PME-NA History and Goals

PME came into existence at the Third International Congress on Mathematical Education (ICME-3) in Karlsrühe, Germany in 1976. It is affiliated with the International Commission for Mathematical Instruction. PME-NA is the North American Chapter of the International Group of Psychology of Mathematics Education. The first PME-NA conference was held in Evanston, Illinois in 1979.

The major goals of the International Group and the North American Chapter are:

1. To promote international contacts and the exchange of scientific information in the psychology of mathematics education;
2. To promote and stimulate interdisciplinary research in the aforesaid area, with the cooperation of psychologists, mathematicians, and mathematics teachers;
3. To further a deeper and better understanding of the psychological aspects of teaching and learning mathematics and the implications thereof.

PME-NA Membership

Membership is open to people involved in active research consistent with PME-NA's aims or professionally interested in the results of such research. Membership is open on an annual basis and depends on payment of dues for the current year. Membership fees for PME-NA (but not PME International) are included in the conference fee each year. If you are unable to attend the conference but want to join or renew your membership, go to the PME-NA website at http://pmena.org. For information about membership in PME, go to http://www.igpme.org and click on "Membership" at the left of the screen.

PME-NA Steering Committee

Elected Members

Name	Position	Term	Institution
Shari Stockero	Steering Committee Chair	2016–19	Michigan Technological
Eva Thanheiser	Secretary	2016–19	Portland State University

Preface

Dear Colleagues,

On behalf of the 2018 PME-NA Steering Committee, the 2018 PME-NA Local Arrangements Committee, the College of Education at the University of South Carolina, and the College of Education at Clemson University, we would like to welcome you to South Carolina and the 40th Annual Meeting of the International Group for the Psychology of Mathematics Education – North American Chapter, held at the Hyatt Regency in Greenville, South Carolina.

As part of our celebration of 40 years of PME-NA, this year's conference will focus on enduring challenges in mathematics education research and look ahead to emerging opportunities in the field. Plenary sessions will address our major conference themes: mathematical and pedagogical demands for P-16 education, equitable mathematics teaching and research, leveraging new technologies, and perspectives on the nature of mathematics and research.

Elham Kazemi will present the opening plenary session on Thursday evening, *How Can Understanding Student Experiences in the Mathematics Classroom Enrich, Challenge, and Help us Improve our Own Learning as Teacher Educators and Researchers?* The talk explores the ways in which learning more about research on students' experiences in mathematics classrooms has the potential to transform the work we do with teachers in teacher preparation, professional development, and research settings. Corey Drake will serve as the discussant. On Friday, Marta Civil will present and Laurie Rubel will serve as discussant on the plenary session entitled *Looking Back, Looking Ahead: Equity in Mathematics Education*, which explores funds-of-knowledge, participation, and valorization of knowledge orientations towards mathematics education. Rubel extends our understandings of the political dimensions of equity in mathematics education, as well as articulates a vision for future work around equity in mathematics education. Saturday's plenary session features Margaret Niess with discussant Jeremy Roschelle in a session entitled *Transforming Teachers' Knowledge for Teaching Mathematics with Technology through Online Knowledge-Building Communities*. Their session describes the development and transformation of Technological Pedagogical Content Knowledge among inservice teachers via online technology courses designed with intentional opportunities to explore and discuss reform-based instructional strategies for teaching with technologies within teachers' communities. Finally, Anderson Norton and Julie Sarama present *Perspectives on the Nature of Mathematics and Research* during Sunday's plenary session. Norton and Sarama provide unique and compelling notions of mathematics as a body of knowledge, helping to ground our understandings of what it means to learn and do mathematics. Each presenter provides powerful implications for the teaching, learning and research of mathematics education.

The concurrent and poster presentations serve to advance our field through a firm grounding in where we have been, our current understandings of mathematical learning, and with an eye towards the work ahead of us - truly, we are *Looking Back, Looking Ahead*. This year's conference will be attended by more than 500 researchers, faculty and graduate students from around the world including Mexico, Canada, Australia, Republic of Korea, and 42 states from the United States of America. The acceptance rate was 37% for research reports as research reports, 69% for brief research reports as brief research reports, 94% for posters as posters, and 100% for working groups. The accepted proposals included 69 research reports, 137 brief research reports, 133 posters, and 17 working groups.

We would like to thank the many people who generously volunteered their time over the past year in preparation for this conference. In particular, we wish to thank Jessica Allen, Graduate Assistant at the University of South Carolina, for her tireless efforts in facilitating planning, communicating with various stakeholders and formatting the conference proceedings.

Professional regards,

Chapter 1

Plenary Papers

Hodges, T.E., Roy, G. J., & Tyminski, A. M. (Eds.). (2018). *Proceedings of the 40th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Greenville, SC: University of South Carolina & Clemson University.

HOW CAN UNDERSTANDING STUDENT EXPERIENCE IN THE MATHEMATICS CLASSROOM ENRICH, CHALLENGE, AND HELP US IMPROVE OUR OWN LEARNING AS TEACHER EDUCATORS AND RESEARCHERS?

Elham Kazemi
University of Washington
ekazemi@uw.edu

Corey Drake
Michigan State University
cdrake@msu.edu

In this paper, we explore the ways in which learning more about research on students' experiences in mathematics classrooms has the potential to transform the work we do with teachers in teacher preparation, professional development, and research settings. We focus in particular on questions of student access to and participation in mathematics and highlight studies of the racialized and gendered experiences of students and the connections between these experiences and broader narratives about race, gender, and ability/disability. We conclude with questions and possibilities raised by these studies for our individual and collective efforts to support and understand teacher learning and changes in teacher practice.

Keywords: Teacher learning, Student experience, Equity

The title of our paper is a question, not a statement, which we hope will provoke conversation among us. To begin, we would like to introduce ourselves and then explain how we came to ask the organizing question for this paper and use selected studies as cases to help us dive into discussion.

How Did We Come to the Focus of this Paper?

We decided to use this occasion as an opportunity to further our own learning by highlighting recent work in the field that we think can inform our work with teachers. To that end, we are not attempting a comprehensive review of any kind. Instead, we selected articles, be they written for researchers or practitioners, that would shed light into how particular students have experienced the mathematics classroom. You will notice that some of these accounts and narratives are first-person accounts, while others were generated through close collaboration between researchers and students.

The ways we think about teacher practice and teacher learning in research and teacher education focus heavily on teacher performance - along a variety of dimensions, with a variety of foci. This focus can be seen in the many studies of changes in teachers' practices, in recent practice-based teacher education efforts, and in the variety of observation protocols used to observe, understand, and sometimes evaluate teaching. Both personally and as a field, we have learned a lot in recent decades from thinking about teaching in this way. In our own work, we have learned about ways in which teaching is difficult and complex for teachers, particularly novice teachers; approaches to supporting prospective teachers in developing ambitious teaching practices; the roles of tools such as student work and frameworks of children's mathematical thinking in advancing changes in teachers' practice; and how to design learning environments for teachers to learn together. We have also learned from work that has examined relational aspects of teaching, though primarily from the perspective of teachers, about the importance of teacher care and productive relationships with students (e.g., Bartell, 2011; Jansen & Bartell, 2013).

Studies of teaching can benefit from more attention to the nature of student experience in mathematics classrooms as a lens for understanding teacher practice and teacher learning. When we make this claim, we want to be sure to note that attending to student experience is not the same as attending to student outcomes/achievement; many studies have tried to link teacher practice and student achievement. Instead, we are interested in understanding teaching in terms of student experience, which is broader than student achievement or even student learning, and also takes into account students' experiences of mathematics in relation to identity, participation, motivation, and agency (Aguirre, Mayfield-Ingram, and Martin, 2013).

Our interest in this paper is in deepening our understanding of teaching by focusing on students and their experiences because although we have learned many important ideas from focusing on teacher performance and practice, we have yet to deeply understand the link between teaching and student experiences or ways in which teaching might disrupt persistently inequitable patterns in student experiences. Jansen & Bartell (2013) note that, "A teacher may intend to enact care, but unless the care has been received by a student, the student will not feel cared for." (p. 36) This points to a key limitation of research on teacher education that focuses on teacher performance without also considering student experience. In order to address this limitation, we, as teacher educators and researchers of teaching, we are going to foreground research on students' experiences. Connecting and expanding the literatures we put into conversation together can further our efforts to prepare teachers who can create transformative and inclusive classroom and support students' access to and participation in mathematics.

What do we Know about Student Experience that Might be Helpful for Thinking about Teacher Practice?

In the cases that follow, we focus first on understanding individual students' motivations and experiences related to participation in mathematics discussions. We then move to cases of studies that explored the racialized, gendered, and networked nature of students' participation in mathematics classes. Finally, we explore cases of participation in and access to mathematics in relation to broader racialized, gendered, and ability-related narratives.

Understanding Students' Experiences as Listeners and Speakers in the Mathematics Classroom

Hintz (2011) studied the experiences fourth-grade students had in two classrooms during classroom discussions. She sat with them as they replayed video from a recent discussion and asked the students to share with her what was happening for them during those segments. In research on classroom discussions, studies have examined how discussions unfold, what children say or do, and what decisions teachers make for discussions to be mathematically productive. Hintz applies a different lens to understanding classroom discussions, as she carefully examines the demands that these discussions place on students both as listeners and speakers and illuminates how students experience those demands. In her 2011 article, Hintz presents the complexities one student, Norah, experienced in a common discussion structure, called strategy-reporting, during which students share the different ways they thought about a problem.

Hintz sat with Norah to look at a particular time when Norah shared her answer to a multiplication problem while also making a hand gesture to indicate that she was not confident it was right. During strategy reporting, teachers commonly ask questions about a student's strategy and often work through any errors that arise. But Norah did not like to share when her solution had a mistake because she anticipated being asked to talk about it in front of the other students. Hintz recounts what unfolded in the classroom and how Norah experienced it:

> During one particular interview, Norah and I rewatched the videotape of an episode during a lesson when she shared a mistake and I listened to her talk about that experience. After solving the problem 14×5 mentally, she had offered up her answer saying, "I think it is 120."

> As she said her answer she was grimacing with a look of uncertainty and concern. She turned to her neighbor and gestured her hand back and forth in a flip-flop motion showing that she was unsure about her answer. Later in the discussion, as a different answer was decided to be correct, Norah raised her hand and said with a shy smile and shrugging downward, "I counted wrong." The teacher responded, "You counted wrong. And that's OK, we do that all the time don't we? That's part of our life," and moved on with the discussion.
>
> As Norah narrated her experience during this episode, she shared,
>
> *Since I did 14 × 5 = 120, I messed up because I added differently than I should have. I did 4 × 5 is 20 and then I put the one from the 10 right on as 100. I should have thought more about it instead of going right to it. It is kind of embarrassing.*
>
> What she felt was embarrassing was "getting it wrong," and she added, "But if you make a mistake then you can keep practicing that problem and it will become a fact that you know. Next time I would still start with 4 × 5 = 20 but then I would do a different step." This comment reveals that she sees the potential for learning from your mistakes and continued practice. Yet the social consequences of making a mistake publicly weighed heavy on her mind and shaped how she chose to take on the roles of sharer and listener. An important part of why Norah did not like to share when her solution had a mistake was because of how she may have been asked to engage in talk about the mistake with her teacher in front of the other students. It is common during strategy reporting for a teacher to ask questions about a student's strategy when there is a mistake in an effort to uncover a misconception and work through an error. In talking about this experience, Norah said, "Sometimes I don't like to make mistakes because it's kind of embarrassing when you thought you got it right and then you got it wrong and then you have to keep working out loud" (Hintz, 2011, p. 268).

Norah explained she was happier not to be called on when her thinking was incorrect. It does not seem, in the way she recounts her experience, that she does not like revising her thinking. But, she feels badly doing it in front of others. The teacher, like many of us, tries to normalize mistake making. Classrooms benefit when a norm is established that it is okay to be wrong. And certainly we do not have evidence other students made Norah feel badly. Still, her worry was real and impacted whether or not she wanted to participate. And Norah's feelings about sharing and listening are not unidimensional. She also told Hintz that she liked hearing and using other students' strategies, and that she was comfortable trying out multiple strategies until one worked for her. If the teacher also understood the complexities of how Norah felt, what kind of dialogue between them could help Norah process these experiences and grow from them?

Amanda Jansen's work (e.g., Jansen, 2006, 2008) similarly focuses on students' experiences with participating in classroom mathematics discussions. In this work, she identifies relationships among middle school students' beliefs, motivation, and participation in whole-class discussions. Through in-depth interviews with students and many hours of classroom observation, she identified student beliefs that both constrained and supported student participation in whole-class discussions. Some students she interviewed echoed Norah's feelings about the risks of verbal participation and the benefits of listening during mathematics discussions.

Students in her study also demonstrated motivation to participate more actively in order to meet social or behavioral goals, such as helping others. In particular, these students believed in the value of participation for supporting their own learning and understanding of mathematics. These views were exemplified by Becky:

> Becky: And when you have to do problems, don't just sit there. You have to get into the conversation in order to actually get it yourself and make you understand it, don't just understand it like how other kids do it. (Jansen, 2006, p. 417)

Consider Becky's perspective and Norah's side by side. One common practice in mathematics classrooms is to collect answers and then ask students to share those answers. While many conceptions of and research on ambitious pedagogy focus on the importance of discussion for learning, it is important to also recognize the risks of participation that can be inherent in participation for some students. Further, while teachers may work on class-wide strategies for encouraging participation, we need to understand that these strategies will be received and understood differently by different students, depending on their prior experiences, beliefs, and goals. How often do we learn about what our students are experiencing in the classroom? How can we create the time and gain the trust for students to tell us? Taken together, Hintz's and Jansen's work remind us that participation in mathematics discussion can take many forms and that understanding the ways in which listening, questioning, and other forms of participation support learning is important work. Finally, Jansen's findings illustrate the deep interconnectedness of students' social and academic goals and beliefs in shaping students' access to and participation in mathematics.

Understanding Students' Participation and Positioning as Racialized and Socially Networked

In the next section, we continue to learn from and about students' experiences in mathematics classrooms with a focus on the social aspect of participation as racialized, gendered, networked, and closely connected to mathematics access and achievement.

Maisie Gholson's and Danny Martin's work (2014) takes a "microsociological (e.g., Shalin, 1978) approach" to understanding Black girls' experiences in a mathematics classroom, "using the girls' voices in this study to make sense of the emergent social structures that organize access to mathematics participation and learning." (Gholson and Martin, 2014, p. 19). Through this approach, they identify the shifting roles, identities, and social networks within a 3rd-grade classroom that not only affect the girls' social identities, but also shape their access to and success in the classroom mathematics. They find that even those students who identified as "competent mathematics students" found their access to participation in mathematics class "mediated" by their positioning within the social network of the classroom, especially their positioning in relation to the "high-status cluster" within the network. (p. 30). The close connection between social positioning and access to classroom content is illustrated through the story of Shawna, a strong mathematics student who identified as good in mathematics, but often found herself outside the "high-status cluster" of the classroom girls' social network:

> M(Gholson): Like if Ms. Robinson calls everybody to the rug, sometimes you'll sit at your desk or sit at the very back. Do you think that's true?
>
> S: [Nods affirmatively.] When she calls us to the rug, I'll stay at my desk sometimes.
>
> M: Why do you like to stay at your desk sometimes?
>
> S: Because I don't like to go to the rug.
>
> M: Is it good to sit away from the rug and get away from people sometimes?
>
> S: Yes.

M: How does it make you feel when you sit away from the group? Does it make you feel good? Does it make you feel bad?

S: Good.

M: It does? And why does it make you feel good?

S: Cause some of the people mess with me.

(Interview 03/01) (Gholson & Martin, 2014, p. 28)

Gholson and Martin go on to say that, "On the rare occasions when Shawna was included by one or more of the girls in a classroom activity, she was highly engaged." (Gholson & Martin, p. 28) Gholson and Martin conclude that, "It is not uncommon for reports of studies of mathematics learning to state explicitly that any talk not related to mathematics was excluded from the analyses. However, this necessarily dismissed children's social worlds as unimportant and misunderstands the intimate connection between children's learning of disciplinary content, such as mathematics, and their social relationships." (p. 31).

In more recent work (Gholson & Martin, under review), the authors use a performative framework to analyze classroom video and student interview data in order to understand how one student, a Black middle school girl, positions herself within mathematics class. They focus in particular on the movement of bodies within the mathematics classroom space and illustrate how the performative lens allows us to see the ways in which "mathematics learning is a contextualized performance, requiring and enabling children to simultaneously negotiate race, class, and gender." (p. 4) In doing so, they illuminate the ways in which mathematical practices, described abstractly in documents such as the CCSSM, are realized through embodied performances.

Gholson and Martin's work helps us understand how we can miss salient aspects of students' engagement with and access to mathematics when we focus only on overt teacher and student behaviors and only on students' interactions with and identities in relation to content. Understanding students' positioning with respect to one another, as well as to the content, provides a lens for making sense of patterns of student participation. At the same time, Gholson's and Martin's long-term and deep interactions with students lead to compelling narratives of the personal, social, familial, and community contexts in which students' mathematical development is situated. We wonder if and how teachers can engage in similar long-term and deep interactions leading to the co-construction of student narratives. Finally, Gholson and Martin point to the ways in which students' classroom and network positioning is situated in broader narratives of race, gender, and ability in mathematics classrooms. These narratives are the focus of the next set of studies described below, by Shah, Lewis, and Rubel.

Understanding Students' Experiences of Narratives of Race, Gender, and Ability/Disability in Mathematics Classrooms

The classroom, while a community onto itself, is of course constitutive of the outside world. Shah (2017) interviewed 35 high school students across 4 classrooms who went to the same high school in Northern California. They identified as Asian, Black or African American, Latinx, Polynesian, White, and mixed race. He was interested in how students invoked racial narratives when they talked about mathematics learning, how these narratives worked in relation to one another, and what these relationalities meant for how students were positioned with respect to race. A primary interest in his work is to study how students make sense of these racial narratives and how it contributes to the shaping of racial ideologies and students' own identify formation.

It is not surprising that the adolescents he talked to reported hearing numerous racial narratives at school and that they were in line with what Danny Martin (2009) has called a racial hierarchy of who is good at mathematics. Within his data corpus, students invoked 98 different racial narratives over a broad range of topics from intelligence, academic performance, and ability to body type, personality, cultural practices and career paths. Shah examines how various racial narratives and their interconnections impacted their everyday experience in the mathematics classroom. For example, at the time of the study, Troi was a higher performing senior in an advanced course of Precalculus. Troi's statements about how a substitute teacher's might react to him conveys how he is aware of the racial hierarchy in mathematics with respect to how Indians and Samoans are perceived in mathematics, "'Yeah, so say a substitute teacher would come in [to class] and she'll see the Indian kid and think, 'Oh he must be the best one here in math,' and she'll look at me and think, 'How did he get into this class? What the heck is he doing here?'" (p. 23). Moreover, as Shah explains in this next excerpt, for Troi, narratives about intelligence were linked to narratives about physicality and mathematical ability:

> Polynesian students at Eastwood High were a small but prominent population on campus. Samoan and Tongan cultural practices were well represented in school events, and the Polynesian male students in particular were known for their participation in contact sports, such as football and rugby. Several of the faculty I spoke with viewed them as "troublemakers" and found them difficult to manage in their classes. In the excerpt below, Troi (Samoan, 12th grade) elaborates on how perceptions of Polynesian bodies and personalities contributed to their being positioned as mathematically, academically, and intellectually inferior:
>
>> Other students just see me as big and mean…and here [at Eastwood High], the Polynesian kids are seen as like we're big, that we do whatever we want. Like we're not very intellectual, and like we're not smart. But once they meet me they'll know that I'm actually very intelligent, and I can do math, I know how to do English, I can do science…all that kind of stuff. I think when I come in they just see me as someone who's going to hurt them or beat them up or someone who freaking wants to kill. They're not going to take time out to sit and talk with me, and actually greet me and actually get to know me.
>
> In this excerpt, Troi draws connections among multiple categories of racial narratives. Initially, he connects a narrative about Polynesians being "big" to narratives about Polynesians being seen as "mean" and "someone who's going to hurt them or beat them up or someone who freaking wants to kill." The relations among these narratives evoke an image of Polynesian students as angry and violent people that others should fear. Indeed, Troi implies that classmates tend to avoid him, and do not attempt to "greet me and actually get to know me." But Troi perceives these narratives to be consequential in ways that go beyond his social standing. They also matter for how Troi is positioned from an intellectual standpoint. After invoking narratives about Polynesians' body type and personality, he notes that people view Polynesians as being "not very intellectual." (Shah, 2017, p. 27-28)

Reading Troi's experience and the many others in Shah's article provides us with a compelling window into how students feel about the way they are read by others and the very real consequences for the educational opportunities they pursue or not. Implicit in Troi's description is a rather segregated social space. If students do not have genuine opportunities to develop friendships across cultural and racial groups, how does the lack of relationships figure into the ways they are asked to interact in the academic setting of the classroom? How do teachers check their own assumptions and views of particular racial and cultural groups in the school? Where do the perceptions about troublemakers get challenged?

Understanding how students with learning disabilities developing systems to compensate for cognitive differences. Katie Lewis studies the characteristics of mathematics learning disabilities. Drawing on sociocultural frameworks, she analyzes how students make sense of mediational tools such as symbols and representation when doing mathematics. Importantly, she tries to understand the resources that students use not what they seem to lack. One important turn in her recent work is to marry the Vygotskian notion of compensation with a critical disability studies frame. By collaborating with individuals with mathematics learning disabilities, she has been documenting the intentional actions that they take to gain access to spaces, context, and mediational tools in mathematics that would otherwise be inaccessible to them. This emancipatory research inverts the typical power dynamic between researcher and researched.

In a recent paper, Lewis and Dylan Lynn (2018) discuss the significant and persistent challenges Dylan, who graduated with a major in statistics from UC Berkeley, encountered when doing mathematics and how she compensated for them in order to succeed. Together they documented eight distinct compensatory strategies by analyzing videos of interactions between and another college student with mathematics learning disabilities and interviews with Katie. Dylan's challenges included inverting numbers, distinguishing symbols, making sense of dense notations, and understanding the impact of operations on values. She had developed her own system of addressing these challenges which included the use of mathematical tools such as graph paper, particular colored pens and pencils in ways that helped her navigate notations and solution processes.

We will give you one particular example of these compensatory strategies. An important aspect of understanding Dylan's experience was how our education system's policies were set up to exclude her and actively discourage her from pursuing mathematics. When she was diagnosed with a disability in college, the university's response was to waive her mathematics requirement. There was no real way for her to be supported to continue with mathematics, and she had to find her own way to persevere. She learned what to ask her tutors to do, and she had to persist through numerous course graders who complained about the length and verboseness of her assignments. In the excerpt below, she explains how one strategy of rewriting mathematical symbols into words supported her understanding of new concepts and notational system.

> Dylan: "This is calculus, but you can see it illustrated with this notation [*writes f(x) = x + 4x3; see Figure 2*] this notation, the way people say this is "f of x" which is also terrible. It's the *function* of *x* equals this [*as writing "function of x = x + 4x3; see Figure 2*]. This little notation here [*points to f(x)*] would throw me off really badly in my classes, because f times x? No, it's a notation that is basically applying this function to the variable x. I would sometimes write out something like this [*writes bracket underneath "function of x"*] right underneath whatever it was and again, this is really verbose, [but] it might be helpful."

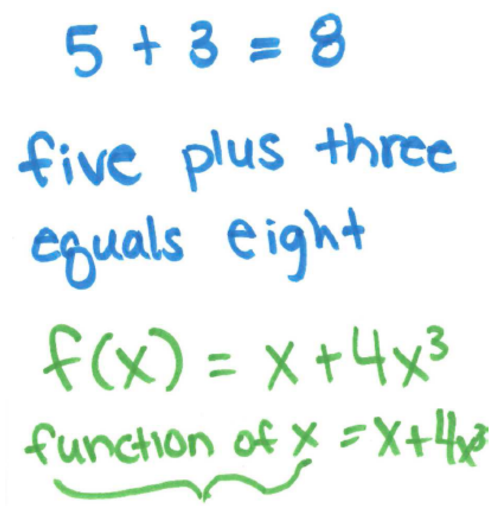

Figure 2. Dylan's examples of rewriting mathematical symbols with words, which helped her translate and make sense of the meaning of the notation.

> Dylan noted that she often used this kind of translation in her notes to help her decode the meaning of the symbols, and described it as her creation of metadata for the notation. ...
>
> This translation of symbols into words took Dylan extra time both when writing notes and when solving problems. Because this kind of translation was not available in her classes or textbooks, she paid tutors to provide this kind of support. She explained that "I would force tutors to give me the English words for the symbols, which was always funny because these are grad students who haven't thought about this stuff in years. 'How would you use this in a sentence? I haven't thought about it that way.'" The kinds of supports that Dylan needed were not something that the tutors were skilled at providing. Although this compensatory strategy provided her with a way of understanding the mathematical symbols, it placed additional demands upon her requiring that she spend more time and money than her peers to have access to mathematics. (Lewis & Lynn, 2018, p. 6-7)

One theme that is beginning to emerge in the selections we have made is how much students are doing and thinking about that is not available to the teacher. The full study documents many more strategies that Dylan generated to help her understand and advance in her mathematics coursework. Her brilliance and ingenuity are so clear, even though it appears that her college instructors are not empathetic to how much more work she does in order to be sure she understands.

Understanding students' gendered experience in the mathematics classroom. There are many issues with respect to gender and sexuality that we need to consider as mathematics educators. Gender narratives around mathematics have been typically associated with masculinity. In a brief article written for practitioners (Rubel, 2016), Laurie Rubel recounts her own experience as a teacher in a professional development session led by a mathematician who was engaging participants in how problems could be modeled with graph theory. He chose a regularly used problem because its purportedly binary categories would simplify the mathematics for learning purposes. But that is not how she experienced it, as she explains in this next excerpt.

> When I was a beginning teacher and in my twenties, I attended a professional development course for mathematics teachers, in which the Stable Marriage problem was explored as an example of a problem that can be modeled with graph theory. The facilitator, a professor of mathematics, led an activity similar to the one described above. He handed pink cards with fictitious names to the people he identified as women in the room and blue cards to the men. He told the women, holding the pink cards, to create rankings of their marriage preferences. If you were a woman, you were holding a pink card, and you were allowed only to rank your choices of men as spouses.
>
> I remember feeling uncomfortable with this arrangement. When I voiced an objection to this constraint, I was told that this is the set-up of the problem. In other words, this problem is not really about marriages. The problem refers to a particular kind of mathematical pairing between set A and set B. The story about men and women and marriages is just a story to lead us to a particular mathematical model. The story is supposed to help clarify the parameters of the mathematical model. "Just focus on the mathematics," I was told, even though I was being handed a pink card and thereby being placed in a particular location on a gender binary. Not only that, but heteronormativity was being reinforced with the statement that, in this model, all women have to want to marry men. (Rubel, 2016, p. 438)

There are several important ideas here that are important for our work with teachers. As a student in this context, Laurie, tried to speak out but was rebuffed. The teacher responded to her by admonishing her to just focus on the mathematics, making her own reaction to the problem irrelevant. So even though the algorithm they were studying had been applied to settings where college applicants are matched with colleges or medical students with residencies, the context of this problem was set in marriage between heterosexual couples, and students were not given a choice in their gender assignment or whether they wanted to use the marriage context for an extended discussion. Through her writing, Rubel pushes us to take up Rands' (2013) idea about gender-complex education, directly acknowledging gender diversity by making our curriculum and pedagogy reflect the existence of transgender and gender nonconforming people. If mathematics is a way of making sense of our world, it seems impossible to discount our world to just focus on the mathematics.

What Theoretical Frameworks are Researchers Drawing on to Study Student Experience?

A rich array of critical theoretical perspectives are used across these studies to help us interpret student experiences. Noting these are important for what theories we study in teacher preparation, doctoral preparation, and our own ongoing learning. Psychological, cognitive, and sociocultural theories of learning are likely to be insufficient in helping us understand students' mathematical learning. In this small collection of articles, scholars are drawing on theories that help us attend more to relations of power and how race, gender, class, ability, and sexuality shape these relations. Social theorists, philosophers, critical race theorists, disability studies, black feminist scholars, and poststructural theorists, to name a few, are being used to bring depth and complexity to our understanding of teaching, learning, schooling in how they shape students' learning, their identification with mathematics, their experiences as learners and the meanings of their education.

How Did Researchers Learn about Student Experience?

Narrative plays a central role in the studies we have highlighted here. Spending time with students over a long period of time to come to understand their varied experiences is common to them all. Interviews aided by video enabled Lewis and Hintz to have moment-by-moment interpretations of what students were thinking, and doing, and feeling. In his interview protocols, Shah asked students to comment on cartoons that conveyed narratives that broadly circulate in society. Rubel and Dylan use personal biography tell us their own stories, albeit in different ways. Rubel shares her own stories as a way of speaking out and speaking up. Lewis, in her collaboration with Dylan, provides an example of emancipatory research, which aims to transform the relationship between researcher and researched. Many of these stories are not readily shared by students with one another or with their teachers. So in some respects we can expect that many of us through our teaching would not necessarily have access to these stories. They demand then, that we think about the relationships we need to foster, and the kinds of interactions we need to have with students in order to better understand what is happening for them as they try to learn with one another.

What are the Implications of Thinking about Teacher Practice in Terms of Student Experiences?

Students' participation in and access to mathematics is not solely or even primarily about the student's mathematical competence or the teacher's moves. Instead, it is about the individual, social, and cultural narratives within which the student is positioned and positions her/himself. Therefore, any study of or work with teachers should include attention to ways in which teachers can learn about these individual, social, and cultural factors, along with how the work of teaching can respond to and/or disrupt their effects in ways that provide opportunities for greater access and participation for all students, particularly those who find themselves marginalized in classroom communities.

The cases we have selected here are not full of joy and delight and liberation while our goals for teaching and education purportedly are. Instead they are filled with tension, with challenge, with being unknown and unseen. Like Shah, we wonder, “Do all students have the opportunity to be seen for what they are truly capable of doing in a classroom?” (p. 36). But we think it is worth pondering how that can be difficult and perhaps not normative. The work discussed above has important implications for the work of teaching and our work with teachers. In our work as teacher educators, we must intentionally build time and space for teachers not to just reflect on their own teaching, what went well and what did not, what did they observe and notice in their classrooms, but also what did their students directly teach them. It leads us to ask how teachers learn about student experiences and how they respond to what they have learned. What did students think and feel and experience during a lesson? How did they feel they were treated? What was challenging to do and what was not? What enables students to develop enough trust to be in honest conversation with their teachers and their peers about how they are experiencing the classroom community?

It would be an understatement to say coming to learn about how students are experiencing the classroom takes a lot of skill and empathy on behalf of teachers and the ability to step outside of one’s own worldview, to suspend judgement. What do teachers need to know and be able to do to understand and engage with student experience? How can teacher educators support teachers in learning these things? Is it possible for teacher and teacher educators, given their positioning and authority in classroom spaces, to elicit and learn about student experiences in the ways that researchers do? In many of the studies described above, teachers were not aware of the student perspectives and experiences uncovered by researchers. Students' experiences remained hidden from teachers, either because the experiences are happening in students' worlds, where teachers may not belong, and/or because teachers and students are not having the kinds of conversations that researchers and students have had. Even if we acknowledge that it is not fully possible for teachers to access students' experiences in the ways that researchers are able to, how do we take what we are learning from these researchers about the emotional, motivational, social, structural, political, and identity-related aspects of students' experiences in mathematics and use these understandings to build mathematics classrooms and teaching practices that pull students in and increase access to mathematics rather than pushing them out and preventing access?

Despite all of these questions, we can begin to imagine how this work related to student experiences might transform the ways we work with teachers in teacher education and professional development settings. For instance, what if the focus of a mathematics methods course assignment or professional development experience was for teachers to deeply understand the experiences of a student who was different from them along one or more dimensions of identity? The goal would be to understand not just their knowledge and ways of thinking about mathematics, not just their home and community-based funds of knowledge, as has been explored in other projects (e.g., Aguirre et al., 2013), but the ways they experience participation, their positioning in the networks of the classroom and community, their relationship to broader racial, gendered, and ability-based narratives? What would this understanding motivate teachers to want to know and be able to do in relation to mathematics teaching? What further questions would they want to ask? What if teachers collected video and sat with a few students to get their take on what was happening in the classroom?

The work on students' experiences also has implications for studying teacher learning and practice. In fact, it was in the context of a project studying novice teacher practice that Elham (a member of the project's advisory board) suggested the focus of this paper. As we explored various protocols for studying (or measuring) teaching practice, we (the project team) asked Elham what we might be missing when viewing teaching through the lens of these protocols. She suggested that student experience was notably absent and asked the question at the center of this paper – What if we focused on student experience as well as teacher performance when studying teaching practice? How would that change the ways we study teaching or work with teachers to improve teaching? Some research projects have begun to move in this direction and we will be interested to follow the extent to which they are able to move the field forward in understanding teaching in terms of student experience. For example, the work of several researchers and partner districts on "practical measures of instruction" builds on ideas related to improvement science (Bryk et al., 2015) to incorporate quick and actionable measures of student experiences in class discussions into professional development and the improvement of teaching. Another example might be the work of Reinholz and Shah (2018) on "equity analytics" - quantitative measures of who is getting access to the mathematics and mathematical discourse during classroom instruction. While neither of these examples fully capture the richness of student experiences in the ways described above, they do provide tools and processes for teachers and researchers to gain some understanding of student experiences as they unfold in the context of instruction. These examples also suggest the importance of research-practice partnerships in both understanding and improving teaching through a focus on student experience.

In conclusion, we wonder about directions for our own learning. How do we continue learning about student experiences in mathematics classrooms and the ways in which those experiences are related to learning, to power and participation, and to dimensions of identity including race, gender, and class? How do we teach each other about these ideas and how do we support teachers in learning about, responding to, and enhancing student experiences in ways that promote access to rigorous mathematics for all students? An important aspect of the studies described above is that they each draw on theories that go well beyond the theories of learning we learned in graduate school. How will we and our doctoral students learn about these theories and/or work together to bring multiple theoretical lenses to these questions? By addressing these questions in collaboration with one another and with teachers, we can begin to make progress in understanding and supporting teaching that disrupts inequitable patterns of participation and provides access to mathematics for all students.

LOOKING BACK, LOOKING AHEAD: EQUITY IN MATHEMATICS EDUCATION

Marta Civil
The University of Arizona
civil@math.arizona.edu

Drawing on the conference theme of looking back and looking ahead, in this paper I first look at the placement of equity throughout PME-NA as a way to set the stage for where to go next. I then focus on aspects of my work on the affordances and tensions around out-of-school and in-school mathematics to discuss equity as opportunity to participate in mathematically rich and socio-culturally grounded experiences. I argue for the need to develop classroom environments where students' mathematical funds of knowledge are brought to the forefront but also where students can use their cultural ways of being and acting as resources for their learning of mathematics.

Keywords: Equity and Diversity

At the suggestion of the conference organizers we (Laurie Rubel and I) decided to collaborate on the elaboration of the plenary and discussion / response papers. While we each wrote our own paper, we exchanged drafts and had online discussions on what we wanted to convey. We share some common interests and concerns in terms of equity and mathematics education, yet our personal histories, trajectories and approaches are different. In particular, in one of our first conversations I remember telling Laurie that sometimes in my own work I felt a tension between socio-cultural and socio-political approaches. I can see my work clearly fitting the socio-cultural framework, and I am aware that I am working with political issues (e.g., language policy, immigrant families), yet I do not necessarily see my work as "fitting" the political category. It is clear to me that issues of power and privilege permeate my attention to valorization of knowledge and participation in the mathematics classroom, but I feel like I leave these issues somewhat implicit. In her response, Laurie's section on "making the political explicit", drawing on one the examples from funds of knowledge that I present in this paper, was particularly inspiring for me. This is just one example of the back and forth exchange of ideas that Laurie and I engaged in as we each wrote our pieces.

In what follows I first provide some background to indicate my positionality with respect to the idea of "equity in mathematics education." Then, I provide a brief historical account of my experience with PME-NA, given that the theme of the conference is "Looking back, looking ahead: celebrating 40 years." This is my personal (and I admit, incomplete) attempt at tracing equity across PME-NA since the first conference I attended. The rest of the paper looks at some aspects of my research around in-school and out-of-school mathematics.

Some Background

I was drawn to issues related to equity through my work with preservice elementary teachers. I have always had an interest in how children and adults make sense of mathematics, how they think about mathematics. To this end, I like to use tasks that may lead to cognitive conflict. In listening to preservice teachers talking about mathematics, I noticed that some of them brought their everyday experiences to the discussion. I also noticed that oftentimes, those who sought to make sense of the mathematics (by connecting it to their life experiences) had had less "successful" trajectories with school mathematics than their peers who basically played by the rules and did not seem to be concerned about whether mathematics made sense outside (or even inside) the classroom. What are we doing in our teaching (K-16+) that leads to this lack of connection between in-school and out-of-school? This lack of connection is what drives much of my work. Shortly after I moved to the University of Arizona in 1990, I was fortunate to join the Funds of Knowledge for Teaching project (González, Moll, & Amanti, 2005), which was a perfect fit for me. The project took me into working-class communities and schools attended largely by students of Mexican origin, many of whom spoke Spanish as their home language, yet another fit for me as that is my home language too. I was able to work with teachers dedicated to developing learning experiences that built on students' and their families' funds of knowledge; teachers who invited family members to come to the classroom to share their expertise. I saw children engaged in discussions, participating in rich classroom activities. This is where my definition of equity developed. For me equity is about the opportunity to participate in mathematical experiences that are both rich from a "mathematics for the sake of mathematics" point of view ("reform / standards-based") and at the same time reflect the socio-cultural experiences of the participants (culturally responsive / sustaining). It is about participants maintaining their cultural identity while also engaging as doers of mathematics. Over the years, I think that what has most influenced my approach is my work and friendship with immigrant families. Learning from them and seeing their enjoyment and sense of humor in mathematical discussions (whether it is a group of mothers or a group of seventh graders) constitute uplifting experiences and are constant reminders of why I do this work. To me, this is particularly important currently, given the stressful and depressing reality that many immigrant families are experiencing.

Looking Back at PME-NA

I attended my first PME-NA when I was a graduate student in 1989. In looking at those proceedings, these were the topics: Affective and cultural factors in mathematics learning (2 papers, 1 on cognitive and affective aspects with 2 prospective elementary teachers; the other reports on a study done in Ciskei (South Africa, though an independent state at the time of the study); that paper mentions "socio cultural" and "lack of continuity between the cultural world of the family and that of school" (p. 13). The author was from a university in South Africa; Algebra/Algebraic Thinking (4 papers); Calculus (3 papers); Computer environments in mathematics learning (3 papers); number concepts (5 papers); geometry, measurement, and spatial visualization (6 papers); multiplicative structures (8 papers); representations, metacognition, and problem solving (6 papers); teacher beliefs (4) (my paper, "prospective elementary teachers' conceptions about the teaching and learning of mathematics in the context of working with ratios", was in that section); teacher education and teacher development (8 papers). There were two plenary lectures (and responses) (one on mathematical processes, the other one around understanding of numbers (the authors have a section on the research on out-of-school mathematics, in terms of how "non-schooled" children and adults understand numbers). There were five Symposia: realistic mathematics education; sex differences in mathematics ability; clinical investigations in mathematics teaching; assessment and function graphing tools; probability.

The next PME-NA I attended was in 1993. In that one, there were several strands including one on equity, which had a panel and discussion sessions. The panel has one Australian researcher (Gilah Leder), one US researcher (Walter Secada), and one respondent from Brazil (Ubiratan D'Ambrosio). There was one paper in the section on language and mathematics (by Judit Moschkovich). And there was a section on social and cultural factors affecting learning (5 papers), where one of my first papers on funds of knowledge was located ("Household Visits and Teachers' Study Groups: Integrating Mathematics to a Socio-Cultural Approach to Instruction").

There were 14 discussion groups; one of them was on “cultural support for mathematics understanding” (related to relationship between culture, language and numerical systems).

The strand on social and cultural factors (renamed later on as “sociocultural issues”) remained till 2007. Then in 2009 through 2011, there was a strand called “equity and diversity” (I am not including 2008 because that was a joint PME / PME-NA meeting). The strands we currently have (with no specific strand for equity or similar terms) were implemented in 2012. One possible argument for not having a strand on equity is that equity should permeate the work we do (Aguirre et al., 2017). Having a separate strand seems to imply that some researchers do equity work and others do not, or that equity is being addressed in one part of the conference and we do not need to worry about it elsewhere. This is something that calls for further reflection.

Finally, I took a more in-depth look at the most recent PME-NA proceedings (2017) to see how equity was featured. There was one plenary talk that focused on equity. There was also a response to another plenary (not-equity focused) that looked at that talk with an equity lens. Finally, one of the papers in the technology panel also addressed equity. Three of the 13 working groups had something to do with equity, with one of them being explicitly about equity, one on critical perspectives on disability, and the third one on special education. Two of the other working groups mention equity a few times in the write-up. I then went through all the strands and searched for the keyword equity. In some cases, where the term equity did not appear, I used my judgment to classify some of the papers as pertaining to equity based on other terms (e.g., culturally relevant; social justice). This is not a scientific analysis and I am aware that I may have missed some papers that are about equity. At the same time, there were some papers that had the keyword equity, but it was not obvious to me why that keyword was there. Here is what I found out: there were 75 research reports (RR) presented; 8 of them had something to do with equity. I counted 134 brief research reports (BRR), with 26 of them mentioning equity. Finally, I counted 141 posters, with 22 mentioning equity.

While over the years I have attended quite a few PME-NA conferences, I have also skipped several of them here and there. For a while, I felt that PME (rather than PME-NA) was more my community. At PME, I always seemed to find several presentations, working groups, discussion groups that related to my research interests in equity, while that was less the case with PME-NA. And yet, even in that more international arena, I should note that there was dissatisfaction with the attention to equity, in particular to social and political issues. In 1996, at PME in Valencia, I recall a fascinating AGM (Annual General Meeting) that discussed dropping the “P” from PME to reflect the fact that many research papers had moved away from the Psychology focus. Shortly after that, in 1998 Mathematics Education and Society (MES) was created in great part as a counter-space to PME (Gates & Jorgensen (Zevenbergen), 2015). In 2000, Lerman’s influential chapter for the field, “the social turn in mathematics education research” was published (Lerman, 2000). In 2004, the book edited by Valero and Zevenbergen (Jorgensen) on the socio-political dimensions in mathematics education research was published (Valero & Zevenbergen, 2004). Of course there are several other researchers who have written on these issues since then. But for me those are two pivotal pieces. For my own work, Lerman’s chapter is particularly relevant as it refers to the influence of Vygostky’s work, which is central to the program of research around Funds of Knowledge (González et al., 2005); that chapter also discusses situated cognition and mentions ethnomathematics, all of which are at the center of my long term interest in studying the affordances and tensions around out-of-school and in-school mathematics. In what follows, I turn my attention to this topic.

Navigating Out-of-school and In-school Mathematics

In the 2006 PME-NA plenary (Civil, 2006), I trace my trajectory from mostly a cognitive preparation to a sociocultural approach in my work, where concerns for equity became central. I am bringing this up here because the cognitive aspect is still very present in my work, but at the same time, I cannot interpret data (a video, students' work) without wondering about sociocultural elements (who is involved? What are their stories?). I argued then and I still argue now that we need these two perspectives (and most likely others too) to make sense of the teaching and learning of mathematics. In fact, what I wrote then is still very present in my thinking now:

> Sometimes I wonder if I have moved away from my initial cognitive-based interest in research in mathematics education to address issues that focus largely on the social and cultural context, with mathematics playing a very peripheral role. As I look over my writing from the last few years, I notice that I often raise the question "where is the mathematics?" Mathematics plays a central role in my work and recently, in our current project, I find myself pushing for the mathematics in our activities and research discussions. (p. 30)

Thus, in this paper I am continuing this thread by focusing on three key elements in my work: funds of knowledge; valorization of knowledge; and participation. As I wrote in 2006, "A concern for those who are being left out of the mathematical journey seems to guide my work" (Civil, 2006, p. 30). This concern has not changed.

Funds of Knowledge

Since the terms "funds of knowledge" is now so widely used in mathematics education research, I thought that providing some history may be useful. Anthropologists Vélez-Ibañez and Greenberg (1992) are credited to have introduced this term, as they write, "strategic and cultural resources, which we have termed *funds of knowledge*, that households contain" (p. 313). Through their collaboration with educational researchers (in particular, Luis Moll and Norma González), the project Funds of Knowledge for Teaching (FKT) was developed in Tucson in the 80s (see González, at al., 2005, for a detailed account of this project). When we bring these ideas to mathematics education, what we are saying is that all communities and families have mathematical funds of knowledge. Children come to school with mathematical funds of knowledge. Yet, as we well know, whether these funds of knowledge are recognized and used as resources for learning varies greatly. How did Alberto (Civil 2016; Civil & Andrade, 2002), a recent immigrant, see himself as a mathematical learner in his fifth-grade class, as he kept largely to himself and was not encountering success? A concerned teacher did not leave it at this and sought to learn more about Alberto and his family, through a funds of knowledge household visit. In that visit she learned about Alberto's unwillingness to leave Mexico and move to the US with his family. He left behind places, people, and activities he enjoyed, including actively helping out with his family's bakery business. He had his set of customers and was in charge of all monetary and goods transactions, yet at school he was struggling with "basic" arithmetic? Alberto's case reminds me of the studies on street mathematics (e.g., Nunes, Schliemann, & Carraher, 1993), which were very influential in my work. If we do not see the relevance in what we are being asked to do, if we do not have an affective connection, is it surprising that we may not do as well?

What about the several children (mostly in grades 5-8) who told me in interviews that they were learning things in mathematics that they had already learned in prior years in Mexico, yet I saw no evidence of them being given more challenging tasks, and in fact sometimes they seemed to be placed at a lower level because they did not know English well yet? This school knowledge (e.g., different algorithms) and learning habits (e.g., use of a notebook for each subject to record their work; bringing their own school tools instead of the school providing them) that they bring from other contexts are part of their funds of knowledge, but schools do not necessarily know of these. The lack of communication between families and school and the differing understandings of each other's roles and expectations are two of the most common findings in my work with immigrant parents.

An example of funds of knowledge in a parents' workshop. Elsewhere (Civil, 2002; 2007) I have discussed examples of applications from funds of knowledge to the mathematics classroom. Here I want to share a brief example (Menéndez & Civil, 2009) of how an activity on comparing fractions became more meaningful when a father participant suggested a connection to wrenches. While I do not know if in this case their children were familiar with how wrenches work (in terms of the different sizes), based on my experience of many years working with families, I would not be surprised if indeed several students at that school had a familiarity with wrenches. Comparing fractions is a typical school activity that can be challenging for children (and for adults, as we have seen in the Math For Parents courses that we have run for several years). In this scenario, the facilitator had asked the participants (most of them mothers and fathers of students at that middle school) to compare ¾ and 6/8. One of the men (Isidoro) successfully drew some pictures to show that they were equal. Another man (Marcos) then mentioned something about wrenches and how they have different measures. The facilitator encouraged both men to bring the wrenches to the next meeting. Isidoro brought "a few wrenches" (people laughed when he said that he had only brought a few of them, as he had about 15 wrenches on display) (see Figure 1). Isidoro very confidently explained what the standard measures are for the wrenches and the facilitator recorded those on chart paper, as Isidoro was mentioning them: 1/4, 5/16, 3/8, 7/16, 1/2, 9/16, 5/8, 11/16, 7/8, 13/16, 15/16, 1) (the facilitator noticed that 7/8 and 13/16 were switched but did not mention anything at that poing); Isidoro commented that there were other wrenches but that these were the most commonly used. Marcos noticed that the ¾ was missing and Isidoro told the facilitator to put it between the 11/16 and the 7/8. Isidoro did not look at the wrenches to see the size, he seemed to have those visualized and knew their ordering (despite the error in the list). The facilitator then said, "I'm not completely convinced that these (the fractions on the chart paper) go like this, in this order. It's just that I have to believe it because I don't know (participants laugh). Or is there a way to find out?"

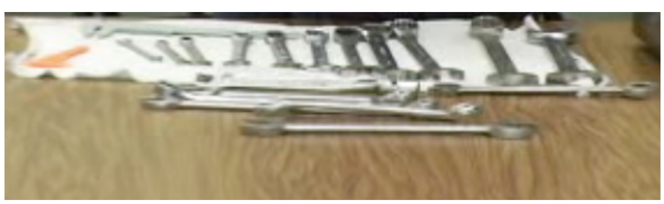

Figure 1. Isidoro's wrenches

The facilitator then encouraged the group to come up with a visual way to help him see how to compare ¼ and 3/8 and 7/8 and 13/16. The participants had grid paper and used this to come up with a visual approach to compare the fractions and resolve the issue with the ordering of 7/8 and 13/16. At this point the activity is a typical school task with the participants representing the different fractions on graph paper and comparing them. But the familiarity with the wrenches provided a context for this activity. The participants remained engaged, and while there were clear gender aspects with the men appearing as experts, some of the women asked questions, probed, and made comments, indicating they were engaged in the task too. There are probably several other mathematical explorations that could use these participants' knowledge of wrenches as contexts. For example, Isidoro and Marcos referred to their knowledge of the metric wrenches. Familiarity with the metric system is one aspect that has come up in other contexts (e.g., recipes). I have noticed students bringing in a knowledge of the metric system either from home or from having lived in Mexico and yet teachers teaching it as if it was new material for everybody.

