Survey

Each CCD school collapsed to fit a QED definition has the same basic weight. This basic weight is the inverse of the probability of selection of a school. In this study, the final weight (SCHWGT) is used for table generation. It is the basic weight times a sampling adjustment factor times a school noninterview factor times a frame ratio adjustment factor. As instructed by NCES, the QED school weight is the average of the CCD school's final weights within a QED-defined school. The calculation of the new final weight is:

$$QEDWGT = (SCHWGT1 + SCHWGT2 + SCHWGT3 + \dots + SCHWGTN) / N$$

Administrator Survey

Weighting for the administrator survey was conducted in the same fashion as described for the school survey. The final weight (ADMWGT), which is the basic weight adjusted for nonresponse, a sampling adjustment factor, and a frame ratio adjustment factor, is used for table generation. NCES suggested the QED school administrator weight should be the average of the CCD school administrator final weights within a QED school. The calculation for the new final weight is:

$$QEDWGT = (ADMWGT1 + ADMWGT2 + ADMWGT3 + \dots + ADMWG TN) / N$$

3. RESULTS

3.1 - QED and CCD Tables

Tables four through 15 on pages 12 through 25 express QED-defined estimates and CCD-defined estimates for seven groupings of public school characteristics: number of public schools and students, and average number of students per full-time teacher; percentage distribution of schools and students, and average school size; percentage distribution of students by racial-ethnic background, and percent minority students; percentage distribution of principals by sex and average age; percentage distribution of principals by race-ethnicity and percent minority; number of public schools and students, and average number of students per full-time teacher by state; and, percentage distribution of principals in public schools by highest degree earned, teacher's average years of teaching experience, and percentage of principals who taught and their average years of teaching experience before becoming principal by state.

Tables 4 through 9 demonstrate the QED-defined estimates for these seven characteristics and tables 10 through 15 demonstrate the CCD-defined estimates for the same characteristics. Table 4 correlates with table 10; table 5 correlates with table 11; table 6 correlates with table 12, etc. Tables 7 and 13 are divided into two tables (7A and 7B, 13A and 13B).

Table 4.--QED-Defined estimates for number of public schools and students, average number of students per full-time teacher

3.2 - Comparison Tables

Tables number 16 through 23 on pages number 27 through 37 are comparisons of SASS estimates derived using both the QED and the CCD definition of a school, by selected school characteristics. The columns below QED and CCD represent actual total numbers and/or percentages for the given estimates. Under the section titled "Difference," the pound sign represents the difference calculated by subtracting the QED estimate from the CCD estimate. The percent difference (% sign) is calculated by dividing the aforementioned difference by the QED estimate to measure the percent difference.

Number of public schools and students and average number of students per full-time equivalent teacher, by selected school characteristics

	QED				CCD				STUDENTS				SCHOOLS					
	SCHOOLS		STUDENTS		SCHOOLS		STUDENTS		AVG SDNT/ FTE TCHR		#		%		#		%

4. ANALYSIS OF RESULTS AND RECOMMENDATION

The tables generated in Section 3 indicate that the largest differences between QED-defined schools and CCD-defined schools are in the characteristics of small town or rural schools versus urban fringe and large town schools. The states which demonstrate the largest difference between QED-defined and CCD-defined estimates are Iowa, North Dakota, and South Dakota. In Iowa, CCD-defined estimates of the total number of public schools are approximately 6 percent points higher than QED-defined estimates for the total number of public schools (table 18). In North Dakota, CCD-defined estimates are approximately 25 percentage points higher than QED-defined estimates for the same characteristic; and in South Dakota, CCD-defined estimates are approximately 38 percentage points higher than QED. In North Dakota CCD-defined estimates are approximately 12 percentage points less than QED-defined estimates for the percent minority students in public schools (table 19). In South Dakota, CCD-defined estimates are approximately 13 percentage points lower than QED-defined estimates for the same characteristic. The characteristics which possess the largest differences in estimates between CCD-defined schools and QED-defined schools occur as a result of the enrollment totals changing when two or more schools are collapsed into one school.