It could be argued that the wrenches' example is a superficial or contrived context to promote a deep understanding of the mathematics behind comparison of fractions. This is a tension that I have expressed before in my work on funds of knowledge and mathematics (Civil, 2007; González, Andrade, Moll, & Civil, 2001). In Civil (2007) I refer to this tension as preserving the purity of the funds of knowledge at the expense, maybe, of the mathematics. This tension is related to what we decide counts as mathematics.

Valorization of Knowledge

I argue that questions around which mathematics for whom and for what purpose are at the center of any equity debate. I am encouraged by the current discussions around school detracking and, at the college level, around the efforts to create more avenues for students' access to mathematics beyond the standard college algebra (in a traditional sense), precalculus, and calculus path. But I am also aware of the potential obstacles to those initiatives, obstacles mostly based on what we count as a "good" mathematics education and who can "really" do it. I work in a mathematics department and this discourse permeates how we talk about the content of the courses, what needs to absolutely be in these courses to be a mathematics course, and who takes which courses.

For me, this is a personal issue because in my own teaching and research I find myself going back and forth between the need to engage students in activities that are culturally relevant (e.g., funds of knowledge based) and the need to engage students in rich mathematical learning experiences. I do not mean to imply that this is an "either – or" situation. Obviously, both can happen. But I do not find that easy to accomplish. Researchers engaged in social justice mathematics teaching report a similar tension between the mathematical and the social justice goals (Atweh & Ala'i, 2012; Bartell, 2013; Rubel, 2017).

My recent conversations with teachers and colleagues around after school projects with middle school students and mathematical modeling of culturally relevant contexts with teachers bring up these questions for me: is the context taking over the mathematics? Is the mathematics superficial or contrived? In a chapter on modeling and culturally relevant pedagogy, we write, "Teachers may encounter some tension between incorporating authentic cultural knowledge into the modeling process while staying true to the goals and modes of analysis of the discipline of mathematics" (Anhalt, Staats, Cortez, & Civil, 2018, p. 326). Elsewhere (e.g., Civil, 2002; 2016), I comment on the difficulty in seeing mathematics in culturally-based activity when our only lens may be that of "academic / formal" mathematics. In these cases we may not be able to appreciate the mathematics in the activity or we may risk trivializing both the mathematics and the activity.

Throughout my current work and teaching, I often bring up the famous question, "where is the math?" Yes, I do ask this question in part probably due to my own view of what counts as mathematics, but in part too because of the many classrooms I have visited where students are not being challenged in mathematics and are subjected to what I would consider quite dry and uninteresting tasks. Most likely, tasks that are related to their funds of knowledge would be more engaging, but they need to also be mathematically engaging. I also raise this question because I have seen these same students engaging in mathematical discussions of tasks that are largely what I would describe as rich tasks, but not necessarily culturally relevant. In the next section I discuss the concept of participation and in particular the importance of developing classroom environments that let students use their cultural ways of being (which includes the use of their home language(s)) as they do mathematics. So, while the tasks themselves may not have been culturally relevant, developing trusting relationships and letting the students use their cultural resources (language, humor, interaction style) seem to support their engagement with mathematics (Civil & Hunter, 2015).

Participation

The idea of participation has been central to my work for many years. For example, in Civil and Planas (2004) we look at "the effects of social and organizational structures on students' participation in the mathematics classroom" (p. 8) in two different contexts, Tucson and Barcelona. In other pieces, I have looked at the effect of language policies on the participation of emergent bilinguals (English Learners (ELs)) in the mathematics classroom (e.g., Civil, 2011) and of immigrant parents in their children's schooling (Acosta-Iriqui, Civil, Díez-Palomar, Marshall, & Quintos-Alonso, 2011). In Civil (2012, 2014), I look at participation and issues around what language gets privileged? Whose experiences are represented in the tasks? Whose knowledge and approaches get valued. Finally, in Civil and Hunter (2015) we look at immigrant students' participation in argumentation in the mathematics classroom through lenses of culture and language in two different geographic contexts, New Zealand and the US.

In this section I present yet another example from the same classroom discussed in Civil, (2011, 2012), and Civil and Hunter (2015) to illustrate how having an atmosphere where students can basically be themselves, can lead to rich mathematical discussions and students' participation. The setting is a small seventh grade class composed of only 8 students, most of whom were recent immigrants from Mexico (within the previous two years) and all classified as ELs. Elsewhere I have discussed the restrictive language policy in Arizona (Civil, 2011; Civil & Menéndez, 2011) that places ELs in basically segregated classrooms for most of the school day. This was the case for these students. I worked with the teacher (an EL herself) and the students for close to a year. We videotaped 30 class sessions from February through May. It is important to note that three of the students' mothers regularly attended the mathematics sessions for parents (and their children) we had at the school (Civil & Menéndez, 2011). The teacher also attended those sessions. Thus, we had developed rapport not only with the students but with some of the parents too. I have been arguing for quite some time for the importance of developing stronger and trusting relationships between home and school, particularly in the communities where my work is located, where families may be less familiar with the school system or worse, where sadly, they have reasons to feel insecure and less trusty of organizations.

By the time formal data collection began (videotaping) the students were starting to become used to the idea of discussing their work and having to justify their thinking to others. We let the argumentation develop naturally, that is we did not use any norms or roles. We basically relied on tasks that would create situations that promote argumentation. For example, in interpreting a distance / time graph of a bike trip, students engaged in spirited discussions arguing about which part of the graph showed the most progress made by the bike rider (Civil, 2012). When showing the video clips to varied audiences, while some do appreciate the level of engagement and mathematical argumentation that is taking place, others are somewhat surprised by the loudness and "chaotic" looking and sounding discussions. Yet, this "chaos" and "loudness" allowed for a student like Octavio to find his mathematical voice. Octavio was somewhat quiet and did not seem very interested in engaging with mathematics. But it turns out that he liked to argue and that gave him an entry into the mathematics. As we encouraged students to talk about mathematics, we discovered a new (to us) Octavio. As he said in an interview towards the end of the year:

> **Marta:** What is it that you like most about math class, well if there is something that you like, of course?
> **Octavio**: To argue
> **Marta:** And why do you like to argue?
> **Octavio**: Because I feel, I feel like a good student when I think that the answer is right.
> **Marta**: What other things do you like about the class?
> **Octavio**: To chat and do work with my group.
> **Marta**: Did you work in groups last year in math class?
> **Octavio**: No, we worked individually.

(All the transcripts in this paper come from exchanges that took place in Spanish. For reasons of space I have only included the English translation. I know that this is unfortunate as we miss the idiomatic turns and the richness of the speakers' home language.)

The example below shows different features of how students (and us) engaged with mathematics, such as use of humor and teasing and use of their home language (Spanish). It was a relaxed atmosphere. Students had been working in small groups on a problem on planning a class party with three options (going to a pizza place and movie theater; going to a water park; or to a skate ring, (Preston & Garner, 2003)). They were given some information on the cost of the three options and the students were to decide which option may be best and why. Carlos and Larissa are at the board to explain how they used equations to find how the cost of the water park ($W = 100 + 5 P$) and the cost of the skate ring compare ($S = 200 + 2 P$). So what they are going to solve is: $100 + 5 P = 200 + 2P$. They have just subtracted 2P from both sides and have: $100 + 3P = 200$.

1. **Carlos**: There it is. Here we take minus one hundred.
2. **Octavio:** But why?
3. **Marta**: Octavio is asking why
4. **Carlos**: Why did we take minus hundred? [smiling]
5. **Octavio**: Yes.
6. **Marta**: Yes, he is the one asking it. I wasn't asking it, he's the one who asked it
7. **Carlos**: Because that's what we have to take away. Because here we subtracted minus one hundred, and here, we also subtracted minus one hundred.
8. **Marta**: No, it's a very valid question.
9. **Octavio**: Ah, yes, okay, it's fine, it's fine.
10. **Carlos**: Then here you get one hundred and here you get three P.
11. **Octavio**: Three P? [with a tone of surprise]
12. **Simón**: Why?
13. **Octavio**: Why?
14. **Lucas**: Why?
15. **Carlos**: Because I subtract one hundred.
16. **Larissa**: Because we subtracted one hundred.
17. **Carlos**: And you get three P.
18. **Ms. Adams**: But what was the reason for subtracting one hundred?

19. **Larissa**: We wanted (incomprehensible) to know for--
20. **Octavio**: Positive. Why negative?
21. **Carlos:** Be quiet. [Softly and smiling in the direction of Octavio]

In this brief exchange we hear Octavio probing four times (lines 2, 11, 13, 20). He is following the explanation and wants to make sure that he understands what they are doing. This is quite different from other cases where students are presenting at the board but the rest of the students are not really engaged. After that, Larissa and Carlos deciding how to solve for P because that is one thing they had not done prior to coming to the board to explain. They end up with P = 33.333…There is also some joking around because the teacher and I ask them to erase what is in blue from the white board (from a previous exercise) so that they can have more room to show their work and Larissa points to the top of the board where part of the date is written in blue. This is sort of an inside joke because from when I started coming to their class I was asking them not to erase their work so that I could see how they were thinking, but it took a while for students to let go of their attachment to the eraser. And this time I was telling them to erase, so Larissa picks up on that.

Next, the teacher and I asked Larissa and Carlos about the meaning of having found P to be 33.333.

1. **Carlos**: That one P is equal to 33.33333.
2. **Marta**: Yes, but what does that mean?
3. **Carlos**: Because we divided it.
4. **Marta**: No, no, what does it mean in the problem?
5. **Ms. Adams**: What is P? What is P? People…
6. **Marta**: What does P represent?
7. **Larissa**: People.
8. **Carlos**: One person.
9. **Ms. Adams**: Okay—
10. **Carlos**: One person is going to pay 33…for the--
11. **Octavio**: Why 33 dollars if it's two dollars per person?
12. **Carlos**: It's cause, nosy [*mitotero*] [to Octavio, as implying stay out of it, in a joking way].
13. **Larissa**: It's cause it's wrong [slightly laughing]
14. **Marta**: It's a good thing that Octavio is, is, really on the ball, eh?
15. **Larissa**: Yes.
16. **Marta**: He's absolutely right
17. **Larissa**: This is the number of people that can go.
18. **Carlos**: That's why!
19. **Octavio**: Ah [incomprehensible; some laughter]
20. **Carlos**: That's what I was saying. [smiling]
21. **Larissa**: That's why, it's not the price! [smiling]

Larissa and Carlos are confused about what the P represents. As soon as Carlos says that it is the cost of one of the activities, Octavio jumps at that (line 11), since the cost of the activities are \$2 per person for the skating and \$5 per person for the water park. In line 12, Carlos uses a cultural term "mitotero" in a joking way to basically tell Octavio to stay out of it ("mitotero" in Sonora, Mexico (which is where many of the families in my context come from) means "gossipy" / "nosy").

Finally, once they have agreed that P is the number of people, and they decide on P=33, the question of how much it is going to be comes up.

1. **Ms. Adams**: And how much would it cost?
2. **Larissa**: I mean we wanted to see, I mean we wanted, cause I mean we wanted to see--
3. **Carlos**: The exact point.
4. **Ernesto**: How much would it cost?
5. **Octavio**: So how much would 33 people cost? (pause- someone else says something) How much? Tell me, well!
6. **Carlos**: How mu—33 people?
7. **Marta**: Do it, do it, all of you --
8. **Carlos**: Ah well, here it is [looks at his notes again]
9. **Ms. Adams**: Let's see, that table--
10. **Marta**: You can all do it, eh?
11. **Carlos**: In the graph.
12. **Marta**: How much does it cost for 33 people?
13. **Carlos**: You can all do it. [repeating what Marta has said / teasing]
14. **Ms. Adams**: How much does it cost for 33 people to go?
15. **Marta**: All of you, yes, yes.

Once again, we see Octavio engaged and asking in a challenging tone to tell him how much it would cost for 33 people (line 5). I then turn it over to all of them and suggest that they all figure it out (line 7 and again line 10). In line 13, Carlos repeats my saying "you can all do it" in a teasing tone. Perhaps some could interpret his repeating what I said as mimicking me and not being respectful, but that is not how I took it at all because it was part of our interaction style. I had known Carlos since the year before; he and his two siblings came regularly to the mathematics workshops for parents with their mother. We had developed a rapport over the two years.

The concepts of "confianza" (trust) and family feeling are often mentioned in research with Latinx communities (González, et al., 2005; Rodríguez-Brown, 2010). The importance of building relationships among students and teachers and more broadly, among school personnel and families has been extensively documented in educational research with "diverse" students (e.g., Gay, 2000; Nieto, 2013). This importance has also been documented in the teaching of mathematics in non-dominant communities (e.g., Berlin & Berry, 2018; Guerra & Lim, 2017; Id-Deen, 2017; Kitchen, 2007; LópezLeiva, Celedón-Pattichis, Pattichis, & Morales, 2017; Martin, 2009; Musgrove & Willey, 2018). What I just presented is one more example of something we have known for a long time: relationships matter. If my view of equity is about the opportunity to participate, we need to develop an environment where students are going to want to participate. I saw this happening in that 7th grade class, and I also saw it in another school, first in a 4th/5th grade combination and then the year after (with the same teacher) in a 6th grade class. While the two settings were different, one aspect in common was a feeling of being a family and to a certain degree, the teachers acted almost as if being a family member. Allowing students to be themselves, to walk around the room and see what others were doing when working in groups, to tease each other (including me), all of this seemed to contribute to developing a safe and supportive environment where students were willing to take mathematical risks.

I have been wondering for quite some time whether what we are missing when working with minoritized students in school is to bring in their home ways of being and acting. While in the work in the 7th grade class, I may have seen glimpses of that, I am certainly not claiming that we succeeded, it was just that, glimpses. In Civil (2016), I argue for the need to gain a better understanding of how people engage in out-of-school settings in practices that are potentially mathematically rich and see how these ways of engaging relate to how, for example, mathematicians engage in the practice of mathematics. Nasir, Rosebery, Warren, and Lee (2006) argue that as learners we navigate through a variety of repertoires of practice as we move through different settings (e.g., home, school, clubs, groups that we may belong to). In looking at "the intersections between everyday practices and important disciplinary knowledge" they claim that "educators can use the varied and productive resources youth develop in their out-of-school lives to help them understand content-related ideas" (p. 493). I wonder, is school helping or hindering connecting these two practices, everyday practices and disciplinary (e.g., mathematics) practices? When we develop learning activities that build on students' funds of knowledge but also engage them in rich mathematics, is it school mathematics that we are working with? Is it disciplinary (mathematicians') mathematics? Should it be something else? In discussing the possible connections between different forms of mathematics (e.g., everyday mathematics, school mathematics, mathematicians' mathematics), Nemirovsky, Kelton, and Civil (2017) point out that schools can only bring in "real world" problems to a certain point since school has its own constraints and after all the students are not really engaged in that real world problem that often serves mostly as a scenario to address school mathematics.

I started this section discussing participation but the questions I just raised relate back to funds of knowledge and valorization of knowledge, thus bringing me back full circle. I want to close with some further thoughts on these ideas in part inspired by my current work as well as what I still see as challenges in the field when it comes to equity research.

Next Steps?

There are quite a few people now doing work in mathematics education building on the concept of funds of knowledge. This is certainly very different from the early 90s. Some of this work is informed by a variety of theoretical frameworks, which makes for a more robust account of the research efforts. In this sense, we are making progress, as researchers build on the concept and take it into different directions, contributing to the deepening of "the field's knowledge base related to equity-based research" (Aguirre et al., 2017, p. 125). I think we can all agree that there seems to be more attention given to equity in mathematics education in recent years. Whether it is because some conference proposals ask for an explicit connection, or whether it is an expectation of funding agencies, or whether it is that there seem to be more researchers coming out of doctoral programs (and some NSF-funded Centers for Learning and Teaching) where equity is central to their preparation, I think that there are more people engaged in equity-related research activity than when I started my career. In Aguirre et al., we argue for the need to make equity part of research in mathematics education, no matter what our main topic of research may be. That is, we call for the need to make equity part of our research as an "intentional collective professional responsibility" (p. 128). In looking at the four political acts discussed by Aguirre et al., I see equity as central to my work (Political Act 1). As for Political Act 2, I have occasionally felt tokenized as the "equity expert" on projects but I would rather have that than the second approach described in that political act, which is having researchers who are not grounded in equity work provide superficial attention to equity issues. I believe that as researchers whose expertise is in equity, we have a responsibility to support others who want to do this work but may not feel knowledgeable. In looking at some of the recent PME-NA proceedings as well as listening to a variety of talks in diverse conferences, I wonder about how widely "equity research" can be interpreted and whether we may be going in the direction that everything we do addresses equity somehow. Is that the case? Do we risk watering down equity?

Where is the mathematics and what counts as mathematics are discussed in Political Acts 3 and 4 (Aguirre et al., 2017) and are the center of my work, as I have addressed earlier in this paper. While I agree that to challenge equity work with the question of where is the mathematics can be problematic and creates a separation that is not (or should not) be there, the reality is that I have raised that question myself quite a few times, about my own work and about those of others, as I mentioned earlier in this paper. Is it mostly related to my views of what counts as mathematics? Are we doing enough in our writing and in our work to bring the centrality of equity to mathematics and the centrality of mathematics to equity?

In my current work, I continue to explore questions centered on equity as opportunity to participate and I wonder about the potential for K-16+ "formal" learning (as in a school / college class) of looking at how people learn in everyday life or in informal mathematics settings (see Nemirovsky et al., 2017 for more on the distinction between mathematics in school, in everyday life, and in informal settings). In particular, as I have discussed elsewhere (Civil, 2007; 2016) learning in everyday settings often takes place through participation in the practice, often by observing first and then engaging with the activity. Lipka, Sharp, Brenner, Yanez, and Sharp (2005) describe the case of a Yup'ik teacher, Nancy Sharp, using a Yup'ik approach to learning (apprenticeship; observing and participating in the practice) to work with her students in mathematics. Similarly in their work with teachers of Maori and Pāsifika students in New Zealand, Hunter and Anthony (2011) refer to how teachers draw on their "students' concepts of collectivism to develop communal responsibility" (p. 6) and build on these strengths to engage students in mathematical discussions.

I am intrigued by the potential for mathematics teaching of building on students' cultural ways of being and acting, as I illustrated briefly with the 7th grade example earlier and elsewhere (Civil, 2011; 2012; Civil & Hunter, 2015). Rogoff (2012; Rogoff et al., 2017) has been studying how children of Indigenous origin learn in communities in Guatemala and other places in the Americas, including some Mexican-origin children in the US, and contrasting these ways of learning to those of children from middle-class families, mostly of European origin. An example of this contrast is captured below:

> The toddlers [in a Mayan community] observed keenly and engaged in multi-way interaction with the group. In contrast, middle-class European American mothers' approach resembled Assembly-Line Instruction, with mock excitement and praise to engage the little one in mini language lessons. These toddlers were less broadly attentive and seldom engaged with the group as a whole. (Rogoff, 2012, p. 236)

Rogoff et al. (2017) discuss the concept of "sophisticated collaboration" that they have seen among Indigenous children, including children in the US of Indigenous Mexican origin. Sophisticated collaboration implies a form of working together that is fluid and coordinated. They noted that "rural Mexican children were more likely to cooperate in a game than were urban children in the United States, who competed with each other even at the expense of any of them winning" (p. 880). Children engaged in sophisticated collaboration think and work together. On the other hand, children from middle-class families tend to split a task and do less sharing, less thinking together, and take bossy roles. In a study of children engaged in computer programming, they note, "pairs from Indigenous-heritage U.S. Mexican backgrounds collaborated twice as much as did pairs from highly schooled European American backgrounds" (p. 880).

One of the key components of equity as opportunity to participate involves productive group work, in particular along the lines of Complex Instruction (Cohen & Lotan, 1997; Featherstone, et al., 2011). Do immigrant origin students from certain communities (e.g., in Mexico) bring strengths along the lines of sophisticated collaboration that we could be tapping onto? My work with families of Mexican origin points to interactions between parents and children in the mathematics workshops that range from direct instruction on the part of the parents to more collaborative, joint meaning construction (Civil, Díez-Palomar, Menéndez-Gómez, & Acosta-Iriqui, 2008; Menéndez, Civil, & Mariño, 2009). Certainly, more work needs to be done to gain a better understanding of the strengths that immigrant-origin students, such as the ones in the 7th grade class I describe, bring with them. Children from different backgrounds are likely to bring cultural ways of participation that may be different from the ones expected by the school. This is an asset, as the example of sophisticated collaboration shows. I think it is worth noting that students who belong to non-dominant groups often have rich experiences and skills such as knowing more than one language (important in a global world), knowing how to collaborate (important for teamwork, a trait that is valued in many professions), learning at home through participation in the activity rather than through direct teaching, contributing to the household functioning (e.g., helping out with the home economy; language brokers). What are the implications of this richness of skills, knowledge, and experience for teachers and researchers in mathematics education?

Why do I do this work? The words of Adrienne Rich (1986) say it much better than I could ever say it:

> When those who have power to name and to socially construct reality, choose not to see you or hear you, whether you are dark-skinned, old, disabled, female, or speak with a different accent or dialect than theirs, when someone with the authority of a teacher, say, describes the world and you are not in it, there is a moment of psychic disequilibrium as if you looked into a mirror and saw nothing (p. 199)

As we reflect on the work we do with teachers, students, communities, I hope that we can provide accounts that counter these words. I would hope that the students and families with whom we work see themselves in the mathematics worlds that we share with them in our classrooms. I close with the words from a Pāsifika student, as a reminder that this is indeed possible: "When the maths is about us and our culture, it makes me feel normal, and my culture is normal" (Hunter & Hunter, in press, p. 16).

LOOKING BACK, AHEAD, AND IN NEW DIRECTIONS

Laurie H. Rubel
City University of New York (Brooklyn College) & University of Haifa
LRubel@brooklyn.cuny.edu

In this paper, I respond to and expand on Civil's plenary address (this volume), in which she articulates key themes related to funds-of-knowledge orientations to mathematics education. I review the themes selected by Civil: funds of knowledge, participation, and valorization of knowledge, and provide additional analysis. Next, I accentuate the often absent but inherent political dimensions of work in mathematics education that emphasizes the cultural, as well as the often absent but inherent cultural dimensions of work in mathematics education that emphasizes the political. Finally, I contribute additional perspectives to future directions for the research community around equity in mathematics education.

Keywords: Equity and Diversity

Introductions

I trace the origins of my work around equity in mathematics education to my involvement as an undergraduate student in a spin-off project prompted by the then-contemporary study, in which Treisman and colleagues (see Treisman & Fullilove, 1990) attributed difficulties in college mathematics for African American students to their social and academic isolation. In 1991, the mathematics department at the college where I was a student, inspired by Treisman's findings, created a co-curricular Calculus "workshop" for first-year students of color. I was tapped as a senior student facilitator, and this experience contributed towards my extension of experience in informal and Jewish education towards mathematics teaching as a profession.

I continue to benefit from the power and privilege that come with whiteness in the U.S., in opportunities around education, employment, and housing. Yet white privilege only goes so far for me, as a queer, gender non-conforming, Jewish woman. In general, through my intersecting life experiences of Otherness (Du Bois, 1903) and my struggles from these marginalized positions, I feel solidarity and identify with people and groups who are being othered, objectified, or oppressed. Once I became a high school mathematics teacher in the mid-1990s, for example, I discovered a system in the elite school in New York City where I taught that was supposedly ability oriented but had produced its lowest track with nearly all of the school's students of color. After sizing up their brilliance, the students and I turned what was supposed to be a low-track senior math class to preparing for and taking the AP Calculus AB exam. The impetus was certainly inspired by my achieved standpoint (Harding, 1993) as a queer Jew, and likely also in part by the then-contemporary *Stand & Deliver*.

In that popular Hollywood rendering of real-life Jaime Escalante's classroom, we saw Latinx students face racial discrimination as, presumed by the College Board to have been cheating, they were forced to retake their AP Calculus exams. Though my students and I were spared the attention of The College Board, they schooled me about the range of everyday racial discrimination and microaggressions they experienced, from regularly being called one another's names by white teachers, to being tailed inside stores by local shopkeepers, to being targeted by city truancy officers on route to school and then missing class while being "processed" by that system, to having to absorb the feeling of being feared on the streets by white women. My love for them as their teacher connected me in an emotional way to what was their marginalization, their pain, their disappointment. I wanted to teach mathematics that would feel relevant, to support their and my own understandings of processes in the world, especially the structural and systemic processes that were designed to keep power and material resources from them.

In my subsequent and ongoing work as a mathematics education researcher and teacher educator, I continue to learn about the importance of providing students with windows through which to use mathematics to understand the outside world but also of mirrors, through which to see themselves and connections to their pasts and potential futures (Gutiérrez, 2007). As Gutiérrez (2007) elaborates: "The goal is not to replace traditional mathematics with a pre-defined 'culturally relevant mathematics,' but rather to strike a balance between the number of windows and mirrors provided to any given student in his/her math career" (p. 3). Otherwise, like the poet Adrienne Rich (1986) warns, without such "mirrors," there is the potential for "psychic disequilibrium" as the teacher, the school, the curriculum, and their aggregated power is describing the world, but without you in it, and it "as if you looked in the mirror and saw nothing" (p.199).

Since the 1980s, mathematics education research and teacher education has considered an array of related sociocultural perspectives about mathematics and its teaching and learning -- ethnomathematics (e.g., D'Ambrosio, 1985), funds of knowledge for mathematics (e.g., Aguirre et al., 2013; Civil, 1998), and culturally relevant or responsive mathematics teaching (e.g., Gutstein, Lipman, Hernández & de los Reyes, 1997). A commonality among these perspectives is around "centering" (Tate, 1995) mathematics on students' experiences, their affiliations with various cultural or social groups, or the everyday practices of those groups, by creating opportunities for hybridity between the mathematical thinking in everyday practices or other out-of-school domains and the formal school mathematics curriculum. Unlike an incremental or vertical development of mathematical expertise typical to school-based learning, horizontal expertise develops through coordination across the diverse set of contexts through which one traverses (K. Gutiérrez, 2008).

In this volume, Civil (2018) reflects on such a perspective about mathematics teaching and learning equity in mathematics education and identifies three interrelated themes that she views as central in her own "looking back": funds of knowledge; participation; and valorization of knowledge. I have been greatly influenced by Marta's corpus of scholarly contributions, and I begin by addressing each of these themes. Next, I follow Marta's lead and present ideas about how we might "look forward," or really, blaze new trails in mathematics education, in vision, mission, and action.

Civil's "Look Back"

Funds of Knowledge

Across the breadth of Civil's work, she emphasizes a baseline premise that every community, family, and person possess mathematical funds of knowledge, and that these funds of knowledge can be leveraged as intellectual resources for school success. This approach to equity in mathematics is considered "asset-based" (Celedón-Pattichis et al., 2018), in how it avoids a deficit construction of minoritized youth, their families, communities, and material spaces. Civil's research includes studies of children's mathematical thinking, mathematics teaching, and parents' mathematical thinking and perceptions, and draws on a blend of cognitive and sociocultural perspectives about learning. One of her most significant contributions to date is her work on immigrant parents' mathematical thinking, their cultural and linguistic funds of knowledge, their views about their children's mathematics education in the U.S., and implications for equity in mathematics education (e.g., Civil & Andrade, 2002; Civil & Bernier, 2006; Civil & Menéndez, 2011).

Much of the related scholarship around funds of knowledge in mathematics education is practice-oriented, around processes or implications for teacher education. Beginning with Moll, Amanti, Neff and Gonzalez' (1992) outline of a process for teachers as co-researchers to conduct home visits with the goal of identifying funds of knowledge, there exists a growing set of studies that present potential protocols for, and demonstrate the effectiveness of, similar approaches in teacher education (Aguirre et al., 2013; Civil & Andrade, 2002; Foote et al., 2013; Rubel, 2012; Turner & Drake, 2015; Turner et al., 2016). In aggregate, these studies guide teacher education in terms of how to foster orientations to teaching that value the funds of knowledge that youth bring to the classroom and in so doing, deflect prevalent deficit framings of minoritized peoples. In addition, these studies identify and analyze ways of supporting teachers in developing and improving instructional practices that leverage those knowledge funds as intellectual resources.

A related area of research comprises curriculum design fueled by a funds of knowledge orientation. The Math in Cultural Context project is an example, in which teachers, researchers, and Yup'ik elders co-designed elementary school mathematics curriculum around mathematics of Yup'ik cultural practices (Kisker et al., 2012). Less well-known examples around curriculum design based on community funds of knowledge can be seen, for example, in Katsap and Silverman's (2015) work with geometry curriculum using traditional Bedouin weaving and embroidery, or Massarwe, Verner and Bshouty's (2010) example of plane geometry curriculum with a focus on Arab art and design. Civil has endowed our field with a variety of such examples, such as elementary mathematics curriculum around the theme of construction (Civil, 2002) or garden-design (Civil & Kahn, 2001).

Curricular design that builds on students' funds of knowledge typically relies on iterative processes of studying one's students to identify funds of knowledge domains, identifying mathematics embedded in those everyday practices, and building curriculum that negotiates the connections and tensions between the mathematical thinking inherent to this domain and the desired school mathematics. Although such processes are productive as equity-directed instructional practices, they extend beyond the normative scope of a teacher's workload. As our research and collaborations with teachers accumulate evidence that such processes are essential, we must concurrently adjust the scale of teacher workload and advocate for teachers as our collaborators in this endeavor so that there is not a disconnect between the necessary and the realizable.

In this volume, Civil (2018) showcases an example of how a funds of knowledge domain emerged in her mathematics workshop for parents of school students. Civil learned from the parents that American wrench sizes are sized in inches and expressed as fractions. Ordering wrenches by increasing size is, therefore, equivalent to ordering fractions. Civil presents the comparison of wrench sizes as an authentic context that can elicit or support mathematical thinking about fraction comparison. Here, with respect to this wrench dimension example, Civil reiterates an essential tension that she has earlier described (e.g., Civil, 2007), between "preserving the purity of the funds of knowledge" and the mathematical goals of instruction, in terms of how a curricular focus on a real-world context might de-prioritize, limit, and constrain mathematical exploration and mathematical content.

This tension is derived, in part, by how lesson planning in mathematics is traditionally driven by a predefined set of mathematical definitions, concepts, and skills, and then so-called "real-world" examples are provided as afterthought applications. Curricular design around a social practice or a social theme takes the opposite starting-point, which in and of itself is new for teachers or designers (Nicol, 2002; Wager, 2012). I have negotiated this tension in my work with mathematics teachers around a binary of teaching the real-world context in service of learning mathematics or teaching mathematics in service of learning about the world. In navigating that false binary, we lose sight of how we are teaching children: our children, the children of our neighbors, and young people all. Their collective well-being, their sense of being cared for, and how mathematics can support the development, cultivation, and refinement of their empathy, creativity, curiosity, and capacity to care for one another and the natural world could be our primary priorities.

Participation in Mathematics

Centering mathematics instruction on students using a funds of knowledge approach typically implies designing thematic curriculum around a selected socio-cultural domain. An alternative way that funds of knowledge can be leveraged in mathematics is in terms of using analogies during instruction that relate a mathematical object or process to students' existing knowledge but without focusing the curriculum thematically around that knowledge domain. For example, in one of my projects, I observed a teacher using one of her student's breakdancing hobby in relation to the mathematical concept of a triangle's center of mass (Rubel & Chu, 2012). The lesson was not organized around breakdancing, but the breakdancing funds of knowledge was used as an analogy to bridge students' experiences with a mathematical object and its definition. Similarly, the example in Moses and Cobb (2001) about using students' experiences with the public transit system as a means of learning integers was absent a thematic focus on the trains themselves.

Here, Civil (2018) presents an additional alternative, in her reminder that students from minoritized groups can engage in mathematical content that is devoid of thematic connection to specific lived experiences. She stresses that building on students' experiences and their funds of knowledge does not need to be limited to building a curriculum focused on a particular everyday practice, real-world artifact or process, but could be implemented through the ways that teachers organize their classroom for participation -- not necessarily what mathematical questions the students are considering, but what kinds of participation are being made available to them, and if or how those kinds of participation are in synch with or in opposition to their ways of participation in other aspects of their lives. For example, apprenticeship models of gaining expertise or assumptions of competence are endemic to various contexts and could be leveraged as resources for classroom learning (Civil & Khan, 2001; Kisker et al., 2012; Nasir, 2005).

I would like to draw attention to this point, especially in the context of current educational policies and mantras. We know that teachers' beliefs about students and about learning underlie how they think what doing mathematics is supposed to look like, and which forms of participation they will make available for their students (Hand, 2012; Rubel & Stachelek, 2018). The common perception of order and silence as prerequisites to learning mathematics constrains individual teachers' views about participation, can lead toward over-interpretation of student participation as off-task or disruptive, and typically results in didactic teaching (Hand, 2010). In this volume, Civil (2018) draws attention to a 7th grade classroom vignette in which she was the instructor and her students engage deeply with evaluating algebraic expressions. She credibly ascribes significance to the blend of humor, use of the students' home language, and *confianza* (trust) among participants.

Civil's observations remind me of my own, recent observations of two accomplished teachers of color, Ms. Hudson and Ms. Garcia (pseudonyms), who collaborated with me on a recent project. Civil's description of the family-like environment in that 7th grade classroom is reminiscent for me of the my sense of the atmosphere in Hudson's and Garcia's classrooms, notably different from the classrooms of the 9 white teachers in that group of teachers. Hudson created a family-life atmosphere through her playfulness and use of youth or informal language. For instance, she would ask the class, "Can I mess with you now?" as a way of initiating a more complicated exercise. This playfulness initiated a kind of lightness and communicated both rapport, support, and a sense of challenge. Garcia also connected to her students through language, but in her case, she drew on strategically using Spanish (her and their first language), to translate mathematical terms, to check in with students about their emotional state, and to redirect behavior. Garcia positioned herself as a loving caretaker for her students by donning an apron around her waist, its pockets filled with pencils, erasers, and calculators for their use. Civil's description of her experience in that 7th grade class corresponds with my observations of Hudson and Garcia, and of the Lee example described in Clark, Badertscher, and Napp (2013). In sum, this suggests that we expand our understandings about fostering hybridity in mathematics classes through participation processes and language and that we could follow the guidance of expert teachers of color and their community cultural wealth (Burciaga & Kohli, 2018). Other kinds of "disruptions" of traditional learning environments, like situating formal learning in places outside of schools and classrooms, are likely productive as well in creating opportunities for hybridity (Ma, 2016).

Valorization of Knowledge

The research literature describes interventions and provides teacher education modules designed around supporting teachers about how to develop mathematics curriculum that builds on students' experiences or everyday practices (Aguirre et al., 2013; Rubel, 2012; Taylor, 2012). As part of this process, we are seemingly led to search in a cultural practice for what Noss, Hoyles and Pozzi (200) have called "visible mathematics," meaning recognizable as school mathematics. Here and in other papers, Civil draws attention to the valorization of knowledge, in terms of the issue of whose knowledge is being valued, meaning that oftentimes we do not sufficiently valorize the mathematical thinking endemic to various cultural practices as mathematics. For example, one of Civil's exemplar funds of knowledge examples relates to a parent's geometric design and measurement work as a dressmaker (Civil & Andrade, 2002). As Civil has discussed, there is a distinction between valorizing the dressmaker's knowledge as itself mathematical or doing so through potential connections to existing school mathematics.

At the same time, Civil cautions about organizing lessons around a real-world context and then have the context "take over" the mathematics. Civil cautions that the social context might be superficial or contrived and draws attention to the oft stated concern "where is the math?" Elsewhere (Rubel & McCloskey, under review), I have written about how the "where is the math?" critique is at times employed to protect Western mathematics as if it were universal and as if success in school mathematics were inherently fair. Culturally relevant pedagogy, or pedagogy organized around funds of knowledge, is then positioned as communicating a "watering-down" of mathematics, for those seen as unable or unwilling to engage otherwise. Here, in reiterating her "where is the math?" concern, Civil comes close to positioning instruction and pedagogy that is fundamentally oriented around building on students' experiences as potentially at odds with rigorous mathematics instruction. When we position culturally relevant pedagogy as threatening mathematics, we falsely re-inscribe Western mathematics as neutral and deny that school and academic mathematics are historically, socially, spatially, and culturally bounded.

Indeed, while ethnomathematics could focus on the mathematics of *any* social or cultural group, it is typically used as a catch-all term for mathematics among "identifiable cultural groups" (D'Ambrosio, 1985), and those groups are typically limited to subordinated social groups (Knijnik, 1997). Western mathematics is then understood as separate from and in opposition to ethnomathematics (Gutiérrez, 2017). But as Knijnik (2002) explains:

> by considering the form of other, non-hegemonic ways of knowing and producing mathematics, ethnomathematics relativises the "universality" of (academic) mathematics and, moreover, questions its very nature. … In problematising academic mathematics, ethnomathematics emphasizes not only that mathematics is a social construction but, more than this, that such a construction takes place in a terrain shaped by political dispute around what will be seen as mathematics, around which will be considered the legitimate way of reasoning, and therefore, around which groups are those that can legitimately produce science…..Thus, it is not a matter of talking naively about different mathematics, but of considering that these mathematics are, in terms of power, unequally different. (p.13)

Hence, if we legitimize mathematical funds of knowledge only in terms of connections to Western mathematics, we are ignoring this political terrain. Using a Western gaze onto our students' funds of knowledge is different than valorizing cultural expertise, curiosity, and other ways of knowing as avenues that will yield new mathematical questions, ideas, representations, and ways of knowing. I call attention to the work of R. Gutiérrez (2002) in which she outlines how making space for people "under the tent" of mathematics will necessarily change, expand, and improve mathematics -- people pose mathematical questions and develop mathematical solutions informed by their experiences. Mathematics is necessarily enriched by participation of a wider variety of people from a broader range of experiences. As Gutiérrez teaches, it is not only that marginalized people need mathematics. Of course, they can use mathematics in a variety of ways to evade their marginalization. However, for mathematics to stay relevant and to be able to solve many problems that remain unsolved, it is mathematics that needs a diversity of peoples.

The Cultural is Political

Although mathematics is an ongoing human creation, only some mathematics is recognized in the Western cannon and included in school curriculum. For students in the U.S., from the White, Christian power-majority, this is not experienced as exclusion, since this is the normative culture. Teachers (as well as textbooks and test writers), who are largely from that power-majority, tend to draw on their own funds of knowledge in selecting, creating, and implementing mathematical tasks. In sum, this means that white students already have their funds of knowledge reflected in typical mathematics instruction and curriculum, without need of intervention and unacknowledged as such. Even when trying to connect to students' funds-of knowledge, mathematics teachers have been found to contextualize mathematics using contexts related to sports or consumer activities of adults like home remodeling, shopping, banking, or budgeting (Bright, 2015; Watson, 2012), domains that are seemingly "safe," or germane for everyone in the same way. However, these domains are neither arbitrary nor neutral, but correspond to the interests, life experiences, and values of communities who already benefit from being part of the power-majority. Moreover, the positioning of the importance of learning mathematics in school as preparation for roles as marketplace consumers or corporate employees demonstrates how mathematics in schooling is being used to support ideologies of individualism, competition, and capitalism, ideologies that benefit that same white power-majority. How might our word problems in mathematics read if they were guided instead around commitments to collective well-being or to the health of our natural environment?

Making the Political Explicit

There is a known tendency to avoid political questions like these in the teaching of mathematics (e.g., Simic-Miller, Fernandes, & Felton-Koestler, 2015), which can be explained by a combination of a lack of sociopolitical awareness among teachers, fear among teachers for job security especially in the current nationalistic climate, or a result of the common misperception that mathematics is apolitical. In one of my projects, for example, I observed teachers struggle with how to take up issues of power and oppression in their teaching of mathematics for all of these reasons. One white teacher with whom I collaborated, for example, created interesting curriculum around using geometric loci as a language with which to analyze or design home or facility location, relative to constraints like environmental pollution. Even though her school was in a low-income area with high asthma rates, presumed to be related to more extreme and multiple sources of environmental pollution, she built the lesson in hypothetical, generic terms. In conversation afterwards, she agreed that she could have provided the students the opportunity to use mathematics to articulate their own physical geometries in the context of actual existing environmental hazards and disease rates. She reflected that she tended to have "blinders on" about specifically engaging in hybridity between relevant political concerns and her teaching of geometry (see Rubel, 2017). I, too, as a teacher educator struggle with how to better support teachers in this regard.

Indeed, despite a vision of mathematics as socially constructed with political ambitions and consequences, funds of knowledge projects in the literature are often described in cultural or linguistic terms absent explicit socio-political contextualization. For example, taking Civil's (2018) new example about wrench sizing, she has demonstrated that this is an interesting and likely productive context in which to explore comparison of fractions. The wrenches, and what they are used for, as well as who is using them is seemingly put aside to focus on the wrench dimensions themselves, because fractions and their relative magnitudes explicitly reside in those dimensions. But what of the unasked question as to the mathematics of why these people, in this moment of time, and in this place possess this specific knowledge about hand tools? What is the mathematics of how this knowledge and expertise is capitalized on by those in power? What is the mathematics of who owns the construction or tool companies, who gives the building permits, and what the zoning processes value? How is this knowledge acquired and how is it shared? Who invented this tool, for what purpose, and how is mathematics used to produce it? What fraction of construction profit goes to those who are doing the actual back-breaking and dangerous construction labor? What is the mathematics of labor unions in the U.S. and their support for construction workers? What else are these tools used for? And further, what is the mathematics of American persistence to have a unique measurement system?

The Political Crowding Out or Denigrating the Cultural

It is not only that funds-of-knowledge curriculum modules are often presented absent political context. There are examples in the literature of projects that are explicitly organized around political questions or themes but that do not honor or sufficiently leverage students' funds of knowledge. In my work with colleagues, as part of the City Digits project, for example, we identified widespread participation in state lottery games as a cultural fund of knowledge in which to explore probability, combinations, scale, measurement, data analysis with youth (see Rubel, Lim, Hall-Wieckert, & Sullivan, 2016c). In a second example, we drew on rampant participation in a local array of alternative financial institutions like pawn shops and check cashers as an entry-point to evaluate spatial distribution of these alternative financial institutions in the context of other social variables (Rubel, Lim, Hall-Wieckert, & Katz, 2016b). In both cases, students built new or more developed mathematical understandings, which contributed to furthering their political formation (Rubel, Hall-Wieckert, & Lim, 2017). Their interest in and curiosity about spatial justice engaged them in furthering their mathematical understandings (Rubel, Lim, Hall-Wieckert, in press). Participating students reflected that contextualizing mathematics through political issues that they identified as connected to their lives and the places in which they live -- their funds of knowledge -- linked their learning to their sense of being agents of change in their families in terms of lottery spending, or decisions about financial institutions (Rubel et al., 2016c).

At the same time, along with these important successes, these curricular modules and their associated maps did not make sufficient use of funds of knowledge as resources and instead, likely reinforced and highlighted common deficit notions about students and their families, at least for some students. For example, central to these modules were data and map representations that could have been interpreted as suggesting that participation in the lottery or loan-taking from alternative financial institutions among low-income people are produced by a lack of mathematical understanding, instead of as products of spatial injustice organized to maintain the status-quo of white supremacy (Rubel, Hall-Wieckert, & Lim, 2016a). The knowledge that the youth accessed in the community about people's sense of hopelessness in the context of their care for loved ones remained largely in the shadows of the project's focus on navigating probability and combinatorics ideas or on the mathematics of loans. How could mathematics be directed at questions or problems related to hope or love instead of only on analysis of or strategies about capital gain amd loss?

As another example, consider Cirillo, Bartell, and Wager's (2016) presentation of a mathematical modeling investigation around the theme of soda pricing techniques used by fast food restaurants. By presenting data showing drink volume and corresponding price per ounce, the finding is that over-sized drinks are sold at a cheaper rate per ounce than smaller, recommended sizes, effectively enticing consumers to buy larger drinks. Since these drinks are heavily caloric but without other dietary benefits, this becomes significant relative to obesity, diabetes, and other health factors. Cirillo et al. (2016) direct readers to contextualize this finding in terms of the density of fast food restaurant locations relative to demographic variables around income, and speculate, indeed, that students in low-income areas saturated with fast food restaurants might surmise that there is not concern for their health. Educating people about their miniscule probability of winning the lottery can be seen as using mathematics to promote abstinence from the lottery. This is akin to how teaching that interest rates charged by pawn shops or check cashers are higher than other financial institutions might lead people to borrow money elsewhere. Similarly, educating people about this value pricing of soft-drinks technique relative to the health risks of drinking soda is intended to guide learners towards abstinence from indulging in those drinks. A commonality across these types of mathematical investigations is that they do not directly challenge why we accept a society that allows, supports, and even encourages these kinds of predatory systems.

Fundamental to this distinction is our current paradigm of democracy, which is a power-over system (Guinier & Torres, 2002), meaning that competition for power yields some who dominate and more who are dominated. Even if one assumes that the current democratic systems in the U.S. are fair and meritocratic, still, these systems are designed to generate inequalities, to yield rewards only to some, and mathematics supports these systems that are designed to rank and order of people (see Valero, 2017). One could argue that teaching young people to understand the lottery as a social project, for example, which necessitates various mathematical understandings, is a way to bolster them in this competitive "power-over" notion of democracy. It is one thing to support youth in navigating the world and its systems as they are, but it is another thing to challenge this underlying conception of democracy. The power-over paradigm could be replaced with a "power-with" democracy (Guinier & Torres, 2002), in which the focus on the individual were shifted to a focus on the collective, wherein an essential value around competition among individuals were replaced with solidarity, resistance, and collective struggle. What would happen to our state-supported lottery systems, our loaning institutions, our fast-food restaurants and their pricing techniques, for example, if our democracy were "power-with" instead of "power-over"? How can mathematics help us to advocate for such a paradigm shift?

Next Steps

In summary of next steps, Civil (2018) reiterates the set of political acts from Aguirre et al. (2017): "1) enhance mathematics education research with an equity lens, 2) acquire the knowledge necessary to do genuine equity work, 3) challenge the false dichotomy between equity and mathematics, and 4) expand the view of what counts as mathematics." Civil's reflections, as well as my comments above, are largely concentrated around the latter two political acts. Inspired by Political Acts #3 and #4 in particular, Civil asks: "Are we doing enough in our writing and in our work to bring the centrality of equity to mathematics and the centrality of mathematics to equity?"

I opened this piece by citing perspectives about learning that guide us in terms of giving students opportunities to draw on their cultural and linguistic funds of knowledge as resources in mathematics. I cited Gutiérrez' (2002) call that we need to offer mathematics as a window through which students can look out onto the world, but also as a mirror in which students can see themselves, their families, their pasts, and their futures in mathematics. And yet, the notion of mathematics as a mirror through which to see self seems not yet fully possible. For example, I have bumped up against the gender binary in and with mathematics, by mathematics teachers, by mathematics exercises and theories that indicate and support a set of untruths (see Rubel, 2016). School mathematics tells me that I was born either a boy or a girl, and that this is a fixed state. Schooling in the U.S. prescribes that liking or doing math is doing masculinity, and that girls can excel at math but at the cost of sacrificing femininity. School mathematics decries sexuality, race, and ethnicity as irrelevant, and that success in school mathematics is determined by a fundamentally meritocratic system. In these and other ways, mathematics, even as a mirror, distorts reality. I never felt safe enough to come out as queer as a classroom teacher, and my physical and material vulnerability remain an issue, especially in the current political context. Mathematics, windows or mirrors, does not protect me, and if anything, my work and interest in mathematics likely make my ideas *more* threatening and put me in greater danger than if I worked in education research around another school discipline. In the U.S., where mathematics is intertwined with white supremacy, patriarchy, and heteronormativity, my scholarly critiques, my publicly funded salary, and even my basic existence pose a challenge to that constellation of hegemonic forces.

And so, what of the centrality of mathematics to equity and equity to mathematics? This circles back to the first two Political Acts from Aguirre et al., 2018, which speak to our participation as mathematics education researchers in the current political context. There is the constant evidence of hegemony across mathematics education in the U.S. of review panels, editorial boards, plenary panels, and faculty rosters comprised largely or exclusively of white, CIS, straight, Christian, gender-normative people. We must acknowledge that by limiting who participates in knowledge-building, including through entrenched processes of institutional elitism in the academy, we limit the knowledge building itself. Peruse the research that I have cited in and across this paper as well as the references cited in this volume by Civil - in nearly all cases, cited works are written by people from minoritized groups. Of course, it is reasonable and appropriate that these scholars lead the field in thinking about equity -- after all, we build knowledge in part on our own life experiences, the standpoints we have achieved, and we draw from our own marginalization to recognize when, where, and how it happens to others (Harding, 1993). Those of you who are part of the power majority, either by being male, white, Christian, straight, gender-normative, or tenured faculty at a research university: how might the workings of our field be different and the knowledge we produce improve if we made space for other bodies and voices, listened to critiques, were better allies and advocates, or if we ceded, or at least shared, power with others who do not share our privileges?

Instead of token nods of inclusion, we should blaze new trails for our research community by shaping our research agendas, methodologies, avenues for sharing knowledge, and ways of collaborating around a priority of *tikkun olam* (Hebrew for "repair the world.") and collective productivity. We could refashion our national and international leadership around a vision for mathematics education that focuses on cultivating kindness, empathy, curiosity, creativity, and collaboration among people in a power-with democracy. That way, we would create mathematics that helps in posing and solving pressing questions about our natural environment and our wellness. As importantly, we would know when to put aside mathematics for other, better suited tools or ways of knowing. Perhaps instead of, or at least in parallel to, the oft-asked "where's the math?" challenge, thinly veiled as a question, we ought to invoke the inverse challenge: "where's the justice?" After all, if a research project does not engage equity, privilege, power or justice, and is not contributing toward repairing our world, then how can such research be relevant to mathematics education?

TRANSFORMING TEACHERS' KNOWLEDGE FOR TEACHING MATHEMATICS WITH TECHNOLOGIES THROUGH ONLINE KNOWLEDGE-BUILDING COMMUNITIES

Margaret L. Niess
Oregon State University
niessm@oregonstate.edu

Jeremy Roschelle
Digital Promise Global
jroschelle@digitalpromise.org

Mathematics teacher educators are faced with designing teacher in-service professional development experiences for developing and transforming Technological Pedagogical Content Knowledge (TPACK) towards integrating digital technologies as mathematics learning tools. Online environments provide opportunities to a broad range of teachers, yet, the asynchronous nature presents communication and collaboration challenges. A researcher-conjectured, empirically-supported learning trajectory guides this online TPACK program for engaging teachers in knowledge-building communities. Three online technology education courses provide teachers with experiences as students, learning about the technologies while confronting challenges to their thinking about teaching with the technologies. The fourth course provides the teachers with key experiences through blended instruction. Through online explorations and discourses in their communities, they examine reform-based instructional strategies for teaching with technologies. Concurrently, they design, implement, analyze and reflect on their teaching experiences through their designed five-day unit in their mathematics classrooms. Four TPACK components reveal how this experience in knowledge-building communities transforms their TPACK.

Keywords: Learning Trajectory, Teacher Education-Inservice/Professional, Teacher Knowledge, Technology

Introduction

Mathematics teachers are challenged to actively engage students with current, more effective technologies as learning tools. A recent handbook chapter (Roschelle, Noss, Jackiw & Blikstein., 2017) highlights three important research-based categories of effective learning digital tools: tools like graphing calculators that can do some of the detail work and students can focus on concepts; tools for providing guidance and feedback to students as they practice mathematics; and tools that help students visualize concepts and develop understanding. With the rapid pace of the development of digital tools, teachers cannot fully realize the value of these tools without teacher professional development. While teachers may have heard about the technologies, this simple knowledge is not sufficient for guiding students in learning mathematics with the technologies. Now recognizing twenty-first century learning, teachers must engage their students in developing four key skills (the 4 C's) in preparation for effectively connecting with a global society: Critical thinking, Communication, Collaboration and Creativity (Partnership for 21st Century Learning, 2015; Thoughtful Learning Organization, 2016). Through these skills, students are prepared to effectively engage in the more complex social, cultural, and educational environments that depend on the advantages offered through the reliance on multiple technological resources. Taking advantage of these 4C's, students participate through various thinking and engagement strategies as they concurrently learn mathematics:

- Critical thinking: Students use analysis as they engage in problem solving where they make comparisons, contrast ideas, analyze ideas, categorize data, and evaluate results of trials.
- Creative thinking: Students engage in open-ended invention and discovery of myriad solution possibilities as they design, improvise, innovate, problem solve and ask questions.
- Communication: Students interact with others, connecting through multiple modes (e.g., text, social media, cell phones, email, Internet and other avenues) where they examine the messages with respect to the purpose, sender, receiver, medium and the context of various communications.
- Collaboration: Student work together toward a common goal, brainstorming ideas, making decisions as a group, delegating, evaluating, goal setting, managing time, resolving conflicts, and team building.

As mathematics teachers consider integrating technologies in their instruction, they must not only determine how the technologies support learning the mathematics, they must consider which pedagogical strategies effectively engage students in learning the mathematics with the tools as they incorporated the 4 C's (Roschelle & Leinwand, 2011). Teachers must identify, orchestrate, and manage different pedagogical strategies and learning tasks for integrating the technologies in new and perhaps different mathematical topics. The challenge involves far more than their understanding of the mathematics content. The experience ultimately challenges their technological pedagogical content knowledge and reasoning (TPACK) with an array of technologies. "Quality teaching requires developing a nuanced understanding of the complex relationships between technology, content, and pedagogy, and using this understanding to develop appropriate, context-specific strategies and representations" (Mishra & Koehler, 2006, p. 1029).

Today's mathematics teachers must continue learning about teaching mathematics beyond their learning in their pre-service teacher preparation programs and typically this learning happens as they are actively teaching. Transforming in-service teachers' TPACK requires more than participation in short-term professional development experiences. Teachers need experiences to actively engage them in the process of "working toward a more complete and coherent understanding," otherwise referred to as knowledge-building experiences (Scardamalia & Bereiter, 1993, p. 39). Knowledge-building communities (e.g., Scardamalia & Bereiter, 1993, 2003; Bereiter, 2002) integrated with classroom teaching experiences are more likely to engage teachers in relearning, rethinking, and redefining teaching and learning to take advantage of new and emerging technologies and methods for teaching mathematics. Through such communities combined with practical teaching experiences, teachers have opportunities to confront their current pedagogical conceptions for integrating technologies as useful learning tools in their content areas (Loughran, 2002) in the process of developing reformed understandings for teaching in the twenty-first century with multiple technologies.

In this paper, we specifically consider the potential benefits but also the potential challenges of providing teachers with learning experiences in online or blended formats that intend to establish online knowledge-building communities. On one hand, online or blended learning is an increasingly recognized educational setting for teachers' professional learning experiences. It can allow teachers more choice about how, when and where they learn, reduce cost, and provide increased access for many more teachers across a broader geographical area. Yet, the primarily asynchronous nature of online learning poses additional challenges for the design of these needed educational experiences (Means, Toyama, Murphy, & Bakia, 2013).

When considering these points, mathematics teacher educators are confronted with a primary and critical question in the design of knowledge-building communities for transforming teachers' TPACK:

What experiences are essential for guiding in-service teachers as they learn about the technologies as well as about teaching mathematics with the technologies?

Building on this broad question, important sub-questions in the design of online professional development instructional programs emerge:

1. What are the key features for online learning for guiding teachers in reframing their current teacher knowledge?
2. What online learning trajectories are not only useful for engaging teachers in knowledge-building communities but also for providing them with an understanding of the pedagogical challenges in their classrooms?
3. How might teachers gain classroom-based learning experiences for applying their theoretical ideas about teaching with technologies?

Through this paper, we report on the first author's research and development project, addressing these questions in the process of developing ad analyzing the outcomes of a new online in-service teacher TPACK program containing four graduate courses. The effort used a researcher-conjectured and empirically-supported learning trajectory (Niess & Gillow-Wiles, 2013, 2014) to frame the experiences and pedagogical strategies to engage the in-service teacher participants in online knowledge-building communities blended with practical teaching experiences when teaching mathematics with technologies. The second author adds comments in the Discussion section.

Theoretical Framework

Teachers' knowledge for teaching with technologies requires far more than just understanding the subject matter. It ultimately necessitates a strong pedagogical knowledge merged with the knowledge for teaching mathematics using a vast array of technological innovations. This task calls for Technological Pedagogical Content Knowledge (Angeli & Valanides, 2009; Mishra & Koehler, 2006; Niess, 2005), otherwise referred to as TPACK (called 'tee-pack', Thompson & Mishra, 2007). TPACK, as shown in Figure 1, describes this teacher knowledge through the intersection of content knowledge, pedagogical knowledge and technological knowledge for guiding their strategic thinking of when, where, and how to guide students' learning of the content such as mathematics with technologies.

TPACK is the composite of the intersecting multiple domains (technological knowledge (TK), pedagogical knowledge (PK), content knowledge (CK), technological pedagogical knowledge (TPK), pedagogical content knowledge (PCK), technological content knowledge (TCK) and TPACK) within the Contexts. Further, the center subset is also described as TPACK. Mishra and Koehler (2008) described this center subset as:

> The representations of concepts using technologies; pedagogical techniques that apply technologies in constructive ways to teach content in differentiated ways according to students' learning needs; knowledge of what makes concepts difficult or easy to learn and how technology can help redress conceptual challenges; knowledge of students' prior

content-related understanding and epistemological assumptions; and knowledge of how technologies can be used to build on existing understanding to develop new epistemologies or strengthen old ones. (p. 3)

Elaborating on TPACK

The TPACK construct is recognized and supported by extensive research and scholarly work. Elaborating on TPACK, Niess (2005) extended from Grossman's (1989, 1991) description of the four components of PCK. The four TPACK components incorporate the influence of technology in teachers' instruction, considering the teachers':

1. Overarching conceptions about the purposes for incorporating technology in teaching mathematics topics;
2. Knowledge of students' understandings, thinking and learning in mathematics topics with technology;
3. Knowledge of instructional strategies and representations for teaching and learning mathematics topics with technologies;
4. Knowledge of curriculum and curricular materials that integrate technology in learning and teaching mathematics topics.

Building on these components, Niess, Sadri and Lee (2007) described TPACK development as a process in transforming teachers' TPACK. They linked Rogers' (1995) five-step process in the ultimate decision of whether to accept or reject a particular innovation with the analysis of extensive observations of teachers' learning about spreadsheets and how to integrate spreadsheets as learning tools in their mathematics classrooms. Through this effort, they found the teachers at different stages in their TPACK transformations:

1. Recognizing (knowledge), where teachers are able to use the technology and recognize the alignment of the technology with mathematics content yet do not integrate the technology in teaching and learning of mathematics.
2. Accepting (persuasion), where teachers form a favorable or unfavorable attitude toward teaching and learning mathematics with an appropriate technology.
3. Adapting (decision), where teachers engage in activities that lead to a choice to adopt or reject teaching and learning mathematics with an appropriate technology.
4. Exploring (implementation), where teachers actively integrate teaching and learning of mathematics with an appropriate technology.
5. Advancing (confirmation), where teachers evaluate the results of the decision to integrate teaching and learning mathematics with an appropriate technology. (Niess et al., 2009, p. 9)

Here's a scenario: Mr. D is a middle school mathematics teacher with a degree in mathematics who was excited as he learned to design dynamic spreadsheets for exploring algebraic problems. However, he was constrained in his acceptance of students using spreadsheets for exploring algebraic changes when thinking about constants and dependent versus independent variables. He believed that students needed to create multiple graphs with paper and pencil in order to identify changes in the constants and variables of different functions. He was willing to use the spreadsheet for his summarization of the results, where he would demonstrate the changes for the students; however, he was not willing to engage the students in spreadsheet explorations. While he was considered to be at the *recognizing* level, even with more work with spreadsheets, he resisted the idea of adding spreadsheets to his mathematics classes.

In a contrasting case, Mrs. A, a teacher with a mathematics education degree, was excited with the ease and visualizations that resulted as she worked with her students in designing dynamic spreadsheets in their explorations. She wanted her students to have this experience as they worked in groups to explore changes in constants and variables. She felt that this more visual approach helped them gain a better understanding than if they had to individually graph each of the problems. As she worked with her students with the spreadsheets, she envisioned additional experiences for using spreadsheets in her mathematics classes and was thus viewed at the *exploring* stage.

These stages were proposed as an iterative process in the development of TPACK rather than a strictly linear process. In essence, some aspects of what is learned about teaching a particular topic with one technology may provide a disposition toward the acceptance of another technology. But teachers need to explore different topics with each new technology, considering its applicability for supporting learning mathematics with that technology

Developing In-service Teachers' TPACK

Reconstructing in-service teachers' knowledge to reflect the ideas as described in TPACK requires teacher engagement in systematic inquiries about teaching, learning, subject matter and curriculum, and schooling, much like that described in Cochran-Smith and Lytle's (2001) conception of "knowledge-of-practice" as a "transformed and expanded view of what 'practice' means" (p. 276). Such a reformed conception assumes that knowledge is "socially constructed by teachers who work together and also by teachers and students as they mingle their previous experiences, their prior knowledge, their cultural and linguistic resources, and the textual resources and materials of the classroom" (p. 280). Transforming teachers' knowledge suggests their involvement in an inquiry knowledge-building community where reflection is a central component (Cochran-Smith & Lytle, 2001; Loughran, 2002; Schön, 1983).

Borko (2004) describes a process for identifying high–quality teacher change programs as called for in transforming teachers' TPACK, as beginning with studies in a single site, exploring relationships between teachers as learners in a specific learning trajectory. Confrey and Maloney (2010) expand this thinking, describing the need for identifying a learning trajectory as a "researcher-conjectured, empirically-supported" description of an "ordered network of experiences" where teachers as students move from "informal ideas, through successive refinements of representation, articulation, and reflection, towards increasingly complex concepts over time" (Confrey & Maloney, 2010, p. 968). In this manner, teachers are engaged in instruction designed to move from informal ideas through successive refinements toward a transformed knowledge for teaching with technology. Through this purposeful learning trajectory, they develop knowledge through their experiences as they are engaged in instructional strategies that ultimately model teaching with technologies.

Teachers as learners are, thus, charged with becoming aware and critical of their own and others' assumptions about teaching to achieve a paradigm shift that transforms their thinking and actions toward the ideas embedded in TPACK. McGonigal (2005) outlines five conditions and processes for fostering such a transformative learning experience for enhancing teachers' TPACK:

1. Teachers need an activating event to expose the limitations of their current knowledge.
2. Teachers need opportunities to identify and articulate underlying assumptions in their teaching knowledge.
3. Teachers need to engage in critical self-reflection, specifically considering the origin of underlying assumptions, and how these assumptions have influenced or limited their understandings about teaching.
4. Teachers need to engage in critical discourse with other teachers and the adult teacher educator in the process of examining alternative ideas and approaches.
5. Teachers need opportunities to test and apply their new perspectives.

Online TPACK Learning Trajectory

We investigated an educational setting where in-service teachers' professional learning experience is provided through online programs. The first author's research group designed an approach based on Niess and Gillow-Wiles (2013, 2014) empirically-supported learning trajectory, to frame online TPACK learning experiences to engage teachers in knowledge-building communities designed toward transforming the teachers' TPACK. The trajectory recognized key instructional strategies through a social metacognitive constructivist instructional framework that identified key tools and processes for organizing the TPACK content development in online asynchronous, text-based inquiry learning experiences.

Tools. Two tools support the online professional development: (1) a community of learners and (2) reflection. With the challenge for establishing connections among the learners and the instructor in online learning, establishing a community of learners provides an important tool for supporting the learners in communicating and interacting through discussions about the tasks and ideas being developed. This tool provides a ***social*** presence such that the community functions as a knowledge-building community. Through this community, the construction of knowledge is a "social activity, with new information and ideas brought into the discourses of a community that shares goals for knowledge advancement and recognizes contribution" (Scardamalia & Bereiter, 1993, p. 38-39). Such a social presence establishes community member participation and educational experiences for meaningful learning, open communication, and group cohesion as the learners engage in active roles to make sense of new information and ideas (Bereiter, 2002; Garrison, Anderson, & Archer, 1999; Garrison & Cleveland-Innes, 2005; Hill, Song, & West, 2009; Kinsel, Cleveland-Innes, & Garrison, 2005; Rourke, Anderson, Garrison, & Archer, 1999; Scardamalia & Bereiter, 1993; Sung & Mayer, 2012; Swan & Shih, 2005).

Reflection was the second important tool in the online learning trajectory. Critical reflection supported the cognitive presence in the online learning trajectory. Learner engagement through reflection happened in multiple ways, such as having learners prepare content reflective essays, reflective essays on the community engagement and peer reviews of another learners' work. The online portfolio provided a consistent way for each teacher to capture, reflect on and share their progress. Basically, the community of learners dynamically integrated the social, cognitive, and teaching presences in the online environment, supporting higher order learning through the reflective actions that result in deep approaches to learning (Garrison & Cleveland-Innes, 2005).

Processes. The online learning trajectory also includes two key processes for incorporating the tools: (1) shared/individual knowledge development and (2) inquiry learning. As the learners participates in the community of learners' activities, they share their understandings of how they are interpreting the ideas. As the discussions evolve through their interactions, the learner's individual knowledge matures. The learners move between group and individual knowledge-building so as to ultimately create an understanding that more clearly reflects a world view with respect to the learning experiences (Dunlap & Lowenthal, 2014; Rienties, Tempelaar, & Lygo-baker, 2013; Swan, 2001). As a result, the learners' individual knowledge expands beyond that which they were able to develop independently.

The second key process with the knowledge-building communities relies on inquiry-based activities to provide the learners with tasks, opportunities and experiences where they negotiated their understandings of the content. The inquiry process immerses them in constructing their understandings, where they take ownership of their learning, beginning with questions and their explorations where they investigated worthy questions, issues, problems or ideas. They ask questions, gathers and analyzes information, generates solutions, make decisions, and justifies their conclusions. The resulting actions interweaves multiple technologies, instructional approaches, and content topics through multiple units. Throughout the process, the participants consistently engage in thinking and reflecting about the dynamic interactions among content, pedagogy and technology that emerges from the tasks in their online learning experiences (Roberts, 2002; Wheatley, 1992).

An Online TPACK Instructional Program

Our program for transforming mathematics teachers' TPACK for teaching with technologies developed four new university graduate level courses. Three of the courses are fully online and focused on technology education. These courses are combined with a blended course that incorporates teachers' practical experiences where they implement their newly developed technological knowledge in their own classrooms with an online experience through a community of learners' inquiry and discourse about reformed-based pedagogical strategies.

Technological Education Courses

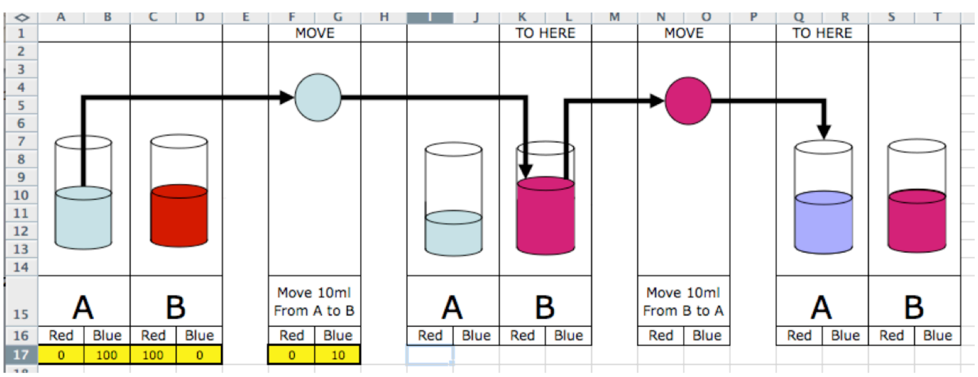
Three courses (SED 520, SED 521, and SED 522) engaged the teachers in experiences as students where they learn about and with some technologies in ways that challenge and advance their thinking about learning mathematics with these technologies. During these experiences, the teachers interact in small communities of learners in discourse, responding to the experiences as students and then as teachers. They use critical reflection in considering the dilemmas, their personal experiences and their discussions to inform their TPACK understandings.

For each unit in these courses, *inquiry* tasks challenge the teachers to examine and explore specific technologies. For example, in SED 520 one unit challenges them to examine and explore the temperature probe, a technology with which they are typically unfamiliar. They are provided with 10 laboratory experiments to guide their explorations as they learn how to collect temperature data and use the accompanying software to analyze the data, both graphically and numerically. As they work with the experiments, they also engage in questioning and discussion with their assigned small community of learner groups, discussing key questions as they examine the readings and their experiences in learning about and with the probeware. The unit emphasizes higher order thinking and inquiry learning to shape their ideas for integrating the technology as a learning tool in mathematics. To conclude the unit, the students prepare a critical reflection on their experiences with the technology, on the key questions and the inquiry processes and how their shared/individual experiences through the community of learner's discussions as well as their individual experiences form their understandings in this unit.

SED520. Integrating Technology and Literacy in Learning Mathematics (SED 520) is a course focused on multimedia technologies for twenty-first century mathematical literacy incorporating the 4 C's in teaching and learning mathematics. The course is arranged in five, two-week unit experiences. The technologies are purposefully selected and organized with the content. Unit 1 begins with presentation software, a technology with which teachers typically have experience. They are charged with using a Google presentation in a cooperative, collaborative experience to inquiry and examine new Web 2.0 technologies (Diigo, Wordle, Blabberize, Glogster, Voki, and Popplet for example). Each class member has responsibility for creating one slide that describes one specific technology term and how it can be used in education and a second slide that introduces them as new members of the class. Unit 2 promotes the teachers as learners exploring a technology with which they are unfamiliar – the temperature probe, as previously described. This experience engages them as students, where they must become familiar with the technology and consider how it might be used in learning mathematics; additionally, in their roles as teachers they consider what instructional strategies are needed to engage students in learning with this technology. The Web Inquiry Unit 3 pairs teachers in the design of a web presentation to guide students in specific mathematical explorations. This unit uses a framework similar to that in WebQuests (http://webquest.org/) to guide students in mathematical inquiries through web experiences (see http://webinquiry.org/ for sample inquiries). Unit 4 expects the teachers to work individually in designing three lessons that require use of a specific web application for learning mathematics. Teachers typically consider applications such as those available through the National Library of Virtual Manipulatives (http://nlvm.usu.edu/en/nav/vlibrary.html) or other similar libraries of interactive mathematics experiences. Finally, Unit 5 organizes the teachers as small cooperative groups for group analysis and writing experiences. These last two units expect the teachers to think about the comparison of knowledge gained as individuals (in Unit 4) versus that gained through cooperative and collaborative sharing with technologies (in Unit 5). The culminating product for this course is a web portfolio that presents the various products produced in each of the units of the course, demonstrating their knowledge of multimedia mathematical literacy.

SED 521. The second course, SED 521 (Teaching Mathematics With Digital and Video Technologies), uses inquiry experiences with digital images and videos to engage the teachers as students in higher order thinking and inquiry in mathematics. The major course difference between this course and SED 520 is the organization of the technology experiences into two major units, one focused on teaching mathematics with digital images and the second on incorporating videos as mathematics learning tools. Weekly, specific inquiry tasks confront the teachers. For example, during the first unit, they are challenged to gather digital images that afford opportunities for engaging students in twenty-first century learning of mathematics. The teachers are challenged to engage in their communities of learners, exploring these images to respond to this question: How might students' selection, acquisition, and presentation of digital images be beneficial for their learning of mathematics topics? The teachers engage in discourse with their assigned communities of learners and complete critical reflections through this question and the accompanying tasks and experiences with multiple digital images. Over the course of all the units they discuss the key questions and how their shared/individual experiences as well as their individual experiences influence their developing understandings. The culminating course product is a collection of digital images and videos with lessons for using them as mathematics learning tools. The collection also includes a video that portrays an example of what students might develop to communicate their higher order thinking when solving mathematics problem.

SED 522. The third course (SED 522), Dynamic Spreadsheets as Learning Tools in Mathematics, provides teachers with opportunities to explore algebraic reasoning when engaging students in learning with spreadsheets. Throughout the 10 units, inquiry tasks that involve developing skills with spreadsheets, the teachers' understanding for designing dynamic and dependable spreadsheets as a mathematics learning technology develops. The units model specific problems for gaining knowledge through access to spreadsheets. For example, Figure 2 presents a problem the teachers as students are to solve using relative cell referencing.



One beaker (A) has 100 ml of a blue liquid and the other beaker (B) has 100 ml of red liquid. First move 10 ml from A to B. Then move 10 ml from B to A. How many exchanges are needed before the liquid in both bottles contains the same concentration of blue and red liquids?

Figure 2. Mixture spreadsheet problem for SED 522

After designing a solution, they must develop a graphical representation (Figure 3) of their design and engage with their communities of learners' knowledge-building communities to explore multiple TPACK-related questions:

1. Where might this problem be useful in the mathematics curriculum?
2. What spreadsheet skills do students need for designing such a spreadsheet solution?
3. How should the students be organized for solving this problem?

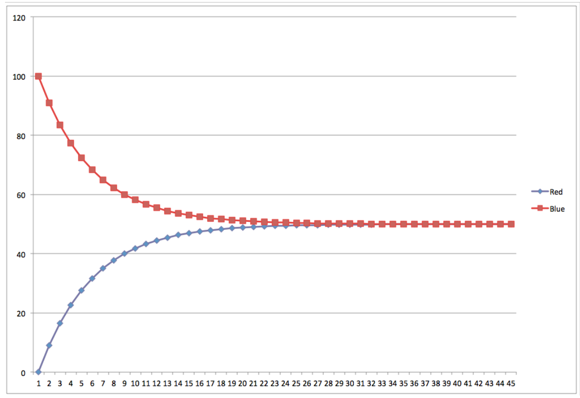


Figure 3. Graphical representation of the solution

In completing this spreadsheet course, the teachers' final project is a portfolio containing their collection of mathematics problems with solutions, curriculum plan for integrating spreadsheets as tools for exploring mathematics problems, and a final reflection on preparing their students to use the spreadsheet as a mathematical tool.

Blended Online and Practical Course: SED 594

Given these new online courses, the program designers questioned whether the experiences actually translated to the teachers' classrooms. For this reason, a fourth course, SED 594 (Advanced Teaching Strategies in Mathematics), was added to the TPACK program. As a blended course, this course combines online discussions and explorations about reform-based instructional strategies with practical teaching experiences in the teachers' own classrooms. Through the online explorations and discussions in their knowledge-building communities, they examine reform-based instructional strategies. Concurrently with their communities of learners' discussions, the teachers individually design, implement, analyze and extensively reflect on their personal, practical teaching experiences in their five-day unit in their mathematics classrooms. Essentially, they engage in action research about their own teaching as they gather artifacts to describe their instructional strategies, tools, and processes for engaging their students in learning mathematics with the selected technologies.

They incorporate extensive reflections in their electronic portfolios. These portfolios incorporate critical reflections from throughout the course to demonstrate how they implement their knowledge for teaching in their classrooms as they integrate technologies in teaching/learning mathematics. They gather two videos of their classroom instruction. They gather student products, examining whether the students demonstrate a strong understanding, average understanding or weak understanding of the concepts or processes. They complete multiple critical reflections throughout their instructional experiences (on the lesson designs before teaching, after teaching the lessons, about their students' work in the lessons, after watching videos of their instruction, and at the completion of the instruction). Weekly, they also reflect on their community of learners' explorations and discussions about the reformed-based instructional strategies. They peer review another teachers' portfolio, providing recommendations for enhancing the communication of the ideas. And, they complete a final in-depth analysis and reflection of the experiences they have had in their classroom teaching and their community of learner's discussions and interactions.

While they engage in the practical teaching experiences, they use the online community of learner groups to explore and discuss different instructional strategies, tools, and processes for teaching with technologies. Throughout their discussions, they cooperatively explore and examine reform-based instructional strategies – visible thinking, student discourse, grouping structures, and multiple representations for motivation and engagement. They peer-review another's electronic portfolio with the goal of improving the communication of the events and thinking. This review prepares them for the final critical reflection on the entire blended course experience, including the instructional experiences, video analyses, plans for improving their future instruction, and discourse in their community of learners where they discuss and consider instructional strategies for teaching with technologies. This final critical reflection reveals how their TK, TPK, and TCK merges with their PCK in the process of transforming their TPACK.

Teachers' TPACK Transformations

To investigate the influence of the online TPACK instructional program on teachers' knowledge transformations, we analyzed observations using the teachers' artifacts, expressions and reflections describe. The analysis reveals their knowledge, thinking and reflection with respect to the four TPACK components (Niess, 2005). Three representative cases (using pseudonyms Janis, Judy, and Lucy) were purposefully selected to display the patterns in the diversity of classroom situations and teaching levels. Janis, an elementary teacher, designed a fraction unit combining concrete and virtual manipulatives and games and activities she found on various websites for building students' understandings for representing, comparing and ordering fractions. Judy, a ninth-grade mathematics teacher chose to incorporate graphing calculators as a technology for her geometry course as they explored properties of transversals and the created angles, parallel lines, and perpendicular lines. Lucy, a high school mathematics teacher, incorporated the temperature probe with spreadsheet software in her pre-calculus class to engage her students in examining exponential, logarithmic and logistic functions.

Overarching Conceptions

As the teachers used technology in their own classrooms in the culminating SED 594 course, they were challenged to evaluate the value of the mathematical learning experiences for their students. In essence they were confronted with the question of whether or not the technology would support student learning in a purposeful and useful way.

Janis had previously taught her unit using only concrete manipulatives to build the students' understanding of fractions. "Using the virtual manipulatives was new and did cause me to change the way that students completed some of the tasks from previous years. The virtual manipulatives were nice because they didn't take up space like the concrete ones, and students were able to work with partners more instead of their whole table group." Janis saw the virtual manipulatives as adding to learning in an important way: "It allowed the students to make an instant connection between the manipulative and the mathematical concept because the symbolic notation was also shown on the screen." Reflecting on the value of the virtual manipulatives, she revised her original conceptions since the technologies provided a larger variety of learning experiences that she found important for student understanding of the concepts.

Judy's conception of graphing calculators as learning tools was intertwined with the importance of having students in working groups. She concluded that having the students work in groups led to solving problems and exploring ideas through technology tasks and deepened their learning because they were developing their own plans for solving the problems.

> When students worked in the groups with the graphing calculators, they helped each other when they were stuck. The groups also allowed students to explore many different equations of lines at the same time. They were exposed to many more possibilities of equations of lines than they would have been if I were leading the whole group.

Lucy designed her instruction to integrate technology and science in her mathematics instruction "The learners were supported in their learning through the computers and the Go!Temp Probe which collected data modeling a logistic curve. They were able to make real-world connections to their learning." She concluded "The connection to science makes the learning richer and fuller."

Students' Understandings, Thinking and Learning

Another concern for the teachers involved the question of how the technology aided in students' understandings, thinking and learning of specific mathematics topics. They were confronted with assessing the students' understandings and whether that understanding and thinking supported a stronger knowledge.

Janis noted that her students struggled to represent a given fraction three different ways but with the addition of the virtual manipulatives and other applications, she noted that when they built their fractions "on the fraction bar site they were forced to re-examine their ideas." She often talked about students' thinking and how their understandings and learning were impacted:

> Many students are visual learners, and it would not be enough for them to simply listen to another students' [explanation]. The combination of visual and auditory increased the number of students…engaged during group sharing and discussions and [increased] the chances that students [would] effectively process and retain the information in a meaningful way.

Judy gained an appreciation for the use of small group work with technologies for understanding students' thinking and understandings. During a Think-Pair-Share activity, she observed many conversations and heard many students mention slope. "It helped that they did not have to share among the larger class first ... more students [were] willing to share than usual, and I feel it is due to sharing with a neighbor first." She noted how using technology in the group work helped her understand the students' thinking. "Students were very engaged within the group work today. Perhaps the most engaged I have seen them in [the] group work. I feel the use of technology was a key factor."

Lucy realized her students' knowledge and thinking in one class did not necessarily transfer to other content areas. After the second day of her unit, she reflected that even though students had used microscopes in their biology class, they had a hard time translating that knowledge into the mathematics classroom. With a little guidance, "they got on track nicely and I anticipate this task to go faster as the days go on."

Instructional Strategies and Representations

Since the teachers were expected to design and implement a five-day unit, they were confronted with the task of identifying and scaffolding multiple instructional strategies to support students in learning the mathematics topics. They recognized the additional challenge for also scaffolding the instruction in such a manner that it supported student engagement with the technologies.

Janis connected the online discussions with her community of learners with her ideas for instructional strategies: "I incorporated some of the research-based instructional strategies that we have been discussing...Primarily, I used a lot of discourse, questioning, and collaborative learning…I tried to provide multiple representations…whenever possible, allowing students to connect their ideas with a visual." She gained a deeper understanding of strategies for integrating technologies through her video analysis. She saw the need to provide more direct instruction with the technologies. "What went really well was engaging students in the lessons and giving them opportunities to share their thinking as they worked collaboratively on the tasks." She also recognized that with students' ages and the novelty of using the technology, "I had to make sure that the tasks we did in the computer lab were very structured."

For Judy, the emphasis in the online discussions and her experiences with her instruction aligned her thinking about instructional strategies with grouping, problem solving, questioning and student discourse because these strategies "allow[ed] the learning environment to be centered on students who are actively engaged." From her work with these various strategies, she indicated that "Overall I want my classroom to be more student-centered and less teacher-centered."

The strategies Lucy implemented included discourse, questioning, inquiry, motivation, multiple representations, compare and contrast, cooperative and collaborative learning, providing feedback, and technology and science integration. Throughout the various science lab lessons, she was a guide. "I did not measure any pH, nor did I tell them which number it best matched. They asked each other and worked very collaboratively during this lesson…I know the more consistent I am with being a guide rather than the sole provider of information, the sooner it will become a habit."

Curriculum and Curricular Materials

A critical concern for the teachers in this final work was to identify a topic that was best suited for the technologies they wanted to include. They each want to make sure they were teaching the expected curriculum in order to support students as they advanced to future topics.

Janis' knowledge and thinking about her curriculum and curriculum materials changed as she reflected on the experiences in the lessons and what she saw in her lesson videos. She saw clear evidence about the importance of allowing students time to learn about and become familiar with the technology tools. "The students really enjoyed using the virtual manipulatives and they were motivated to complete the relevant tasks. However, I simply had not factored in enough time to let them explore with the manipulatives so that they could effectively utilize them during the lessons."

Judy indicated she needed to look for more ways to integrate technology: "Technology can aid in their learning and provide opportunities for them to be engaged." However, she noted that adding technologies to the learning required extending the curriculum and the need to "find activities and tasks" that would support students in learning with the technology.

A main objective in Lucy's unit was to "connect mathematics and science with the help of technology." She claimed that a promising practice might be for team teaching with the science teacher, where they would co-teach, and she would have the responsibility for the mathematics. "We plan to team teach using real-world data for mathematics…[making] an even better connection [of] math, science, and technology."

In Sum: Teachers' TPACK Transformations

After designing the online TPACK instructional program, our research effort focused on identifying the influence on the teachers' TPACK. The challenge was to identify how the teachers' thinking was transformed as a result of their engagement in their experiences. The most significant shift in their knowledge and thinking for all the teachers was a shift in their thinking about instruction. The majority of the teachers' primary approach prior to this program involved teacher-centered instruction. Yet, through the program, they shifted to valuing student-centered instructional strategies for teaching with technologies. This shift was reflected in the examination of the TPACK components.

Their overarching conceptions of the purposes for incorporating technology in teaching mathematics expanded, identifying the importance and value of multiple technologies, considering more than just content and thinking about the pedagogical strategies and the technological features. For example, they now considered technologies for communication, collaboration, and inquiry as important technologies for displaying mathematical ideas. In other words, their overarching conceptions shifted to a broader range of technologies for teaching in ways that were more student-centered.

Their reflections about student-centered strategies caused them to think more about student thinking and understanding. They reflected more on students' thinking with the technologies and what strategies were more supportive of their learning of mathematics with the technologies. They reflected on how students needed time to practice and work with the technologies before moving to more in-depth problems. They discussed and reflected on the scaffolding that they needed to do in their lessons as they integrated the technologies. They needed to allow students opportunities to discover and explore ideas with the technologies. Based on their experiences of working in groups and engaging in discourse with their communities of learners, they tested more student-centered strategies as they taught their lessons. After observing their videos, they saw how they needed to be "a guide rather than the sole provider of information."

The expanded vision on technologies in mathematics instruction also influenced their thinking about the curriculum. They shifted to the importance of expanding the curriculum to include teaching about the technology before expecting students to automatically gain understanding of mathematics immediately from working with the technology. During their work with various probeware technologies, they were engaged as students; through these experiences they identified the importance of learning about the technologies within content-specific explorations. As they designed and taught their lessons, they tried to incorporate explorations of mathematical ideas during the time in which their students were learning about the technologies.

In essence, the most obvious transformation in the teachers' TPACK was toward student – centered instructional strategies and the integration of multiple technologies for teaching in their classrooms. As teacher educators consider the design of programs to support the transformation of teachers' TPACK, they need to remember the importance of practical experiences. This work also identified the importance of combining practical experiences with opportunities for the teachers to engage in discourse through the knowledge-building communities of learners and extensive critical reflection on teaching in their classrooms. The combination provides teachers with opportunities to rethink, unlearn and relearn in ways that result in changing, revising and adapting their mathematical content and pedagogical strategies in light of the affordances of the multiple technologies – a TPACK transformation that reveals a deeper understanding of the role of technology and meaningful integration into their mathematics classrooms.

Discussion

From an outside perspective (that of the second author), this paper is a case study of how ambitious and laudatory teacher professional development goals can be achieved in an online or blended environment. The dual challenge it focuses on – of helping teachers learn to use technology effectively, through the medium of online and blended coursework – is also a key challenge of our time. Here I reflect on what general lessons and open issues emerge from thinking about this program as an example of where we should head in the future.

Transforming, Not Only Translating

Studies of successful online and blended learning highlight that when it works, it is not simply a matter of putting existing courses online (Bakia, Means & Murphy, 2004). Here, the dramatic shift is from a set of *courses* to a *knowledge building community.* Clearly, essential content from the courses was important to the firm foundations of the knowledge-building community. A knowledge-building community, however, implies a long-term structure of engagements, activities and supports that is much different from a typical course. For example, the engagements may start much more from teachers' own problems of practice. The activities may involve elements closer to that of lesson study (Hurd & Lewis, 2011) than to case studies in conventional courses. The supports involve more peer reflection and coaching, and less feedback from an authority. The concept of a knowledge-building community is also aspirational and would go beyond the results reported here. This report emphasized progress on individualized problems of practice, but a yet-richer knowledge-building community would also define community-level challenges and community-level knowledge about them.

From Courses to Competencies

The shift in this case also evokes a broader shift latent in professional learning more widely, a shift from counting course credit hours to recognizing new competencies (Nodine, 2016). Clearly, courses provided initial structure to the online experience. And yet, it is not clear that giving course credit is the most appropriate way to give teachers' recognition – course credit is normally tied to how many hours a teacher spent in activity and completion of assignments, but course credit much less frequently recognizes what a teacher now can actually do in a classroom. The focus here is nicely balanced, with clear opportunities to both shape teacher's experience based on course content but also to focus on and recognize classroom practice changes – not just seat time and assignment completion.

An emerging framework that would recognize this shift is the framework of educator micro-credentials (Berry, Airhart & Byrd, 2016). In this framework, complex shifts in teaching practice are broken down into smaller component competencies, and teachers have an opportunity to be recognized as they demonstrate the competencies. Importantly, there is no requirement to spend a fixed number of hours learning the competency, or to follow a set path in doing so. It seems in this example, and in many to follow in the future, online and blended learning will offer teachers lots of choices in how they learn and develop – and teachers clearly are not only showing a commitment in time and assignment completion, they are also reporting what they really do differently in their classrooms. This challenges us to think harder about how we will recognize and reward teachers for their learning, and the micro-credential movement gives one clear alternative (still much in development) to think with.

Coherent and Cumulative Frameworks, Leveraging Personal Experiences

A positive feature of online and blended learning is that the asynchronous and non-linear nature can make learning more relevant and timely given immediate challenges. It is clear these features can help teachers too, but if not balanced might lead to fragmentary knowledge. For example, the specific cases give a good sense of how this environment allowed teachers to effectively pursue personal goals. At the same time, this case also makes clear the value of a framework that helps organizing teacher learning to be coherent and cumulative – not just a reversion to the feels good, low calorie "take away" that old fashioned workshops have been critiqued for. In this case, the framework is TPACK, and the case shows how TPACK can organize the kinds of advances in individual teachers' practice into a more coherent whole. For example, TPACK can help us to see when teachers are making advances on many fronts – in their content knowledge, their technology knowledge, and pedagogical knowledge, and also in the relationships among these. Clearly, we need teachers who are learning on all these fronts.

And yet, TPACK is far from the only high-quality framework available. What TPACK appears best at – at least in this paper, is organizing qualitative observations of what teachers learned into categories. It is less obvious that TPACK is powerful in giving teacher's a sense of coherence and direction in their journeys. For example, if the journey is primarily towards student-centered learning, one might like a broad theoretical frame to organize the why, how, and what of that transformation. What might be the role of a framework like the one from *How People Learn* (National Research Council, 2000), which describes the best learning environments as learner-centered (one of the characteristics here), but also knowledge-centered, assessment-centered, and community-centered? There are also recommendations like the TRU framework (Schoenfeld and the Teaching for Robust Understanding Project, 2016), which is more specific to mathematics, and focuses on content, cognitive demand, equitable participation, agency, and formative assessment – and a framework like this might give coherence and direction to what teachers are learning overall. Overall, TPACK is clearly a valuable guiding framework, but for the field as a whole, it is not clear if focusing on the categorical differences among types of knowledge gives enough of a normative of what great math teaching with technology looks like to direct and make coherent teachers' long-term growth.

Further Challenges of Digital Professional Development Futures

One huge advantage that is apparent in this case is that the presenting problem is that teachers do not have enough prior experience as *digital learners.* And thus, it seems highly appropriate that professional development position the teachers themselves as digital learners. For example, as the case shows, teachers can more directly experience learning with the types of virtual manipulatives, online spreadsheets, and algebraic tools that their students can use. This is valuable because as mathematics is represented in digital form, how conceptual understanding arises shifts – new paths to learning emerge. For example, in the case of Dynamic Geometry, construction becomes more powerful in digital form than with compass and straight edge and a fuller counterpoint to proof in the learning experience (De Villiers, 2004). Social learning is also transformed through digital possibilities, such as the possibility to contribute to share mathematical constructions and experiences (Stroup et al., 2002). Teachers need to experience this first hand and be supported to reflect on their experience as learners and what implications this can have for their teaching, in a process of *Instrumental Genesis* (Drijvers et al., 2010).

Finally, challenges of access and equity arise constant in a digital world, and careful work is needed to understand who participates and how the online experience can produce beneficial or harmful experiences. We cannot pretend naively that online experiences will be safe and positive for all. There are also likely major challenges of data sharing as teachers share their classroom experience not just in a closed course classroom, but also now in an online environment where there is no limit to where the content they share may end up. There are also the positive and potentially negative implications of teachers' online activities producing data. On the positive side, we can potentially track and learn much more about the trajectories of teacher professional growth by studying the trajectories of their online activities (through the data those activities leave behind). Rather than a single university course progression, we can learn in detail about the multiple varied paths that teachers take towards professional knowledge; the different resources they use; the nature and range of social interactions that support them. But on the challenging side, there is always the possibility of such data being exploited in inappropriate ways, and the need to develop guards against this.

Conclusion

As more and more technologies become available as mathematics learning tools, teacher educators will be challenged to identify professional development avenues for supporting teachers in transforming their skills for teaching with the technologies. The online TPACK instructional program provides only one example of an online professional development program focused as a knowledge-building community to engage teachers in experiences that influence how their TPACK is transformed as they think about and learn from their experiences while learning as students and as they are implementing their accumulated knowledge in classroom practices. The combination of online learning with practical experiences provides a context within which these experiences were provided. The impact supports them in recognizing and valuing shared knowledge for expanding and enhancing their individual knowledge about learning with technologies. A significant teacher knowledge shift from their personal experiences found a change in their beliefs about their primary instruction to actively engaging students for learning with technologies – toward more cooperative and collaborative inquiry activities where students engage in discourse and reflection. The impact of the collective transformative learning experiences provides an important direction for in-service teacher professional development in the twenty-first century.

PERSPECTIVES ON THE NATURE OF MATHEMATICS

Anderson Norton
Virginia Tech
norton3@vt.edu

As mathematics educators, we teach and research a particular form of knowledge. However, in reacting to Platonic views of mathematics, we often overlook its unique characteristics. This paper presents a Kantian and Piagetian perspective that defines mathematics as a product of psychology. This perspective, based in human activity, unites mathematical objects, such as shape and number, while explaining what makes mathematics unique. In so doing, it not only privileges mathematics as a powerful form of knowledge but also empowers students to own its objects as their own constructions. Examples and interdisciplinary research findings (e.g., neuroscience) are provided to elucidate and support the perspective.

Keywords: embodied cognition, mathematical epistemology, neuroscience, radical constructivism, reflective abstraction

Mathematics has been described as both a science and a language. Most sources define it as a collection of abstract sciences, but its objects of study are so varied that, according to Wikipedia, “mathematics has no generally accepted definition” (“Definitions of mathematics,” n.d.) Consider the following attempts:

- “the abstract science of number, quantity, and space” (“Mathematics,” n.d.)
- “the science of numbers and their operations, interrelations, combinations, generalizations, and abstractions and of space configurations and their structure, measurement, transformations, and generalizations. Algebra, arithmetic, calculus, geometry, and trigonometry are branches of mathematics” (“Mathematics,” n.d.)
- “a group of related sciences, including algebra, geometry, and calculus, concerned with the study of number, quantity, shape, and space and their inter-relationships by using a specialized notation” (“Mathematics,” n.d.)

What do number, quantity, space, and the various branches of mathematics have in common?

Mathematics is a unique body of knowledge owing to its apparent infallibility. Across millennia, continents, and cultures, mathematics has produced stubborn facts, so much so that we confidently assume that any alien life form, if intelligent enough, would recognize the prime numbers (Sagan, 1975). Students often appreciate the way that mathematics builds on itself, such as the way real numbers build on rational numbers, which build on integers. Scientists marvel at the “unreasonable effectiveness of mathematics in the natural sciences” (Wigner, 1960), such as when mathematical models predicted the existence and location of Neptune before it was discovered (see Norton, 2015). No wonder Platonism still holds sway in society and scientific communities alike.

As a mathematics education community, we often confront Platonist ideals, which position mathematics as something that lies beyond human experience. We understand the cultural influences and psychological roots of mathematical development and mathematics itself. We challenge mathematical myths but rarely acknowledge their persistent epistemological basis. For example, we cite Kline’s (!982) “Loss of Certainty” to break down perceptions of mathematics as a collection of immutable truths because such perceptions disinvite students to participate in creating mathematics (e.g., Chazan, 1990). However, we overlook the apparent certainty of mathematics as a feature that garners students' interests to begin.

Popular characterizations of mathematics do have a valid basis. There is a sense in which mathematics is infallible and builds upon itself, and mathematics holds a privileged position of predictive power among the sciences. However, these characterizations require psychological explanation rather than a Platonic dodge. Moreover, we need a definition that presents mathematics as a unified field of study rather than a collection of abstract sciences. What unifies mathematics? What are its objects of study? What is the basis for its reliability, utility, and ubiquity?

This paper presents a Kantian/Piagetian response—one grounded in cognitive psychology and buttressed by recent findings from neuroscience. Kline (1982) summarized the Kantian position as follows: "mathematics is not something independent of and applied to phenomena taking place in an external world but rather an element in our way of conceiving the phenomena" (p. 341). Piaget (1942), with Inhelder (1967), built upon this position by specifying children's development of mathematical structures used to organize the world, such as space and number. These structures depend on operations that, at once, demonstrate the unity and power of mathematics.

Mathematical Objects

Mathematical objects arise from our own activity within the worlds we experience. This is a view espoused by social constructivists, radical constructivists, and embodied cognitionists alike (Núñez, Edwards, & Matos, 1999; Vygotsky, 1986). The distinguishing feature of the Piagetian perspective concerns the role of abstraction, particularly *reflective abstraction*, in constructing those objects. Reflective abstraction is a psychological process that is notoriously difficult to grasp. As Chomsky lamented during a debate with Piaget, "my uneasiness with reflective abstraction is … that I do not know what the phrase means, to what processes it refers, or what are its principles" (Piattelli-Palmarini, 1980, p. 323). Here, we will attempt to specify the process of reflective abstractions and its principles, as well as its role in constructing mathematical objects.

We find Piaget's plainest description of reflective abstraction in *Genetic Epistemology* (1970). There, he describes the sensorimotor basis for logic and mathematics: "the roots of logical thought are not to be found in language alone, even though language coordinations are important, but are to be found more generally in the coordination of actions, which are the basis of reflective abstraction" (p. 19). He goes on to describe how actions become coordinated with one another, through reflective abstraction; but reflective abstraction does not apply to any and all actions—only those that are reversible.

Reversibility is another distinguishing feature of mathematics. Addition-subtraction, greater than-less than, integration-differentiation all form inverse pairs. However, Piaget (1970) refers primarily to reversibility of the mental actions that constitute these formalized operations, rather than the formalized operations themselves. For example, a student might know the sum of 10 and 5 but not know the sum of 9 and 6, even if she also knows that 9 is 1 less than 10 and 6 is 1 more than 6. In other words, she has not yet coordinated the actions of iterating (repeatedly integrating) units of 1 and disembedding them (separating units of 1 within the whole). Such a coordination relies upon organizing the actions of iterating and disembedding within a structure for composing and reversing them (compared to 5, 6 has an extra iterated unit of 1, which can be disembedded and composed with 9 to make 10). As educators, we might think about these as strategies, but through reflective abstraction, strategically coordinated actions become structures for assimilating mathematical situations so that the two sums become the same mathematical object, 15. Of course, numbers do not exist in isolation, so the coordination of mental actions like iterating and disembedding reorganize the child's entire number sequence, including 5, 6, 9, 10, and 15 (see Steffe, 1992).

Figure 1 illustrates the process of reflective abstraction. Several mathematics educators have recognized this process, or similar processes, as essential for mathematical development: Sfard (1992) referred to it as reification; Dubinski (2002) as interiorization; and Tall as encapsulation (Tall, Thomas, Davis, Gray, & Simpson, 2000). They all describe a process by which existing mental actions become coordinated to constitute a new mathematical object.

	i	A	B
i	i	A	B
A	A	B	i
B	B	i	A

Figure 1. Reflective abstractions and the construction of mathematical objects.

The table on the right side of Figure 1 represents the organization of actions within a mathematical group. This is a researcher's model for describing how the students' mental actions become coordinated with one another as composible and reversible operations; it does not imply that students are aware of a group structure (Piaget, 1970). Figure 1 illustrates the simplest example of coordinating mental actions, wherein two actions (A and B) are coordinated as inverses of one another and where i represents the identity element of the group (note that Piaget also referred to group-like structures that do not satisfy all conditions of a mathematical group but nonetheless model the coordination of reversible mental actions). The two arrows in Figure 1 represent the two aspects of objects noted by Piaget and Garcia (1986): "First of all, it is 'what can be done with them' either physically or mentally… (2) The meaning of object is also 'what it is made of,' or how it is composed. Here again, objects are subordinate to actions" (pp. 65-66).