A larger total enrollment is created when two or more CCD-defined schools are collapsed into one QED-defined school. Total enrollment (TOTENRLL) is used to determine the grouping variable school size (SCH_SIZE), therefore this group of estimates reflects a greater number of schools within a large school size category. This situation affects all estimates that use TOTENRLL. For example, the "average number of full-time equivalent teachers per student" decreases in central city and rural or small town schools from QED definition to CCD definition. In schools with less than 150 students, the difference is as high as 11 percentage points in rural or small town schools and over 2 percentage points for central city schools. Collapsing two or more CCD-defined schools into one QED-defined school also has an effect on minority enrollment estimates. In rural or small town schools, the percentage of minority principals increases approximately 3 percentage points from QED definition to CCD definition in schools with minority enrollment of less than 20 percentage points and decreases 2 and one-half percentage points in schools with 20 percent or more minority enrollment.

In looking at the minority status of principals of schools by state, only two states represent a significant difference in comparing QED school definitions to CCD school definitions. In Nevada, the percentage of minority principals decreases 12 percentage points from QED to CCD and in South Dakota, the same characteristic increases over 38 percentage points.

The average school size for rural or small town schools with less than 150 students decreases approximately 1 percentage point from QED definitions to CCD definitions. For all rural or small town schools the percentage decreases almost three percentage points from QED to CCD definition.

In the 1990-91 CCD file, there are 9,054 public school administrators of which 272 were eliminated because they did not have enrollment or school level information, leaving 8,782 public school administrators for the study. In the 1990-91 QED file, there are 8,515 public school administrators including 229 cases where two schools with different physical locations were collapsed into one administrative unit and 19 cases in which three schools were collapsed into one school administrator. The administrator selected to represent the collapsed schools was the administrator of the school with the largest enrollment.

4.1 - Schools With Missing Assigned Permanent Institutional Numbers (APIN)

In the 1990-91 SASS public school survey, there are 681 records with missing Assigned Permanent Institutional Numbers (APIN) values, the variable for the QED identification number. As instructed by NCES, these schools have had the CCD identification number assigned to the variable APIN. The records which have a CCD number assigned to the APIN variable are not candidates for collapsing to the QED definition because the input file is based on unique CCD numbers. These schools are, however, included in the overall total of 8,969 public schools. Assigning CCD identification numbers to the 681 schools with missing APINs affects the magnitude of the difference between CCD and QED estimates because they are not evaluated on the same basis as the other public schools. The possibility of these schools requiring collapsing in order to fit into the QED definition of a school is removed.

Twenty-three percent of the 681 schools are located in urban areas, 24 percent are located in suburban areas and 53 percent are located in rural areas. The states with the highest number of schools without a QED identification number are California, Illinois and Texas. Within California: 28 percent of these schools are in urban areas, 38 percent are in suburban areas and 34 percent are located in rural areas. Within Illinois: 18 percent are in urban areas, 38 percent are located in suburban and 44 percent in rural areas. Within Texas: 43 percent of these schools are in urban areas, 32 percent in suburban areas and 25 percent of these schools are located in rural areas.

4.2 - Collapsed Schools

The 1990-91 CCD file contains 8,969 public schools. The 1990-91 QED file contains 8,684 public schools, including 243 cases where two schools were collapsed into one definition and 21 cases where three schools were collapsed into one definition.

Fifty out of the 243 schools (20 percent) which have been collapsed from two schools into one definition are located in North and South Dakota. Other states which have a large number of schools which were collapsed from two schools into a single definition are Iowa, Minnesota and Texas. Ninety-four percent are located in rural areas and only six percent are located in suburban and urban areas.

The following table examines the 243 schools which were collapsed from two definitions into one definition by state, number of schools collapsed, geographic category, and school level.

Table 24.--Schools collapsed from two administrative units into one physical location

State	Number of Collapsed Schools	Geographic Category (in percent*)	School Level (in percent*)
Alabama	1	Rural	Combined
Alaska	1	Rural	Secondary
Arkansas	6	Rural	Secondary
California	8	Urban-50, Suburban-12, Rural-38	Elementary-38, Secondary-62

South Dakota	24	Rural	Elementary-14, Secondary-86
Texas	13	Rural	Elem.18, Second.-36, Comb.-46
Utah	2	Rural	Elementary-50, Secondary-50
Washington	1	Rural	Elementary
Wisconsin	5	Rural	Elementary-20, Secondary-80
Wyoming	2	Rural	Elementary-50, Combined-50

Source: U.S. Department of Education, Schools and Staffing Survey (1990-91)

* no number represents 100 percent

Twenty-one schools were collapsed from three schools to one school. Twelve of these schools, or 57 percent, are located in South Dakota. Again, we see the same trend as in the 243 schools which were collapsed from two definitions of a school to one to meet QED standards. Ninety percent of these schools are located in rural areas, and ten percent are located in suburban and urban areas.