The coordination of mental actions within group-like structures explains many of the unique features of mathematics. In particular, the reversibility of mental actions within the structure explains the reliability of mathematics. In the sciences, reliability is repeatability. The natural sciences never attain perfect repeatability because the initial conditions of a situation cannot be precisely reproduced. However, in mathematics, reversing one action with another action (e.g., A and B compose to form i, in Figure 1) returns one to the same exact starting point every time.

Coordinations of action also explain the ubiquity of mathematics because they become structures for organizing experience. For example, when I see seven cars in a parking lot, nothing in the parking lot imposes 7 upon me. Instead, I assimilate my perceptual experience by coordinating mental actions of unitizing (separating out each perceived car and treating it as a unit identical to the others) and iterating resulting units in one-to-one correspondence with my number sequence.

Furthermore, coordinations of action explain how mathematics builds upon itself, because the process of reflective abstraction does not end with the construction of the first structures. Rather, those structures, as objects, become material for further operating. For example, I can consider any multiplicity of 7 by acting upon one copy of my number sequence with another copy of it (Steffe, 1992). Such structures explain the subjectivity of mathematical experience when, for example, I see three rows of seven cars and assimilate them as three 7s, whereas a young child might see a spatial pattern but not the numerical structure of 3 times 7.

Evidence from Neuroscience

As noted in the introduction, definitions of mathematics generally refer to the study of a collection of objects, usually including number and space. As mathematics educators, the construction of number may seem more familiar, but Piaget and Inhelder (1967) used space (along with number; Piaget, 1942) as a primary example of a mathematical object. They demonstrated that space does not exist as an innate construct, as Kant had assumed, but that children construct it through the coordination of displacements within a group for composing and reversing them. In this section, we will see tight connections between space and number as psychological and neurological phenomena that depend on coordinated actions, beginning with sensorimotor activity.

One early connection concerns object permanence and the onset of self-locomotion (crawling). Developmental psychologists take object permanence as a critical marker in early child development, whereby children learn that objects persist in space even when removed from the child's perceptual field. Bell and Fox (1996, 1997) conducted studies on 76 eight-month-old infants, separated into four groups: pre-crawlers, crawlers with 1-4 weeks of experience, 5-8 weeks of experience, and 9 or more weeks of experience. Greater experience in crawling was associated with the development of object permanence.

Piaget and Inhelder (1967) had tied object permanence to children's construction of sensorimotor space, wherein objects would have residence. More recently, psychologists have associated object permanence with "spatial working memory", wherein children coordinate spatial transformations, such as displacements and rotations (e.g., Bell, 2001). Together with the findings from Bell and Fox (1996, 1997), the collective literature suggests that crawling provides sensorimotor experience that is critical to the construction of space as a coordination of displacements. After all, crawling enables children to transform their perceptual fields through voluntary movement, which (from the child's perspective) amounts to a displacement of space itself, similar to the transformations of space described by a vector field (or the group of vectors, under addition).

We find similar connections between embodied/sensorimotor experience and the child's construction of number. In particular, manual and numerical digits go hand-in-hand, in a manner that transcends etymology (see Norton, Ulrich, Bell, & Cate, 2018). For example, as mathematics educators, we know that children generally learn to count with the aid of their fingers as manipulatives, but recent neuroimaging studies indicate that the connection persists into adulthood. Specifically, neural substrates for finger recognition and finger use (e.g. pointing) overlap with those for counting and arithmetic, even among adults (Soylu, Lester, & Newman, 2018)—so much so that researchers now hypothesize that areas of the brain that evolved for manual dexterity (e.g., tool use) have been re-purposed to support mathematical development (Penner-Wilger & Anderson, 2013). In considering these neural substrates, the intraparietal sulcus (IPS) stands out.

Figure 2 presents a diagram of the neo-cortex—the outer layer of the human brain—and a few of its main regions. The frontal lobe lies above the eyes and plays the leading role in executive function (working memory, inhibitory control, and decision making). The parietal lobe rests toward the back of the brain and is generally associated with spatial reasoning, including hand-eye coordination. Between those two lobes sits the sensorimotor cortex, which initiates voluntary movement. The IPS aligns with the sensorimotor area associated with hand movement and runs between the upper and lower halves of the parietal lobe. This positioning would suggest that the IPS plays an important role in the manipulation of objects in space, which it does.

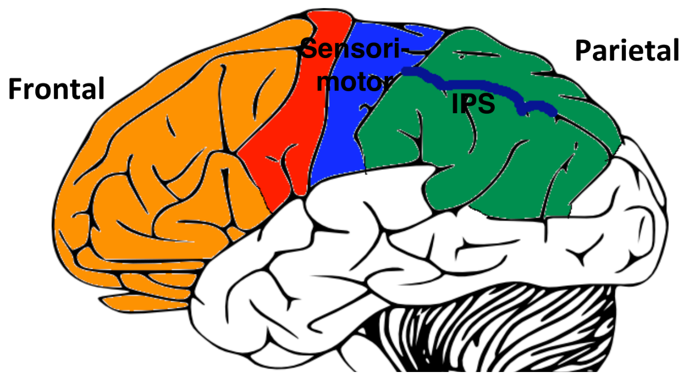

Figure 2. Neo-cortex.

In addition to its role in tool use and other coordinated actions involving the hand (e.g., Mruczek, von Loga, & Kastner, 2013), the IPS is implicated in virtually every neuroimaging study of numerical and spatial reasoning (e.g., Dehaene, 1997; Kucian et al., 2007). In and around the IPS we find the common neural substrate for the two primary objects of the mathematical sciences: space and number. There we also find their common link to coordinated sensorimotor activity, especially involving the hands.

The IPS exists as part of a network that includes the frontal lobe and the angular gyrus—an area in the lower part of the parietal lobe associated with memorized tables of information (e.g., multiplication tables). Studies of mathematical development generally show a shift, from frontal to parietal areas of the network, as children learn: "Solving a new multiplication problem involves the IPS bilaterally and also the frontal lobes, while dealing with the same problem a second time shifts the focus of activity to the angular gyrus in the left parietal lobe" (Butterworth & Walsh, 2011, pp. 19-20). Other studies (e.g., Ansari, 2008), show a similar frontal-parietal shift associated with age.

As we have mentioned, executive function is a primary role of the frontal lobe. It directs limited working memory resources (including spatial working memory) to solve novel problems. As children learn—either rotely through memorizing multiplication tables or through the development of conceptual structures—working memory is offloaded so that the same task becomes less demanding. We posit that areas in and around the IPS serve as the neural substrate for spatial-numerical structures. This view, too, is supported by neuroimaging studies (Hubbard, Piazza, Pinel, & Dehaene, 2005) and implies that the IPS is heavily involved in assimilating mathematical experiences. Resources from the frontal lobe are recruited when the assimilated experience becomes problematic. As such, frontal-parietal coherence (areas within the two lobes working in tandem, as indicated by brain wave frequencies) would be the neural correlate of mathematical development.

Returning to Bell and Fox's (1996) study of crawling, infants with 1-4 weeks of crawling experience exhibited greater frontal-parietal coherence than pre-crawling infants and infants with more crawling experience. Thus, self-locomotion appears to provide a sensorimotor foundation for the development of object permanence and the construction of space—the play space for subsequent geometric construction. In the next section, we consider the case of Euclidean geometry.

Euclidean Objects

Euclid was the first mathematician to formalize mathematics on an axiomatic basis. The purpose of the Elements, Book I, was to prove the Pythagorean (sic) theorem from common notions and postulates (axioms). This is evidenced by the appearance of the Pythagorean theorem and its converse as the final two propositions in the book (Propositions 47 & 48). But what was the basis for these axioms and formal arguments? Evidence appears in the axioms and arguments themselves. The first three axioms (Postulates 1-3) are Plato's rules for straight edge and compass constructions, indicating their sensorimotor basis within Greek culture. The chain of propositions leading from those axioms to the Pythagorean theorem indicates the kinds of mental actions behind Euclid's intuitions. Here, we demonstrate how coordinations of spatial transformations, like sweeping, shearing, and rotating, form the psychological basis for geometric objects.

Figure 3 illustrates the diagram Euclid used to support his arguments for the Pythagorean theorem. Essentially, he argued that the areas of the yellow and blue squares were equivalent to the areas of the yellow and blue rectangles, respectively (Proposition 47). The argument depended on previous propositions demonstrating that shearing triangles and parallelograms does not affect their areas (Propositions 35-38). In Figure 3, triangle DAC is the result of shearing triangle DAG (half of the blue rectangle) along segment FC. Likewise, triangle ABE is the result of shearing triangle ACE (half of the blue square) along segment HB. Because these triangles are congruent (Euclid relied on Proposition 4—a side-angle-side argument, which he demonstrated through Common Notion 4, displacing those elements from one triangle onto another and showing that the remaining sides must also coincide), the areas of the blue rectangle and blue square (each having twice the area) are equivalent. The same argument works for the yellow regions, thus proving the Pythagorean theorem.

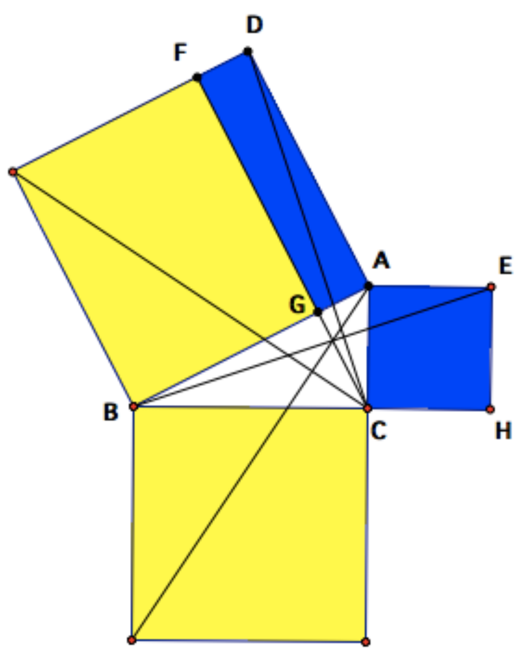

Figure 3. Euclid's proof of the Pythagorean theorem.

In sum, Euclid proved the Pythagorean theorem by transforming mathematical objects (e.g., squares) through mental actions of bisecting, displacing, and shearing. The mathematical objects being transformed are themselves the result of mental actions, such as sweeping (sweeping a point to make a line segment and sweeping a line segment to make a square, as in Proposition 46). Constructing and transforming mathematical objects in this way fits Piaget's descriptions of mathematical objects as coordinations of mental actions, as indicated by the two arrows in Figure 1: (1) mathematical objects arise through the coordination of actions and (2) can be subsequently transformed through further action. Thus, mathematical objects are characterized by both the actions that constitute them and the manner in which actions transform them, particularly aspects of the objects that remain invariant under transformation (e.g., the area of a parallelogram as invariant under the transformation of shearing).

Consider the simpler example of angle sums within a triangle (Proposition 32). Like number, children have to construct triangles: "children are able to recognize and especially to represent, only those shapes which they can actually reconstruct through their own actions" (Piaget & Inhelder, 1967, p. 43). Understanding triangles as mathematical objects requires children to move beyond the figurative material that represents or symbolizes them and to focus on the underlying mental actions that constitute them. The perfect triangle does not exist as a Platonic ideal, but rather as a coordination of actions, including sweeping and rotating.

To demonstrate that the angles in a triangle sum to a straight angle (pi, or 180 degrees), consider the construction of the triangle itself. It begins with a segment (side) swept from one vertex to another. Each pair of adjacent sides forms an angle, which measures the degree of openness, or rotation, between them (Moore, 2013). Figure 4 illustrates the three rotations (A, B, and C) that occur between pairs of adjacent sides. Each rotation is a transformation of one side onto the adjacent side, preserving the property of being a straight segment (a sweep from one vertex to another) but transforming its length and direction. After three such transformations, the original segment has been transformed back onto itself but in the reverse direction. In other words, the combined effect of composing the three angle rotations is a rotation of 180 degrees.

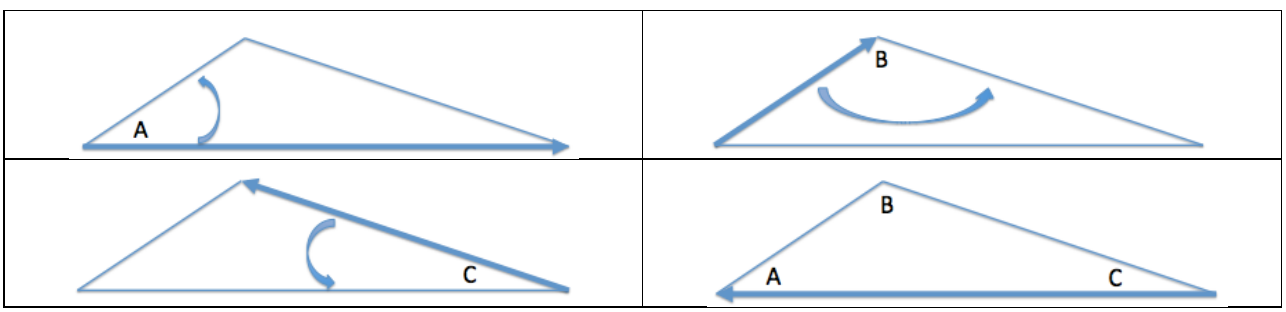

Figure 4. Sum of angles in a triangle.

What we see in the *Elements* is the historical trace of Euclidean geometry from sensorimotor activity all the way up to the first axiomatic system. Thus, we can trace formal mathematical objects, such as right triangles with all of their properties, all the way back to their psychological roots. Like numbers, shapes and their properties (e.g., the Pythagorean theorem) depend upon the coordination of mental actions. For the Greeks, those mental actions were derived from the sensorimotor activity of playing in the sand with compass and straight-edge. Reflective abstraction provides the mechanism for moving from each stage to the next: from sensorimotor activity to mental actions, to the construction and transformation of triangles, to the formal demonstration of the Pythagorean theorem.

Summary

From the Kantian/Piagetian perspective described here, mathematics can be defined as the study of reversible mental actions and the structures that organize them (Piaget, 1970). This unifying definition applies to shape as well as number, both of which arise from the coordination of actions that have a sensorimotor basis (Piaget, 1942; Piaget & Inhelder, 1967). The definition also explains unique features of mathematics while empowering students to construct, transform, and study mathematical objects on the basis of their own activity. The infallibility of students' constructions owes to the reversibility of the mental actions that undergird them (Piaget, 1970). For example, if a child has defined a triangle on the basis of its three planar angles (rotations), composing those rotations with one another inevitably leads to the conclusion that they form a straight angle—a single 180-degree rotation that can be partitioned into the three angles that constitute it. The trick is to find a way to compose all three rotations without appealing to the drawn figure itself but rather to the organization it represents. This process of organizing rotations within a structure for composing and reversing them is the process of reflective abstraction.

When we focus on students' available mental actions and their engagement in sensorimotor activity, we are valuing students' mathematics as they construct new mathematical objects—objects that empower students to model and structure the worlds they experience. Thus, the appeal to students' mental actions is an appeal for equity in mathematics education. Building from the work of Noddings (1999), Hackenberg (2010) has described the appeal in terms of *mathematical caring relations*, wherein the teacher builds models of the students' available mental actions and engages the student with tasks likely to foster new coordinations.

Although Kant and Piaget set the stage for investigating students' mathematical constructions, researchers have just begun the work of describing those constructions as coordinated mental actions. The task before us is compounded when we consider the entire body of formal mathematics, ultimately entailing an account of the sensorimotor basis of the mental actions that undergird it. For example, can we account for the development of geometry from the onset of crawling to the Pythagorean theorem? This work too is mathematical because it requires us to explicitly identify the structures that organize reversible mental actions. Only then will we fully understand mathematics as a human construction rather than a Platonic ideal.

PERSPECTIVES ON THE NATURE OF MATHEMATICS AND RESEARCH

Julie Sarama
University of Denver
Julie.sarama@du.edu

When people address early mathematics education, commonly they write or reference policies, standards, "scope and sequences" and curriculum, or documents on instructional strategies. These are important; however, we believe that the core consideration should be the nature of mathematics and the development of mathematics *in children*.

An 80-year-old incident illustrates what we mean. A mother attending parents' night asked Fawcett (1938), "How is Willie doing in mathematics?" Fawcett replied: "Madam, you ask the wrong question. You should ask, 'How is mathematics doing in Willie?'"

This is what we mean by the "nature of mathematics and the development of mathematics in children": The mathematics that *does well in Willie* and all other children. We develop this position by describing *learning trajectories* and our theoretical framework for them, *Hierarchic Interactionalism*.

Learning Trajectories: Construct and Theory

Learning trajectories are a device whose purpose is to support the research-grounded development of a curriculum or other unit of instruction, as well as to conduct rigorous research in learning and teaching. The term "curriculum" stems from the Latin word for race course, referring to the course of experiences through which children grow. Thus, the notion of a path, or trajectory, has always been central to curriculum development and study. Simon stated that a "hypothetical learning trajectory" included "the learning goal, the learning activities, and the thinking and learning in which the students might engage" (Simon, 1995, p. 133). Building on Simon's definition, emphasizing a cognitive science perspective and a base of empirical research, "we conceptualize learning trajectories as descriptions of children's thinking and learning in a specific mathematical domain, and a related, conjectured route through a set of instructional tasks designed to engender those mental processes or actions hypothesized to move children through a developmental progression of levels of thinking, created with the intent of supporting children's achievement of specific goals in that mathematical domain" (Clements & Sarama, 2004, p. 83).

The name "learning trajectory" reflects its roots in a constructivist perspective. That is, although the name emphasizes learning over teaching, both these definitions clearly involve teaching and instructional tasks. Some appropriations of the learning trajectory construct emphasize only the "developmental progressions." Although studying either psychological developmental progressions or instructional sequences separately can be valid research goals, and studies of each can and should inform mathematics education, we believe the power and uniqueness of the learning trajectories construct stems from the inextricable interconnection between these all three components, goal, developmental progression, and correlated instructional tasks.

Our learning trajectories base *goals* on both the expertise of mathematicians and research on students' thinking about and learning of mathematics (Clements, Sarama, & DiBiase, 2004; Fuson, 2004; National Governor's Association Center for Best Practices & Council of Chief State School Officers, 2010; Sarama & Clements, 2009). This results in goals that are organized into the "big" or "focal" ideas of mathematics: overarching clusters and concepts and skills that are mathematically central and coherent, consistent with students' (often intuitive) thinking, and generative of future learning. Our goals also include productive dispositions, including, curiosity, imagination, inventiveness, risk-taking, creativity, and persistence (National Research Council, 2001). With that in mind, we turn to the question of *how* children think about and learn mathematics.

Research is reviewed to determine if there is a natural developmental progression (at least for a given age range of students in a particular culture) identified in theoretically- and empirically-grounded models of children's thinking, learning, and development (Carpenter & Moser, 1984; Griffin & Case, 1997). That is, researchers build a cognitive model of students' learning that is sufficiently explicit to describe the processes involved in the construction of the mathematical goal across several qualitatively distinct structural levels of increasing sophistication, complexity, abstraction, power, and generality.

The issue of what is meant by a *natural* developmental progression is sure to arise. We believe the research supports a synthesis of aspects of previous theoretical frameworks that we call *Hierarchic Interactionalism* (for a full explication, see Sarama & Clements, 2009). The term indicates the influence and interaction of global and local (domain specific) cognitive levels and the interactions of innate competencies, internal resources, and experience (e.g., cultural tools and teaching). Mathematical ideas are represented intuitively, then with language, then metacognitively, with the last indicating that the child possesses an understanding of the topic and can access and operate on those understandings. The tenets of Hierarchic Interactionalism therefore lay the foundation for the creation of both the developmental progression and instructional tasks of research-based learning trajectories.

1. *Developmental progression.* Most content knowledge is acquired along developmental progressions of levels of thinking. These progressions play a special role in children's cognition and learning because they are particularly consistent with children's intuitive knowledge and patterns of thinking and learning at various levels of development,
2. *Domain specific progression.* These developmental progressions often are most propitiously characterized within a specific mathematical domain or topic. Children's knowledge, that is, the objects and actions they have developed in that domain, are the *main determinant of the thinking within each progression, although hierarchic interactions occur at multiple* levels within and between topics, as well as with general cognitive processes (e.g., executive, or metacognitive processes, potentialities for general reasoning and learning-to-learn skills, and some other domain general developmental processes). See Figure 1 for an illustration.
3. *Hierarchic development.* Development is less about the emergence of entirely new processes and products and more an interactive interplay among specific existing components of knowledge and processes. Also, each level builds hierarchically on the concepts and processes of the previous levels. The learning process is more often incremental and gradually integrative than intermittent and tumultuous. A critical mass of ideas from each level must be constructed before thinking characteristic of the subsequent level becomes ascendant in the child's thinking and behavior. Successful application leads to the increasing use of a particular level. However, under conditions of increased task complexity, stress, or failure this probability level decreases and an earlier level serves as a fallback position.
4. *Co-mutual development of concepts and skills.* Concepts constrain procedures, and concepts and skills develop in constant interaction.

5. *Initial bootstraps.* Children have important, but often inchoate, premathematical and general cognitive competencies and predispositions at birth or soon thereafter that support and constrain, but do not absolutely direct, subsequent development of mathematics knowledge.
6. *Different developmental courses.* Different developmental courses are possible within those constraints, depending on individual, environmental, and social confluences.
7. *Progressive hierarchization*. Within and across developmental progressions, children gradually make connections between various mathematically-relevant concepts and procedures, weaving ever more robust understandings that are hierarchical in that they employ generalizations while maintaining differentiations.
8. *Consistency of developmental progressions and instruction.* Instruction based on learning consistent with natural developmental progressions is more effective, efficient, and generative for the child than learning that does not follow these paths.
9. *Learning trajectories.* A particularly fruitful instructional approach is based on hypothetical learning trajectories. Curriculum developers design instructional tasks that include external objects and actions that mirror the hypothesized mathematical activity of children as closely as possible. These tasks are sequenced, with each corresponding to a level of the developmental progressions, to complete the hypothesized learning trajectory. *Specific learning trajectories are the main bridge that connects the "grand theory" of hierarchic interactionalism to particular theories and educational practice.*
10. *Instantiation of hypothetical learning trajectories.* Hypothetical learning trajectories must be interpreted by teachers and are only realized through the social interaction of teachers and children around instructional tasks.

For example, consider one *goal* regarded as important in all standards documents: young children should learn to be competent in whole number, including meaningful verbal and object counting and the application of counting to solve a variety of arithmetic problem types. The *developmental progressions* for each of these learning trajectories are sampled in the left column of Figure 1. The second column provides an example of children’s behavior and thinking for each level. The third column presents an example of an instructional task designed to catalyze that level of thinking.

In summary, learning trajectories describe the goals of learning, the developmental progression through which children pass, and the learning activities in which students might engage. The *source* of the developmental progressions— the thinking and learning processes of children at various levels—are extensive research reviews and empirical work that cannot be presented here due to space constraints. Also beyond the scope of this chapter are the complex, cognitive actions-on-objects that underlie the LTs (see Sarama & Clements, 2009). Here we will provide one illustration of both cognitive actions-on-objects and how different trajectories grow not in isolation, but interactively.

Consider learning a critical competence—counting on, used especially at the *Counting Strategies* level in Figure 1b. Children need to develop competencies from three trajectories: counting (Fig. 1a), subitizing (not shown, but see Clements & Sarama, 2009; Sarama & Clements, 2009), and the addition and subtraction trajectory (Fig. 1b) to learn to count on meaningfully. From the counting trajectory, they learn to count forward from any number. Then they learn to understand explicitly and apply the idea that each number in the counting sequence includes *the number before, hierarchically*. That is, 5 includes 4, which includes 3, and so forth. From the subitizing trajectory they quickly learn to recognize the number of—not just visual sets, but also *rhythmic patterns.* From the addition and subtraction trajectory, children learn to interpret situations mathematically, such as interpreting a real-world problem as a "part-part-whole" situation. They also learn to use counting to determine what is missing. The creative combination of these developments allows them to solve *meaningfully* problems such as, "You have three green candies and six orange candies. How many candies do you have in all?" by counting on. They understand that these numbers are two parts and that they need to find the whole. They also understand that the order of numbers does not matter in addition. They know, in practice, that the sum is the number that results by, starting at the first number and counting on a number of iterations, equal to the second number. They can use counting to solve this, starting by saying "siiiiix…" because they understand that word can stand for the counting acts from 1 to 6 (because 6 includes 5…). They know *how many more* to count because they use the subitized "rhythm of three" "Du de **Du" ("Doo – Day – Doo")** "seven (du…), eight (day…), nine (*du*)—*nine!*"

Consider Justin, who participated in the successful scale-up of the learning-trajectories-based Building Blocks curriculum (Clements, Sarama, Spitler, Lange, & Wolfe, 2011). At pretest, he operated at the Reciter level of counting, as he verbally counted correctly but when counting toy bananas, broke one-to-one correspondence as he counted a space between the bananas. He did not solve any arithmetic problems. After 7 months moving through the learning trajectories for counting, subitizing, and the counting-based addition and subtraction trajectories (among others), Jason showed remarkable growth. He counted up to 30 randomly-arranged objects accurately and could verbally count up or down from any number in that range. In arithmetic, he solved a variety of problems. For "…you have 3 candies and I gave you 2 more; how many do you have?" Justin put out 3 fingers, then 2 more, and then said, "Five. I was just counting but no words" (i.e., he didn't count out loud). Later, , shown 6 blocks, which were then covered with a cloth, and 4 secretly removed, leaving 2, he said "Two. There were six." "So, how many am I hiding?" Justin quickly counted the two and then counted, pointing to the table and said, "Four." These solutions suggest he was now operating at the Counting Strategies level of arithmetic.

a. Counting

Developmental Progression	Example Behavior	Instructional Tasks
Reciter Verbally counts with separate words, not necessarily in the correct order.	Count for me. "one, two, three, four, six, seven."	Provide repeated, frequent experience with the counting sequence in varied contexts.
Corresponder Keeps one-to-one correspondence between counting words and objects (one word for each object), at least for small groups of objects placed in a line.	Counts: ☆ ☆ ☆ ☆ "1, 2, 3, 4" But answers the question, "How many?" by re-counting the objects or naming any number word.	*Kitchen Counter* Students click on objects one at a time while the numbers from one to ten are counted aloud. 

Counter (Small Numbers) Accurately counts objects in a line to 5 and answers the "how many" question with the last number counted.	Can you count these? ☆ ☆ ☆ ☆ "1, 2, 3, 4… four!"	*How Many?* Tell students you have placed as many cubes (3, hidden) in your hand as you can hold. Ask them to count with you to see how many. Take out one at a time as you say the number word (so, when they say "two" they *see* two). Repeat the last counting number, "three," gesturing in a circular motion to all the cubes, and say "That's how many there are in all."
Counter and Producer (10+) Counts and counts out objects accurately to 10, then beyond.	Counts a scattered group of 19 chips, keeping track by moving each one as they are counted.	*Road Race* Board game.
Counter from N (N+1, N-1) Counts verbally and with objects from numbers other than 1 (but does not yet keep track of the *number* of counts).	Asked to "count from 5 to 8," counts: "5, 6, 7, 8!" Determines numbers just after or just before immediately.	*One more!.* Have the children count two objects. Add one and ask, "How many now?" Have children count on to answer. Add another and so on, until they have counted to ten.

b. Arithmetic

Developmental Progression	Example Behavior	Instructional Tasks
Small Number +/- Finds sums for joining problems up to 3 + 2 by counting-all with objects.	Asked, "You have 2 balls and get 1 more. How many in all?" counts out 2, then counts out 1 more, then counts all 3: "1, 2, 3, 3!."	*Finger Word Problems* Tell children to solve simple addition problems with their fingers.
Find Result +/- Finds sums *by direct modeling, counting-all, with objects.*	Asked, "You have 2 red balls and 3 blue balls. How many in all?" counts out 2 red, then counts out 3 blue, then counts all	*Places Scenes (Addition)—Part-part-whole, whole unknown problems.* Children play with toy on a background scene and combine groups.

	5.	
Counting Strategies +/- Finds sums for joining (you had 8 apples and get 3 more…) and part-part-whole (6 girls and 5 boys…) problems with finger patterns and/or by counting on.	Counting-on. "How much is 4 and 3 more?" "Fourrrrr…five, six, seven [uses rhythmic or finger pattern to keep track]. Seven!"	*How Many Now?* Have the children count objects as you place them in a box. Ask, "How many are in the box now?" Add one, repeating the question, then check the children's responses by counting all the objects. Repeat, checking occasionally.

Figure 1. Selected Levels/Descriptions from the Learning Trajectories for Counting and counting-based Arithmetic (these and other figures adapted from Clements & Sarama, 2014)

This study compared area lessons from Korean textbooks and US standards-based textbooks to understand differences and similarities among these textbooks, as well as how these textbooks address known learning challenges in area measurement. Several well-known challenges have been identified in previous studies, such as covering, array structure, and linking array structure to area formula. We were interested in knowing if textbooks addressed these issues in their treatments of area measurement, and in doing so provided students with opportunities to overcome or become familiar with known challenges. The results show that both countries textbooks demonstrated similar limitations, only few area and area related lessons are covered and three important learning challenges in area measurement are not covered well, which need to be informed to practicing teachers.

Keywords: Area, Textbooks, Learning Challenges

For the last few decades, mathematics education researchers have been interested in how students in different countries learn mathematics. Such interests are the result of studies such as the Trends in International Mathematics and Science Study (TIMSS) and Programme for International Student Assessment (PISA), which indicate that students in East Asian countries perform consistently well. One important area we can examine among various opportunities to learn (OTL) is what textbooks offer to students for their learning, as textbooks play an important role in lesson enactment process, teachers use textbooks and other resources to select and modify tasks to prepare their lessons (Remillard & Heck, 2014). Among many mathematical topics, US students' performance in measurement is weaker than any other content area on TIMSS (Mullis, Martin, Foy, & Hooper, 2016). While researchers conducting international comparative studies of textbooks have examined various mathematical topics (Cady, Hodges, & Collins, 2015; Son & Hu, 2016), area lessons have not been examined and compared often. The purpose of this study was to examine and compare area lessons in US Common Core-aligned textbooks and Korean textbooks, and explore how textbooks address well-known learning challenges in area measurement.

Related Literature

Textbooks in the curriculum enactment process

Although not all contents in textbooks will automatically be transformed to mathematics lessons directly (teachers will likely modify textbook contents), examining the treatment of mathematical topics in textbooks can tell us how much attention is given to that specific topic. In the curriculum enactment process, teachers select and possibly modify mathematical tasks and activities from textbooks and other curriculum materials (Remillard & Heck, 2014). Textbook content and how teachers enact their lessons jointly influence what students experience in their classrooms (Smith, Males, Dietiker, Lee, & Mosier, 2013). For example, if textbooks do not address well-known challenges, we can interpret that as a possible reason for students' struggle because it is possible that those challenges are not well reflected in the teacher's lesson plans and decrease students' OTL to learn and get familiar with those challenges (Smith, Males, & Gonulates, 2016).We cannot say textbooks are the only reason for students' struggle in learning area measurement. However, limited coverage of topics will limit opportunities to learn for students and is a possible explanation for their performances.

How Students Learn Area Measurement

Foundational concepts for area include covering a region without gaps or overlaps, counting unit measures, iterating, understanding array structure and linking the number of squares to length and width (Battista, 2004). Being able to use same – sized units repeatedly to cover a region and iterating are fundamental skills to understand measurement in general (Smith et al., 2016). However, studies have shown that it is challenging for students to develop a good conceptual understanding of area. Students are not able to cover a two dimensional region with equal-sized units. Instead, they often use unequal unit or leave gaps or overlaps (Battista, 2004; Outhred & Mitchelmore, 2000). Without having conceptual understanding, students often use the area formula *length width* without understanding why and for the wrong figures (Zacharos, 2006). However, when students learn using the conceptual approaches of partitioning and covering (partitioning, filling a given space and seeing array structure), they are more likely to develop a better understanding of area measurement (Huang, 2017; Na, 2012; Outhred & Mitchelmore, 2000). Here are research questions that we attempt to answer.

- How do US and Korean textbooks distribute attention to area and area-related lessons?
- In what order do the curricula present concepts related to measuring area, and do the sequences differ significantly between textbooks?
- How well do the curricula address well-known students' challenges in learning area measurement?

Methods

Data Sources

Three textbooks series - *enVisionMath*, *Go Math*, and *MyMath* - are Common Core-aligned textbooks, which were not examined in recent study (Smith et al., 2016). A total of 9 US textbooks were examined, three textbooks from grade 1 through grade 3 from each publisher. Two recent studies examined length and area lessons in other non - Common Core American textbooks and also several other studies examined textbooks that were developed before the introduction of the Common Core State Standards (CCSS) (Hong & Choi, 2014, 2018; Smith et al., 2013; Smith et al., 2016; Son & Senk, 2010). Therefore, examining these common core aligned textbooks series may expand our understanding of how more current American textbooks treat volume measurement. In all, 431 (*enVision Math*), 441 (*My Math*) and 550 (*Go Math*) items were analyzed.

For Korea, the textbooks examined in this study, Elementary School Mathematics, were published by the government and the only mathematics textbooks used in elementary schools in Korea. For Korean textbooks, we examined 129 items from grades 1, 3 and 5. Table 1 describes the number of pages and lessons examined for this study.

Table 1: Textbooks used in the study

Textbook Series	Publisher	Publication Date	Pages	Items	Lessons
envisionMath series	Pearson	2015	86	431	18
Go Math series	Houghton Mifflin	2015	133	550	15
MyMath series	McGraw-Hill	2014	69	441	12
Korean Textbooks	The Ministry of Education in Korea	2014, 2015	31	129	6

Framework for Analyzing Textbooks

When textbooks are analyzed, exposition (e.g. introductory paragraphs, text boxes with definitions, formulas, or theorems), worked examples (problems presented together with an explained solution) and exercise problems (mathematical items students are expected to solve) should be examined because they can provide potentially different OTL for students.

We also searched for studies that examined measurement lessons in textbooks. Smith and his colleagues (2013, 2016) examined length and area measurement in US textbooks. Their framework specifically targets how textbooks address challenges in learning length and area. We adopted and modified Smith and colleagues' framework to analyze area measurement lessons. Table 2 describes our framework for this study.

Table 2: Analysis framework of content and problems

Area of Focus

• Number of area and area related lessons
• Timing and topic sequence
• Procedural and conceptual knowledge
• Known challenges in learning area measurement
  o Covering with equal-sized units
  o Row and column array structure
  o Area formula and definition
• Response type

Coding Procedures and Examples

Each exposition, worked example, and exercise problem in textbooks has its own instructional purpose (potentially different OTL). Each exposition introduces mathematics content including definitions, formulas, and procedures; each worked example demonstrates how certain problems are solved; and each exercise problem gives students opportunities to engage in problem solving. Thus, when we discussed our unit of analysis, we first considered each worked example, exercise problem, and exposition as one unit of analysis as each item provides OTL to teachers and students. Figure 1 shows examples of how we coded each item.

Translation:
• This is the floor plan for Chul Soo's home. Find out the area of each room. Parents' Room Chul Soo's Room Brother's Room

Figure 1. Coding examples from a Korean textbook (The Ministry of Education in Korea, 2015, p. 139)

First, we decided there are three items (three exercise problems or three units) to be coded. Students are asked to use the area formula to compute the area of each room. In terms of topic, these items are coded as area formula because students just need to multiply numbers to get the correct answers. In terms of procedural and conceptual knowledge types, these were coded as procedural (only multiplying two numbers is required). Finally for response type, these were coded as short response (only numbers are required). For all other textbook pages, we used the same method to identify expositions, worked examples, and exercise problems to count the number of units to be coded from each page.

Reliability

Each textbook included exposition, worked examples and exercise problems. After discussing the established codes, two authors coded approximately 20% of the textbook items to check inter-rater reliability. After comparing codes for sample items and finding an acceptable high inter-rater reliability, the authors coded all textbook items jointly to produce a final set of tables for analysis, resolving coding differences of individual items when they arose. To determine reliability, we applied a generalizability theory D study (Alkharusi, 2012). This technique produced a reliable coefficient of 0.964.

Results

Area Measurement Lessons in Textbooks

Table 3: Number and Percentage of Area and Area Related Lessons to the Total Lessons

	Grade	Area and Area-Related Lessons	Total
enVision Math	1 2 3	5 (4.5%) 8 (6.9%) 5 (4.2%)	110 116 119
Go Math	1 2 3	3 (3.0%) 4 (3.6%) 8 (7.6%)	101 110 105
MyMath	1 2 3	3 (3.2%) 2 (2.2%) 7 (6.2%)	95 92 113
Korean Textbooks	1 3 5	1 (1.4%) 1 (1.5%) 4 (5.7%)	70 68 70

Table 3 indicated that little curricula attention was given to area and area-related topics in these textbook series, supporting earlier findings by Smith et al. (2016). These percentages were less than the 1% to 12% range found by Smith et al. (2016).

Time and Sequence

With regards to the sequencing of topics, Korean and US textbooks differed. The Korean textbook series first introduced area in grade 1, with a lesson titled "Comparing Area". This was a short lesson that asked students to compare and make visual judgments between two objects. These items were not found in US textbooks. After a brief introduction to area in grade 1, Korean textbooks had one lesson about partitioning shapes into equal parts in grade 3. Lessons on area then began in grade 5, where the textbook introduced unit squares, area of rectangles and the area formula. In contrast, all three US textbook series included several lessons in grades 1 and 2 about partitioning regions, including rectangles and circles. Then, the area formula was introduced in grade 3 US textbook series. In terms of timing, it appeared that Korean textbooks introduced area first in grade 1, but ideas of partitioning, understanding and finding area of rectangles were found earlier in US textbook series.

Procedural, Conceptual and Conventional Knowledge

The majority of items (83 to 100 % in all textbooks) in both countries' textbooks were procedural. This finding supports previous work examining American textbooks, where procedural items accounted for more than 87% of items in US textbooks (Smith et al., 2016). Such findings imply that the focus of area lessons in both American and Korean textbooks are more about procedures than concepts. Again, this can be one way to lead both countries' students to a more procedural understanding of area.

Knowledge Needed in Understanding Area Measurement

Covering. Covering may be introduced with drawing, using tiles or iterating. Only limited number of covering items were included in textbooks (less than 17 % area items in each grade). Compared to US textbooks, Korean textbooks included covering items much later, only introducing them in the fifth grade. Such a lack of inclusion is problematic, as previous studies have shown that it was challenging to second graders to cover a region completely without gaps or overlaps (Battista, Clements, Arnoff, Battista, & Caroline Van Auken, 1998; Lee, 2010). We also noticed that when textbooks include covering items, the terms "gaps" and "overlaps" are used only few times: less than 10 times in each American textbook series and never in the Korean textbooks. Since students often struggle with covering a region without gaps and overlaps (Outhred & Mitchelmore, 2000; Sarama & Clements, 2009), careful attention to covering and explicit remarks about why gaps and overlaps are important will lead students to a more conceptual understanding of what it means to measure area.

Array structure. Items in this group included drawing, tiling or partitioning a region into rows or columns (the terms "rows" or "columns" needed to be included, or students needed to have opportunities to show array structure) and then counting them or using partial array structure. In US textbook series, partitioning a rectangle into rows and columns appeared first in grade 2, and grade 3 but coverage of the topic was brief and limited (less than 7 % area items in each grade). In Korean textbooks, the topic of array structures appeared in grade 5 but limited number of items were included (about 11 % of its area-related items).

Area definition and formula. Items were coded as area formula if they showed that multiplying two numbers gives the area, or if they used the *length width* formula to compute the area. Both countries' textbooks used array structure to introduce the area formula. Korean textbook lets students derive the formula after working on tasks counting unit squares in grade 5 textbook. US textbook series also used an array structure in grade 3. As previously mentioned, with limited opportunities to explore how array structure and the area formula are related, students are likely to resort to more procedural approaches to area. Such a tendency was reinforced by every textbook, as they all moved quickly to items, where students were only required to use a procedure, multiplying length and width.

Other area topics

One of the frequent topics in both countries' textbooks is counting unit squares in a shape without focusing on array structure (ranging from 23% to 41% of items in grade 3 textbooks and about 26 % in grade 5 Korean textbook). With such a heavy focus on counting squares, paired with limited experience with array structures in previous years, it will be challenging for students to connect array structure to the area formula. Prior studies have shown that even with drawn lines and squares, the connection between counting unit squares and area is not apparent to elementary students (Battista, 2004; Battista et al., 1998). Students may count unit squares procedurally without seeing array structure or understanding the purpose of not having gaps or overlaps. With limited opportunities to experience covering and array structure in grades 1 and 2, it will be challenging for students to see array structure when they are trying to count unit squares.

Summary and Conclusion

This study compared area lessons from Korean textbooks and US textbooks to understand differences and similarities among these textbooks, as well as how these textbooks address known learning challenges in area measurement. Our results indicated that textbooks from both countries paid modest or limited attention to area measurement lessons. In terms of timing, US textbook series introduced area related topics, partitioning, covering, array structure and area formula much earlier than Korean textbooks. In terms of sequence, US textbooks progressed through partitioning, tiling and then presenting the area definition and formula. Studies showed, 2nd and 3rd graders often struggled with covering and array structure (Battista, 2004; Sarama & Clements, 2009). However, textbooks from both countries introduced such topics either later or not at all. Such findings indicate that both timing and sequencing were an issue for both countries' textbook.

Both countries textbooks placed strong focus on procedures rather than concepts. Also, the most frequent items were partitioning regions without array structure. Compounded with issues of sequencing and timing, a procedural focus, and limited coverage of important conceptual area ideas are highly like to lead to students' challenges in learning area measurement. What may we conclude from our findings? As we mentioned previously, although textbooks do not provide mathematics lessons directly (content will likely be modified by teachers), they are one of the main resources teachers use when planning lessons. With the issues identified in these textbook series thus far, it is possible that limitations in textbooks can lead to area lesson plans that do not reflect challenges and important concepts of area measurement. In turn, limited coverage may lead to limiting elementary students' learning opportunities and they may be inclined to adopt a more procedural understanding of area, without attaining a conceptual understanding. With our findings, it will be important to provide teachers with additional supports so that they can attempt to modify tasks in these textbooks to properly address students' learning challenges in area measurement.

In terms of international comparative studies, we cannot say that the learning opportunities these textbooks offered are directly related to US students' performances in TIMSS. However, our results showed that how these textbooks treat area measurement could be one of the reasons for US students' TIMSS results. Despite Korean students' high performances in measurement, we did find that Korean textbooks shared many of the same conceptual limitations as US textbooks. As Smith and colleagues (2016) noted, further studies are required to examine the link between curriculum use and students' performances in assessments in order to make more distinct claims about influence of textbooks on students' performances.

A lo largo de los años la modelación matemática ha ganado gran atención internacional, no sólo en la investigación sino también en el desarrollo de propuestas curriculares y en su implementación en salones de clases. Pero, a pesar de la muy extensa cantidad de publicaciones, existen pocas revisiones de literatura sistemáticas. En este reporte presentamos algunos resultados de una revisión de 485 publicaciones internacionales sobre modelación matemática. Nos centramos en las publicaciones que reportan estudios realizados en América Latina y encontramos que, en términos de la cantidad de publicaciones, la producción es relativamente modesta; sin embargo, la vitalidad de los temas actualmente discutidos y la innovación de sus perspectivas dan cuenta de la importancia que tiene el trabajo desarrollado en la región.

Keywords: Modelación matemática, Investigación documental, Investigaciones en América Latina

La Necesidad de una Revisión de la Literatura

La incorporación de la modelación matemática a los currículos de varios países tiene sus raíces en un movimiento de finales de los años 1950's, cuando defensores de la modelación pugnaron por restaurar el foco en la utilidad de las aplicaciones de las matemáticas en escuelas y universidades (Niss, Blum y Galbright, 2007).

Un momento clave para el movimiento internacional de la modelación matemática fue la inauguración de la *Conference on the Teaching of Mathematical Modelling and Applications*, organizada en 1983 por la *International Community of Teachers of Mathematical Modelling and Applications* (ICTMA). Otro momento importante tuvo lugar en el año 2004 con la realización del estudio sobre Modelación Matemática organizado por la *International Commission on Mathematical Instruction* (ICMI). La publicación derivada de este ICMI Study (Blum, Galbraith, Henn y Niss, 2007) sigue siendo una referencia básica para la investigación en este tema. Desde entonces, los estudios en modelización se han incrementado significativamente ampliando los métodos e intereses más allá de las aproximaciones tradicionales (Stillman, Blum y Kaiser, 2017). No obstante, a pesar de la gran cantidad de publicaciones en educación sobre modelación matemática, son escasas las revisiones sistemáticas del estado del arte sobre el tema.

En la revisión efectuada por Kaiser y Sriraman (2006) se propone una clasificación de las investigaciones en la que se identifica seis perspectivas en modelación matemática: la *perspectiva realista* que tiene por objetivo resolver problemas de la vida real, más allá de las matemáticas; la *perspectiva epistemológica* que se centra en el desarrollo de teorías matemáticas e incluye modelos intra-matemáticos que son usados en la teoría matemática avanzada; la *perspectiva educacional* que considera que la modelación debe servir armoniosamente a propósitos prácticos, científicos y matemáticos; la *perspectiva contextual*, también llamada enfoque de modelación provocada (*model-eliciting*) que se centra actividades de resolución de problemas usando principios de diseño instruccional específicos; la *perspectiva socio-crítica* que enfatiza la necesidad de desarrollar una postura crítica frente al rol y la naturaleza de los modelos matemáticos y su impacto en las problemáticas sociales; y la *perspectiva cognitiva* que es transversal a las anteriores y se centra en aspectos cognitivos de los procesos de modelación matemática.

A pesar de que la clasificación de Kaiser y Sriraman sigue siendo vigente, la gran cantidad de trabajos y de perspectivas producidos en la última década demanda actualizarla y ajustarla. En nuestra revisión de la literatura, retomamos esta clasificación para identificar y contrastar temas contemporáneos sobresalientes, para ello analizamos sistemáticamente algunas de las publicaciones internacionales más importantes, tanto en revistas como en libros, como describimos a continuación.

Metodología de la Revisión de Literatura

Nuestra revisión es resultado del trabajo realizado en un seminario interinstitucional en el que participamos investigadores, profesores y estudiantes de grado y de posgrado de universidades de México y Canadá. Identificamos una vasta cantidad de literatura y gran variedad de perspectivas en modelación matemática. También notamos que las revisiones sistemáticas, como la realizada por Frejd (2013), son muy escasas. Esta escasez definió nuestro interés en realizar nuestra propia revisión, la cual comenzamos a en el primer semestre del año 2017.

Desarrollamos nuestra revisión en dos etapas. En la primera, recurrimos a la base de datos *SpringerLink* y buscamos las palabras “modeling” o “modelling” en el título. Filtramos la búsqueda usando “education” como disciplina y “mathematics education” como subdisciplina. Los artículos que no se relacionaban con modelación matemática fueron eliminados. De esta manera obtuvimos una lista de 73 artículos. A pesar de las restricciones impuestas en esta primera búsqueda, consideramos que la lista es representativa de los artículos de modelación publicados en Springer ya que la búsqueda centrada en los títulos sugiere que la modelación matemática es el principal foco de interés de estos artículos. El análisis de los artículos de esta lista nos ayudó a clarificar y refinar nuestras categorías de análisis; además, nos permitió identificar otras publicaciones clave en libros y artículos de otras editoriales.

En la segunda etapa de nuestra revisión incluimos: (a) los artículos provenientes de números especiales de revistas de Springer y completamos la revisión de artículos publicados en 2017, que no habían sido incluidos antes (debido al traslape de tiempos de edición, sólo fueron consideradas las versiones preliminares publicadas en línea de los dos números especiales sobre modelación publicados por ZDM en 2018); (b) los artículos del *Journal for Research in Mathematics Education* (JRME); (c) los cinco libros derivados del ICTMA y publicados por Springer y el libro correspondiente al 14th *ICMI Study* (Blum et al, 2007); (d) los artículos de algunas revistas internacionales de investigación en español; (e) un libro publicado recientemente que reporta investigación latinoamericana sobre modelación matemática (Arrieta y Díaz, 2016); y (f) los reportes de investigación, presentaciones de grupos de trabajo y conferencias plenarias de los últimos 10 años de las memorias del PME-NA.

Elegimos incluir JRME porque, de acuerdo con Toerner and Arzarello (2012), es la revista de mayor importancia a nivel internacional en el área de la Educación Matemática, junto con *Educational Studies in Mathematics*. Incluimos las revistas en español y el libro sobre investigación latinoamericana para ampliar nuestra mirada más allá de las publicaciones realizadas en lengua inglesa. Las revistas en español seleccionadas fueron *Revista Educación Matemática* y *Revista Latinoamericana de Investigación en Matemática Educativa*, debido a que se especializan en Educación Matemática, son relevantes en la región y pertenecen a índices internacionales prestigiosos (Scopus y JCR). Para la búsqueda de artículos en estas revistas se procedió con los mismos criterios que con las revistas en inglés.

En nuestro análisis nos concentramos en identificar aspectos metodológicos y teóricos de las investigaciones. Específicamente, ubicamos: propósitos de las investigaciones, población, instrumentos de levantamiento de datos, tipo de diseño metodológico (cualitativo, cuantitativo, mixto, etc.), perspectiva teórica y perspectiva de modelación, país donde se realiza la investigación y país de los autores, así como contenidos matemáticos abordados. Es necesario señalar, que el trabajo fue arduo pues muchas veces la definición de los aspectos teórico-metodológicos no está hecha explícitamente por los autores y hay que inferirlos de lo que se dice y hace en el artículo. Por ejemplo, para la definición de la perspectiva de modelización, partimos de las características señaladas por Kaiser y Sriraman (2006), identificamos los propósitos y elementos teóricos señalados en los artículos, cruzamos con las conclusiones y, finalmente, revisamos a los autores citados como referencias clave. Los artículos fueron revisados en paralelo por dos investigadores. En caso de diferencias en la determinación de las características, los investigadores se juntaron a revisar los detalles y tomar una decisión; los casos más difíciles se discutieron en reuniones plenarias. Los criterios de análisis fueron ajustados continuamente a lo largo de los meses que duró la revisión.

Un total de 485 documentos fueron revisados: 111 artículos de revistas de investigación, 341 capítulos de libros y 33 contribuciones del PME-NA. En el presente artículo reportamos los resultados de nuestro análisis sobre producción de América Latina en modelación matemática encontrados en estos documentos.

Tendencias y Producción en Modelación Matemática en América Latina

En contraste con la afirmación de Blum y Niss's (1991) de que la modelación matemática fue inicialmente desarrollada en regiones como Alemania y el Reino Unido, nuestra revisión revela actividad significativa en modelación matemática en América Latina desde los años 90's. De hecho, de acuerdo con Biembengut (2016) en el caso de Brasil esta actividad puede rastrearse hasta los años 70's. En nuestra revisión identificamos dos tendencias en las publicaciones sobre modelación matemática en América Latina: por una parte, la cantidad de producción es relativamente pequeña; pero, por otra parte, las aproximaciones y problemáticas abordadas presentan aproximaciones innovadoras para la investigación educativa en modelación matemática.

La Cantidad de Publicaciones

Identificamos en total 66 publicaciones de autores latinoamericanos del total de 485 que ubicamos en nuestra base de datos, es decir, aproximadamente el 13% de las publicaciones. En las publicaciones de lengua inglesa (las cuales fueron en total 454) identificamos 47 contribuciones de autores latinoamericanos (aproximadamente el 10%). La mayor parte de ellas pertenecen a capítulos de libro de la serie *International Perspectives on the Teaching and Learning of Mathematical Modelling* (41 contribuciones). Estos capítulos representan aproximadamente 14% del total de los capítulos de la serie. Hay que señalar que una cantidad significativa de las investigaciones fueron reportadas en el volumen 2013 de la serie ICTMA (11 capítulos). Es posible que esto se deba a que en ese año la conferencia del ICTMA fue realizada en Brasil.

Respecto a las aproximaciones y problemáticas abordadas, encontramos que gran parte de las investigaciones latinoamericanas son de tipo cualitativo (21 publicaciones), incluyendo metodologías de estudios de caso y etnográficas; además, la mayor parte de las investigaciones se realiza en los niveles de secundaria, post-secundaria y formación inicial de profesores. También es importante señalar que la perspectiva socio-crítica aglutina al conjunto más numeroso investigaciones latinoamericanas publicadas en lengua inglesa (8 publicaciones). La presencia de investigaciones realizadas bajo la perspectiva contextual también es significativa (6 publicaciones).

En las publicaciones realizadas en lengua española identificamos en total 15 contribuciones de autores latinoamericanos, la mayor parte de las cuales involucra a autores mexicanos (10 publicaciones). La mayoría de estas investigaciones se realizó en los niveles de secundaria y post-secundaria (10 investigaciones) y prácticamente todas son de tipo cualitativo (14 publicaciones). El conjunto más numeroso de investigaciones latinoamericanas (8 publicaciones) se ubica en las perspectivas socio-crítica y la educacional. Es necesario señalar que hay 4 investigaciones que no pudimos clasificar debido a que los autores no mencionan su adherencia a alguna de las perspectivas, ni encontramos las características que permiten clasificarlas (Kaiser y Sriraman, 2006; Preciado-Babb et al., 2018).

Finalmente, respecto a nuestra revisión de las memorias de los 10 últimos años de PME-NA, es importante señalar que con nuestros criterios de búsqueda ubicamos únicamente 4 contribuciones que involucran a autores latinoamericanos: dos del grupo de trabajo en "Models and Modeling" (2016 y 2017), el foro de investigación "Mathematical Modeling in School Education" (2014) y un reporte de investigación (2009).

Aproximaciones, Propósitos y Temas Innovadores en Modelación Matemática

Aunque numéricamente son pocas, las investigaciones latinoamericanas que identificamos tienen tendencias innovadoras en problemáticas y aproximaciones; en particular, enfatizan los aspectos sociales y culturales de la educación en modelación.

Al respecto, Stillman, Blum y Biembengut (2015) identificaron elementos de "a unique Latin American perspective to modelling" en el trabajo del autor brasileño Ubiratan D'Ambrosio, quien discute la generación de conocimiento (cognición), su organización individual y social (epistemología) y los modos en que es confiscado, institucionalizado y devuelto a las personas que lo generan (política). Su aproximación a la modelación matemática extiende la perspectiva socio-crítica y constituye una estrategia para la construcción de sistemas de conocimiento en contextos culturales diversos. D'Ambrosio señala:

> Through models, humans try to give explanations of myths and mysteries, and these explanations are organized as arts, techniques, theories, as strategies to explain and deal with facts and phenomena. These strategies, have been historically organized, in different groups, in different spatial and temporal contexts, which are the support of cultures, as systems of knowledge. (D'Ambrosio, 2015, p. 43)

Otra tendencia de la modelación en América Latina corresponde a las investigaciones reportadas como socio-epistemológicas (ver por ejemplo Arrieta Vera y Díaz Moreno, 2016). Esta aproximación comprende la modelación matemática en términos de prácticas sociales, tanto escolares como en las matemáticas formales.

Es importante señalar también que entre las investigaciones mexicanas reportadas resultan significativas las realizadas en el nivel de educación superior y específicamente en la formación de ingenieros (Domínguez, de la Garza y Zavala, 2015; Rodríguez, 2015).

Sobre los Propósitos de la Modelación Matemática

La revisión de los artículos y capítulos de libro permitió identificar propósitos de la modelación que extienden la lista propuesta por Kaiser y Sriraman (2006), ver Tabla 1 (la discusión detallada de la extensión de estos propósitos se hace en un reporte de investigación presentado por Preciado-Babb et al., (2018). En la parte inferior de esta tabla presentamos los propósitos característicos de las perspectivas epistemológicas y critica-social, notables en publicaciones de América Latina.

Tabla 1: Propósitos de la modelación matemática

Propósitos	**Ejemplos**
Aprender contenidos matemáticos	Álgebra, Geometría, Cálculo, Estadística
Aplicar matemáticas	Resolución de problemas
Aprender otras disciplinas	Química, Biología, Economía, Ciencias de la salud
Investigar sobre la conducta	Investigación sobre aprendizaje en ambientes virtuales
Diseñar ambientes de aprendizaje	Diseño de simuladores y ambientes virtuales de aprendizaje
Desarrollo de competencias de modelación	Elementos de modelación, criterios para determinar la calidad de la modelación matemática
Desarrollar habilidades de aprendizaje	Generalizar la solución de un problema a problemas similares
Propósitos específicos de los estudios latinoamericanos	
Generar teoría matemática	Comprensión conceptual y prueba matemática
Desarrollar pensamiento crítico	Juzgar modelos usados en la vida diaria; cuestionar los propósitos y los supuestos de diferentes modelos
Comprender las matemáticas como una disciplina	Aspectos históricos, sociales y políticos de las matemáticas como una disciplina
Desarrollar conciencia de problemas sociales y globales	Crear y criticar modelos usados para predecir crecimiento económico, calentamiento global, recaudación fiscal
Promover actitudes participativas	Comprometerse en la solución de problemas reales y la toma de decisiones dentro de la comunidad
Promover la cultura de la innovación	Crear soluciones para clientes, programar software para distintas audiencias
Participación en estrategias de emancipación	Descolonización, prácticas culturales en matemáticas y modelación matemática

De esta tabla se puede destacar que varios de los propósitos característicos en las perspectivas latinoamericanas buscan modificar entornos específicos, y promueven culturas de innovación y actitudes participativas. Por ejemplo, Orey y Rosa (2017) reportan tareas que abordan problemáticas reales de tarifas de transporte público con lo cual los autores no solo abordan un problema auténtico, sino que también buscan proponer soluciones que orienten la toma de decisiones de la comunidad afectada.

Contribuciones a Temas en Debate

Uno de los temas en que los estudios latinoamericanos han contribuido ampliamente es el relacionado con el reciente debate sobre las nociones de “autenticidad” y “mundo real”. Desde la llamada perspectiva realista, Kaiser y Sriraman (2006) afirman que los procesos de modelación se realizan como harían los matemáticos y científicos en la práctica. En este sentido, la autenticidad del conocimiento generado en el salón de clases puede considerarse a partir de su analogía con la actividad científica. Sin embargo, Jablonka (2007) ha sugerido que la recontextualización de prácticas de modelación de fenómenos científicos es problemática porque "causes a transformation of the unmediated discourses found in out-of-school practices of mathematical modelling, even though a modelling perspective overcomes the philosophy of naive realism encapsulated in traditional word problems" (Jablonka, 2007, p. 196).

Respecto a este debate, han surgido varias posiciones a las que se han sumado las investigaciones latinoamericanas. Por ejemplo, una propuesta consiste en considerar los elementos de la modelación auténtica dentro de algunas tareas específicas, y no para todo el ciclo de modelación. Al respecto, Silva Soares (2015) considera la modelación como una perspectiva de enseñanza en la cual los estudiantes analizan modelos ya existentes en lugar de crear algún modelo a partir de datos reales; es decir, no se comienza con el "mundo real".

Más recientemente, Carreira y Baioa (2017) participan en este debate introduciendo el concepto de "credibilidad" de las tareas matemáticas. Mientras que otros autores consideran que las situaciones de la "vida real" tienen potencial para convertirse en situaciones de aprendizaje atractivas, el enfoque de la credibilidad coloca la relevancia a nivel personal para los estudiantes. Finalmente, otros trabajos en Latinoamérica han usado simulaciones computacionales como modelos para enseñar contenidos matemáticos y científicos específicos (por ejemplo, Gomes Neves, Carvalho y Duarte, 2011). Aunque quizás los estudiantes no se involucren con datos reales, en estos casos sí pueden hacer experimentos con el comportamiento de los modelos y aprender tanto contenidos matemáticos como extra-matemáticos.

Reflexiones Finales

Este reporte complementa otros estados del arte y se centra en las contribuciones que sobre modelación matemática se han realizado por investigadores de América Latina. Encontramos que, en términos de la cantidad de publicaciones, la producción sobre modelación realizada en Latinoamérica es relativamente modesta: aproximadamente el 10% de las revistas de investigación en lengua inglesa revisadas y 12% de las contribuciones en las memorias de los últimos 10 años del PME-NA (reportes de investigación, grupos de trabajo y conferencias plenarias). Sin embargo, de nuestra revisión se deriva también que hay una riqueza de temas y perspectivas innovadoras en los estudios sobre modelación matemática que se realizan en América Latina. Cabe destacar en particular, la tendencia a realizar estudios que enfatizan las influencias sociales y culturales de la educación en modelación. Esta tendencia se refleja tanto en la adopción de perspectivas innovadoras (como la de U. D'Ambrosio), como en la identificación de propósitos comunes a un amplio número de investigaciones latinoamericanas.

Consideramos que las cantidades modestas de las publicaciones sobre modelación no se deben únicamente a un problema de lengua (publicaciones en inglés en relación a publicaciones en español), pues la mayor cantidad de publicaciones realizadas por investigadores latinoamericanos está hecha en publicaciones en inglés (aproximadamente el 77%). Además, la vitalidad de los temas actualmente discutidos en América Latina da cuenta de la importancia que está cobrando el trabajo en modelación matemática en la región. Pensamos que es necesario promover la realización de más investigaciones en los temas y perspectivas identificadas, pero también difundir el importante trabajo regional ya desarrollado.

LATINAMERICAN TRENDS IN MATHEMATICAL MODELING

Throughout the years, Mathematical Modeling has gained international attention, not only in research but also in the development of curricula and its applications in the classroom. However, systematic literary surveys are scarce. In this paper, we present some findings from a survey of 485 international publications related to different aspects of mathematical modeling. While the number of Latin-American publications is rather small compared to the number of international publications, the vitality of the currently discussed themes in this region and their innovative perspectives testify to the international relevance of this developed work on mathematical modeling.

Need for a Survey

The incorporation of mathematical modeling into the curricula has its roots in a movement in the late 1950s, when modeling advocates attempted to restore focus on the utility and applications of mathematics in schools and universities (Niss, Blum y Galbright, 2007).

A key moment for this international movement was the inauguration of the biennial *Conference on the Teaching of Mathematical Modelling and Applications* in 1983, organized by the *International Community of Teachers of Mathematical Modelling and Applications* (ICTMA). Another important moment took place in 2004 with the study on Mathematical Modeling organized by the *International Commission on Mathematical Instruction* (ICMI). The publication derived from this ICMI Study (Blum, Galbraith, Henn y Niss, 2007) continues to be a basic reference for research in this subject. Since then, international research has increased significantly, and research methods and focuses have extended beyond traditional approaches (Stillman, Blum y Kaiser, 2017). Despite the large number of publications on mathematical modeling in education, systematic reviews of the literature are scarce.

In their review, Kaiser and Sriraman (2006) proposed a classification identifying six perspectives on mathematical modeling research: the *realistic* perspective aims to solve real-life problems beyond mathematics; the *epistemological* perspective focuses on the development of mathematical theories, and includes intra-mathematical models that are used to advance theory in mathematics; the *educational* perspective considers different aims for modeling that serve scientific, mathematical and pragmatic purposes harmoniously; the *contextual* perspective, also called the model-eliciting approach, focuses on problem-solving activities constructed using specific instructional design principles; the *socio-critical* perspective emphasizes the need to develop a critical stance towards the role and nature of mathematical models, as well as their impact on social issues; and the *cognitive* perspective on modeling is transversal to the previous five and focuses on cognitive aspects of the mathematical modeling process.

Although Kaiser and Sriraman's classification is still in use, the large amount of work and perspectives produced in the last decade demands updating and adjusting it. In our review of the literature, we retake this classification to identify and contrast outstanding contemporary issues for which we systematically analyze some of the most important international publications, both in journal and book form, as described below.

Literature Review Methodology

This survey is the result of a seminar consisting of graduate and undergraduate students and educators from universities in Mexico and Canada. We identified multiple perspectives on modeling and found the literature on this topic to be vast. We also noticed that systematic reviews, such as the one conducted by Frejd (2013), were scarce. This influenced our decision to conduct our own review, which we started at the beginning of the year 2017.

We conducted the review in two stages. In the first stage, we searched peer-reviewed articles with ‘modeling’ or ‘modelling’ in the title through the SpringerLink database. Then, we refined the search using ‘Education’ as discipline and ‘Mathematics Education’ as subdiscipline. Articles that did not relate to mathematical modeling were excluded, resulting in a list with 73 articles. Despite the restrictions imposed in this first search, we consider that this list is representative of the modeling articles published in Springer because the use of these key words in the titles suggests that mathematical modeling was a main focus for the selected articles. The analysis of the articles in this list helped us to clarify and refine the categories that guided the review, and it also allowed us to identify key publications in books and articles from other publishers.

In the second stage of the review we included: (a) articles from the special issues on mathematical modeling, as well as articles published in 2017 not included previously (due to the overlap of editing times, we only considered Online First versions of the two special issues on modeling published by ZDM in 2018); (b) articles from the *Journal for Research in Mathematics Education* (JRME); (c) five books related to ICTMA and the 14th ICMI Study (Blum et al., 2007); (d) articles from journals on mathematics education published in Spanish; (e) a recent Latin-American book addressing research on mathematical modeling (Arrieta & Díaz, 2016); and (f) research reports, presentations of working groups, and plenary conferences from the last 10 years in the proceedings of PME-NA.

We chose *JRME* because it is at the top of the list of journals identified by Toerner and Arzarello (2012), along with *Educational Studies in Mathematics*. The same search criteria for the titles used in the first stage was followed to search articles in this journal. We included the Spanish journals and the Latin-American book to extend the scope of the review beyond publications in English. The selected journals were *Revista Educación Matemática* and *Revista Latinoamericana de Investigación en Matemática Educativa*, because they are specialized in mathematics education, are relevant among the Spanish journals, and appear in prestigious international indexes (Scopus and JCR). For the search in these journals, we proceeded with the same criteria as with the English journals.

In our analysis we focused on identifying methodological and theoretical aspects of the research. Specifically, we identified: research objectives, target populations, data collection instruments, type of methodological design (qualitative, quantitative, mixed, etc.), theoretical and modeling perspectives, country where research was carried out and authors’ country of residence, and mathematical themes.

It is necessary to point out that the work was arduous: often, authors did not explicitly state the theoretical-methodological underpinnings of their work and we had to infer these from the content. For example, for the definition of the perspective of modeling, we started from the characteristics pointed out by Kaiser and Sriraman (2006); then, we identified the purposes and theoretical elements indicated in the articles, triangulated this information with the conclusions, and, finally, considered the cited authors as key indicators.

Papers were also reviewed in parallel by two researchers. In case of differences in their analysis, the researchers reviewed the details together in order to come to a consensual decision; the most difficult cases were discussed in plenary meetings. The analysis criteria were adjusted continuously throughout the months when the review was conducted.

A total of 485 documents were included for this paper: 111 journal articles, 341 book chapters, and 33 PME-NA papers. Here, we report the results of our analysis of Latin American contributions to mathematical modeling found in these documents.

Latin American Trends in and Contributions to Mathematical Modeling Literature

In contrast to Blum and Niss's (1991) assertion that mathematical modeling was initially developed in regions such as Germany and the United Kingdom, our review reveals significant activity in mathematical modeling in Latin America since the 1990s. In fact, according to Biembengut (2016), this activity can be traced back to the 1970s in the case of Brazil. In our review, we identified two trends in publications on mathematical modeling in Latin America: on the one hand, the number of publications is relatively small; but, on the other hand, the approaches and problems addressed present innovative approaches for educational research in mathematical modeling.

Number of Publications

We identified a total of 66 publications by Latin American authors out of 485 documents in our database — approximately 13% of all the publications.

In the English publications (454 in total), we identified 47 contributions from Latin American authors (approximately 10%). Most were book chapters in the series *International Perspectives on the Teaching and Learning of Mathematical Modelling* (41 contributions). These represent approximately 14% of the total chapters that constitute the series. It should be noted that a significant number of studies was reported in the 2013 ICTMA volume (11 chapters). This is possibly related to the fact that the ICTMA conference was held in Brazil that year.

Regarding the approaches and problems addressed in the surveyed documents, we find that a large amount of Latin American research is qualitative (21 publications), including case study and ethnographic methodologies. In addition, most of the research deals with secondary and post-secondary education, and initial teacher training. It is also important to note that the socio-critical perspective brings together the largest group of Latin American research published in English (8 publications). The presence of research carried out under the contextual perspective is also significant (6 publications).

Within the category of articles published in Spanish, we identified 15 contributions from Latin American authors, most involving Mexican authors (10 publications). The majority of these studies focus on secondary and post-secondary levels (10 publications) and practically all are qualitative (14 publications). Most of the research (8 publications) assume socio-critical and educational perspectives. It is necessary to note that we could not classify four publications because the authors did not mention their adherence to any of the perspectives, and we could not identify particular classification characteristics (Kaiser & Sriraman, 2006; Preciado-Babb et al., 2018).

Finally, regarding our review of the last 10 years of the PME-NA proceedings, our search criteria only allowed us to find four contributions involving Latin American authors: two from the working group in “Models and Modeling” (2016 and 2017); a research forum “Mathematical Modeling in School Education” (2014); and a research report (2009).

Approaches, Purposes and Innovative Themes on Mathematical Modeling

Despite the reduced number of publications, the Latin American studies identified in our survey propose innovative ideas regarding addressed issues and approaches. They particularly emphasize the social and cultural aspects of education in modeling.

Stillman, Blum, and Biembengut (2015) identified elements of a unique Latin American perspective to modelling in the work of Brazilian author, Ubiratan D’Ambrosio, who discusses knowledge generation (cognition), its individual and social organization (epistemology), and the way it is confiscated, institutionalized and given back to the people who generated it (politics). This approach to mathematical modeling extends the socio-critical perspective and is a strategy for building up systems of knowledge in different cultural environments. As D'Ambrosio notes:

> Through models, humans try to give explanations of myths and mysteries, and these explanations are organized as arts, techniques, theories, as strategies to explain and deal with facts and phenomena. These strategies, have been historically organized, in different groups, in different spatial and temporal contexts, which are the support of cultures, as systems of knowledge. (D'Ambrosio, 2015, p. 43)

Another Latin American modeling trend corresponds to research reported as socio-epistemological (see, for instance, Arrieta & Díaz, 2016). This approach understands mathematical modeling in terms of social practices, both in school and in formal mathematics. The studies carried out at institutions of higher education, specifically in the training of engineers, stand out among the Mexican publications (Domínguez, de la Garza y Zavala, 2015; Rodríguez, 2015).

Purposes of Mathematical Modeling

Our review of articles and book chapters allowed us to identify some modeling purposes that extend the list proposed by Kaiser and Sriraman (2006) as presented in Table 1 (a detailed discussion of this extended list is presented by Preciado-Babb et al. (2018). In the lower part of Table 1 we present the characteristic purposes of the epistemological and critical-social perspectives notable in Latin American publications.

Table 1: Purposes of mathematical modeling

Purposes To:	**Examples**
Learn mathematics content	Algebra, Geometry, Calculus, Statistics
Apply mathematics	Problem solving
Learn other disciplines	Chemistry, Biology, Finances, Heath Care
Conduct research	Research on learning in virtual environments
Design learning environments	Design simulators and virtual environments for learning purposes
Develop modeling competencies	Elements of modeling; criteria for quality in mathematical modeling
Develop learning skills	Generalize the solution of a problem to other similar problems
Specific purposes of Latin American studies To:	
Generate mathematical theory	Conceptual understanding; mathematical proof
Develop critical thinking skills	Judge models used in daily life; question purpose and assumptions of different models

Understand mathematics as a discipline	Historical, social and political aspects of mathematics as a discipline
Develop awareness of social and global issues	Create and critique models used to predict economic growth, global warming, tax revenue, etc.
Promote a participatory attitude	Engage in addressing real problems and decision-making within the community
Promote a culture of innovation	Create something for a customer; create program software for an audience
Engage in emancipation strategies	Decolonization initiatives; cultural practices in mathematics and mathematical modeling

From Table 1, it is worth mentioning that several of the Latin American purposes seek to modify specific environments and promote cultures of innovation and participative attitudes. For example, Orey and Rosa (2017) reported a task addressing a real issue of tariffs in public transportation. Through their study, the authors not only addressed a real problem but also sought to propose solutions that guide the decision-making of the affected community.

Emergent Discussion Themes

Latin American studies have contributed extensively to the recent debate on the notions of ‘authenticity’ and ‘real world’. Regarding the realistic perspective, Kaiser and Sriraman (2006) claimed that modeling processes are carried out in a similar way to what mathematicians and scientists would do in practice. In this sense, the authenticity of the knowledge generated in the classroom can be considered based on its analogy with the scientific activity. However, Jablonka (2007) has suggested that recontextualization of modeling practices of scientific phenomena is problematic because it “causes a transformation of the unmediated discourses found in out-of-school practices of mathematical modeling, even though a modeling perspective overcomes the philosophy of naive realism encapsulated in traditional word problems” (Jablonka, 2007, p. 196).

Regarding this debate, several positions have emerged — and Latin American research has contributed to the discussion. For instance, one position is to consider the elements of authentic modeling within some specific tasks, not including the whole process of modeling. In this respect, Silva Soares (2015) suggested *model analysis* as a teaching approach in which students analyze an already existing model instead of creating a model from real data — in other words, it is not necessary to begin with the ‘real world.’

Most recently, Carreira and Baioa (2017) participated in this debate introducing the concept of ‘credibility’ of mathematical tasks. While authors have argued that real life situations have the potential to make the learning experience more attractive, this focus on credibility places the relevance at a personal level for students.

Finally, other Latin American studies have focused on computer simulations as models to teach specific mathematical and scientific content (e.g. Gomes, Carvalho & Duarte, 2011). While students may not engage with real data when using a simulator, they can experiment within the model and learn both mathematical and extra-mathematical content.

Final Remarks

This report complements other reviews of the state of the art focusing on the contributions made by Latin American researchers to mathematical modeling. We found that, in terms of number of publications, Latin American production on modeling is relatively modest:

approximately 10% of the contributions in English research journals and 12% of the reports from last 10 years of PME-NA (research reports, working groups and plenary conferences). However, we also found richness of innovative themes and perspectives in Latin American studies. It is particularly noteworthy the tendency to conduct studies that emphasize the social and cultural influences of modeling education. This trend is reflected both in the adoption of innovative perspectives (such as that of D'Ambrosio), and in the identification of the common purposes of a large number of Latin American research projects.

We consider that the modest number of publications is not solely due to language issues (English publications compared to Spanish publications), since we found that the largest number of Latin American research is published in English (approximately 77%). In addition, the vitality of the currently discussed themes in Latin America reveals the importance that mathematical modeling is gaining in this region. We think that it is necessary not only to promote more research in the identified topics and perspectives, but also to disseminate the significant regional work already developed.

THE COMMON CORE MORAL PANIC

Kevin Watson

williams@mathed.byu.edu

The Common Core State Standards (CCSS) Initiative was initially met with great enthusiasm from politicians and education experts. However, as states began rolling out the standards, backlash against the Common Core became widespread, and several states ended up pulling out of the initiative. To explore and better understand why there was such a negative reaction to the Common Core, we make use of the sociology construct of moral panics, and present an argument that the response to the CCSS was indeed a moral panic.

Keywords: Standards, Curriculum, Policy Matters

For decades, mathematics educators and politicians have called for a uniform, national set of mathematics standards as a way of improving mathematical instruction in the US. In 1989, the National Research Council, in the book *Everybody Counts* (National Research Council, 1989), asserted that "America needs to reach consensus on national standards for school mathematics" (p. 46). In 2009, President Barrack Obama called for states to work together to set higher standards and combat the disparities that arise from the fifty states' different sets of educational benchmarks (Montopoli, 2009). More recently, mathematics educators Deborah Ball, Mark Thames, and James Hiebert (Hiebert, 2013; Thames & Ball, 2013) argued "that the lack of a central or a common [national] curriculum is a major impediment" (Thames & Ball, 2013, p. 34) to improving the mathematical education of children in the US, and suggest that by unifying the nation on the mathematical learning goals for our students, we can greatly improve the teaching of mathematics.

With so many advocating for a set of national mathematics standards as a way to improve mathematics education in the US, it is no wonder that the Common Core State Standards Initiative ("Common Core State Standards Initiative," 2015), was initially met with great enthusiasm. The Common Core State Standards (CCSS) ("Common Core State Standards for English Language Arts," 2010; "Common Core State Standards for Mathematics," 2010) were developed by a state-led initiative in 2009, that included

> … governors and state commissioners of education from 48 states, two territories and the District of Columbia, through their membership in the National Governors Association Center for Best Practices (NGA Center) and the Council of Chief State School Officers (CCSSO). State school chiefs and governors recognized the value of consistent, real-world learning goals and launched this effort to ensure all students, regardless of where they live, are graduating high school prepared for college, career, and life ("Standards in Your State," 2015).

Through examining the best state standards then in existence, consulting with teachers, educational leaders, state political leaders, and leading thinkers, and eliciting and reviewing feedback from the public, the CCSS were developed to achieve the goal of unifying the states' learning goals for students across the nation.

Many in the mathematics education community had largely positive outlooks at the time the CCSS were unveiled. The 2010 Critical Issues in Mathematics Education conference at the Mathematical Sciences Research Institute (Rehmeyer, 2010) called the CCSS "an unprecedented

Hodges, T.E., Roy, G. J., & Tyminski, A. M. (Eds.). (2018). *Proceedings of the 40th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Greenville, SC: University of South Carolina & Clemson University.

opportunity to promote reasoning and sense-making across the United States," (p. 5), and further described the standards as "coherent: build[ing] the mathematical concepts in a logical, orderly way, introducing new ideas only when students have had a chance to master the concepts they are built on" (p. 5). The National Council for Teachers of Mathematics (NCTM) President Diane J. Briars also described how political leaders and educators were enthusiastic about the CCSS "and how having common, rigorous, world-class college- and career-ready standards would benefit both their students and the nation" (Briars, 2014). It seemed the CCSS would be a major step in improving the mathematical education of students in the US, unifying the mathematical learning goals of a majority of the states, and fulfilling a dream of many mathematics educators.

Despite the overwhelming optimism that the CCSS originally generated, these standards grew hugely controversial after their initial implementation. Views among large numbers of parents, educators, and politicians soured, and many began acting for the repeal of the CCSS, citing numerous negatively charged reasons for disposing of them.

As we examine how hostility towards the CCSS grew and became more widespread, it makes sense to ask: What happened? Why did a unified, research-based, national set of mathematics standards designed to improve mathematics education in the US become so controversial? To explore these questions and better understand the nation's reaction to the Common Core, we make use of a sociology construct originally developed by Stanley Cohen (2002), namely that of a *moral panic*.

The Moral Panic

Cohen (2002) defined moral panics as moments when

> A condition, episode, person or group of persons emerges to become defined as a threat to societal values and interests; its nature is presented in a stylized and stereotypical fashion by the mass media; the moral barricades are manned by editors, bishops, politicians, and other right-thinking people; socially accredited experts pronounce their diagnoses and solutions; ways of coping are evolved or (more often) resorted to; the condition then disappears, submerges or deteriorates … Sometimes the panic passes over and is forgotten, except in folklore and collective memory; at other times it has more serious and long-lasting repercussions and might produce such changes as those in legal and social policy or even in the way the society conceives itself. (p. 1).

These moral panics arise quite suddenly when a large, empowered sector of society labels something as deviant and threatening to the norms of that society, and urges that steps must be taken to repair the damage and prevent the perpetrators from further destruction of the moral order (Goode & Ben-Yehuda, 2009). These perpetrators become "folk devils" (Cohen, 2002), and are seen as "legitimate and deserving targets of self-righteous anger, hostility, and punishment" (Goode & Ben-Yehuda, 2009, p. 35).

Elements of a Moral Panic

Goode and Ben-Yehuda (2009) elaborated on the initial definition of the moral panic given by Cohen (2002) by identifying five crucial elements that appear within moral panics. First, there must be a heightened level of concern over the actions of a certain group or category of society whose behavior supposedly endangers other sectors of society. This concern should be manifest through a variety of outlets, such as public opinion polls, public commentary, media attention, and proposed legislation.

Second, there must be an increased level of hostility towards the deviant group, for the harm thought to be caused by them. In other words, "not only must the condition, phenomenon, or behavior be seen as threatening, but a clearly identifiable group in or segment of the society must be seen as responsible for the threat" (Goode & Ben-Yehuda, 2009, p. 38). As society begins to see a split between "us" – good, honest members of society – and "them" – the troublemakers or deviants – stereotyping of these outsiders occurs. This results in the creation of "folk devils" or villains whom society can blame for the phenomenon, and fight against, in order to maintain societal order.

Third, there must be substantial agreement or consensus that an actual threat exists, and is being caused by the behavior of the deviant group. "This sentiment must be fairly widespread, although the proportion of the population who feels this way need not be universal or, indeed, even make up a literal majority" (Goode & Ben-Yehuda, 2009, p. 38). Thus, if only a few scattered, separate individuals believe that a threat exists, then there is no moral panic, despite these individuals heightened emotions and concerns.

Fourth, as implicitly assumed in the term moral panic, the reaction to the supposedly harmful occurrence or behavior needs to be disproportionate. This disproportion is manifest through: (1) a belief that a more sizeable number of individuals are engaged in the deviant behavior than actually are; (2) a belief that the threat, danger, or damage is far more extensive than what is warranted; and (3) the wild exaggeration of numbers and figures, such as the number of deaths, violent acts, crimes committed, injuries, and dollars of damage caused by the behavior of the misbehaving group. "In short, the term moral panic conveys the implication that public concern is in excess of what is appropriate if concern were directly proportional to objective harm" (Goode & Ben-Yehuda, 2009, p. 40).

Fifth, moral panics are volatile, erupting suddenly onto the scene of social conscience, and, almost as suddenly, subsiding from the awareness of the concerned members of society. Some moral panics become institutionalized, that is, the concerns that arose during the moral panic lead to the creation of social movement organizations, legislation, or rules of enforcement. Other moral panics simply fade away, with little to no trace or effect on society. The volatility of moral panics does not mean that the issues involved had no structural or historical antecedents; in fact, "the specific issue that generates a particular moral panic may have done so in the past, perhaps even the not-so-distant past" (Goode & Ben-Yehuda, 2009, p. 42). However, the degree of hostility generated during a moral panic flares up quickly and is not typically sustainable, hence its volatile nature.

Actors in a Moral Panic

Goode and Ben-Yehuda (2009) further point out that within a moral panic, there are usually five main "actors" or groups of participants. The first and most important actor is the press or mass media. As noted by Cohen (2002), within industrialized societies, the information that society uses to build ideas about societal norms, and who or what should be labeled as deviants, is received second hand. In other words, what the general public receives as "news" has already been processed by the mass media, who determine what is newsworthy and how it should be presented, based upon the commercial and political constraints within which the media outlets operate. Thus, one of the main instigators and sustainers of a moral panic is the press, who plays a large part in defining and displaying to the public the groups or episodes that should be considered as "the enemy," by exaggeration and over-reporting of events, as well as stereotyping characters and behaviors (Goode & Ben-Yehuda, 2009). The second actor is the public. A moral panic cannot erupt unless the issues pointed out by the media strike a responsive chord within the general public, where the perpetrators identified can be focused on and vilified as a symbol for larger problems plaguing society. The third actor in a moral panic is the social control culture, or those who are responsible for keeping order within society. Within most moral panics studied in sociology, this group consists of police and the courts, or law enforcement. Public concern about a supposed threat within a moral panic leads to the creation of public attitudes about what law enforcement should be doing to quash the problems "the enemy" is producing. The fourth actor within a moral panic is the group consisting of politicians and legislators. In past moral panics, when politicians and legislators recognized that the media and general public identified a threat to society, they "… aligned themselves against the devil and on the side of angels; the fact is, they picked an 'easy target' … What counted was not the nature of the target but what side they were on and what they were against." (Goode & Ben-Yehuda, 2009, p. 26). These politicians and legislators within a moral panic push for immediate action within government and the law to end the disturbances to society caused by the groups or events branded as deviants. The fifth actor comprises "action groups," or members of the public who come together to advocate for solutions to the problems created by the deviants to society, usually claiming that existing remedies are insufficient.

While some of the actors involved in the reaction to the Common Core fall into the above categories (e.g. the press, the public, politicians, and action groups), there are some differences. First, since the Common Core does not involve crime or criminal acts, the police, courts, and law enforcement are not relevant. However, the analog of law enforcement within education, those who are part of the social control culture that are expected to uphold and enforce societal norms and improve the quality of the education of children locally, are state school boards. Thus, in examining the reaction to the CCSS, it is important to study how school boards reacted to the standards. Second, in the past few years, social media has vastly changed (1) the way people interact with one another, (2) the ease and accessibility of creating groups that call for action and change, and (3) how the public receives and interprets news. In fact, a recent study by the Pew Research Center found that about 30% of US citizens get their news on Facebook (Anderson & Caumont, 2014). Hence, in studying the nation's reaction to the CCSS, we also must pay particular attention to the public opinions, "news" displayed, and action groups active on social media.

Methods

Data sources for this paper include social media posts, news outlets, school board meeting notes, and legislative action. In particular, four states were chosen to examine in depth: Indiana, Massachusetts, South Carolina, and Utah. Data analysis consisted of descriptive statistics to examine volatility and consensus, and qualitative coding and thematic analysis (Braun & Clarke, 2006) of various sources to identify concerns, hostility, and disproportionate reactions of the public towards the common core. In the next section, we present evidence that all of the elements of a moral panic existed in the reaction against the Common Core.

Evidence of the Common Core Moral Panic

Concern

A wide variety of concerns arose as the Common Core was implemented, as illustrated by a popular picture circulated on Facebook, presented in Figure 1. These concerns manifested through Facebook posts, school board meetings, legislation, and news outlets, and include loss of state and local control over education decisions, developmentally and age inappropriate standards, relentless testing that students will be subjected to, and the privatization of education.

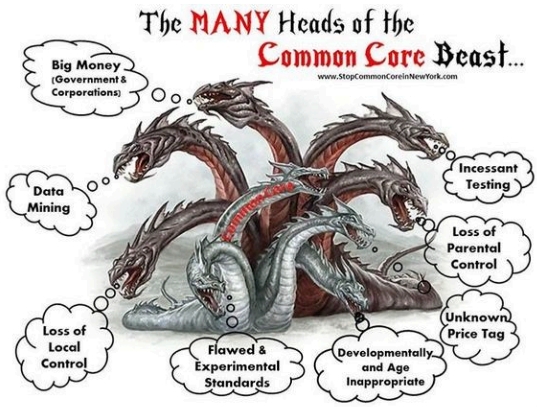

Figure 1. Widely circulated Facebook illustration from www.StopCommonCoreinNewYork.com.

Hostility and Folk Devils

Through examination of hundreds of Facebook posts of anti-Common Core groups, we were able to identify two categories of folk devils that were vilified as those responsible for the CCSS. The first category consisted of those who could be blamed for taking over state and local control of educational decisions, such as President Barrack Obama, Education Secretary Arne Duncan, or the federal government in general. The second category consisted of people or companies that people felt would benefit financially from adoption of the standards, including Bill Gates, Pearson, and other educational "big businesses" or test developers. In each post, the identified folk devil was blamed for the problems that the CCSS were believed to cause, including concerns mentioned in the previous section, as well as criticized for trying to make money through exploiting children's education.

Consensus

We identified three types of evidence for consensus that the CCSS were problematic. First, hundreds of anti-Common Core Facebook groups were created, with some consisting of thousands of members. Second, numerous articles about the CCSS were produced by national news outlets in 2013 and 2014. Third, because the voice of opposition became so loud, and had such a large number of people behind it, several states were forced to legislative action, such as Governor Herbert of Utah organizing a team to review the quality and legality of the standards (Herbert, 2014), or states (e.g. Indiana, Oklahoma, South Carolina) choosing to completely pull out of the standards altogether (Strauss, 2014).

Disproportion

Disproportionate claims that the CCSS were detrimental and causing great harm were not uncommon. Klein (2015) reported on five of the extreme claims, including that the Standards (a) "turn kids gay," (b) "indoctrinate kids under a Nazi society," or (c) "turn kids into communists or socialists." Considering that the CCSS are only a set of learning goals and not a brainwashing effort, these claims were clearly unfounded and over-reactive.

As another example of the disproportionate reaction towards the CCSS, consider what happened in the state of Indiana. On May 11, 2013, Governor Mike Pence signed a bill that paused implementation of the CCSS (Castleman, 2013), and by March of 2014, Pence signed legislature that completely withdrew Indiana from the Common Core Initiative (Nicks, 2014). Despite clear warnings from the Obama administration that fines would be enacted if the state's new standards were subpar (Lucas, 2015), Indiana pushed forward trumpeting their actions as an act of support toward state's rights. "By signing this legislation, Indiana has taken an important step forward in developing academic standards that are written by Hoosiers, for Hoosiers, and are uncommonly high," Governor Pence said in a statement (Calvert, 2015). The committee for creating new state standards met in October 2013, but after a draft of these new standards was released, the Indiana Department of Education found that 70 percent of the standards were exactly the same as the CC with another 20 percent of the content simply a modified version of the CC ("Open the Floodgates", 2014). These similarities to the CCSS continued on through to the final draft, with many seeing the new standards as little more than a "rebrand" (Kurtz, 2014) or a "warmed-over version of Common Core's standards" (Calvert, 2015). Hence, it seems that the negative reaction towards the standards themselves was unwarranted, and most likely an overreaction, as the state found it difficult to write high-quality standards that were different from the Common Core.

Volatility

Despite the CCSS development in 2009-2010, and the adoption of the standards by a large majority of states from 2010-2012, news coverage about the CCSS was fairly minimal until midway through 2012, when the number of news articles mentioning the CCSS grew rapidly. According to a LexisNexis Newspaper article search analysis of US publications conducted by the American Enterprise Institute (Hess & McShane, 2014), this rapid growth in articles reporting on the Common Core rose quickly from August 2012 to a peak in the number of articles in August 2013 (see Figure 1).

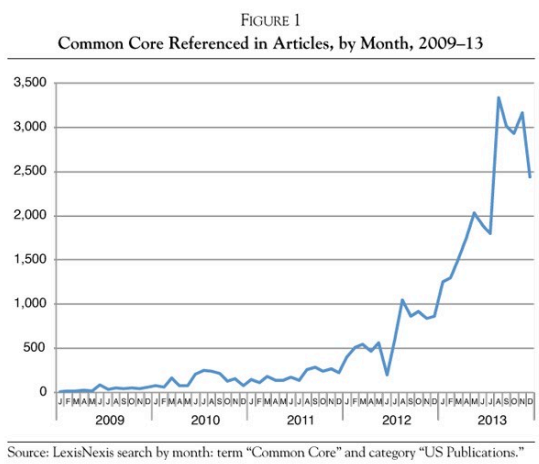

Figure 2. Number of US newspaper articles mentioning "Common Core" per month. From Hess & McShane (2014). Adapted with permission.

As additional evidence of the volatility of the reaction towards the CCSS, Figure 2 presents the number of anti-Common Core Facebook groups created by month, from a sample of 191 of the largest of these groups across the US:

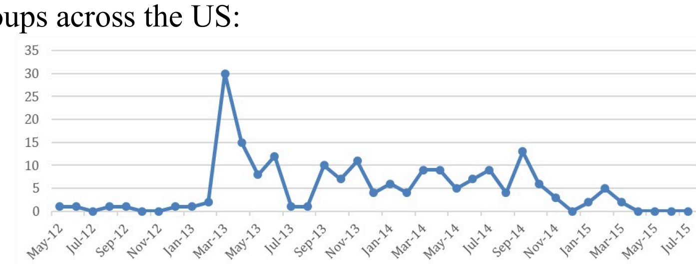

Figure 3. Number of anti-Common Core Facebook groups created per month from a sample of 191 of the largest groups in the US.

From these two figures, it is clear that public and press awareness of, and concern with, the CCSS erupted during the spring and summer of 2013, but over the past five years, concern and calls for repealing the CCSS have lost their prominence in the public square. However, this is not to say that distress over the Common Core will not reach these levels again, as some moral panics can become "a conceptual grouping of a series of more or less discrete, more or less localized, more or less short-term panics" (Goode & Ben-Yehuda, 2009, p. 42). Thus, other spikes in concern about the CCSS may still occur in the future.

Discussion

As education is a highly politicized, highly charged discussion within the US, it might not seem surprising that such opposition to the CCSS arose during their implementation. However, the sociological construct of moral panic gives us a more detailed description of the negative reaction towards the Common Core, helping us see why it was so easy for the public and media to paint the CCSS as a terrible idea.

Intriguingly, the Common Core moral panic afforded both sides of the political spectrum concerns and arguments against the Common Core. For those on the Left, the idea of big businesses profiting from the education of the nation's children was maddening. For those on the Right, Federal Government taking over local control was a large overstep of power. In both cases, calls for the repeal of the CCSS ran rampant across the country.

This leads us to end with the following question: if more educational reforms are desired, how can we avoid another moral panic in the future? Sadly, because education is so politicized, the answer may be that a moral panic cannot be avoided; nevertheless, it could be minimized. Better communication with parents and teachers, and a slower implementation of standards could have benefitted the CCSS greatly. Future educational reformers, including educators and politicians, should look closely at the Common Core Moral Panic, and consider carefully how mistakes made in its implementation could be avoided in implementing future reform.

Acknowledgments

We want to give sincere thanks to the help and efforts of the BYU Mathematics Education students who contributed to the work of this paper during the Winter 2015 seminar.

Math Mapper 6-8 (MM68) is a digital learning system (DLS) that scaffolds curricular coherence, supporting assembly and iterative improvement of diversely-resourced curricula. MM68 includes a learning map consisting of learning trajectories organized around the big ideas in middle grade mathematics and a diagnostic assessment and reporting system. We report on how a design-based implementation research (DBIR) study supported the development of a new framework for curriculum enactment, the “agile curriculum framework,” and explore how such a framework can productively blur lines among curriculum designer, user, and researcher.

Keywords: classroom assessment, learning trajectories, agile curriculum, digital learning system

Perspectives or Theoretical Framework for the Research

The research is grounded in constructivist learning theory (Confrey & Kazak, 2006; Thompson, 2002; von Glasersfeld,1982): student thinking around key ideas goes through predictable, albeit probabilistic, transformations from naïve to sophisticated thinking to reach a target concept. The sequence of the transformations can be described as *learning trajectories* (LTs) or *progressions* (Confrey, Maloney & Corley, 2014; Sarama & Clements, 2009; Simon, 1995). They begin from students’ prior knowledge, which is refined and revised based on their interactions with a carefully sequenced set of curricular tasks. Those tasks challenge students to solve new problems that represent more sophisticated reasoning. We emphasize that a learning trajectory draws fundamentally from genetic epistemology (Piaget,1970), enacting the idea that to “know” something, one has to consider what conditions create and render the need for the idea. However, LTs do not assume Piagetian stage theory (Lehrer & Schauble, 2015), and they do not manifest as biological development such as maturation. Movement along a trajectory occurs via building and refining schemes, through a process of assimilation and accommodation as students solve tasks (Simon & Tzur, 2004). It depends on instructional experiences and on students’ “opportunities to learn”: opportunities to undertake the carefully sequenced tasks, use appropriate tools, and engage in discussions and debates with teachers and peers. Unlike most meanings of instructional design, which involve logical deconstruction of how to reach targeted ideas (Gagne, 1965), LTs are grounded in empirical research on the patterns of responses shown by students in learning (sometimes called “emergent” (Gravemeijer, 1999)).

The Study

This study reports on the “agile curriculum framework” (Confrey, et al., 2018) and how it can be supported by Math Mapper 6-8 (MM68), a new type of digital learning tool. The agile curriculum framework (figure 1) describes how curricula are enhanced through iterative short-term (during instructional units) and long-term (across months and years) cycles, based on feedback.

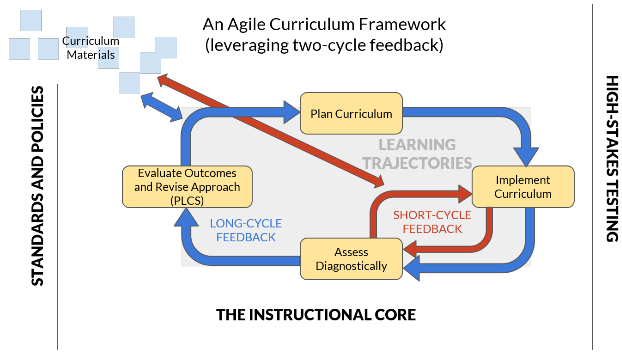

Figure 1. The agile curriculum framework (Confrey et al., 2018, p.7).

MM68 is a digital learning system (DLS) (Confrey, 2015) that is built on an explicit research-based foundation in learning trajectories (LTs), aligned to the Common Core State Standards in Mathematics (CCSS-M) (Confrey et al., 2014). MM68's front end is a learning map that organizes the content of middle grades math around nine "big ideas," each of which is subdivided into 2-5 "relational learning clusters." Each cluster comprises a set of constructs whose interconnected meaning supports the big idea. Each construct is embodied by an LT of 5-12 progress levels, which are used to build periodic "classroom assessments" (Pellegrino, DiBello, & Goldman, 2016). MM68 generates ongoing assessment reports—for teachers and students—that are used to refine instruction. In this paper, we present the results of a 4-week design study investigating if—and, if so, how—three elements interact to have positive impacts on students' learning: 1) teacher knowledge of LTs, 2) a curriculum designed to promote student progress along related LTs, and 3) the use of diagnostic assessments to monitor progress on those LTs. The goals of the study were to: a) improve sixth grade students' ratio reasoning, b) learn how teachers share, discuss, and act with students on assessment data, and c) use classroom observations and student data as one source of validation of the LT-based assessments.

Methods

To hold one critical factor constant in this complex system, a single set of curricular materials was created to be implemented across all sixth grade sections at a high needs middle school. The materials were aligned to the LTs in two ratio clusters: "key ratio relationships" (cluster 4) and "comparing ratios and finding missing values" (cluster 5). We conducted a design-based implementation research (DBIR) study (Penuel & Fishman, 2012). Our research conjecture (Confrey & Lachance, 2000) was that if teachers understand the LTs, they can assist students in progressing through the materials to build and demonstrate more sophisticated ratio reasoning. We further conjectured that *how* the teachers discussed the data from periodic assessments with students would provide an explanatory framework on how the LTs can most directly support improvement in practice. Therefore, we sought to observe how the teachers discussed and reviewed the data with students, how they adjusted their instruction, and whether and how students resolved to improve.