The following table examines the 21 schools which were collapsed from three schools into one school by state, number of schools collapsed, geographic category and school level.

Table 25.--Schools collapsed from three administrative units into one physical location

State	Number of Collapsed schools	Geographic Category (in percent*)	School Level (in percent*)
Illinois	1	Rural	Combined
Iowa	3	Rural	Elementary-67, Secondary-33
Michigan	1	Rural	Secondary
Mississippi	1	Rural	Secondary
New York	1	Suburban	Elementary
South Dakota	12	Rural	Elementary-17, Secondary-83
Texas	2	Urban-50, Rural-50	Elementary-50, Secondary-50

4.3 - Recommendations

We do not recommend converting the 1987-88 SASS to a system which uses a single administrative unit for its definition of a school (the CCD definition) or converting the 1990-91 SASS to a system which uses a physical address for its definition of a school (the QED definition). The percentage of CCD-defined schools which needed to be adjusted to meet the QED definition of a school is very small, 2 percent. In addition, the magnitude of the difference in school characteristics is not significant. In general, the majority of schools which needed to be altered to meet the QED definition can be isolated to certain states and rural areas.

The magnitude of the difference between estimates using the QED definition and CCD definition is not significant enough to warrant converting estimates for either the 1987-88 or the 1990-91 Schools and Staffing Survey. In only 264 out of possible 8,969 sampled public schools, 2 percent, do two or more public schools collapse into one school. In most categories of selected characteristics, the difference is less than one percentage point. There is not a statistically significant difference in characteristic information as a result of the QED adjustment. In addition, users of the data who are interested in comparing information from the 1987-88 SASS and the 1990-91 SASS only need to be concerned about the effect of the definitional difference in the sampling frames for 264 schools out of 8,969 sampled public schools on the 1990-91 survey.

There is, however, information about these 264 schools which users of the 1987-88 and 1990-91 SASS may need to know. In South Dakota, North Dakota, Iowa, and Texas among other states (tables 21 and 22) changes in the estimates of characteristics which are related to the number of public schools and total student enrollment in an individual state from the 1987-88 SASS to the 1990-91 SASS are affected by the difference in QED and CCD definition of a school. For example, in South Dakota, 36 sampled schools required collapsing to fit into a QED definition of a school; in North Dakota, the same number of schools required collapsing to fit into a QED definition of a school. In examining and comparing estimates from these two states related to total enrollment and number of public schools, users of the data should be sensitive to the how a school was defined in the sample frame, particularly if estimates of change between 1987-88 and 1990-91 are studied.

Rural states which demonstrate changes in estimates of the number of public schools and total enrollment from the 1987-88 SASS to the 1990-91 SASS should be examined in light of the number of administrative units which are located on one physical location. One hundred and thirty-three out of the 264 schools (approximately 50 percent) which required collapsing from two or more administrative units into one QED definition of a school are located in South Dakota, North Dakota, Iowa, Minnesota and Texas. Changes in estimates of the number of public schools and total enrollment in these states from the 1987-88 SASS to the 1990-91 SASS should be examined in light of the different definition of a public school on the sampling frame for both surveys, the QED (1987-88 SASS) and the 1988-89 CCD (1990-91 SASS).

We recommend identifying the 264 schools by state and individual CCD identification number on the 1990-91 SASS. Users of the data would then be able to compare estimates from the 1987-88 SASS to estimates from the 1990-91 SASS with an understanding of the effect of the difference in definition of a public school in the sampling frame for each survey. Users of the data may, however, wish to apply the QED weight (Section 2.6 of this report) to data from rural states in the 1990-91 survey for the purposes of comparing characteristics from the 1987-88 and 1990-91 SASS. Changes in the number of public schools and total enrollment from 1987-88 to 1990-91 could then be evaluated on the basis of actual increases or decreases versus increases attributed to the difference in the definition of a public school in the sampling frame from each survey.