Data Sources and Analysis

Five assessments were administered during the study: One pretest and one posttest, scored digitally, both containing items from both clusters 4 and 5; two diagnostic assessments administered following instruction on each cluster (one containing only cluster 4 items and one containing only cluster 5 items), scored digitally; and an independent posttest from Student Achievement Partners administered on paper, scored manually by two members of the research team. The mean scores on the pretest, diagnostic assessments, and posttest were computed and the difference between the means was determined. Results are reported for students completing both the pretest and posttest (n=165 for cluster 4 and n=143 for cluster 5). Some students mistakenly took a cluster 4 assessment as a posttest, and others mistakenly took a cluster 5 assessment as a posttest, resulting in a difference between the number of students completing both the pretest and posttest for cluster 4 and the number of students completing both tests for cluster 5. Teachers were also observed implementing the curricular materials, administering assessments, and reviewing assessment feedback with their students. Teachers and students were interviewed to understand how they were interpreting and acting on assessment feedback.

Results and Discussion

For students who completed both the pretest and posttest, mean scores increased from 35.59% (SD=20.67%) to 50.19% (SD=22.85%) in cluster 4 (a gain of **+14.6**), and from 31.59% (SD=21.53) to 47.14% (SD=25.34%) in cluster 5 (a gain of **+15.55**). The effect sizes were 0.67 (cluster 4) and 0.66 (cluster 5). On the independent posttest, students achieved a mean score of 38.3% (SD=20.6%, n=262). Some difference between the independent posttest and the MM68 posttest is to be expected. The curriculum, diagnostic assessments, and MM68 posttests were built with the LTs as a common framework, providing a coherent classroom experience. The independent posttest was not built using this framework and the alignment between assessment and classroom experience was not as strong. However, as will be discussed below, the results of the independent posttest informed revisions to both the LT levels and long-cycle modifications to the curricular materials.

Examples of the type of short-cycle and long-cycle revisions described by the agile curriculum framework were evident in the ways researchers and teachers presented, discussed, and shared results and insights. These insights took the form of: a) recommendations about reporting and acting on diagnostic assessment data, b) general instructional suggestions, c) content-specific suggestions, and d) proposed changes to the curricular materials.

To encourage student discussion and reflection, and to help ensure that students perceived the diagnostics as constructive, teachers encouraged each other to focus on both strengths *and* weaknesses of students. Researchers worked with teachers to emphasize the LTs as a way of monitoring progress and guiding future learning. Teachers, in turn, focused on the interpretation of the scores as “getting started,” “showing some understanding,” or “showing proficiency” rather than the specific percent correct score. Students reported positive attitudes about revising and resubmitting answers and were observed “taking up the language” of the constructs and clusters to focus their learning. Researchers leveraged diagnostic assessment data to address gaps in student understanding by providing supplemental activities to be used during the unit.

Researchers also made long-cycle revisions to the curricular materials based on assessment data. Responding to weak performance in the construct “finding unit ratios,” researchers revised the curricular materials for future use by strengthening the treatment of unit ratio. Similarly, the independent posttest revealed insufficient treatment of the connection between part-to-part and part-to-whole ratios. The materials were revised to specifically address this gap.

Finally, researchers provided content-specific suggestions to inform future implementation of the curriculum. For example, researchers suggested teachers encourage students to consistently make, label, and use ratio tables and ratio boxes, and to use “broken arrow” diagrams to stress the multiplicative relations both as covariation and as correspondence (Vergnaud, 1988).

Conclusion

The DBIR work carried out in this partnership led to a variety of means of ongoing improvement, including professional development, curricular revisions, and tool redesign aimed at strengthening and supporting short-cycle and long-cycle instructional adaptations characteristic of the agile curriculum framework. Although this study reports on findings from one grade level team in one school, it nevertheless demonstrates how a school partnership can be formed to work together for ongoing improvements and the types of learning gains that can be achieved when students, teachers, and researchers all have a stake and a role in that improvement.

RE-LEARNING CURRICULUM THROUGH FOCAL EXPERIENCES TO CREATE SPACE FOR DIALOGIC CURRICULUM

Jennifer Y. Kinser-Traut
New York University
jkt3@nyu.edu

Learning to teach mathematics is a complex endeavor. Particularly challenging is making sense of the various levels of curriculum (societal, technical, and enactment) and engaging in problem-solving, or dialogic, mathematics curriculum. This self-study examines how one early career teacher transformed her enactment of curriculum, through specific experiences during her first five years teaching science and mathematics. Narrative inquiry was used to examine past artifacts (i.e., lesson plans) and experiences. The findings highlight the importance of specific focal experiences that support teachers throughout their first five years of teaching to create space in the technical curriculum for enacting dialogic mathematics.

Keywords: Curriculum, Teacher Beliefs, Teacher Education-Inservice

Experience is the foundation for learning (Dewey, 1902), as such prospective teachers (PSTs) draw upon their many years of experience as mathematics student when they are learning to teach. Despite recent calls for dialogic instruction, which includes challenging problem-based curriculum, group work, and an emphasis on mathematical thinking over finding correct answers (NCTM, 2000, 2010), PSTs often draw on their own classroom experiences to define mathematics teaching. These formative experiences as a learner, often learning mathematics through direct mathematics instruction, limit PSTs' understanding of elementary mathematics (Ma, 1999). This self-study, drawing on levels of curriculum (Doyle, 1992), utilizes a narrative approach to examine how specific focal experiences can transform one's mathematics curriculum enactment. I begin by unpacking my learning to teach experience, using the lens of extant literature, and conclude with implications for teacher education.

Theoretical Framework

In this proposal, I utilize the levels of curriculum—societal, technical, and classroom enactment (Doyle, 1992)—to examine how an early career teacher's (ECT) understanding of curriculum levels changed as her experiences changed.

Societal Level of Understanding Curriculum

PSTs enter mathematics methods with varying beliefs about how school should be taught based on their own experiences (Ambrose, 2004). These ideas and understandings come from their experience of being students. This level of curricular understanding is termed the *societal level*. Such an understanding "may mislead prospective teachers into thinking that they know more about teaching than they actually do" making "it harder for them to form new ideas and new habits of thought and action" (Feiman-Nemser, 2001, p. 1016). Therefore, one of the first goals of many mathematics teacher educators (MTEs) is supporting PSTs in expanding their pre-existing beliefs of mathematics curriculum. Here the emphasis is often placed on support PSTs in gaining a better understanding of the realities and complexities of dialogic curriculum enactment (e.g., Ambrose 2004). Unfortunately, the societal level of curricular understanding is often in conflict with the ideas in mathematics methods.

Technical Level of Understanding Curriculum

The technical level of curriculum is often concrete, albeit frequently changing, and includes standards, textbooks, and curriculum documents (Doyle, 1992). While these standards can be straightforward they can also be challenging for prospective teachers to enact for a myriad of reasons, i.e., prospective elementary teachers may not have sufficient mathematical content knowledge (e.g., Ambrose, 2004). Additionally, as Westbury (2002) highlighted prospective teachers may view standards-based textbooks as "curriculum-as-a-document." In other words, novice teachers may view the textbook as *the curriculum* that they enact—not something that supports the curriculum. Due to this conflation between the technical curriculum and the enactment level of curriculum, ECTs too often rely on their understanding of mathematics curriculum at the societal level to support their enactment, rather than their new understandings from methods.

Enactment Level of Understanding Curriculum

As ECTs experience teaching they begin to understand curriculum at the level of enactment. At this level of understanding, teachers have more experiences and are more familiar with classroom variables. ECTs draw on these experiences and the resulting stories when deciding on their daily classroom curricula (or lesson plans). Ideally, by building on their understandings of dialogic mathematics from mathematic methods, ECTS understanding of curriculum will begin to expand. However, ECTs often face a tension between the technical curriculum and what works in classrooms, or at the enactment level of curriculum. This tension, can be viewed as recontextualization, or how teaching practices and ideas introduced in methods are enacted, or not, by ECTs (Ensor, 2001). In summary, the enactment level is the actual implementation (or teaching) of the curriculum, building on understandings that include their societal view, the technical curriculum, and understandings from teaching and mathematics methods.

Methods

In this self-study, I took my first five years of teaching as a case to offer a "deep and critical look at practices and structures of teacher education" (Zeichner, 1999, p. 11). I utilized a narrative approach (Carter, 1993) to identify both my curricular enactment and my understanding of curriculum levels. I open-coded (Strauss & Corbin, 1990) lessons plans, journal entries, and specific recalled experiences that comprised my narrative of learning-to-teach. Through this process I identified five specific focal experiences that impacted my curricular enactment and my understanding of curriculum levels.

Findings

The Starting Point—Societal View of Curriculum

Growing up particularly engaged in my classroom education I believed I understood curriculum. However, my view changed as I advanced in high school mathematics. We were learning material that was engaging on its own, yet I had no idea *why* we were learning it. I tried to trust the teacher, but while learning Conic Sections in Algebra II, I finally had to ask, "How do we use conic sections in the real-world?" In response, we (the class) were given a new project, to explore how Conic Sections are used in real life. As I was learning to teach, I regularly reflected on this early experience questioning how content, and curriculum were taught in schools. Specifically, I wondered why the real-world was often separate from the classroom.

Technical Curriculum and the Foundation for Creating Space

Several years later, I had earned a BS in Biology with a minor in environmental education, and I was an AmeriCorps member, responsible for running a Title 1 elementary school garden.

Through one school garden conference and a handful of education courses (for my minor and general interest), I knew I should connect the garden activities to standards. I thought this connection would facilitate classroom engagement. Having limited support in making connections I turned to the standards, and thus began my first real experience with the technical curriculum. I read (and re-read) the state standards, which formed the foundation for three garden activities I created. Each activity addressed several mathematics and literature state standards.

Through my narrative analysis, I also recognized that this year provided the foundation for developing my knowledge of students and their communities, or Community Funds of Knowledge (CFoK). I worked with families before and after school and I began to understand the wealth of knowledge, or CFoK, that *each* family had to offer. I found that connecting to and eliciting CFoK helped the garden flourish. During this year, I began to think of ways to connect this knowledge with the technical curriculum (a key component of my future curricular enactment). In this position, I experienced both the value of state standards and the importance of working with families and community.

Dialogic Curriculum Enactment in Three Steps

Phase 1: Technical curriculum is not enough. The following year, as I started my first teaching position, at a relatively new charter school, my developing understanding of curriculum was challenged. In preparing for the school, I studied the standards for middle school science and mapped these onto to the school calendar, ensuring I would "hit" each standard. During this process, my curricular understanding was limited to the technical level, despite having worked in the same neighborhood the year before, recognizing the value of CFoK. Yet, as my students filled the classroom, my view of curriculum complexified as I was met with the realities of being a new teacher in a school with few resources. Throughout this first year teaching my curricular focus included my students and my attempts of curricular enactment. I still recognized that standards had value, but I now understood that they were not sufficient to teach diverse middle school students. Rather there were *many* more details to attend to and I began to develop and implement approaches to connect to families and the community.

Phase 2: Engaging students in their education. The following year I taught at a well-established private school where my understanding of enacted curriculum changed again. This child-centered school was aligned with Dewey's (1902) emphasis on student experience as a critical component of learning. Therefore, with the support of a colleague and veteran math teacher, my students (and *not the standards*) became my key focus when developing lesson plans. My classes were much smaller, yet much more individualized and involved. Here I connected my understandings from my prior focal experiences (the importance of real-world mathematics, CFoK, and standards), and when I developed or enacted curriculum I drew on my knowledge of students, their engagement, and real-world mathematics. For example, through problem-solving lessons, I had students derive pi and identify real-life applications for quadratic functions. Overall, this teaching experience proved essential in my understanding of successful curriculum enactment, specifically my expanding view of what enactment could include—dialogic mathematics.

Phase 3: Creating space in the technical curriculum to engage students. When I began teaching at a large public high school, I was provided with structured mentoring, re-introduced to state standards and introduced to new technical aspects of the district. As such, my enactment level of curriculum began with the state standards and incorporated the district level expectations, but I also made space for student engagement, real-world applications, and student interest in their own education. For example, I began each year with the students writing a short essay entitled, "Why Mathematics?," in which students researched and explained why math was personally important. Building on my prior focal experiences, I now saw room in the technical curriculum to include enactment of curriculum that created a community of learners, supported each student in understanding *why* we were learning the content, focused on problem-solving, *and* sought to authentically addressed the standards.

Conclusion

This narrative approach to self-study offers insights into the complexities ECTs face when learning to teach, specifically understanding the varying levels of curriculum. For me, it took five years of teaching and key focal experiences to understand the complexities of curricular enactment and to recognize that, contrary to my pre-existing beliefs, there is *space* in the technical curriculum for a dialogic approach to teaching mathematics. While moving schools provided me with specific focal experiences that pushed my understanding of curricular levels, it is not a sustainable model for teacher education. Yet, my experience and narrative, highlights the challenges MTEs face (often in one-year or less) in supporting PSTs to move beyond a societal understanding of curriculum to one that includes enactment of research-based practices. This study suggests implementing explicit focal experiences (i.e., focus on child-centered learning) to support PSTs and ECTs in developing a comprehensive understanding of mathematics curriculum.

This and other self-studies, presented as case studies, may offer MTEs opportunities to begin the conversation around curriculum levels and identify additional focal experiences (Zeichner, 1999). Introducing case studies and focal experiences addressing curricular levels may support ECTs successful transition from a societal understanding of curriculum to an understanding that recognizes there is space in the technical curriculum for enacting dialogic mathematics. Future research examining the impact of case studies and curriculum level work in methods classes and during professional development would support the refinement of such an approach.

THIRD GRADE TEXTBOOKS' MODELS FOR MULTIPLICATION & DIVISION

Karl W. Kosko
Kent State University
Kkosko1@kent.edu

Rashmi Singh
Kent State University
rsingh9@kent.edu

Multiplication and division are important topics that are formally introduced in third grade. Visual models and representations are key scaffolds for facilitating the teaching and learning of these topics, but there is little research on the prevalence of these models in classrooms. The present study examined six U.S. textbooks and found that three quarters of independent practice and homework tasks did not incorporate visual models. Additionally, textbooks vary significantly regarding which specific models are incorporated.

Keywords: Curriculum; Elementary School Education; Number Concepts and Operations.

Overview & Purpose

Multiplicative reasoning is an important topic that is typically introduced formally in third grade in U.S. schools. Analyses of textbooks suggest that many different visual representations are used in various textbooks in different nations (Davydov, 1991; Harries & Sutherland, 2000; Watanabe, 2003). The variety of representations available for multiplication and division is extensive, with Lay (1963) noting the benefits of set models, length models, area models, tree diagrams, and tables/figures. Although some research has focused on the affordances and constraints of particular models (e.g., Barmby et al., 2009; Huang & Witz, 2013), there has been relatively little research examining the prevalence of particular models in U.S. textbooks or their use by elementary teachers.

Various researchers have found that textbook content influences teachers' instructional decisions and content selection (Grouws et al., 2004; Porter, 2002). International comparisons of U.S. textbooks to those of other nations suggests that U.S. textbooks do not sufficiently promote the relationship between a visual representation and the symbolic notation associated, and there is less focus within such representations on the structure of multiplication (Harries & Sutherland, 2000; Watanabe, 2003). In his implementation of visual representations in a textbook, Davydov (1991) suggests that not only the use but the means of using representations is essential in promoting multiplicative meaning for children. Specifically, Davydov (1991) notes that while visual representations are important, they are not "equivalent to demonstrating the object conditions of multiplication…that create a basis for the subsequent transfer to operation with signs" (p. 30). Thus, the types of representations that are used in textbooks matter and may affect how teachers scaffold students' learning of multiplication and division. Although the prior literature suggests a comparison of children's engagement is both necessary and useful, the current study takes a different approach. In addition to the need for understanding which models (and the pedagogy associated with their use) promote multiplicative reasoning, there is a need to understand which models are currently promoted in U.S. textbooks. Thus, the purpose of the present study is to examine various U.S. third grade textbooks for the visual representations provided or solicited for students in tasks for independent work.

Sample & Methods

Six third grade textbooks were selected for analysis, based on their prevalence of use in area school districts. The textbooks include: enVision Math (2016); Eureka Math (2016); Everyday Mathematics (2016); GoMath! (2012); Investigations in Mathematics (2017); and My Math

(2018). Analysis focused on tasks most likely to be assigned to students for individual practice in class, or for individual homework. Additionally, tasks were analyzed only from sections of the book explicitly designated as focusing on multiplication or division by the publisher. For example, analysis of enVision Math included tasks within *independent practice* and *homework & practice* for sections the publisher aligned with multiplication and division mathematics standards. The current sample includes 4,937 tasks across all six textbooks.

Tasks were coded as either providing or soliciting specific visual representations. Although we did code for variations of representation, the present study focuses on eight specific nominal codes: *no visual representation*, *set model*, *length model*, *area model*, *number line*, *tree diagram*, *table/figure*, *other visual representation*. Each task was coded for types of provided and solicited representations it included. Provided representations are those illustrated within tasks whereas solicited representations required students to construct them in some manner. Both authors independently coded 100 tasks from one textbook. Interrater reliability was computed using the Kappa statistic and indicated near perfect agreement for provided representations (K=.96) and solicited representations (K=.89) between both authors (Landis & Koch, 1977). This supported the use of independent coding of remaining tasks across textbooks.

Analysis & Results

Figure 1 illustrates the distribution of provided and solicited models used to represent multiplication or division across all textbooks. Given the coding process, there are some tasks (n=31) that included both provided and solicited models. However, the descriptive statistics still provide a clear indication of how prevalent particular models are across textbook tasks designed to be individually assigned to students. Evident in Figure 1 is the relative dominance of tasks with no visual model for multiplication/division either provided or explicitly solicited. When such tasks did provide or solicit a visual model, the most common model across textbooks was the set model, followed by tables or figures, and then length models (excluding number lines).

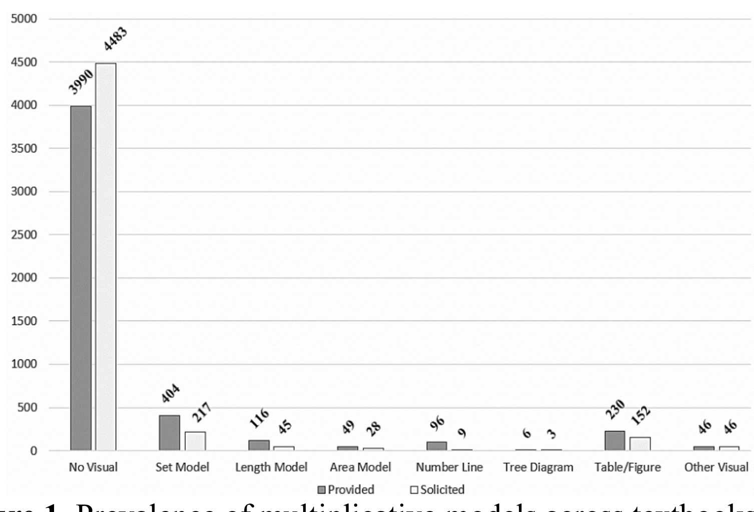

Figure 1. Prevalence of multiplicative models across textbooks.

Next, we sought to examine whether textbooks differed comparatively in regards to the visual models provided or solicited. The distribution of observed and expected counts for both provided (P) and solicited (S) visual models is presented in Table 1. A Chi-square statistic for provided models suggests that the observed distribution was independent from chance ($\chi^2(df=35)=554.78$, $p<.001$), and a similar result was found regarding solicited models

($\chi^2(df=35)=350.88$, $p<.001$). An examination of differences in both observed and expected counts in Table 1 suggests that while Eureka Math had fewer observed tasks with no visual model provided than was expected by chance, all other textbooks had more such tasks than were expected. However, it should be noted that 71.9% of Eureka Math tasks provided no visual representation. Other trends of note reveal that Eureka Math had comparatively higher frequencies of providing and soliciting set models, while enVision and Investigations had comparatively lower frequencies in both regards. Some textbooks differed in their consistency with either providing or soliciting the same model. For example, Everyday Math provided set models for only one task, but solicited a much higher frequency. Numerous other trends emerged across models, suggesting that, in general, certain textbooks emphasized the use of particular visual models over others, and these differences were statistically significant.

Table 1: Observed and Expected Counts for Visualizations of Multiplication and Division

	Set Model		Length Model		Area Model		Number Line		Tree Diagram		Table/ Figure		Other Visual		None	
	P	S	P	S	P	S	P	S	P	S	P	S	P	S	P	S

Note: Italicized numbers are expected by chance, and non-italicized numbers are observed. Provided models are designated in black text in column P, and solicited models are designated in gray text in column S.

Discussion

The present study describes the preliminary findings of an ongoing analysis of visual models in third grade textbooks. Findings suggest that current third grade textbooks' tasks for independent student work (both within and outside of class) engage students with few visual models of multiplication or division. Specifically, when accounting for both provided and solicited visual representations, approximately a quarter (27.7%) of analyzed tasks were designed to engage students with a visual model of multiplication and/or division. Additionally, there appeared to be little consistency across textbooks in regards to which visual models were more prevalent.

The results presented in this brief report reflect our preliminary analysis of models used in U.S. textbooks. Further analysis of the present data will focus on when representations are incorporated in each textbook, and with what aspects of multiplication and/or division. For example, a surface level analysis does suggest that textbooks differ in regards to the prevalence of visual representations in later chapters on multiplication/division, but analysis is currently ongoing.

There are several potential implications from the preliminary analysis provided here. One implication is that the relatively infrequent use of visual models appears at odds with research literature promoting specific use of such models (Sherin & Fuson, 2005). Another potential implication is that the inconsistency between textbooks on the use of particular models may promote confusion in professional discourse on such models for teachers (and students) who have used and are familiar with different textbooks. Although research suggests that textbooks do influence teachers' pedagogical decisions (Grouws et al., 2000; Porter, 2002), future research is needed to understand whether, and to what degree, the use of specific visual models in textbooks affects teachers' use of such representations in their lessons.

The present study focused on independent practice and homework assignment tasks, in regards to provided and solicited visual representations for multiplication and division. Results indicate that textbooks provide relatively few such tasks that incorporate visual models (27.7%). However, it is unknown how teachers use these tasks. It is possible that some teachers select primarily tasks with visual models, while other teachers may select mostly tasks without visual models. There are likely many factors that influence such task selection including pedagogical content knowledge, teaching philosophy, institutional obligations, etc. This preliminary analysis provides a report on only what visual models are present in tasks designed for independent work. Future work is needed to unpack how such distributions influence teachers' decision making, and affect students' mathematical learning.

THE ROLE OF THE TWO-COLUMN PROOF IN THE GEOMETRY CLASSROOM

Rashmi Singh

Our research team surveyed members of the mathematics education community to gain insight into the community's perceptions of the two-column proof. We asked participants to describe the value of the two-column proof and discuss whether they would be in favor of eliminating it from the high school curriculum. There was a wide-range of diversity in the responses and we present several themes that we observed. We found that about 36% of the respondents were definitely or probably in favor of eliminating the two-column proof, 42% were definitely or probably not in favor of eliminating it, while about 22% were unsure.

Keywords: Reasoning and Proof, Geometry and Geometric and Spatial Thinking, Curriculum

Reform documents (e.g., Common Core State Standards Initiative, 2010; National Council of Teachers of Mathematics, 2000) have longed called for mathematical proof to be a part of K-16 students mathematical education. However, despite these efforts, proof still has a marginal role in schools (Stylianides, Stylianides, & Weber, 2017). Historically in the U.S., most students' experience with proof is limited to geometry; and a common way of engaging students with proof is through the two-column format (Herbst, 2002b). According to Stylianides et al. (2017),

> At least in the United States, proofs in geometry are sometimes written in a two-column format where a geometry statement appears in the left column and a reason for why that statement is logically permissible appears in the right column (Herbst, 2002b). Herbst (2002a) observed that this format places implicit (and sometimes conflicting) demands on teachers and students that constrain what is possible in a secondary school classroom. For instance, the two-column format implicitly requires giving students a statement (in the form of premises) and a conclusion, and testing students' abilities to reason logically from the statement to the conclusion. This practice discourages students from generating key ideas from a proof, constructing their own diagrams, or making conjectures by choosing their own premises and conclusions (Herbst & Brach, 2006). (p. 248)

Herbst (2002b) described how the two-column format developed as a way to meet a Committee of Ten mandate, introduced in 1893, that students learn to prove in geometry. The intention of this mandate, decreed by college professors, was to prepare students for college and create opportunities for students to develop mental discipline. The two-column proof emerged as a way to make it "possible for teachers to claim that they were teaching students how to prove and for students to demonstrate that their work involved proving" (Herbst, 2002b, p. 283). Conceptions of mathematics, and proof specifically, have shifted significantly since 1893, yet the ways in which proof is taught, especially in geometry, have not undergone much change.

How do members of the mathematics education community currently view the role of the two-column proof in high school geometry? Through an e-mail survey, we sought to gain insight into the perceptions held amongst members of the mathematics education community regarding the perceived value of the two-column proof and opinions regarding its place in the curriculum.

The Authors' Perspective on Proving as a Disciplinary Practice

Proving is an important aspect of mathematical practice (Hemmi, 2010), and students of all ages should have the opportunity to learn mathematics through proof (Stylianou, Blanton, & Knuth, 2010). Proof has a variety of meaningful functions and can be useful for engaging students in verification, explanation, discovery, and communication (Bleiler-Baxter & Pair, 2017; de Villiers, 1990). But the dominant two-column proof approach for teaching and practicing proof in high school geometry is counterproductive to students' productive engagement in mathematics. The two-column proof has evolved into a one-sided conceptualization of proof as a means of logical verification that deemphasizes the communicative aspects (e.g., negotiating the norms for acceptable evidence and explanations) of problem solving (De Villiers, 1998).

Herbst (2002b) argued that the two-column proof separates the practices of proving from the practices of knowing. We agree with Herbst (2002b) that "proving should be as natural [as other disciplinary practices such] as defining, modeling, representing, or problem solving" (p. 283). In order to reconceptualize proof as a disciplinary practice and to change the way we teach proof, we need to deemphasize the two-column proof because it is antiquated and counterproductive to the kind of thinking mathematics educators aim to foster in today's classrooms. Through our survey, we sought not only to determine if our views of the two-column proof were shared in the mathematics education community at large, but also to learn more about perceptions of the two-column proof that differ from our own.

Methodology

What are the perceptions of the two-column proof held by members of the mathematics education community? To answer this question, we designed a five-question survey which we sent to about 900 e-mail addresses gathered from public lists of attendees of mathematics education conferences. Each question received 152-172 responses. Question 1 asked the participants to describe whether they were a university professor, in-service teacher K-12 teacher, graduate student, or other. Question 2 was "Is there value in having students write two-column proofs?" Participants were asked to respond "yes" or "no." Question 3 requested an open response: "Why or why not?" Question 4 was "Do you support eliminating the two-column proof from the high school geometry curriculum?" The participants responded either definitely yes, probably yes, might or might not, probably no, or definitely no. Question 5 requested an open response: "Why or why not?" We present a summary of the quantitative results and a preliminary summary of qualitative themes that we see emerging from our data at this time.

Results

Quantitative Results

Participants included 133 university professors, 22 graduate students, 5 in-service K-12 teachers, and 12 participants who fell into the category "other." Regarding Q2, "Is there value in having students write two-column proofs?" we found 132/169 or 78% of participants responded "yes" and 37/169 or 22% of participants responded "no." In response to Q4, "Do you support eliminating the two-column proof from the high school geometry curriculum?", 28/171 or 16% responded definitely not, 44/171 or 26% responded probably not, 37/171 or 22% responded might or might not, 34/171 or 20% responded probably yes, and 28/171 or 16% responded definitely yes. Note that about 36% were probably or definitely in favor of eliminating the two-column proof, 22% might or might not, and 42% probably or definitely were not in favor of eliminating the two-column proof.

Qualitative Results

We now present fives themes that are emerging from our data during the preliminary stages of our analysis of the open responses to questions 3 and 5.

Theme 1: Proof is needed in the curriculum. Many participants expressed worry that if the two-column proof was eliminated, then proof would disappear entirely from the K-12 curriculum. Such participants wrote that they see value in students' reasoning, argumentation, and justification, and if the two-column proof was eliminated, they would like to see it replaced by another form of proof.

Theme 2: The two-column proof should be regarded as one, but not the only way to write proofs. Participants expressed a desire for students to be exposed to multiple formats, perhaps with two-column proof as a scaffold to other formats. Furthermore, students should choose the type of format with which they are most comfortable.

Theme 3: The two-column proof format helps students think logically and organize their thinking. Many participants described the value of the two-column proof as helping students to think logically or organize their thinking. Some participants wrote that the two-column proof format might help students understand the way mathematical theorems are logically dependent upon prior results.

Theme 4: The two-column proof format does not meet our goals for students' engagement with mathematics. Many participants wrote about how the two-column proof format runs contrary to other goals we have for our students (e.g., view proof as communication). Some participants noted that mathematicians do not write two-column proofs, and such proofs are inauthentic and contrary to the goal of having students think like mathematicians. Others claimed that the two-column proof emphasizes form rather than reasoning. Some participants claimed that high school students are not ready for the formal reasoning required by the two-column proof and would be better served by other justification and reasoning activities.

Theme 5: We would need professional development and detailed planning if we were to eliminate the two-column proof from the high school curriculum. Many participants noted that if there was a decision made to eliminate the two-column proof from the curriculum, then a lot of planning and professional development would be needed. Other participants had a desire to become more familiar with the research literature before making a decision about keeping the two-column proof in the curriculum.

Discussion

Our analysis reveals that members of the field of mathematics education have diverse opinions about the place of the two-column proof in the geometry curriculum. While most participants stated that the two-column proof does have pedagogical value, many of those participants' comments were reserved, noting that the two-column proof may do more harm than good. However, participants were also hesitant to say that they were in favor of eliminating the two-column proof from the high school geometry curriculum, citing concerns that this may lead to the total removal of proof from the curriculum.

Beyond expressing the need for more alternative types of proof formats in the schools, some participants expressed serious concerns regarding the negative aspects of the two-column proof. We do not believe it is wise to ignore these concerns. Herbst (2002b) noted,

> The two-column proving custom was an accomplishment of geometry instruction in the sense that it helped comply with a mandate. But that accomplishment did not come for free. It

> brought to the fore the logical aspects of a proof at the expense of the substantive role of proof in knowledge construction. (p. 307)

The mandate that students learn to prove in geometry still exists today in the Common Core (2010). The requirement that students prove in geometry is part of the state standards for all fifty states, including those not using the Common Core standards. The two-column format developed as a way to meet this mandate, and it is questionable whether the two-column format's dominant place in the curriculum could be diminished unless we remove entirely the standard that students learn to prove in geometry. Perhaps there are other creative options for making proof more meaningful for students in school. Moving forward, we believe that the field could benefit from research that explores students' understandings, proficiency in constructing, and comprehension of a variety of types of proof formats. The research community needs to be informed about the benefits and constraints of having students write proofs both in the two-column format and other formats. Additionally, we agree with many of our participants that teachers need professional development with proof if it is to gain more than a marginal place in K-12 mathematics classrooms.

THE DIFFERENCES IN HOW CALCULUS TEXTBOOKS INTRODUCE THE CONCEPT OF DERIVATIVE COULD IMPACT CONCEPTUAL UNDERSTANDING

Anita Alexander
Kent State University
aalexa17@kent.edu

Keywords: Curriculum Analysis, High School Education

Textbooks remain a common source of content, pacing, and instruction for mathematics educators. With this in mind, it is critical to examine how the textbooks that educators use as a primary resource introduce essential concepts. The purpose of this study is to explore how calculus textbooks introduce and display the definition of derivative, along with the specific examples and definitions they provide.

The following textbooks were selected for analysis from the College Board's suggested AP Calculus textbooks list: Anton & Biven (2015); Finney et al. (1999); Foerster (2005); Larson & Edwards (2018); and Stewart (2016); see poster for references. Each textbook was analyzed for the first instance of the definition of derivative, then recorded along with the context, and the examples immediately following the definition. Analysis suggests three distinct methods of introducing the concept and definition of derivative. Anton and Biven's Calculus textbook (2015) is denoted as an AP Edition, introducing the definition of derivative as follows: "The function f' defined by the formula f'(x) = is called the ***derivative of f with respect to x***" (p. 90). The example immediately following the definition uses the function $f(x) = x^2$ and asks the reader to find the derivative at x = 2. In this particular case f(2) = f'(2), which could be misleading as a primary example for students to record in their notes. The structure of the Foerster (2005) textbook lends pedagogically to a more problem-based approach to teaching calculus. The definition provided in the text box of section 3.4 states, "Derivative as a function (Δx or h form) f'(x) = " (p. 86). This textbook emphasizes Δx, possibly because of the focus on application problems. The current version of James Stewart's calculus textbook, (2016), begins with the definition of derivative at a point, also stated in a text box, says "The **derivative of a function f at a number a**, denoted by f'(a), is f'(a) = if this limit exists" (p. 151).

The choice of Foerster, (2005), and Larson and Edwards, (2018) to use Δx instead of h has several implications. While this is a robust definition and should be included when teaching the concept of derivatives, it may be intimidating and discouraging for students who do not come to calculus with a strong sense of context in math and/or science coursework to be exposed to as a primary definition (Sofronas et al., 2011). The pedagogical implications in this analysis range from introducing a critical concept in a variety of ways, to making the conscious decision not to begin with an example where f(2) = f'(2). While the latter seems like a minor detail, not attending to a pedagogical decision such as this can have an impact on students' conceptual understanding of the concept of derivative.

Keywords: Policy Matters, Standards, Technology

Local implementation of changes in state educational policy initiatives has proven to be a broad challenge for the field. One challenge to these efforts are the mixed messages and multiple interpretations that arise as policy change efforts are enacted locally and the infrastructuring work necessary to overcome these challenges (Spillane, et al., 2002). In other system-wide change efforts, social media tools have been used to mitigate this challenge (Terantino, 2012), however, there is a gap in the literature in mathematics education on the ways in which social media tools can be used to address these challenges.

After the recent adoption of new state mathematics standards, a partnership between our state education agency and researchers from four universities in our state was formed to assist in implementing new state mathematics standards. As a part of these efforts, we use organizational sensemaking (Weick, 1995) to guide the use of social media tools aimed at promoting common messages and interpretations of the new state mathematics standards and the ways in which these standards can be embodied in reform-based instruction with students. Theoretically, organizational sensemaking is the process that individuals within organizations go through when they encounter moments of uncertainty and ambiguity as they make sense of change (Weick, 1995). During sensemaking, researchers highlight three cyclic processes: *cues* that trigger sensemaking; *intersubjective meaning making* among members of organizations, and the *action* needed to continue to promote organizational sensemaking (Maitlis & Christianson, 2014).

For this proposed poster, we share how we have leveraged Twitter to support the statewide implementation of new mathematics standards. Using organizational sensemaking, we share an emerging framework for using social media to promote systemic coherence during implementation that goes beyond dissemination and communication to promote individual and collective learning. This poster will provide examples of how the framework guided our use of Twitter to provide opportunities to engage in the sensemaking processes.

PERIODIC CONFUSION: EXAMINING TWO CONTEMPORARY TEXTBOOK UNITS ON TRIGONOMETRIC FUNCTIONS

Julien Corven
University of Delaware
jcorven@udel.edu

Keywords: Curriculum, Curriculum Analysis, High School Education

The purpose of this study was to examine two textbook units on trigonometric functions to understand what opportunities to learn they provide to students. Despite its reputed content difficulty, trigonometry is under-researched in the field. Obstacles to understanding trigonometry may stem from a lack of opportunities to develop deep conceptual knowledge, which the Common Core State Standards for Mathematics (CCSS-M) were designed to address. Two features associated with tasks that give students such opportunities are grappling with mathematics and explicit connections to concepts (Hiebert & Grouws, 2007). These features define high cognitive demand tasks, as operationalized by Stein and Lane (1996). Thus, to fully understand how each text gave students opportunities to learn trigonometry meant examining both the content and the intended cognitive demand of tasks. My research questions were:

1. What specific mathematics content do students have opportunities to learn by studying trigonometric functions using each of the two selected texts?
2. What are the intended levels of cognitive demand of tasks in the two selected texts?

The textbooks selected for this study were Pearson's *Algebra 2: Common Core* and the second (2011) edition of Key Curriculum Press's *Interactive Mathematics Program: Year 3*. I conjectured there would be important differences between the two texts; for example, IMP, an NSF-funded "reform" textbook, might have a higher percentage of problems at high levels of cognitive demand than Pearson, a "traditional" textbook. Over 950 student tasks were coded for trigonometry concepts implicated, using author-developed codes from a collapsing coding methodology, and level of cognitive demand, using the framework of Stein and Lane (1996).

Analysis revealed Pearson's text covered all trigonometry topics required by the CCSS-M, but it emphasized procedural fluency, with relatively few opportunities for students to engage with high cognitive demand tasks to build conceptual understanding. IMP, in contrast, provided ample opportunities for students to first develop conceptual understandings by using high cognitive demand tasks, followed by opportunities to build procedural fluency. However, IMP omitted some trigonometry content crucial to prepare students for Calculus from the CCSS-M. As a result, both texts may have shortcomings for students if enacted as intended. This work invites discussion of ways curricula can balance development of deep conceptual understandings of trigonometric functions with procedural fluency skills given limits on instructional time.

HOW TWO PROJECT-BASED MATHEMATICS TEXTBOOKS POSITION STUDENTS TOWARDS MATHEMATICS

Kelly Curtis
University of Delaware
kbcurtis@udel.edu

Keywords: textbook analysis, positioning theory, cognitive demand, voice of textbook

Mathematics is often seen as neutral and free of bias and subjectivity because it is comprised of numbers and calculations. However, the way that we use words and language to teach and communicate about mathematics sends a powerful message to students about who they are and what they can do in relation to mathematics (Langer-Osuna, 2017). Therefore, we need to attend more carefully to the language we use in mathematics curriculum materials.

Inspired by prior analyses of tasks and curriculum materials, I created a framework to analyze two problem-based textbooks: Core Plus (CP) 1 and the Mathematics Visions Project (MVP), Year 1. Herbel-Eisenmann (2007) analyzed the inclusive and exclusive imperatives used in textbooks and found that textbooks either position (Harre & van Langenhove, 1999) students as *thinkers* (asked to draw a conclusion or make a connection) or *scribblers* (asked to simply make a calculation). Additionally, I drew upon Stein and Lane's (1996) work with cognitive demand of mathematical tasks because the task itself sends messages to students about whether they are expected to engage as *high thinkers, low thinkers, high scribblers,* or *low scribblers*.

On in-class tasks, students were positioned as *high thinkers* in CP 50% of the time while students were positioned as *high thinkers* in MVP only 18% of the time. Students in the MVP curriculum were positioned most frequently as *low thinkers* on in-class tasks, 74% of the time. For CP, the percentage of times students were positioned as *high scribblers* increased from 13% (on the in-class tasks) to 36% (on homework). For MVP, the number of problems with high cognitive demand decreased (from the in-class tasks to homework) while the number of problems with low cognitive demand increased which resulted in students being positioned as *scribblers* 88% of the time on the homework! The CP materials collectively (in-class tasks and homework) almost equally position students as *high thinkers*, *low thinkers*, and *high scribblers*. The MVP materials collectively position students as *high scribblers* the majority of the time.

Because these curriculum materials both claim to align with the NCTM standards and the CCSS-M, I expected to find more similarities than differences. However, I found that the CP tends to position students more as *thinkers* than MVP does and that the CP homework problems tend to be more cognitively demanding than the MVP homework. I also found that there may be more opportunities for students to move out of the scribbler position in the CP materials.

Keywords: Pacing Guide, Research-Practice Partnership, Design Based Research, Standards

In many districts, pacing guides strongly filter the sequencing, planning, and timing of instruction. Furthermore, they often vary from district to district and are created by local individuals or teams who may or may not have particular expertise in mathematics education. Research suggests that while pacing guides can support teachers in learning of curriculum (Bauml, 2015), pacing guides and the pressure to comply with them can also undermine the professionalization of teaching, prevent teachers from meeting the individual needs of their students, and decrease teachers' use of cognitively demanding tasks for the sake of "covering" the content in the pacing guide (Bauml, 2015; David, 2008). We report on a research-practice partnership (Penuel, Allen, Coburn, & Farrell, 2015) in which multiple partners across our state collaborated to mediate these challenges by designing pacing guides, which we renamed as instructional frameworks, to support districts and teachers in their implementation of new statewide mathematics standards adopted in 2017.

In this poster session, we provide an overview of activity theory (Engeström, Miettinen, & Punamäki, 1999) as our theoretical perspective and design-based implementation research (Fisherman, Penuel, Allen, Cheng, & Sabelli, 2013) as our approach to share how a co-design team of 70 diverse stakeholders (state agency consultants, administrators, district curriculum directors, teachers, and higher education faculty) brought different lenses to inform decision-making about the clustering and sequencing of content standards and the duration needed to teach them. We report on the tensions in critical conversations about clustering and sequencing of standards during the initial phases of our design process, highlighting the ways in which actors drew on previous experiences, assessment concerns, curriculum materials, and mathematical learning progressions/trajectories to inform decision-making during the development of the instructional frameworks.

INFLUENCE OF INTEGRATED STEM CURRICULA ON INSTRUCTION

Christa Jackson
Iowa State University
jacksonc@iastate.edu

Mollie Appelgate
Iowa State University
mollie@iastate.edu

Ashley Delaney
Iowa State University
delaneya@iastate.edu

Kari Jurgenson
Iowa State University
karij@iastate.edu

Recent research has shown the importance of including STEM education programs in elementary schools (Dringenberg, Wiener, Groh, & Purzer, 2012). Teachers may integrate the STEM disciplines at varying degrees (Nathan, Tran, Atwood, Prevost, & Phelps, 2010), focusing more on one discipline than another. Given more and more teachers are being asked to integrate STEM into their instruction, we examined two fourth grade teachers, Ms. Khanna and Ms. Devries, implementation of DESCARTES, an integrated STEM curricula. We analyzed how DESCARTES influenced the teachers' conceptions of teaching and their instructional practices.

In the DESCARTES curriculum, students construct their own knowledge by engaging in an authentic context (designing and building boats) to solve a real-world problem (shipping cargo efficiently across a body of water). The students are presented with a challenge of designing a boat that could carry the most load across a body of water. The students engage in multiple hands-on activities to examine and test buoyancy, pressure, cross-sections, water displacement, speed, and volume. The students test similar factors in the DESCARTES software environment, which is a gamified design, simulation, prototyping, and collaborative environment.

Both teachers participated in a 45–minute initial interview prior to implementing DESCARTES. Field notes were recorded each day of the 4½ week unit. At the end of the unit, the teachers participated in a 45–minute final interview. Data were analyzed using an inductive approach.

Although the teachers were "veteran" teachers, they experienced some trepidation prior to implementing the DESCARTES curriculum. Ms. Khanna expressed, "I was unsure first [about the DESCARTES curriculum]. I was like, oh gosh! What did I get myself into? You know, thinking this is going to be hard. And it was." (Final Interview, 2016). Both Ms. Khanna and Ms. DeVries became aware how their STEM instruction showed different outcomes compared to their siloed-discipline instruction– learning gaps amongst students were almost non-existent and the teachers observed students' "willingness to not give up. They don't ever feel like they are trying to achieve the right answer. They are just constantly making it better" (Final Interview, 2016). After implementing the DESCARTES curriculum, the teachers noticed the positive effects it had on their instruction, student learning, and student engagement.

PROJECT VERSUS PROBLEM BASED LEARNING: IS THERE A DIFFERENCE?

Y. Rhoda Latimer
Clemson University
ylatime@clemson.edu

Keywords: Curriculum Analysis

Project and problem based learning are commonly used interchangeably. There are, however, important differences between the two. The Buck Institute for Education (2017) defined project based learning as a method focused on students learning by working for a period of time on an investigation in response to a problem or task. While problem based learning is a student-centered approach where learning is done through group work to explore open-ended problems (Center for Teaching Innovation at Cornell University). It appears problem based learning is driven by the problem, while project based is driven by the project, but both have the overarching goal of letting students lead the investigation.

The purpose of this study was to conduct a literature review to compare how researchers have used project and problem based learning to enhance mathematical learning over the last two years (2015 to 2017). The articles reviewed provided insight into contemporary ways researchers have enacted problem and project based learning. The goal of the literature review was to provide insight on how the different conceptualizations of project and problem based learning may influence the choices made by the researchers.

To collect the most recent articles about project and problem based learning, I conducted an EBSCO and ERIC search within scholarly peer-reviewed journal and keywords problem based learning in the title and mathematics and education within the entire paper. We repeated these searches in EBSCO and ERIC for project based learning. Initial search results found 65 articles total. Out of the 65 articles (37 problem based learning and 28 project based learning), only 36 matched the criteria of being empirical studies in English language peer-reviewed scholarly journals. Twenty articles were classified as focused on problem based learning and 16 articles were classified as focused on project based learning.

Conducting a literature review of both project and problem based learning has afforded the opportunity to research how the two methods are enacted in classrooms. Initial findings demonstrate a lack of consistency in both defining problem and project based learning and how they are used. Preliminary results also yield limited empirical studies within the last two years of project based and problem based learning in the discipline of mathematics. Mathematics was included or part of the project but the studies did not focus on mathematical concepts. Studies are also limited within the United States. The results across both studies show project and problem learning do enhance the instruction of mathematics.

AN INTERNATIONAL COMPARISON OF MKT AND EDUCATIVE CURRICULUM MATERIALS FOUND IN TEACHERS' MANUALS

Matthew Melville
University of Delaware
Melbob@udel.edu

Keywords: Curriculum, Curriculum Analysis, Mathematical Knowledge for Teaching

This study compares teachers' manuals from the U.S. and Japan to determine the extent and the ways in which mathematical knowledge for teaching (MKT) is developed in teacher manuals from each country. Ball, Thames, & Phelps (2008) discuss the importance of MKT because, in part, it plays a critical role in planning and enacting the intended curriculum (p. 399).

In addition to providing opportunities to develop MKT, there are other ways in which curriculum materials can support students' learning. According to Davis and Krajcik (2005), curriculum materials could be educative if they provide teachers with opportunities to learn *why* developing pedagogical content knowledge (PCK) is important. Therefore, this study is not only an analysis of the comparison of the textbooks that are educative, and the level at which MKT is developed. It is also an analysis between Japan and the US textbooks, which can provide insights into the differences in the materials provided to the teachers in each country. This study was guided by the following research questions:

1. In what ways do teachers' manuals provide opportunities for Japanese and US teachers to develop their mathematical knowledge for teaching (MKT) about triangle congruency statements? What are the similarities and differences?
2. In what ways do the teachers' manuals in Japan and the US provide opportunities for teachers to learn about the mathematics in the lesson and students' thinking about the mathematics? What are the similarities and differences?

For the purposes of this exploratory study, to draw a fair comparison between the teachers' manuals in Japan, *Core-Plus Mathematics* (Hirsch, 2008), a reform-based curriculum, was selected to represent the U.S. manual. The U.S. and Japanese curriculum materials had similar numbers of instances to develop MKT, although the Japanese curriculum instances were spread more widely among the different categories of MKT. However, there were more differences than similarities in the other opportunities teachers had to learn from these materials. The Japanese curriculum devoted more space and time to helping the teachers understand the *why* behind certain decisions, which could help teachers develop a deeper understanding of the lesson and also can provide insight into possible student thinking. In contrast, the US textbook focused mostly on areas where the students may struggle. Therefore, the curriculum materials were similar in providing opportunities to develop MKT, but they varied otherwise in the level at which they were educative for teachers.

DYNAMIC GEOMETRY SOFTWARE (DGS) TASKS IN SECONDARY CURRICULA

Milan Sherman
Drake University
milan.sherman@drake.edu

Sarah Wenaas
Drake University
sarah.wenaas@drake.edu

Charity Cayton
East Carolina University

Keywords: Technology, Curriculum Analysis, High School Education

As Dynamic Geometry Software (DGS) becomes more ubiquitous in secondary mathematics classrooms, it is important that the development of tasks in mathematics curricula mirrors research findings concerning its use. Textbooks have a strong influence on teachers' selection of the content that they include and the instructional strategies that they utilize (e.g. Banilower et al., 2013). While research shows that the strategic use of technology has the potential enhance students' mathematical thinking and understanding (e.g., Hollebrands & Dove, 2011), the question remains as to whether the use of DGS as promoted in current secondary curricula leverages that potential. Thus, we pose the following research questions: (a) to what extent is DGS integrated into current secondary curricula, (b) how is DGS used in secondary curricula?

A nationally representative sample of 20 textbooks was chosen, the unit of analysis for coding each textbook being a mathematical task. Tasks were coded for whether or not they used technology, and what type (e.g., DGS, calculator). To answer the second research question, tasks were coded as using technology as amplifier or reorganizer (Pea, 1985), and whether the use of DGS involved one of three types of reasoning: exploration, justification, or verification (Oner, 2009). Technology is used as an *amplifier* if it is *only* used to perform computations with increased speed or precision, and is considered to be used as a *reorganizer* if the purpose of using technology is to support a shift in students' focus or thinking. *Exploration* involves observing relationships or patterns, *justification* involves providing reasoning for a conjecture, and *verification* involves testing a result; these codes are not mutually exclusive as a single task could ask students to do more than one.

A total of 1316 of 10,100 tasks were identified as making use technology, with 110 of those using DGS. Results indicate that 39 tasks used DGS as an amplifier, while 71 used DGS as a reorganizer. With regard to DGS use, 90 tasks included exploration, 22 included justification, and 48 included verification. Results will highlight associations (and implications) between these distinctions and whether the curriculum was (a) investigate vs. conventional, and (b) integrated vs. subject-specific.

CO-CONSTRUCTING STATEWIDE CURRICULUM FRAMEWORKS: PURPOSE AND PROCESSES

Michelle Stephan
UNC Charlotte

Catherine Schwartz
East Carolina University

Arren Duggan
UNC Greensboro

Keywords: Curriculum Guides, Design Experiments, Statewide Collaboration

Addressing problems of practice and implementation at scale is an issue that continues to challenge education researchers (Cobb & Jackson, 2011). As part of a statewide research-practice partnership, we are currently using a design implementation research (Fishman et al., 2013) approach to organize the collaborative design of a multifaceted intervention for new state mathematics standards and the promotion of more equitable classroom learning opportunities for teachers. We convened multiple education partners in an ongoing project to create a statewide curriculum framework to support the implementation of new state mathematics standards.

Considerable research suggests that pacing guides and the pressure to comply with them can undermine the professionalization of teaching (Bauml, 2015). Novice teachers fear reprimand from administrators if they do not strictly adhere to the sequence and timing of the guides.

Teachers may sacrifice cognitively demanding, real world tasks to "cover" the content in the guide (David & Greene, 2007). Some schools with pre-packaged instructional programs require teachers to teach the same lessons on the same day (Achinstein & Ogawa, 2006). Despite the negative consequences, Kauffman, Johnson, Kardos, Liu, & Peske (2002) found that curriculum guides can be a significant resource for new teachers who are still building their professional knowledge. Our research-practice partnership convened K-5 and 6-8 Framework Design Teams to create two statewide collaboratively-designed Instructional Frameworks that could be adapted by all districts to implement the new state mathematics standards.

In this poster presentation, we describe our purposes for creating K-5 and 6-8 statewide instructional frameworks (i.e., pacing guide and instructional resources) and how findings from research shaped our work in the Design Teams. We then describe the processes we used to ensure that all stakeholders were invited to design (e.g., teachers, administrators, higher educators, etc.), and enough resources were included so that all districts would be able to adapt the frameworks to their specific community. We also present preliminary findings from "framework rollout" meetings across the State that illuminate the ways in which instructional leaders anticipate challenges to plan professional development in their personal districts.

TRENDS IN CROSS-NATIONAL COMPARATIVE EDUCATIONAL RESEARCH

Hilary R. Tanck
Clemson University
htanck@g.clemson.edu

Keywords: Curriculum

The increase of worldwide social relations promoted by a global economy links the local to the distant in unprecedented ways. This interconnectedness plays a unique role in education highlighting common problems for education by providing opportunities for generalization and creating a system of lending and borrowing of educational ideas (Arnove, 2013). Contrasting different systems of education provides opportunities to illuminate factors that would otherwise go unnoticed (Cai, 2002). This research space has the potential to provide insights into successes and failures of educational policies to promote productive change. Mathematics education provides a unique space for cross-national comparisons. The purpose of this study is to uncover what is considered valued research in the realms of cross-national comparative educational research. This research was guided by the following research question: what are the trends in cross-national research in mathematics education top-tier journals in the last ten years?

Empirical research articles from five of the top peer reviewed journals ranked by Williams and Leathams (2017) were searched for studies focused on international comparisons: *Journal of Research in Mathematics Education, Educational Studies in Mathematics, Journal of Mathematical Behavior, Mathematical Thinking and Learning,* and *Journal of Mathematics Teacher Education*. To collect the articles, I did a keyword search for each journal using "cross-cultural comparison," "international comparison," and "cross-national comparison". I also set a range for publication between 2007 and 2017. Initially 39 articles matched the search criteria. After closer examination, 26 articles matched the criteria of empirical international comparisons. Examining the studies matching the criteria provided a picture of the current landscape in cross-national comparative education in mathematics education in the last 10 years. A spreadsheet was used to organize and analyze the data extracted from each article including mathematical/pedagogical topic discussed, databases or test used (e.g. PISA), and countries compared.

Initial findings indicate an under representation of articles that include a South American or African country in their study. While comparisons between the United States and China accounted for 30% of cross-national comparisons in top tier mathematics education journals. Additionally, seven of the 26 articles were textbook comparisons and fractions were the most common mathematical topic discussed.

GRADE 5 STUDENTS' NEGATIVE INTEGER MULTIPLICATION STRATEGIES

Camilla H. Carpenter
George Fox University
Ccarpenter15@georgefox.edu

Nicole M. Wessman-Enzinger
George Fox University
nenzinger@georgefox.edu

Twenty-four Grade 5 students participated in clinical interviews where they solved integer multiplication number sentences. Drawing on the theoretical perspective of strategies that students use with whole number multiplication and integer addition and subtraction, we describe the strategies that students employ when negative integers are incorporated with multiplication. The students, although drawing on similar strategies for whole number multiplication (e.g., repeated addition, direct modeling), used these strategies differently (e.g., using Unifix cubes to represent -1). The students also used unconventional strategies for solving integer multiplication, such as analogies and invented procedures. The results highlight the important constructions of students prior to formal instruction on integer multiplication, where prior research has been mainly situated in thinking about integer addition and subtraction.

Keywords: Number Concepts and Operations, Elementary School Education, Cognition

Investigations of strategies that students invent, and even struggle with, for integer multiplication number sentences, will provide teachers and researchers with insight into students' thinking about integers. With this understanding, we can begin to develop instructional strategies that support building on students' thinking about integer multiplication, a neglected topic in our field. In order to improve instructional approaches, we must first investigate students' constructions and reasoning.

Children invent sophisticated and robust ways of reasoning about integers and integer addition and subtraction (e.g., Bofferding, 2014; Bishop et al., 2014). As children approach addition and subtraction of integers for the first time, they use different strategies (Bofferding, 2010), ways of reasoning (e.g., Bishop et al., 2014; Bishop, Lamb, Philipp, Whitacre, & Schappelle, 2016), and conceptualizations (e.g., Aqazade, Bofferding, & Farmer, 2017; Bofferding & Wessman-Enzinger, 2017; Wessman-Enzinger, 2015). Although there has been an increased focus on children's reasoning about integers (e.g., Aquazade et al., 2017; Bofferding, Aqazade, & Farmer, 2017; Bishop et al., 2016), investigations into integer multiplication remain overlooked.

The goal of this research report is to present an inaugural framework of strategies students created as they engaged with integer multiplication number sentences for the first time. Our research question focuses on students' invented strategies for integer multiplication number sentences (e.g., $-2 \times 3 = \square$): What strategies do Grade 5 students use as they solve integer multiplication number sentences?

Theoretical Perspective

Because children often build on their whole number knowledge and extend this to integer reasoning (Bofferding, 2014), looking towards strategies that children employ with whole number multiplication may provide insight into how children may begin to reason about integer multiplication. Multiplication and division problems are often approached by children through a variety of invented strategies, such as repeated addition or direct modeling with grouping collections of countable objects (Carpenter, Fennema, Franke, Levi, & Empson, 2015).

Carpenter et al. (2015) and Baek (1998) demonstrate that children are able to understand multiplication when they can invent their own strategies. Some of the strategies for single-digit (Carpenter et al., 2015) and multi-digit (Baek, 1998) multiplication with whole number include: direct modeling strategies, counting strategies, repeated addition, and derived fact strategies. The extent to which students will use similar strategies with negative integer multiplication is an open question.

With *direct modeling*, students model groups using manipulatives (e.g., Unifix cubes) or drawings. When students use *counting* strategies they may skip count accounting for groups, sometimes using fingers or choral counting. Students draw on *repeated addition* or *doubling* (e.g., $4 \times 3 = 3 + 3 + 3 + 3$). *Derived facts* strategies include drawing on factual knowledge and creating a new algorithm based on previously known facts (e.g., 2×3 may be solved by know that $2 \times 2 = 4$ and then 2 more added to that product is 6).

From the integer addition and subtraction literature, we know that students use a variety of strategies different from the CGI frameworks. These include using *computations* or *procedures* (Bishop et al., 2014), drawing on *recalled facts* (Bofferding & Wessman-Enzinger, in press), and making *comparisons* or *analogies* (Bishop et al., 2016; Bofferding, 2011; Wessman-Enzinger, 2017; Whitacre et al., 2017).

As we began our study, we drew on both single-digit and double-digit strategies for multiplication with whole numbers and strategies for integer addition and subtraction. We thought these strategies would provide insight into the ways that students may solve multiplication problems involving negative integers.

Methods: Participants, Interviews, and Analysis

We conducted clinical interviews (Clement, 2000) with 24 Grade 5 students from the rural Pacific Northwest. We selected Grade 5 students that did not have formal school experiences with integers; *Common Core State Standards* recommendations include integer operations in Grade 7 (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010). We interviewed each student once, using the following integer multiplication number sentences (see Figure 1). Students solved the integer multiplication number sentences, with each number sentence provided on a singular piece of paper. Manipulatives and tools provided during this interview included: Unifix cubes, two-colored chips, empty number lines, and markers. We asked prompting questions throughout the interviews, without giving the students the answer or additional information. These types of questions included: “How did you come up with that?”; “Can you explain your thinking?”

$$3 \times 5 = \square$$

$$-2 \times 3 = \square$$

$$3 \times -4 = \square$$

$$-4 \times -2 = \square$$

Figure 1. Integer multiplication number sentences provided to students.

We videotaped and transcribed each interview. Our unit of data included the video clip, drawings, and transcripts associated with each integer multiplication number sentence. We began coding with the framework delineated in the analytical framework (Baek, 1998; Carpenter et al., 2015). For instance, we looked for the use of manipulatives and drawings for direct modeling strategies. We looked for choral counting, skip counting, and use of fingers for counting strategies. Using the definitions established for these various strategies, we employed constant comparative methods (Merriam, 1998). We modified the strategies to include the ways that students used negative integers, not previously captured with only positive integer multiplication strategies or integer addition and subtraction strategies. We met to compare codes and negotiated any disagreements. In the results section, we highlight the integer multiplication strategies that the students in our study used.

Results: Strategies for Integer Multiplication

We highlight the descriptions of the strategies, rather than focusing on correctness or incorrectness. Because the students have powerful strategies paired with some correctness, this is provides a space to understand children's thinking as a vehicle for leveraging discourse in the classroom in the future.

Direct Modeling

Example of direct modeling. Edie solved -2 × 3 = □, using a direct modeling strategy, that resulted in a solution of -6 (see Figure 2). Edie assigned the value of -1 to each Unifix cube. She constructed three groups of two blocks (see white blocks in Figure 2). Because she attributed the value of -1 to each of the white Unifix cubes, she modeled -2 × 3 = □, instead of 2 × 3 = □.

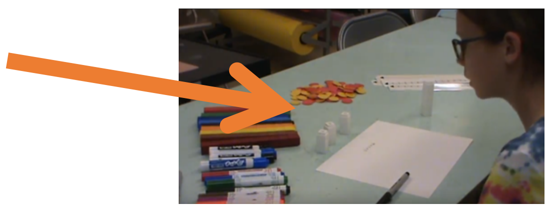

Figure 2. Example of direct modeling strategy for -2 × 3 = □.

The following transcript excerpt illustrates how Edie shared her strategy:

> (Reaches for Unifix cubes) I'm going to pretend this is negative… okay this is negative 2 (pulls off 2 white Unifix cubes) negative plus a negative would be a negative… so if these are negatives then that would 3 times the 2 negatives which would equal 6 negative (writes "-6" on paper).

Description of direct modeling. Students used a direct modeling strategy when they illustrated integer multiplication with physical tools (e.g., Unifix cubes, two-colored chips, pictures)—modeling (number of groups) × (number of things in each group) = total. The students who used direct modeling strategies determined the solutions to integer multiplication through physically manipulating and modeling with these objects.

The students used two-colored chips (one yellow side, one red side) to be a physical representation of the difference between a negative number and a positive number. Notably, the students flexibly used the colors. Sometimes, red chips represented negative integers and yellow chips represented positive integers; other times, red chips represented positive integers and yellow negative integers.

Using Unifix cubes, the students used the cubes to model multiplication as groups of the same amount of quantities. The students who used the cubes mapped values of -1 to each of the cubes. The cubes represented a way to account for groups of negative quantities and provided a physical way to add the groups together in order to determine their solutions.

Use of direct modeling. The students used direct modeling strategies seven times for 3 × 5 = ☐. For the number sentences with negative integers, the students used direct modeling strategies five times for -2 × 3 = ☐ and four times for 3 × -4 = ☐. Direct modeling was used only once for -4 × -2 = ☐, which is not surprising given the physical limitations of negative amounts of groups.

Repeated Addition and Subtraction

Example of repeated addition. Eliza solved 3 × -4 = ◻ using repeated addition (see Figure 3) and obtained the solution, -12. Eliza demonstrated repeated addition as she repeatedly added -3 four times in order to get her product of -12. Notably, she added -3 four times, instead of adding -4 three times; her strategy actually aligns to 4 × -3 = ◻ instead of 3 × -4 = ◻. Essentially, Eliza implicitly recognized the equality of 4 × -3 and 3 × -4, without commenting on it. In Figure 3, the black writing illustrates her final computed product. However, the red writing illustrates her repeated addition, which she wrote first.

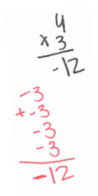

Figure 3. Example of repeated addition strategy.

Description of repeated addition and subtraction. Repeated addition, as a strategy, describes multiplication with adding positive integers repeatedly (Baek, 1998; Carpenter et al., 2015). The students in our study drew on repeated addition with negative integers. However, they also used *repeated subtraction* of positive integers.

Use of repeated addition and subtraction. The students used repeated addition strategies ten times for 3 × 5 = ☐. For the number sentences with negative integers, the students used repeated addition and subtraction four times for -2 × 3 = ☐ and three times for 3 × -4 = ☐. A student used repeated addition and subtraction only once for -4 × -2 = ☐, which is also not surprising given the challenges of adding -4 “negative two” times.

Recalled Fact

Example of recalled fact. Zoe first solved -2 × 3 = ◻ and obtained -6 as a recalled fact, even though it was her first time engaging with integer multiplication. She quickly stated the answer, -6, before the interviewers even completely finished reading the multiplication number sentence, -2 × 3 = ◻. Zoe relied on her factual knowledge of the product of 2 × 3 = 6, when questioned. With probing she justified her solution with a procedure “you just do 2 times 3 and then you make it a negative,” which will be discussed later.

Description of recalled fact. Within the CGI strategy framework, students often draw on facts to make derived facts (e.g., Carpenter et al., 2015). In our study with integer multiplication, students did not seem to use derived facts, but did use their factual knowledge about whole number multiplication quickly for integer multiplication without verbal explanation. Students used recalled facts when they stated their solutions to integer multiplication as a fact, likely memorized from whole numbers. Or, they drew on their memory so much that it did not require any form of deliberation. Students stated their solution quickly with an often “just is” explanation.

Use of recalled fact. The students used recalled fact four times for -2 × 3 = □, six times for 3 × -4 = □, and five times for -4 × -2 = □. The students demonstrated confidence with single digit whole number multiplication (e.g., fifteen stated the answer of 3 × 5 = □ as a recalled fact).

Procedure

Example of procedure. Lia solved 3 × -2 = □ with a solution of 4, using a procedure as a strategy. In this example, Lia solved the integer multiplication sentence by using a "negative integer as a singular subtrahend" procedure (see Figure 4). She first computed 3 × 2 by solving 3 + 3. Then, Lia incorporated the singular integer in the number sentence, -2, by subtracting 2 from the product of 3 × 2. This procedure is one of various types used in this study by the students.

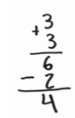

Figure 4. Example of procedure strategy.

Description of procedure. When students used an algorithm or created an invented procedure to find the solution they used the procedure strategy. Although this represents an addition to existing CGI framework for multiplication strategies (e.g., Baek, 1998), many integer researchers have stated that students use computational reasoning (Bishop et al., 2016) or procedures (Wessman-Enzinger, 2015; Bofferding & Wessman-Enzinger, in press) as they solve integer addition and subtraction problems. Thus, it seems to be a natural extension that students would also use computational and procedural strategies with integer multiplication.

The students in this study used different types of procedures (e.g., appending a negative sign to the solution, negative numbers as equivalent to zero, exclusive negativity). Describing the extensive use of procedures is beyond the realm of this research report. But, Zoe used the "appending a negative sign" procedure in her justification of derived fact strategy -2 × 3 = -6 when she stated that the negative sign is just "added on." Other students said that number sentences, such as -4 × -2 = □, needed to be "all negative," concluding that -4 × -2 = -8 based on a procedure of "exclusive negativity."

Use of procedure. Students used or invented various procedures for dealing with integer multiplication throughout the study (e.g., eleven times for -2 × 3 = ☐, sixteen times for 3 × -4 = ☐, and fifteen times for -4 × -2 = ☐). The students did not use a procedure for 3 × 5 = ☐ and used procedures only for multiplication number sentences with negative integers (e.g., -2 × 3 = ☐).

Counting

Example of counting. Cittie used counting on a number line to solve -2 × 3 = □, obtaining a solution of 7. Figure 5 illustrates Cittie's number line. She reasoned that she could start at -2 and counted in sequential order on the number line, moving right, to her destination, 7; she skip counted by 3, three times. Although this does not represent a correct solution, Cittie ordered the negative and positive numbers correctly and started her counting at -2, which represents beginning, ordered integer reasoning necessary for integer multiplication.

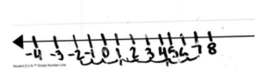

Figure 5. Example of counting strategy.

Description of counting. Students, sometimes with the help of a number line, counted in sequential order when solving multiplication number sentences. Students often described their strategies as "skip counting." The students sometimes drew on the number line, as a tool for facilitating their skip counting. In addition to number lines, students also used fingers and even cubes as number paths (Bofferding, 2010). Challenges with negative integer multiplication for students included deciding which direction to count in, as directions are not fixed like they are with whole number numbers, and determining the quantities of the skip counts (see, e.g., Cittie counting amounts of 3 three times).

Use of counting. The students used counting strategies three times for $3 \times 5 = \square$, four times for $-2 \times 3 = \square$, three times for $3 \times -4 = \square$, and eight times for $-4 \times -2 = \square$. When the students used counting strategies with integer multiplication, they sometimes did so with a number line. It is likely that students used counting strategies the most for $-4 \times -2 = \square$ because of challenges in physically representing this number sentence with strategies like direct modeling.

Analogy

Example of analogy. Jaxon first solved $-2 \times -4 = \square$, with analogy, determining that $-2 \times -4 = -8$. The following transcript highlights Jaxon's reasoning:

> Well, because it wouldn't really make as much sense for a negative multiplied by a negative to equal a positive. It's like, um, I'm not sure how to … it just wouldn't make as much sense. Because if a positive multiplied by a positive would equal a positive, then I would assume that it would be the same for a negative. And, it would be a negative times a negative would equal a negative.

In this excerpt, Jaxon compared $-2 \times -4 = \square$ to $2 \times 4 = \square$. Reasonably, he concluded that because a positive number times a positive number is positive (e.g., $2 \times 4 = 8$), then a negative number times a negative number is another negative number (e.g., $-2 \times -4 = -8$). Again, like the previous example where we highlighted a strategy with an incorrect solution, there is still powerful reasoning embedded in Jaxon's strategy. Jaxon connected his reasoning about whole numbers in a logical way (albeit not a culturally/mathematically correct way).

Description of analogy. Students used analogy when they connected previous knowledge about whole numbers to integers and compared it to a whole number multiplication number sentence for constructing or justifying new claims when solving the integer multiplication number sentences. Although this is an addition to the CGI framework for multiplication strategies, there is evidence that students use analogies with integer addition and subtraction (Bishop et al., 2016; Bofferding, 2011; Wessman-Enzinger, 2017; Whitacre et al., 2017). We distinguish this from recalled facts or procedures in that the students made explicit comparisons, with reasoning focused on these comparisons.

Use of analogy. The students did not use an analogy strategy for $3 \times 5 = \square$, $-2 \times 3 = \square$, or $3 \times -4 = \square$. But, students used analogy twice for $-4 \times -2 = \square$. Although not used often in this study, students use analogies frequently with integer addition and subtraction (e.g., Whitacre et al., 2017). We conjecture that if we gave more "negative number multiplied by negative number" number sentences we would have seen analogy strategies employed more—analogies seem like potentially productive strategies for these types of integer multiplication number sentences.

Counter Movement

Example of counter movement. Warren solved $-2 \times -4 = \square$, determining a solution of 8. The following transcript excerpt highlights Warren's solution of 8.

> Um. So. I… this subtraction, this negative symbol. Scratch out this one and this one … counters this one too. So it takes both these out and then it's just 4 times 2. … I just thought that since they're both negative numbers and that one's whole, it's basically, kinda like dividing except you're multiplying. And… you just kinda just… I just thought that you counter them. … It's kind of like dividing because instead of making this uh… -8, you just make it normal 8, which means that the number … if these numbers were whole numbers … well no since their negative numbers… if like cause they're not equal to ... they're not equal to 0 they're this way (left of 0) and the whole numbers are this way (right of 0) it's kind of like since these numbers were divided …these ones were dividing they would get smaller or go the opposite way. Like if these ones they would go this way.

At first, Warren's strategy sounds procedural because he talks about "scratching" out symbols, referencing the negative symbols in front of -2 and -4. Then, Warren references a "countering" of movements in the negative and positive direction (e.g., -1 × -1 = 1 or -1 $\boxed{v?}$ -1 = 1), making -8 "a normal 8." He discusses how we can treat this multiplication problem as "whole numbers" since multiplying the negative integers "counter" the directions of each other. Multiplying by -1 moves a number "this way (left of 0)" and multiplying it by -1 changes the direction.

Description of counter movement. Students use the counter movement strategy when they employ continuous movement or motion that "counters" each other. Use of this strategy includes a reference to changing directions, where the movement is countered or balanced. Consider this equation: -2 × -4 = (-1 × 2) × (-1 × 4) = (-1 × -1) × (2 × 4). Multiplying by negative one refers to a movement or translation in one direction and multiplying by the other negative one is a movement or translation in the other direction—consequently *countering* the overall movement.

Use of counter movement. Of the twenty-four students we interviewed, only one student constructed this strategy. Although this may not warrant the creation of a new category, the strategy uniquely helped Warren construct a correct solution to -2 × -4 = □, a notoriously challenging problem type. Honoring the student's use of the word "counter" and the use of continuous movement for constructing meaning, we called this strategy "counter movement."

Discussion and Final Remarks

The results of this work are significant in that we provide an inaugural framework for integer multiplication strategies that students use prior to school instruction, modified from CGI multiplication strategies frameworks and integer addition and subtraction literature. Previous research has focused on thinking and strategies of integer addition and subtraction (e.g., Bofferding, 2010; Bishop et al., 2014) and we extend the scholarly discussion on students' thinking about integers by describing their invented strategies for integer multiplication.

Our focus is on the powerful ways that students, prior to formal school instruction, solved integer multiplication number sentences, whether correct or incorrect. If we wish to support student inventions and discourse in the mathematics classroom, we must first understand their sophisticated reasoning (Carpenter et al., 2015). Jaxon, for example, obtained -2 × -4 = -8. Although we know this to be an incorrect solution, it is rooted in a logical analogy (e.g., if 2 × 4 = 8, then -2 × -4 = -8). As teachers and researchers, how do we promote conceptual change when students invent strategies that are logical, but not mathematically correct? We might consider pairing number sentences like 2 × -4 = □, where students had success in correct answers, with number sentences like -2 × -4 = □, where students had more difficulty, to leverage growth or change in the students' sophisticated reasoning (Bofferding et al., 2017).

Empowering students in the classroom requires building on their thinking. Consequently, we must first learn about the ways students enter the mathematics classrooms and the invented strategies they construct; then, we can draw on their reasoning to build future instructional interventions.

Middle school is a critical time when students begin formal study of functional relationships in algebra. However, many students struggle in understanding functions as relationships between quantities that change according to a dependency relationship. We report on the influence of Scaling Continuous Covariation in fostering productive ideas about graphical relationships and rates of change. Scaling Continuous Covariation entails the ability to imagine a re-scaling to any increment for x and coordinate that scaling with associated values for y. We present findings from two students, one who reasoned with Scaling Continuous Covariation and one who did not, and report on how Scaling Continuous Covariation supported students' reasoning in three ways: (a) sense making about graphs, (b) forming constant rates of change, and (c) understanding constantly-changing rates of change.

Keywords: Algebra and Algebraic Thinking, Cognition, Middle School Education

Introduction: Supporting Function Understanding in Middle School

Functions and relations comprise a critical aspect of secondary mathematics, with recommendations for supporting students' algebraic reasoning emphasizing an early introduction to functional relationships in late elementary and middle school (Stephens, Ellis, Blanton, & Brizuela, 2017). Middle school in particular represents a key time when students enter a formal investigation of function and begin to develop the algebraic tools to express and represent different functional relationships. However, students' difficulty in acquiring the function concept is well documented (e.g., Stephens et al., 2017; Thompson & Carlson, 2017). In particular, students struggle to use functions to model real-world contexts that require a conceptualization of quantities and how they change together (Carlson et al., 2002; Monk & Nemirovsky, 1994).

One potentially fruitful approach to better support students' understanding of function and rates of change is an instructional emphasis on variational and covariational reasoning (Carlson, Smith, & Peterson, 2003; Kaput, 1994; Thompson & Carlson, 2017). Early research suggests that providing students with opportunities to reason covariationally can position them to make meaningful sense of functions (e.g., Ellis, 2007, 2011; Johnson, 2012; Moore, 2014), as well as the ideas in calculus (Thompson & Carlson, 2017). We report on a study investigating the reasoning of two middle school students who explored linear and quadratic growth within the context of continuously co-varying quantities. We found that a particular form of covariational reasoning, scaling continuous covariation, supported a robust understanding of graphical relationships and rates of change.

Background and Theoretical Framework

One contribution to the challenges in building and supporting a robust understanding of function is the lack of attention to variation in algebra curricula. Thompson and Carlson (2017) reviewed seventeen U.S. secondary textbooks, ranging from Algebra I through Precalculus, and found that all relied on a correspondence definition of function. Under this definition, y is a function of x if each value of x has a unique value of y associated with it (Farenga & Ness, 2005). This static view underlies much of school mathematics, with the associated set theoretic meaning of variable becoming the foundation for school definitions of function (Cooney & Wilson, 1996). Students' function concepts are consequently dominated by static images of arithmetic computations used to evaluate outcomes at individual values (Carlson & Moore, 2015). This results in students viewing functions through the lens of symbolic manipulations rather than as a mapping (Carlson, 1998).

Integrating the mathematics of change into students' investigation of functional relationships provides opportunities to interpret how a function's output values can change in relation to its input values, which is an essential component of making sense of dynamic situations (Carlson & Moore, 2015). These opportunities are typically reserved for introductory calculus courses, thus effectively restricting access to these forms of reasoning to the minority of students who will reach the highest level of high-school mathematics (Roschelle, Kaput, & Stroup, 2000). Thinking about functions covariationally, however, can support students' abilities to make sense of linear (Ellis, 2007; Johnson, 2012), quadratic (Ellis, 2011), exponential (Ellis et al., 2015), and trigonometric (Moore, 2014) functions.

Covariational Reasoning

Researchers have addressed covariational reasoning in a number of ways, but for the purposes of this paper we draw on work that considers the possible imagistic foundations that can support students' abilities to think covariationally (e.g., Castillo-Garsow, Johnson, & Moore, 2013; Thompson & Carlson, 2017). These researchers describe covariational thinking as the act of holding in mind a sustained image of two quantities' values varying simultaneously. One can imagine how one quantity's value changes while imagining changes in the other. A person thinking covariationally can couple two quantities in order to form a multiplicative object (Thompson & Carlson, 2017); once such an object is formed, one can then track either quantity's value with the immediate understanding that the other quantity also has a value at every moment.

Castillo-Garsow (2013) distinguished between two types of continuous variation, chunky and smooth. Chunky continuous variation entails thinking about values varying discretely, except that one has a tacit image of a continuum between successive values. One imagines that a change in values occurs in completed chunks, without imagining that variation occurs within the chunk. In contrast, smooth continuous variation entails an image of a quantity changing in the present tense; one can map from one's own experiential time to a time period within the mathematical context, thinking about a value varying as its magnitude increases in bits while simultaneously anticipating smooth variation within each bit (Thompson & Carlson, 2017). Building on these distinctions, Thompson and Carlson (2017) created a covariational reasoning framework that attends to students' images of quantities' values varying. They stressed that smooth continuous variational and covariational reasoning necessarily involves thinking about motion.

Ely and Ellis (in press) subsequently introduced a related but distinct form of reasoning they call *scaling continuous covariation*, which entails imagining that at any scale, the continuum is still a continuum and a variable takes on all values on the continuum. One can conceive of the continuum as arbitrarily or even infinitely "zoomable", in which the process of zooming will never reveal any holes or atoms. Thus, one can imagine a re-scale to any arbitrarily small increment for x and coordinate that scaling with associated values for y. Importantly, unlike smooth continuous covariation, this way of thinking does not fundamentally rely on an image of motion.

Just like chunky continuous covariation, scaling continuous covariation relies on partitioning a domain and then reasoning about the corresponding chunks of the covarying quantity. A chunky reasoner can re-chunk the domain to a different sized chunk, but then must re-run his or her chunking scheme from scratch. A person using scaling continuous reasoning, on the other hand, can abstract the chunking process and imagine the result of this chunking scheme for chunks at all scales. This enables one to generalize properties of the covarying quantity's chunks at all of these scales as well, enabling him or her to coordinate the covariation of the two quantities on increments of any scale. With this in mind, we can distinguish between students' use of chunky continuous and scaling continuous covariation and study how these reasoning types support their understanding of rates of change.

Methods

We conducted a 10-day, 15-hour videotaped teaching experiment (Steffe & Thompson, 2000) with two 7th-grade students in general general mathematics (neither had yet taken algebra). The first author was the teacher-researcher. We assigned gender-preserving pseudonyms to each student. The aim of the teaching experiment was to support the students' emerging understanding of linear, piece-wise linear, quadratic, and higher-order polynomial functions from a rate-of-change perspective.

Building on the literature emphasizing the importance of continuously-covarying quantities, we developed tasks to support a conception of linear growth as a representation of a constant rate of change, and quadratic growth as a representation of a constantly-changing rate of change. The tasks emphasized these ideas within the contexts of speed and area. The area tasks presented "growing rectangles", "growing stair steps", and "growing triangles" via dynamic geometry software, in which the students could manipulate the figure by extending the length and observing the associated growth in area (Figure 1).

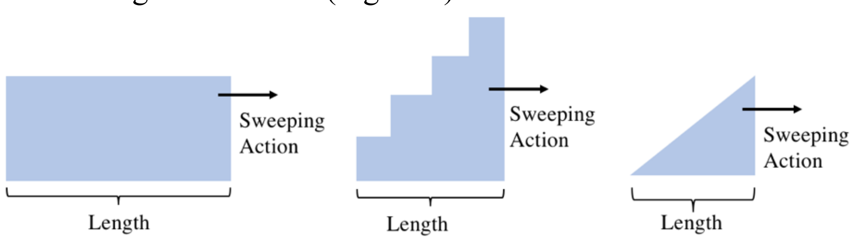

Figure 1. Growing rectangle, stair step, and triangle tasks.

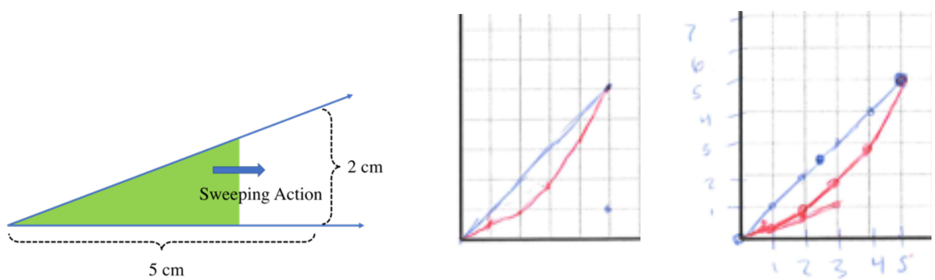
Relying on the videos and transcripts of each teaching session and copies of the students' work, we used the constant-comparative method (Strauss & Corbin, 1990) to analyze the teaching-experiment data in order to identify (a) students' forms of covariational reasoning, and (b) the students' conceptions of constant and changing rates of change. For the first round of analysis we drew on Thompson and Carlson's (2017) framework of variational and covariational reasoning. We used open coding to infer categories reasoning based on students' talk, drawings and graphs, gestures, and task responses. The first round led to an initial set of codes, which then guided subsequent rounds of analysis in which the project team met regularly to refine and adjust the codes in relation to one another. This iterative process continued until no new codes emerged. The final round of analysis was descriptive and supported the development of an emergent set of relationships between students' covariational reasoning and their conceptions of constant, changing, and instantaneous rates of change.

Results

One student, Wesley, exhibited evidence of scaling continuous covariation, while the other student, Olivia, exhibited evidence of chunky continuous covariation. We report three ways in which the form of covariational reasoning influenced students' sense-making about functional relationships: (a) reasoning about graphs, (b) constant rates of change, and (c) constantly changing rates of change. We address each in turn.

Reasoning about Graphs

Wesley and Olivia interpreted and discussed their graphs of quadratic phenomena differently. Wesley conceived of his graphs as smooth continuous curves that, for any given increment, regardless of its size, did not reduce to a straight line within the increment. In contrast, Olivia conceived of curved graphs as being composed of line segments. For instance, the students graphed the relationship between the total accumulated area and the length swept for a shaded cm by 5 cm triangle in which the area and the length swept out together (Figure 2).



(a) (b) (c)

Figure 2. Wesley (b) and Olivia's (c) graphs for the growing triangle (a).

Both students plotted five points in order to draw their graphs, and also drew the "average journey" graph that would be represented by a rectangle sweeping out the same total area for a length of 5 cm. The teacher-researcher (TR) asked the students whether their triangle graphs were curved everywhere, or whether they were piecewise linear. Wesley's response was that the graph was curved everywhere, explaining, "I think in between these points [indicates two points on his graph], if you added a bunch of little points in between, it would make a curve." Wesley understood that the total accumulated area increased with respect to each additional centimeter swept, but he also understood that this relationship would hold even for a smaller increment. He did not need an increment to be any particular size, such as 1 cm, in order to claim that the graph would be curved in between any two points; he already had an image of growth occurring with each increment, no matter how small. In contrast, Olivia could imagine re-sizing an increment, but within each increment, the graph would be a straight line:

> I think, because, if you made the increments even smaller like into 0.1 as your first point then I think it'd be, all the little lines together, I think they'd make a very subtle curve but relatively straight. So, when I did it with the increments as 1, I see them as straight, but if they were smaller they might *look* as if they were curved to make one big curve.

In order to better probe the students' thinking, the teacher-researcher asked the students to consider what the graph would look like if a perfectly precise robot could construct the graph with almost imperceptibly tiny increments:

TR: Would it be curved in between the points or straight in between the points?
Wesley: I believe it would be curved.

TR: What do you [Olivia] think?

Olivia: I think [long pause]. Well I mean, I think it'd be small enough to the point because the way I think of curves is a whole bunch of straight lines together to make a curve. So, I think if it was to the smallest possible thing even if it could go to infinity, but if it had to be down to the smallest possible things I think it'd be straight lines.

Olivia's remarks suggest that she still saw the graph as composed of straight segments for infinitesimal increments. She could explain the change in area with respect to each additional centimeter, but she viewed the rate of change in area with respect to length swept within a given increment to be constant. This imagery is consistent with chunky continuous covariation, in which one does not imagine change within a given increment. Wesley, however, remained consistent in his belief that such a graph would be everywhere curved, and provided supporting remarks such as: "There's tiny points *in between* those tiny points", "It goes on infinitely, kind of, the points", and "In between those, there's still more points, and it goes on forever."

Wesley appealed to a scaling image in his explanations. He described zooming to smaller and smaller scales, a process that could go on forever and never ground out at an atomic level. In this iterative process, he treated each re-scaled increment as being similar to the bigger increments. This image of scaling continuous *variation* supported his scaling continuous *covariation*, because he generalized across scales a property he noticed about the covariation of area and length: Namely, because the area grows at a changing rate over a large increment, it must also grow at a changing rate over increments at each smaller scale, and thus be curved everywhere. This generalization could extend to an infinitesimal scale just as his image of scaling continuous variation appeared to.

Constant Rates of Change

Wesley and Olivia could both discuss length and area growing together. However, their conceptions of the ratio of area to length differed. Olivia conceived of this relationship as a static ratio, whereas for Wesley, it was a rate of change. For instance, at one point the students investigated the way the area changed as a rectangle with a constant height of 4 cm grew in length (Figure 1). Both students produced a number of equivalent ratios to represent the rate at which the area accumulated relative to length. Olivia could not produce a ratio for a length less than 1 cm, whereas Wesley generated equivalent ratios such as 2 cm^2:0.5 cm, 0.4 cm^2:0.1 cm, and $4x cm^2$:x cm. Wesley explicitly referenced both quantities, but Olivia's descriptions appealed to an image of breaking the area into parts. We believe that Wesley's ratio of 4 cm^2 for 1 cm of length represented a rate. Thompson and Thompson (1992) described a rate as a reflectively abstracted constant ratio. A ratio is a multiplicative comparison of two taken-as-unchanging quantities, whereas a rate is a conception of a constant ratio variation as being a single quantity. It symbolizes the ratio structure as a whole while giving prominence to the constancy of the result of the multiplicative comparison. In order to understand the ratio as a rate, Wesley needed to have an image of change such that 4 cm^2:1 cm represented an equivalence class. Thus, he would need to understand that the unit ratio was simply a convenient measure of expressing the growth in area for a standard unit of length, and was just one of infinitely many equivalent ratios. A scaling continuous covariation image could enable this understanding, as Wesley would be able to mentally zoom in and out for different length increments, generalizing that any arbitrarily-sized increment of length would imply an associated amount of area adhering to the 4:1 ratio.

Both students also produced drawings of a 4 cm-high rectangle, but only Wesley believed that the shape of the rectangle would not change if the provided rate of 4 cm^2:1 cm were represented as 8 cm^2:2 cm. In justifying his belief, Wesley explained, "The height doesn't – like, it's not a different shape, it's the same. So, it [the rectangle] would be the same, I think." Wesley recognized that all of the ratios were instantiated in the same rectangle *height*; he appeared to understand the height as a representation of the rate of change of area, which does not depend on an amount swept. In contrast, Olivia could only justify the sameness of the picture for any equivalent ratio by converting the new ratio to the original 4 cm^2:1 cm ratio and comparing.

Constantly Changing Rates of Change

The students were also asked a series of questions about situations in which area was constantly changing, such as when the growing area was bounded by a line slanting upward at 45º-angle, or a slope of 1 (Figure 1). Wesley expressed his answer using the quantities length and area: "Every time you increase by 1 in. in length, the area for that will grow by [an additional] 1 in^2." Wesley's care in expressing the change in the growth in area for a specific length increase is additional evidence that he understood the unit ratio as a convenient representation of the constantly-increasing rate that depended on a particular increment. In contrast, Olivia had to draw pictures to visually determine the amount of increase from one increment to the next (Figure 3). She came to the same conclusion, but conceived of the 1-inch increments as "columns". When asked whether the size of the length increment mattered in terms of determining that the rate of change was constantly increasing, Olivia was uncertain and had to check with a new column size of 2 cm. She found that the new constantly-increasing rate was 4 cm^2:2cm for each of the columns. Wesley knew without having to check that the rate of the rate of change would remain invariant for any given increment, even though that value was dependent on the increment size. Scaling-continuous reasoning enabled him to generalize this observed property across all possible scales.

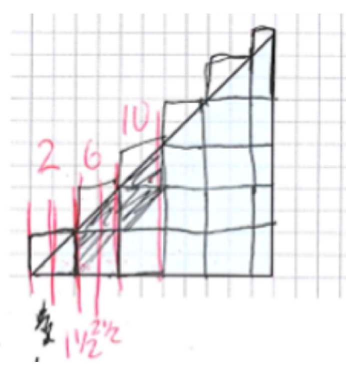


Figure 3. Olivia's drawing to find the amount of area accumulated for each 1-cm increment.

In a second example, when investigating the constantly-increasing rate of change of the area for a 3 cm:2 cm triangle, Olivia again relied on a visual strategy, explaining, "I counted it out." Wesley did not have to draw increments or make any calculations. He instead wrote "1.5", and then explained, "It [the rate of change] increased by the slope." Olivia's drawing, partitioning, and counting strategy was sensible given her image of growth across completed chunks. It enabled her to make calculations for each column and then compare the increases from one column to the next. Wesley's reliance on the slope of the triangle indicates a different conceptual foundation. He could conceive of the slope as a convenient way to express a unit ratio while also understanding that it was dependent on a particular chosen increment of 1 cm. For Wesley, the slope was a multiplicative object (Thompson & Carlson, 2017), which was produced by mentally uniting accumulated area and accumulated length simultaneously. Scaling continuous covariation could potentially support the development of such a multiplicative object because an image of re-scaling the continuum to any increment for x, including infinitesimal increments, while simultaneously coordinating that scaling with associated values for y provides a set of operations conducive to creating a new conceptual object "that is, simultaneously, one *and* the other" (Thompson & Carlson, 2017, p. 433, emphasis original). Scaling-continuous covariation enables the generalization of the ratio over any elapsed increment.

Discussion

Our findings indicate that scaling continuous covariational reasoning has the potential to support a meaningful understanding of constant and constantly-changing rates of change. In particular, it affords productive generalization of covariational properties across arbitrarily small, even infinitesimal, scales. Thompson and Carlson (2017) noted that the idea of a non-constant rate of change "is actually constituted by thinking of the function having constant rates of change over small (infinitesimal) intervals of its argument, but different constant rates of change over different infinitesimal intervals of the argument" (p. 452). As evidenced by Wesley's language, this image is compatible with scaling continuous covariation, in which one can imagine zooming to any scale, even an infinitesimal one, to visualize a tiny interval over which the function's rate of change is constant. Wesley recognized that the changes in the changes of area under a sloping line were uniform no matter the scale, which is precisely the constant second-differences characteristic that is unique to quadratic growth. Because he could imagine this at arbitrarily small scales, he could also connect this idea to the curvature of the area graphs he made.

In addition, scaling continuous covariational reasoning has the potential to support an image of instantaneous rate of change and other foundational ideas in calculus. A student who reasons with chunky continuous covariation may struggle to think about a rate of change that is not dependent on an elapsed amount of swept length. This was the case for Olivia, who needed to imagine a completed increment and an associated amount of area in order to create comparisons across same-size increments (Ely & Ellis, 2018). Wesley, however, was able to construct the height of a figure at any given instant as a multiplicative object representing the rate of change of the area compared to the length swept. This enabled him to conceive of the height as a potentiality; once it would sweep out, it would turn the potential rate into an amount of area depending on how much length has been swept. Alternatively, one could imagine the rate of change at a point to be an average rate of change over an infinitesimal interval, which offers a natural motivation for the limit definition of the derivative.

The case of Olivia and Wesley offers evidence that middle school students can develop powerful ideas about constant and changing rates, and that scaling continuous covariation could potentially offer a foundation for building sophisticated ideas about instantaneous rates of change. Situating students' exploration of functional relationships within contexts that foster images of covariation and address ideas of infinitesimal increments is critical for providing this foundation. Given the potential of scaling continuous covariation for supporting important ideas about function, we advocate for additional research to better understand the nature of this form of reasoning and its affordances for algebraic thinking.

RELATIONSHIPS BETWEEN UNITS COORDINATION AND SUBITIZING

Beth L. MacDonald
Utah State University
beth.macdonald@usu.edu

This proposal explores relationships between young children's unit development/coordination and young children's subitizing. In particular, this theoretical commentary considers students' degrees of abstraction, students' development of actions on units, and students' operations with units when subitizing. As a result of this commentary, this author offers questions regarding how subitizing may elicit actions on units and perceptual/figurative material in a different order. These questions indicate possible alternative means in which comprehensive operations with natural numbers may develop. Possible educational implications and future research around these questions are also discussed.

Keywords: Early Childhood Education, Number Concepts and Operations

Steffe's (2017) plenary for PME-NA outlined comprehensive means in which radical constructivist learning theory has explained children's construction of mathematical concepts that have children's construction and coordination of units as a foundation. Steffe also explained that on average about 40% of first graders do not yet use figurative material to stand in for perceptual material when counting and unitizing. By third grade, this figure remains at about 5-8% of students. This finding suggests differences in children's number abstractions in early elementary grade levels that may also indicate distinct differences in their unitizing activity later. This theoretical commentary explores how young children's unitizing may relate to *subitizing* activity (individuals' quick apprehension towards the numerosity of a small set of items), which may explain differences in children's number abstractions in early grade levels.

Freeman (1912) first proposed that subitizing requires an individual's attention towards units of units when encoding number. MacDonald and Wilkins (under review) found that one child's subitizing activity may relate to her composite unit development. However, these findings are still exploratory and provide more questions than answers. In particular, if young children are developing units and/or acting on these units through their subitizing activity, how might this affect the development of their actions and operations? For instance, Steffe and Cobb (1988) found that young children develop a singular unit through their counting activity, which they iterate before engaging with partitioning. However, subitizing activity requires students partition patterned sets of items to associate with number before they iterate singular units.

If children order their actions on material differently, how might this affect their ability to coordinate actions and form operations? If both counting and subitizing promote children's coordination of actions earlier, which promotes early operation development, how would this affect children's number development? Therefore, when considering subitizing activity in relation to students' composite unit development, there seems to be new perspectives when investigating learning trajectories in number. Through this theoretical commentary, I will discuss how actions and operations may develop differently when young children subitize versus count. Resulting from this commentary are future research directions and educational implications.

The purpose of this commentary is to consider alternative learning trajectories that take on theoretical aspects in the Neo-Piagetian literature and may explain how subitizing relates to young children's development and their coordination of units. To discuss the intersect between subitizing and children's development of units, I will (a) provide a theoretical framework, (b) define unit construction, (c) describe how subitizing activity may relate to unit construction, and (d) propose future research that should consider how the two types of activity may relate.

Theoretical Framework

This theoretical commentary is grounded in the radical constructivist paradigm and more specifically, a Neo-Piagetian perspective. Essentially, in adopting a radical constructivist paradigm, I acknowledge that children learn through active engagement and reflection of their perceived reality. By adopting this paradigm, I also acknowledge that each individual constructs a unique mathematical reality that can be partially understood by others developing a second-order model of his or her mathematics.

Abstractions

With this paradigm, Piaget explains changes in mathematical realities in varying means through degrees of abstraction children rely on when engaging in mathematics. Piaget (1977/2001) described abstractions students rely as beginning as a reliance on *empirical abstractions* (abstractions of actions on perceived objects) towards *reflective abstractions* (abstractions on projected operations). Glasersfeld (1995) explains that individuals rely on two types of empirical abstractions (empirical abstractions and pseudo-empirical abstractions). *Empirical abstractions* explain children's attention towards rules and patterns when acting on perceived objects (e.g., counting manipulatives and knowing the last number word signifies the total). *Pseudo-empirical abstractions* are defined as children's ability to coordinate figurative material, which is indicative when students represent perceived objects with figurative material (e.g., fingers, tapping, verbal utterances), when solving a task. Students transitioning from empirical abstractions towards pseudo-empirical transitions internalize mathematical patterns and rules while coordinating their unitizing, regardless of material presented to them. As children internalize their actions and further step away from perceived material presented to them their degree of abstraction transitions from empirical abstractions towards reflective abstractions.

Piaget (1968/1970) first defined reflective abstractions as simply "coordinated actions" (p. 18). Glasersfeld (1995) further interpreted Piaget's (1977/2001) reflective abstraction delineations by describing two types of reflective abstractions (reflective abstraction and reflected abstraction) that children rely on when interiorizing mathematical patterns to form logical structures. *Reflective abstraction* (first subset of reflective abstraction) explains an individual's projection and reorganization of his or her coordinated actions or operations at another conceptual level (1995). *Reflected abstraction* (second subset of reflective abstraction) explains this same activity, but also explains that an individual is also aware of his or her projection and reorganization (1995).

Actions Versus Operations

As children rely on different degrees of abstractions, they develop operational fluency with number operations, as structures for number become interiorized. Boyce (2014) explained how these structures develop in weak forms versus relatively stronger forms. Essentially, Boyce distinguishes between children's development and coordination of actions versus their development and coordination of operations to explain different forms of reflective abstractions. For instance, if a child is capable of coordinating his or her <u>actions</u> to create a goal and develop a means in which to take a unit and iterate it, then the child has created goal-activity and an iterable unit (an abstract unit capable of iteration). The unit has become abstracted, but the operational structure has not been developed to allow student anticipation of his or her actions on the unit and in coordination with his or her other actions. This is an example of a lower form of reflective abstraction because the unit is acted upon in activity. An operation to anticipate this activity is not created. This would explain why a child may be transitioning away from a reliance on perceptual material towards figurative material, but still struggles to interiorize structures for natural numbers. Comparatively, if a child is capable of developing an iterating operation, then the operation is one that can be acted upon, not the unit. This allows for anticipated activity (c.f., Tzur & Simon, 2004; Steffe, 1992; Ulrich & Wilkins, 2017), which allows a child's natural number schema to become interiorized.

In this commentary, I will not focus on the operations, which are beyond the capability of a young child in the early childhood years, but on how early perceptual actions may explain later conceptual operations. For instance, Piaget (1968/1970) posits, "in developmental psychology … there is never an absolute beginning" (p. 19). What Piaget seems to be referring to as the "absolute beginning" in this argument is the beginning of logical structures. When the coordination of actions begin framing our discussion, Piaget posits that the coordination of actions can go back to biological or organic coordination of actions.

I posit that many of these early roots of biological coordination do not directly relate to a child's development of his or her mathematical structures for number, but may explain the root of his or her early perceptions and coordination of activity when explaining latter operation development and unitizing (Glasersfeld, 1981). Therefore, I want to focus in on the roots of early development and coordination of actions to determine how early forms of operations may explain unitizing that young children engage in. Coupling this focus with subitizing development may explain differences in young children's unit development. Thus, this proposal will further discuss how particular actions with subitizing may be important for young children and how the coordination of these actions with their counting actions may relate to earlier forms of operations.

Unit Construction and Unit Coordination

The term *unit* has become polysemous in the Neo-Piagetian field, as a unit symbolizes a variety of means in which unitizing develops relative to the context the proposed unit is set in. Ulrich (2015) cited Glasersfeld (1981) when defining unitizing as the "generalized and generative process of abstracting out the 'one'-ness from some aspect of experience" (as cited by Ulrich, 2015, p. 3). Frege (1884/1974) and Husserl (1887/1970) found in their work that children engaged in conceptual activity when required to cut "discrete items out of the flow of experience," which were found to promote the construction of "unitary wholes and ultimately of countable units" (as cited by Steffe & Cobb, 1988, p. 3). Steffe and Cobb posited that children younger than two years of age are capable of this activity, yet it is rare to find studies investigating or even theorizing this development or its nature in the early childhood years. For instance, Clements (1999) first proposed that subitizing relates to young children's number development and MacDonald and Wilkins (Under Review) found that one preschool student's subitizing activity related to her conceptual forms of units that she used when solving a counting task. However, it has not been determined how subitizing activity may relate to unitizing and how this development may relate to latter counting development.

A Unit

Boyce (2014) defines a unit as "something that has been unitized or set apart for further action" (p. 3) and characterizes a unit as "an object that can be transformed" (p. 4) and something that can be iterated (p. 24). A very different definition comes from Ulrich and Wilkins's (2017) study where they define a unit as "interiorized counting acts, so they can be used to enumerate the size of the sets of visible or invisible items and can themselves be counted" (p. 2). Finally, a third (very different) definition from Ulrich (2015) where a unit is defined as that, which "allows [students] to measure the number of items in a collection" (p. 3). These definitions are distinctly different because each researcher investigated different aspects of students' mathematics learning. Thus, the term unit becomes polysemous because this one word has multiple meanings that are related, but not alike. As described earlier, when the context becomes more sophisticated, the word, unit represents that which is the basis for measuring what the children are developing and coordinating within their respective mathematical structures. To provide insight into how a unit and unitizing action might relate or not relate to early childhood subitizing and number development, I will adopt Boyce's definition in hopes to explain early forms of empirical and pseudo-empirical abstraction development.

Actions and Operations on Units

The coordination of actions upon a unit explain how students develop operations. Boyce (2014) explains that a coordination of operations allow anticipatory frameworks (see Tzur & Simon, 2004) to develop, as operations are acted upon and allow for anticipation. This iterative cycle explains the nature of development and learning in mathematics. For instance, Norton and Boyce (2015) explain that children produce and coordinate four actions (unitizing, iterating, partitioning, and disembedding) when developing operations (e.g., distributing operation) that promote unit coordination. When students are able to operate flexibly and anticipate appropriate actions and results within a particular mathematics domain, Norton and Boyce posit they are able to do so because they have produced and coordinated levels of units. Coordination of these units results from students' development and coordination of the aforementioned actions.

Steffe and Cobb (1988) also found that young children evoked counting actions to develop early forms of units described as prenumerical singular units. These prenumercial singular units were described as evidence of young children's reliance on actions with perceptual material, figural patterns, motor patterns, verbal utterances, and abstract numbers (1988). As children distance themselves from perceptual material towards more abstract material, Steffe and Cobb found that children unitized the perceptual and figurative material before developing actions upon singular abstract units. Once actions upon abstract singular units are developed, children are able to iterate these units to construct numerical sequences that they segment. Through their segmenting actions, children develop composite abstract units. Once children iterate and partition composite units, they are capable of disembedding parts from whole sets. These actions promoted more operational understandings so that they are able to be aware of and work within mathematical structures for number. Steffe and Cobb found that when children could (1) count-on, (2) double count (i.e., 1, 2, 3, … one three; 4, 5, 6, … two threes), and (3) count by multiples (i.e., 3, 6, 9, 12) to solve problems, they were using all four actions to develop a nesting of sums for multiplicative and fractional reasoning.

With this learning theory in place, mathematics educational researchers have been able to explain nuanced development of children's counting, fractions, and multiplication. However, it is still not clear how subitizing activity may relate or not relate to children's unit development and coordination. Thus, these unit development and coordination learning theories will be discussed as related to different types of perceptual and conceptual subitizing.

Perceptual and Conceptual Subitizing Related to Composite Unit Development

Subitizing, initially defined in the psychology field (Kaufman, Lord, Reese, & Volkmann, 1949), describes individuals' quick attention to the numerosity of a small set of items. Unitizing and unit coordination have not been described in this research. Historically, subitizing has been described in the psychology field as a quantification encoding process and visual information processor where the numerosity of a small sets of items (ranging 1 to 5) are identified (Klahr, 1973). More recently in the mathematics education field, Sarama and Clements (2009) delineated a hypothetical trajectory of subitizing activity and explained subitizing as relying on either perceptual or conceptual activity when developing early number understanding. More specifically, Sarama and Clements explain that individuals *perceptual subitizing* use an encoding process for small numerosities, but also draw from attentional resources when associating a number word with the numerosity of the set. Individuals engaging with *conceptual subitizing* use relatively more advanced number understandings to make sense of larger sets of items (≥ 5) (Sarama & Clements, 2009). However, unit development and coordination may explain, in more nuanced ways, how conceptual subitizing develops in relation to number understanding.

Perceptual Subitizing and Unit Development

Freeman (1912) initially proposed that subitizing may introduce children to the perception of "units of units" when encoding number. To consider early forms of unit development with subitizing activity, I consider actions students use to determine how "units of units" may be produced through subitizing activity. Clements (1999) first described *perceptual subitizing* and *conceptual subitizing* activity as relying on actions that promote early unit development. Perceptual subitizing was defined as students' ability to intentionally quantify a set of items through their subitizing activity yet be unable to be aware of any mathematical processes. To be capable of engaging in perceptual subitizing, Sarama and Clements (2009) suggest that students would need to be capable of cutting away a set of items to determine these as a unit. Sarama and Clements defines conceptual subitizing as children's ability to be aware of units of units when quickly associating sets of items with number words. However, it is not yet clear what type of units students may be developing and coordinating when subitizing.

MacDonald and Wilkins (2016) found in an exploratory study that preschool children engage in unitizing that may relate to early forms of composite unit development. For instance, children were found to engage in *Initial Perceptual Subitizing* where simple associations were made between shapes or motion when intentionally naming a number word. I argue this is very similar to Sarama and Clements (2009) description for perceptual subitizing and explains early forms of figural or motor singular unit item development. This form of unit development would explain how students rely on patterns shown to them visually with figurative patterns and how they may even represent them rhythmically with motor patterns. Through this unit development, young children may begin acting upon the rules of the patterns instead of simply acting on the actions related to the patterns. This would be indicative of a child pointing to his or her paper to show the pattern or shape when justifying why he or she knows she saw "three."

MacDonald and Wilkins (2016) also found that young children could subitizing two or more subgroups of items before they were capable of composing these subgroups. This type of perceptual subitizing activity was described as *Perceptual Subgroup Subitizing*. Quite often, the orientations shown to the students were clustered and regular. For instance, an orientation shown to a child may have two dots in a column on the right-hand side of the mat and three dots in a triangular orientation on the left-hand side of the mat. These orientations afforded students the opportunity to unitize more than one subgroup without requiring them to partition or iterate.

MacDonald, Boyce, Xu, and Wilkins (2015) also found that when students were shown orientations with regular patterns that were symmetrical (i.e., four dots in a rectangular orientation) in nature, they were capable of unitizing and iterating subgroups. For instance, when Frank, a four year-old student, was shown four dots in a rectangular orientation he initially said he saw, "T … four" (p. x). This suggests that he iterated two to build up towards four. This also suggests that he was capable of using a unit of two and partitioning a unit of four. Through these actions, MacDonald et al. posited that Frank was capable of coordinating actions to produce a unit for four. The symmetrical aspects of the orientation may have also afforded Frank the opportunity to partition because the line of reflection fell upon these same partitioning lines. Empson and Turner (2006) found that early forms of partitioning that began with paper folding were foundational for students' construction of functional relationships. Thus, this activity may provide foundations for more sophisticated coordination of units later.

Perceptual Subitizing and Actions on Units

If students are capable of (1) subitizing and then composing units after subitizing – *Perceptual Ascending Subitizing*, or (2) composing and subitizing and then decomposing units – *Perceptual Descending Subitizing*, then MacDonald and Wilkins (2016) found students were building necessary activity for conceptual subitizing. The distinction between this activity and conceptual subitizing is that students are shown items that are clustered and patterned, which does not require partitioning. Thus, this Perceptual Ascending Subitizing and Perceptual Descending Subitizing can allow students to unitize and act on the units developed. It is not clear how these operations develop and what type of composite unit (perceptual or figurative) students are developing or coordinating. These early operations may develop through a coordination of counting actions, through a segmenting of numerical sequences, or through students' development of patterned or figurative patterns. Regardless, this transition from students' development of actions to their development of operations is key, as students are now capable of being aware of number structures that afford them units of units perspectives.

Furthermore, when children engage in Perceptual Descending Subitizing, MacDonald and Wilkins (2016) argue that children are engaging in bi-directional activity. For instance, students who subitize two clustered subgroups may state that they saw "two and three." Once asked, "how many is that altogether?" they may then compose these units and state "five." MacDonald and Wilkins explain that this is Perceptual Ascending Subitizing because the student is ascending from the groups to the total set. However, students who subitize and compose two clustered subgroups may state that they saw "five." When asked, "how do you know there are five there?" they would then need to reflect on their actions and decompose the total set. Steffe, Glasersfeld, Richards, and Cobb (1983) described this bi-directional activity when children reversed their counting actions and found that this activity provided foundation actions for reversible counting later. Steffe explained that the distinction between bi-directional counting and reversible counting was that in bi-directional counting children would rely on prenumerical units and in reversible counting, children would rely on abstract units. This distinction leaves a lot to educators to determine the nuances of the development between bi-directional counting and reversible counting. Thus, in Perceptual Descending Subitizing, I argue that children are not relying on abstract composite units and therefore require the activity and other means to represent these units when reversing their activity. Also, questions arise from some this development in subitizing. For instance, how could different types of perceptual subitizing activity describe different types of prenumercial composite units?

Conceptual Subitizing and Unit Action Coordination

Once children are capable of partitioning and unitizing subgroups from a total set of items, MacDonald and Wilkins (2016) found that children were capable of conceptual subitizing. When children conceptually subitize, it seems that are capable of partitioning and unitizing before they iterate units. Children inverse these actions when they are counting. For instance, when counting, Steffe and Cobb found that children iterated units before they were capable of partitioning or segmenting numerical sequences. As students develop operations, they begin coordinating actions, which I posit occurs when students reverse the order of these actions. For instance, if children only engage in counting, then they will develop schemes that promote a particular order of actions. Children will first unitize to develop units and then iterate their actions in accordance with these units in a 1:1 correspondence. Here the actions are still in the material presented to the children and number is also present in their actions on these objects. However, through a distancing of these, children's reliance upon particular items shown to them (e.g., through use of fingers, through use of motor actions) children's units become more abstract until they are capable of operating on a series of abstract units. These early operations involve children segmenting numerical sequences that they built through their unitizing and iterating of abstract units. Thus, when counting children unitize, iterate, and then partition.

Comparatively, if children only engage in subitizing, then they may develop schemes that promote a different order of actions. Children will first unitize to develop units (perceptual subitizing) and then partition these units to develop a unit of units understanding (conceptual subitizing). Only then, will they begin to iterate units (e.g., five and five make ten) to (de)compose multiplicative units. Thus, when subitizing children unitize, partition, and then iterate. I posit that when children engage in counting and subitizing, their actions become operations because they are now asked to change the order of their actions and coordinate them in operational structures that are more comprehensive. This allows for more sophisticated reflective abstractions where children can use when anticipating actions and solutions in mathematics (Boyce, 2014).

In closing, by investigating relationships between subitizing and composite unit development, mathematics educational researchers may be able explain differences in children's composite unit development and provide alternative trajectories in learning mathematics.

Future Research and Possible Educational Implications

This theoretical commentary provided insight into how subitizing may or may not relate to unit development and coordination. From this discussion, it seems evident that when students engaging in counting activity they unitize and iterate before partitioning their developed number sequences. This allows students opportunities to develop actions and abstract these actions on their developed units. However, students engaging in subitizing activity may be unitizing and partitioning before iterating their developed spatial patterns. This allows students opportunities to develop these same actions on their developed units, but in a different order. However, if students develop more than one order of actions, would this provide a more comprehensive set of operations and allow students operation development earlier? By leveraging this development, I posit that gaps that Steffe (2017) and others (e.g., Clements & Sarama, 2011; Siegler & Ramani, 2008) have found in early elementary school may shrink. Thus, future research should focus on how different forms of activity in early elementary years may provide students alternative means to develop operation and units in which to operate on. Findings from studies like this might serve educators alternative actions that would serve children's disembedding actions and distributive operations. Also, when engaging in trajectories with different ordered actions, would children be capable of simultaneously coordinating these actions to develop operations similar to a splitting operation (see Wilkins & Norton, 2011)? Finally, how might alternative trajectories be used to leverage development for students who require different curricula or educational support (e.g., students identified as having a learning disability)? Thus, future research in how subitizing and counting relate to unit development and coordination could serve theoretical frameworks and educational curricula and should be explored further.

STRATEGIES USED BY MEXICAN STUDENTS IN SEEKING STRUCTURE ON EQUIVALENCE TASKS

Cesar Martínez-Hernández
Universidad de Colima
cmartinez7@ucol.mx

Carolyn Kieran
Université du Québec à Montréal
kieran.carolyn@uqam.ca

This paper presents strategies identified in Mexican rural school students in seeking structure on equivalence tasks that involve the equal sign and tasks that do not. The results arise from the pilot study of a research project on the structure of numbers and numerical operations – a key aspect of early algebraic thinking.

Keywords: Algebra and Algebraic Thinking, Elementary School Education.

Research on algebraic thinking in young students is a trending topic worldwide (Kieran, 2018; Singh & Kosko, 2017). In this and other works, different approaches to early algebra that recognize in arithmetic a strong algebraic feature can be identified (Carraher & Schliemann, 2007). Studies on equivalence in numerical sentences have centered on relational thinking (Carpenter, Franke, & Levi, 2003; Molina & Ambrose, 2008), as well as on generalization, as main aspects of algebraic thinking. However, another important aspect is that of structure in arithmetic (Kieran, 2018).

Recent studies show some of the relationships between expressing the structural and the operational on equivalence tasks. For instance, Asghari and Khosroshahi (2016), with tasks that do not involve the equal sign, propose the existence of an operational approach in developing algebraic thinking in the context of the associative property. According to these researchers, mathematical thinking in elementary school may involve both an operational and a structural conception. Hence, the authors identify the development of algebraic thinking as operationally experienced in the ability to transform a numerical structure.

Schifter (2018) states that an important feature of early algebra includes observation, development, and justification of structural properties in numerical operations expressed in students' computational strategies. This is seen, for instance, in students' verbalizations of the property that in an addition, adding and subtracting the same amount does not affect the value of the expression. Thus, it is important to engage students in discussions on their strategies to determine the veracity or not of numerical sentences such as $57 + 89 = 56 + 90$. If students indicate a relational mode of thinking, it suggests that they are focused on the structure of such equalities. Schifter also analyzed students' thinking when they explored structural properties in related expressions in a sequence of expressions not involving the equal sign (14+1, 13+2, 12+3, 11+4).

In another work, Pang and Kim (2018) using sentences such as $67 + 86 = 68 + 85$ reported that participants tended to use computational strategies; however, they also showed their ability to use a structural approach. According to Pang and Kim, one structural strategy consists in observing that an addend increases by one and the other decreases also by one. In Schwarzkopf, Nührenbörger, and Mayer (2018), however, it is considered that describing patterns in a sequence of expressions such as $30 + 20 =$, $31 + 19 =$, $32 + 18 =$, … is not actually structural reasoning, even if they point out the importance of such thinking in patterns or regularities. These researchers agree with Mason, Stephens, and Watson (2009) in the sense that structural thinking is much more than only observing patterns.

It is clear, then, that there are different perspectives regarding the structural in arithmetic as a component of algebraic thinking, as well as the importance of its development. From here, the purpose of our work is to research the reasoning of Mexican students from rural schools in seeking structure on equivalence tasks that involve the equal sign and tasks that do not. The research question was: What are the strategies used by Mexican students from rural schools regarding structure on equivalence tasks?

Theoretical Framework

Structure in Numbers and Numerical Operations

One of the key aspects in developing algebraic thinking is the notion of structure; however, there are different perspectives on this notion. As mentioned in Kieran (2018), several researchers have worked in this area in the teaching and learning of algebra. Linchevski and Livneh (1999), for instance, recognize that students experience difficulties with structure in algebra and that these difficulties are due to lack of understanding of structure in arithmetic. Mason et al. (2009) have suggested that working with tasks that focus on relations rather than on procedures strengthens students' attention to the structural aspect of arithmetic. They refer to this as *structural thinking* and propose that it allows students to move away from the particular in a situation.

According to Kieran (2018) generalization-oriented activities encompass a structural aspect, but more attention is needed to the process that is complementary to generalizing, that is, the process of *seeing through mathematical objects,* decomposing and recomposing them in several structural ways. Kieran (2018, pp. 80-81) argues that to observe the structure of mathematical objects is to see through them. This means being aware of possible and different ways to structure number and numerical operations, for example, observing that 989 may be decomposed as $9 \times 109 + 8$, as $9 \times 110 – 1$, or as $9 \times 10^2 + 8 \times 10^1 + 9 \times 10^0$. According to this researcher, the generalization of mathematical ideas in arithmetic is linked to the idea of expressing structure. So generalization involves identifying the structural, and the structural involves identifying the general. Kieran (2018, p. 82) states that structure in numbers and numerical operations may be explained, firstly, by drawing on Freudenthal (1983, 1991, quoted in Kieran, 2018). That is, that the system of whole numbers constitutes an order structure, where addition is based on the order of this structure: in the addition structure, to each pair of whole numbers a third number (its sum) can be assigned. It is emphasized that, in Freudenthal's discussions of structure, there is not just one all-encompassing structure. He refers, for example, to order structure, additive structure, multiplicative structure, structure according to divisors, structure according to multiples, etc.

Based on the literature regarding perspectives on mathematical structure, specifically arithmetical structure, Kieran (2018) suggests promoting student experiences with equivalence through decomposition, recomposition, and substitution. Following Freudenthal, she points out that the structure in numbers and operations involves different *means of structuring*, according to factors, multiples, powers of 10, evens and odds, decomposition of primes, etc. Such structures expressed through decomposition, in other words, uncalculated forms, have properties. This perspective on structure constitutes a wider conceptualization of the fundamental aspect of structure in number and numerical operations as a means to develop early algebraic thinking. Taking into account the points made by Kieran (2018), as well as the suggestion of Schifter (2018) that structural properties can be implicit in students' procedures, this work will explore Mexican students' structure sense in equivalence tasks as evidenced through their strategies.

Methodological Considerations

Included in this report we present the preliminary results from an ongoing qualitative research aimed at investigating the strategies that students use in equivalence tasks.

Initial Task Design

Three tasks were designed in order to explore students' strategies; two of these did not include the equal sign. Task 1 aims at identifying the way in which students relate two numbers *a* and *b* with a third one *c* (i.e., its sum) and the rationale they use. It is a 4-item task with a main question: Can number *c* be written from numbers *a* and *b*? (*a* and *b* being specific numbers). Also, the task includes a generalization question: Can any number be written from other numbers? For all the questions, students were asked to provide an explanation.

Task 2 was based on the sequence proposed by Schifter (2018) and includes seven items. The aim is to observe the regularities students find in the proposed sequence based on this first item:

14+1
13+2
12+3
11+4
10+5

The rest of the items focus on two particular expressions from the sequence (e.g., 14+1 and 13+2). Students are asked to explain how to write an expression from the other. Another set of items focuses on discussing the equivalence of expressions without computation. The task ends with a question where a sequence of the same type is proposed, but involves subtracting; here we want to observe if students extrapolate from the discussion involving the case of adding.

Task 3 involves the use of the equal sign to show the equivalence of expressions, for instance, 4 + 5 = 4 + 3 + 2. The aim is to explore if students indicate relational thinking based on the structure of such equalities. The main goal in the task is to determine if the numeric sentences are true, as well as the possibility of rewriting them in an equivalent form. Task 3 also included numerical sentences with "big numbers".

Participants

Six sixth graders, ages 10 and 11, from a public Mexican school participated. This grade level was chosen because such students are finishing primary school and have been exposed to the official Mexican public education curricula. In the curriculum for the elementary school (SEP, 2016) the equivalence of numerical expressions is not mentioned. However, several tasks from the official textbooks have the potential to promote students' early algebraic thinking (Cabañas, Salazar, & Nolasco, 2017).

Data Collection

Prior to the unfolding of the designed activity, the teacher in charge of the group reviewed it. In her opinion, the students had never solved similar tasks; they had only worked with the use of the equal sign in an operational sense. The data collection technique was that of the Group Interview, so that students could verbalize their rationales. Data were obtained during three sessions, one session per task, with sessions lasting 30-40 minutes each. All six students participated in each of the three sessions.

Results and Discussion

The preliminary results of an ongoing study are herein reported. The analysis focuses on the work of three students (S1, S2, and S3), those who participated most fully in the group interviews. Data for these results come from students' worksheets, videotaped footage of the sessions, and researcher's field notes.

Results from Task 1

Task 1 does not include the equal sign so as to see whether students use it spontaneously and, if so, in which way. Three of the items were the following:

1. *May number 7 be written from numbers 6 and 1? If so, how?*
2. *May number 19 be written from numbers 14 and 5? If so, how?*
3. *Is it correct to write number 7 as 3 + 4? As 8 + 2? Explain.*

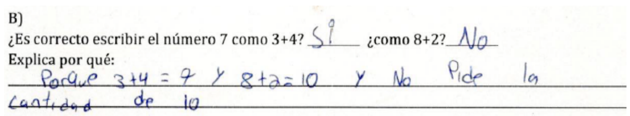
The students answered affirmatively items 1 and 2, their explanation being based on what in the literature is known as an operational use of the equal sign. For example, see S1's work in Fig. 1.

A)
¿El número 7 puede escribirse a partir de los números 6 y 1? Si ¿Cómo? 6+1=7.

May number 7 be written from numbers 6 and 1? Yes If so, how? 6 + 1 = 7

Figure 1. S1's operational form of justification.

In his explanation, S1 relates 7 with 6 and 1 in an *operational sense*: 6 + 1 = 7, through a computational strategy. None of the students write, for example, 7 = 6 + 1, which would be recognized as a not strictly operational response. From a structural point of view, 6 and 1 can be interpreted as a decomposition of the number 7, which can then be recomposed from these numbers. In item 3, students answer in the same sense (Fig. 2) based on *the result they must obtain*.

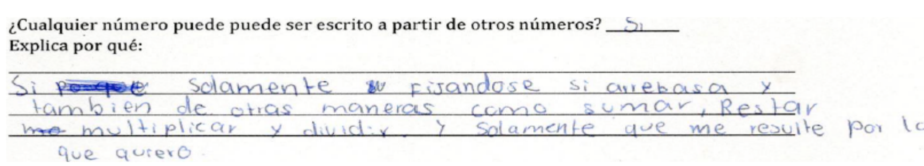


B)
¿Es correcto escribir el número 7 como 3+4? Sí ¿como 8+2? No
Explica por qué:
Porque 3+4 = 7 y 8+2=10 y No Pide la cantidad de 10

B)
Is it correct to write number 7 as 3+4? Yes As 8+2? . No
Explain
Because 3+ 4 = 7 and 8 +2 = 10 and [3+4] does not ask for a 10

Figure 2. S3's justification in terms of the result.

The same idea is present in the answers involving a generalization. *Can any number be written from other numbers?* Students identify the generality in terms of the response that they must arrive at. This is observed in S1's final explanation (Fig. 3) where he states *"...only if I get what I want"*.



¿Cualquier número puede puede ser escrito a partir de otros números? Si
Explica por qué:
Si Solamente fijandose si quebasa y también de otras maneras como sumar, Restar multiplicar y dividir y Solamente que me resulte por lo que quiero.

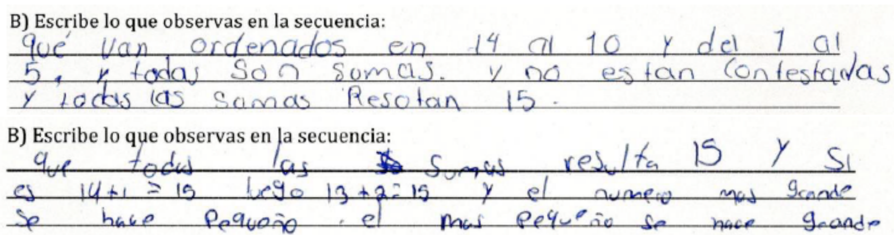
Can any number be written from other numbers?
Explain why
Yes, "*...only if I get what I want*

Figure 3. S1's general statement.

Students' answers show a lack of relational thinking by their use of the equal sign as a symbol that indicates the result. In other words, their strategy doesn't match with a notion of number decomposition, but with the idea of *operating with numbers* in order *to get a result*. The way in which they justify their answers – according to their teacher – shows how they have been systematically exposed to this way of thinking. In order to test whether the way in which Task 1 was designed led to the strategy that students used, Tasks 2 and 3 were designed differently.

Results from Task 2

The analysis of data from Task 2 (involving the sequence from Schifter, 2018) focuses on the features of the $a + b$ form of expressions that were observed by the students, as well as on the possibility of transforming one expression of the sequence into another expression of the same sequence. Regarding the first aspect, students' answers show that they identify the regularity in the sequence. For instance, they write *about the involved operation (addition)*, *the sum (the result)* and the existence of an *order* in the sequence (*increase* and *decrease* of the addends). See S2's and S3's answers to the first item (Fig. 4).

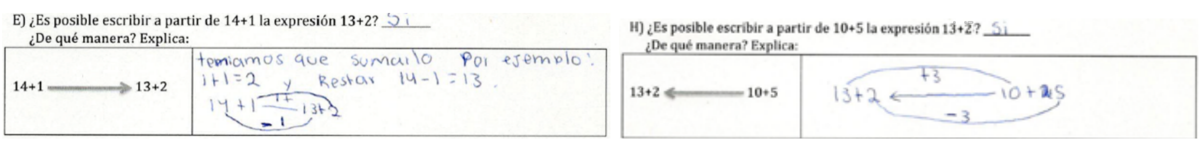


B) Write what you observe on the sequence
There is an order, in the 14 to 10 and in the 1 to 5, all of them are additions, they are not answered and all the additions result in 15.

In all the sums the result is 15, you have 14+1=15 then 13+2=15 and the biggest number becomes small, the smaller becomes big.

Figure 4. Features of the sequence as indicated by S2 (above) and S3 (below).

The kind of answers students produce regarding the presented sequence relates, on the one hand, to the kind of thinking they show throughout Task 1. That is, they identify the expression as an operation that must be carried out in order *to obtain a result*. This feature is clear in S2's response when he writes: *"…all of them are additions and they are not answered and all the additions result in 15"*. This suggests that these students do not see the expression as a mathematical object in itself, reflecting what is described in the literature as the *lack of closure* dilemma. On the other hand, there is some evidence of a train of thought that could be associated with *the structural*. According to Pang and Kim (2018), to identify patterns such as "increases by one and decreases by one" is a part of structural sense. This can be seen in S3's work (the lower half of Fig. 4) when he states: *"…and the biggest number becomes small, the smaller becomes big"*. However, he does not relate the feature he observes to the equivalence of the expressions. In the second part of Task 2, the students were asked how to obtain one expression in the sequence (e.g., 13 + 2) from another (e.g., 14 + 1). In these cases, all the students use an *additive compensation strategy*, as observed in Fig. 5.



E) Is it possible to write from 14+1 the expression 13+2? Yes
In which way? Explain
We have to add. For instance 1+1=2 and subtract 14 -1=13

H) Is it possible to write from 10+5 the expression 13+2? Yes
In which way? Explain
[Student illustrates an additive compensation strategy]

Figure 5. S1's additive compensation strategy.

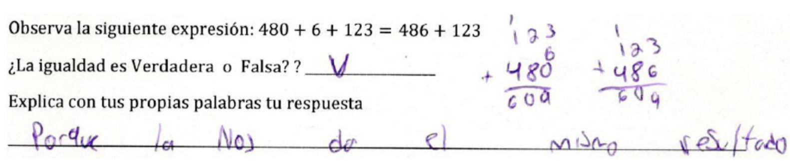
The aim of our research was to study how students move from one expression to another, if they decompose and recompose the involved numbers. It was noticed that they identify the parts of the expressions, but not as a mathematical object that can be decomposed and recomposed to transform one expression into another. It was also seen that students use a *compensation strategy*: adding and subtracting the same amount to and from the involved addends in order to obtain the second expression. The following is an extract from an interview when, in the course of presenting the task, the interviewer asked for a generalization of the student's strategy:

> *Researcher*: …Can you do it [referring to his strategy] in any case? Is there a rule for it?
> [After other students offer suggestions, S2 answers]
> *S2*: It's only a matter of adding and subtracting, depending on the required numbers.

Despite such structurally-related responses as S2 produced, there is not enough evidence, however, to determine if students identify an equivalence relationship among the expressions (e.g., 14+1 and 13+2). Nor is there enough evidence, with respect to the additive compensation strategy, to determine if they are aware that their strategy is generalizable to all additions (e.g., that 27 + 15 can be converted to, say, 30 + 12 or that 44 + 19 can be converted to 43 + 20) or simply applicable to the set of additive expressions provided in Task 2. If the latter, then — as suggested in Schifter (2018) — this would be an *ad hoc* strategy aimed at getting the numbers needed for the second expression from the first one, and viceversa.

Results from Task 3

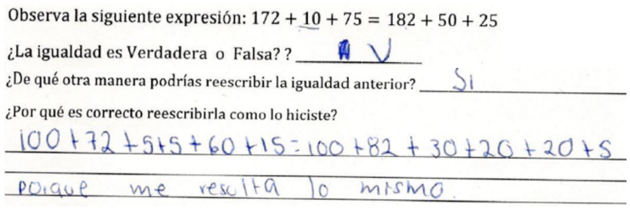
This task includes the equal sign – in expressions such as $a + b = c + d$. As mentioned, Task 3 involves "big" numbers to see if this deters the use of computational strategies.
On the one hand, students accept expressions such as $a + b = c + d$; however, they justify the equality of both sides by calculating the result on each side. Again, this computational strategy demonstrates that students are not relying on relational thinking. Their computational strategy is called upon in both cases, whether with "small" or "big" numbers (Fig. 6).



Observe the following expression: 480 + 6 + 123 = 486 + 123
Is the equality True or False? *T*
Explain with your own words
Because we get the same result

Figure 6. S3's computational strategy.

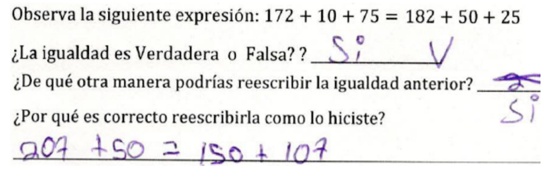
On the other hand, students rewrite the equalities in the form of other equivalent equalities according to two strategies. In the first of these strategies, they decompose each of the addends, but not in a way that shows a clear relationship between one side and the other of the equality (see S1's work in Fig. 7). In the second, which is based on calculating the *total (the result) for each side* without first decomposing the involved addends, students then look for two or more numbers for which they could obtain the same total (see S3's work in Fig. 8).



Observa la siguiente expresión: 172 + 10 + 75 = 182 + 50 + 25
¿La igualdad es Verdadera o Falsa? ? V
¿De qué otra manera podrías reescribir la igualdad anterior? Si
¿Por qué es correcto reescribirla como lo hiciste?
100 + 72 + 5 + 5 + 60 + 15 = 100 + 82 + 30 + 20 + 20 + 5
porque me resulta lo mismo

Observe the following expression: 172 + 10 + 75 = 182 + 50 +25
Is the equality True or False? *T*
In which other way could you re-write the previous equality? *Yes.*
Why it is correct re-write the expression in such a way?
100 + 72 + 5 + 5 + 60 + 15 = 100 + 82 + 30 + 20 +20 + 5
Because I get the same result

Figure 7. S1's equality rewriting.



Observa la siguiente expresión: 172 + 10 + 75 = 182 + 50 + 25
¿La igualdad es Verdadera o Falsa? ? Si V
¿De qué otra manera podrías reescribir la igualdad anterior? Si
¿Por qué es correcto reescribirla como lo hiciste?
207 + 50 = 150 + 107

Observe the following expression: 172 + 10 + 75 = 182 + 50 +25
Is the equality True or False? *Yes*
In which other way could you re-write the previous equality? *Yes.*
Why it is correct re-write the expression in such a way?
207 + 50 = 150 + 107

Figure 8. S3's equality rewriting.

This task shows that students accept equalities in the form of $a + b = c + d$. However, they transform them without relating the right and left sides except according to their totals. Their strategy is to maintain the equivalence through the two above-mentioned strategies. Hence, as observed in Figs. 7 and 8, there is not a natural inclination in students to re-express the equalities in such a way that both sides of the equalities look alike; for instance, 172 + 10 + 50 + 25 = 172 + 10 + 50 + 25, or 170 + 2 + 10 + 50 + 25 = 170 + 2 + 10 + 50 + 25, or even as 182 + 75 = 182 + 75. However, S1's work shows some structural sense according to the reviewed literature. Even when S1 and S3 write correct equalities, each side is considered on an individual basis. The left side is decomposed in one fashion and the right side in a different way, without showing explicitly the equality of both sides. S1 (Fig. 7) does not explain that both sides look more or less the same, he only mentions that the result (on both sides) is the same.

Conclusions

From the strategies students used, only one can be considered to illustrate a structural approach (S1 in Task 3, as shown in Fig. 7), even though the accompanying explanation refers to the result of both sides of the equality. The rest of the students' strategies are clearly computational, referring to the expected result, whether it involves operating with the numbers of an expression so as to calculate the result on both sides of an equality (the strategy observed in Tasks 1 and 3), or operating with the addends of one expression to obtain the addends of the other expression (the strategy observed in Task 2). In this sense, the presence or absence of the equals sign in the tasks seems not to influence the students in their chosen strategy.

Our results coincide with those reported by Pang and Kim (2018), in the sense that students tend to use computational strategies. This means that they show a strong operational sense, even when they accept equalities in the form of $a + b = c + d$. Nevertheless, this acceptance could be used as a base to promote the development of structural sense within algebraic thinking by designing tasks in such a way that students are explicitly requested not to pass through the intermediate step of computing the total for each expression in their work on judging the equivalence of the component expressions. Accepting expressions as bona fide numerical objects, and operating with and on these objects, is essential to seeking and expressing structure within the domain of arithmetic and thereby fostering the development of algebraic thinking.

Acknowledgements

We thank the Mexican Secretariat of Public Education (Secretaría de Educación Pública, SEP) for funding this research, through the PRODEP Program (Announcement 2017). We also thank the primary school where data was gathered, the teachers, and the participating students.

LEARNING FROM NAEP RELEASED ITEMS: U.S. ELEMENTARY STUDENTS' GRASP OF MULTIPLICATIVE RELATIONSHIPS

John P. Smith III
Michigan State University
jsmith@msu.edu

Curricular analysis indicates that the U.S. students are introduced to multiplication in additive terms (as the replication of equal groups and repeated addition). But the virtue of this introduction for supporting students' understanding of the full range of multiplicative relationships is unclear. This paper reports an analysis of all grade 4 released NAEP items that expressed a multiplicative relationship, focusing on the range of relationship types, related quantities, and item difficulty. Results show that multiplicative items (1) frequently presented discrete quantities and equal group situations, (2) were easier when they involved discrete versus continuous quantities, and (3) within discrete items, equal groups and array items were easier than other types. These results provide measured support for the conjecture the additive introduction to multiplication may limit the development of elementary students' understandings.

Keywords: Number Concepts and Operations, Elementary School Education, Assessment and Evaluation

Objectives of the Study

Can analyses of released items from the National Assessment of Educational Progress (NAEP)—the "nation's report card"—and performance on those items shed light on questions of interest to mathematics educators, beyond what has been reported in summary volumes (e.g., Klosterman & Lester, 2007)? This analysis addressed that question for the broad content area of multiplicative relationships. "Multiplicative relationships" designates a set of tasks and situations, numerical and quantitative, that engage students in multiplicative reasoning and in carrying out numerical operations of multiplication or division. Given the introduction of multiplication and multiplicative relationships in grades 2 and 3 in U.S. classrooms, the analysis examined released items from grade 4.

Multiplicative relationships are significantly more diverse and challenging for students to master than additive relationships (Nunes & Bryant, 1996; Vergnaud, 1983, 1988). Students work on multiplicative relationships for many years, and this work is intensive in the upper elementary through middle school years. They are introduced to the operations of multiplication and division and some "applied" situations in grades 2 and 3. In the U.S., this introduction is essentially additive in nature. Quantitatively, multiplication is presented as involving the replication of equal-sized groups of discrete objects; numerically, it is presented as repeated addition (Smith, 2017). Research on students' understanding of different multiplicative relationships raises questions about whether this instructional foundation effectively supports students' access to and understanding of the full range of multiplicative relationships. This analysis of released NAEP items is one small step in a larger effort to address that critical question. The NAEP analysis complements the results of many prior studies that have assessed students' understanding of multiplicative relationships (as summarized in Greer [1992] and Harel & Confrey [1994]).

Two main questions focused the analysis: (1) what multiplicative situations (type and frequency) appear in released Grade 4 items and (2) how well do the performance results align with the additive introduction to multiplication? For example, are items presenting the replication of equal groups easier than other types of situations that are less amenable to replication and repeated addition?

Theoretical Perspective

Broadly, the larger inquiry that motivated this analysis was framed in constructivist terms. If learning is a social and psychological process of adapting prior understandings to cope with new and problematic mathematical situations (e.g., Wood, Cobb, Yackel, & Dillon, 1993), then how we introduce students to multiplicative relationships matters greatly for their subsequent work to engage the full multiplicative conceptual field (Vergnaud, 1983). Understanding multiplication and division means knowing where and why situations encountered in the world are "multiplicative," not additive. Mastery of the numerical aspects multiplication and division (i.e., basic facts, algorithms, and properties of operations) may contribute to understanding multiplicative relationships but is neither sufficient nor central.

A framework of types of multiplicative reasoning and quantitative situations that typically elicit such reasoning framed the analysis of the released items. *Quantities* are countable or measureable attributes of objects or collections of objects that are constituents of situations that student encounter and reason about in school and the everyday world (Smith & Thompson, 2008). To use their mathematical knowledge effectively in reasoning about and resolving these situations, students must consider the quantities involved and how they are related. Table 1 presents (and relates) different types of multiplicative reasoning and types of situations. But situations do not determine students' reasoning about them. Rather, the correspondence below reflects how prior research has characterized situations in relation to multiplicative reasoning. "Replication," an additive form of reasoning, has been included for "coverage" of the released items and because U.S. curricula treat replication as multiplicative.

Table 1: Types of Multiplicative Reasoning and Situations

Types of Multiplicative Reasoning	Types of Quantitative Situations
Replication	Equal groups; rectangular arrays; some area and volume situations
One-to-many	Unit conversion
Scaling	Comparison; price (discrete); rate/cost (continuous)
Successive partitioning	Folding; splitting
Composition	Cartesian product (discrete); area; volume (continuous)

Central to the analysis of situation types is the distinction between *discrete* and *continuous* quantities. Discrete quantities are sets of objects; their numerical value can be determined by counting. Continuous quantities are initially attributes of unsegmented objects (e.g., distances or lengths, areas, time periods between two events). Their measurement requires the selection and iteration of a unit (a smaller piece of the target quantity). Their numerical value is the number of such units that collectively fill up or "exhaust" the initial quantity.

Rectangular arrays and some area and volume situations are listed in Table 1 along with equal groups because (1) array situations support replication reasoning (when a row or column of objects is interpreted as a group) and (2) area and volume situations are often presented as arrays of squares or stacks of cubes that similarly support replication. Price indicates situations where some discrete number of items has been purchased. It is related to, but a special case of the more general set of rate/cost situations that accept measured quantities (e.g., “9.45 gallons of gas”). Cartesian product and area/volume are both multiplicative compositions, where the product differs from both factor quantities. In the former, “pants” and “shirts” are different quantities than “outfits.” Similarly, both rectangular area and prism volume are different quantities than the lengths from which they are composed.

The entries in Table 1 suggest that understanding multiplication involves grasping fundamentally different forms of multiplicative relationship that many students may see as conceptually distinct, especially early in their mathematical experience.

Methods

Items from nine Mathematics assessments (administered in 1990, 1992, 1996, 2003, 2005, 2007, 2009, 2011, and 2013) have been released for public examination (https://nces.ed.gov/nationsreportcard/nqt/). NAEP characterizes items by content area—*Number properties and operations* (NPO), *measurement* (M), *geometry* (G), *data, statistics and probability* (DSP), and *algebra* (A) and by format—multiple-choice, short constructed response, and extended constructed response. Released NAEP items are characterized by difficulty, as “easy” (performance ≥ 60% correct), “medium” (performance is between 40% and 59% correct), or “hard” (performance < 40% correct).

All 388 released grade 4 items were examined and coded by the author as either additive, multiplicative, or other. Multiplicative items presented one of the situation types listed above in Table 1 (including replication). *Additive* items presented one of three types of additive relationship—combine, separate, or compare. Additive items included area and volume/capacity items that presented collections of squares and cubes that supported counting and (additive) comparison. *Other* items presented content topics such as place value, ordering, estimating, fractions, graphing, and stating probability, where neither an additive nor multiplicative relationship between numbers or quantities was expressed.

Multiplicative items were found in all five content areas but were most common in NPO and M domains. All multiplicative items were first coded as “numerical” or “quantitative.” Numerical items presented written numerals and operations with minimal prose. “Quantitative” items were primarily expressed in words, where numerals were associated with quantities. Some items were presented entirely in prose (as “word problems”); others presented tables or figures with the written text, and the tabular or figural information was necessary for solving the item. Quantitative items were then coded for the type of quantities involved, discrete or continuous. Discrete items were further distinguished according to the type of relationship presented. Eight types proved sufficient for coding all discrete items: *Equal groups*, *equal shares*, *rectangular arrays*, *money*, *price*, *multiplicative comparison*, *unit conversion*, and *Cartesian product*. Continuous items presented length, area, or volume/capacity measurement situations where the quantity could not be evaluated with additive reasoning. Four types were sufficient for coding continuous items: *Unit conversion, equal shares, multiplicative comparison*, and *computation*.

Results

For a broad overview, Table 2 presents an overview of all 388 released grade 4 items by year. Column 3 lists the total number of multiplicative items; column 4 lists the total number of additive items; and columns 5–8 characterize the multiplicative items, first as numerical or quantitative items and then for quantitative items, as discrete and continuous.

Table 2: General Character of Grade 4 Items (1990-2013)

Year	All	Mult	Add	M; Number	M; Quan	M, Quan; Discrete	M, Quan; Continuous
2013	46	14	9	6	8	6	2
2011	49	20	14	7	13	10	3
2009	31	6	8	1	5	3	2
2007	54	14	12	3	11	9	2
2005	32	5	11	2	3	3	0
2003	59	23	9	3	20	16	4
1996	25	9	6	1	8	6	2
1992	59	20	13	6	14	12	2
1990	33	10	7	6	4	3	1
Total	388	121	89	35	86	68	18

The number of released items and the number of multiplicative items varied substantially across the nine assessments, but multiplicative items were generally more frequent than additive items. In most years, multiplicative quantitative items outnumbered multiplicative numerical items, often dramatically. Among quantitative items, those presenting discrete quantities were at least twice as frequent as those presenting continuous quantities.

More substantively, the distribution of discrete items across the eight types listed above was not uniform (Table 3).

Table 3: Frequency of Grade 4 Discrete Multiplicative Items by Type (1990-2013)

Year	Disc	Grps	Share	Array	Comp	Unit	Money	Price	C.P.
2013	6	2	0	0	2	1	0	0	1
2011	10	3	2	0	2	3	0	0	0
2009	3	1	0	0	0	1	1	0	0
2007	9	3	0	0	1	3	1	1	0
2005	3	2	0	0	1	0	0	0	0
2003	16	5	2	1	1	1	0	5	1
1996	6	2	0	2	0	1	0	1	0
1992	12	5	0	0	0	0	1	5	1
1990	3	0	0	1	0	0	0	2	0
Total	68	23	4	4	7	10	3	14	3

Note: “Grps” = equal groups, “Comp” = comparison, “Unit” = unit conversion, “C.P.” = Cartesian product

Equal groups was by far the most frequent type of situation presenting discrete quantities in multiplicative relationship, followed by price and unit conversion. Equal groups and unit conversion items always involved quantities with whole number values, where price items involved some whole number of items at a cost represented as decimal (e.g., \$0.87 or \$2.79).

Many authors have argued that multiplicative relationships are intrinsically more difficult for students to master than additive relationships (e.g., Vergnaud, 1983, 1988). Is this claim reflected in the NEAP results? Overall, the entries in Table 4 indicate an affirmative answer.

Table 4: Relative Difficulty of Grade 4 Additive and Multiplicative Items (1990-2013)

Year	All	Mult.	Add.	Avg % Corr; A	Avg % Corr; M	%A – %M
2013	46	14	9	46.8	43.6	3.2
2011	49	20	14	58.2	48.8	9.4
2009	31	6	8	57.4	52.8	4.6
2007	54	14	12	61.3	46.0	15.3
2005	32	5	11	53.3	58.2	-4.9
2003	59	23	9	57.8	50.8	7.0
1996	25	9	6	54.2	42.0	12.2
1992	59	20	13	45.2	40.4	4.8
1990	33	10	7	44.6	44.2	0.4
Total	388	121	89			

On seven of nine assessments, multiplicative items were more difficult than additive items, and in three (1996, 2007, and 2011) significantly so. The difference was negligible in 1990 and had the opposite sign in 2005.

But item difficulty across types of multiplicative relationships was the central focus of this analysis. Table 5 below reports percent correct for items presenting each type of discrete multiplicative relationship. The first value in right-most column lists the average percent correct for all items of that type. The values in parentheses are the average percent correct for a meaningful subset of those items, as explained below. The other columns list the number of items rated "easy," "medium," and "hard" and the percent correct for each item in those three categories.

Table 5: Difficulty of Grade 4 Discrete Multiplicative Items by Type (1990-2013)

Discrete sub-type	N	N Easy	%	N Med	%	N Hard	%	Avg %
Equal groups	23	4	75, 61, 80, 70	11	50, 53, 59, 53, 56, 46, 57, 50, 55, 47, 48	8	38, 35, 23, 21, 36, 39, 37, 37	49.0 (56.4)
Price	14	2	70, 62	4	58, 58, 53, 48	8	4, 35, 39, 31, 17, 8, 9, 21	39.3 (53.2)
Unit Conversion	10	6	66, 75, 65, 85, 78, 61	2	53, 44	2	17; 39	58.3 (62.9)
Compare	7	1	72	2	47, 47	4	32, 34, 24, 34	43.0 (36.3)
Array	4	1	79	2	50, 48	1	35	53.0
Money	3	1	60	1	58	1	20	46.0
Equal shares	4			2	47, 51	2	23; 38	39.8
Cartesian product	3			1	48	2	24; 28	33.3
Total	68	15		25		28		45.9

Items in three discrete types were somewhat easier overall (Unit Conversion, Array, and Equal Groups, in descending order), with average correct at or slightly above 50%. Six of the 10

Hodges, T.E., Roy, G. J., & Tyminski, A. M. (Eds.). (2018). *Proceedings of the 40th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Greenville, SC: University of South Carolina & Clemson University.

Unit Conversion items provided the conversion ratio explicitly in the item (e.g., 1 qt. = 2 cups). The two "hard" conversion items (39% and 17% correct) both presented 3:1 ratios, where the other eight items presented conversion ratios of 2:1, 5:1, 10:1, or 100:1. Arrays were either represented directly in diagram (n = 1) or described in words (n = 3). The "easy" item (79% correct) described a particularly familiar array—two rows of six cookies on a cookie sheet.

As shown, Equal Groups and Price items were often difficult; eight items of both types were "hard." But within both types, hard items often involved two or more steps, where a multiplicative relationship was involved in at least one step. For example, some two-step Price items asked for the change received for the purchase of a set of items at a given price when a specific bill was given for payment—requiring both multiplicative and additive reasoning. Some two-step Equal Groups items introduced more than one group (e.g., students in a class and buses with maximum capacity for students). Most multi-step items were more difficult than single step items of the same type. The average percent correct for the thirteen single-step Equal Groups items was 56.4% (as shown), where the corresponding average for the ten multi-step items was 39.2%. Similarly, the six single-step Price items were considerably easier (average 53.2% correct) than the eight multi-step items (average 28.9% correct).

By contrast, Compare, Equal Shares, and Cartesian Product items were more challenging, at 43%, 39.8%, and 33.3% average correct, respectively. The majority of Compare and Cartesian Product items were "hard," even when six of the seven Compare items involved a 2:1 ratio. Only one, presenting ten stars and five triangles in a 3 by 5 array and four possible ratios, was "easy" (72% correct). Without that item, average correct fell to 36.3%. Of the four Equal Shares items, none called for simply distributing some discrete quantity equally to a given number of recipients. One "hard" item (38% correct) asked students to distribute 24 wheels to bikes and wagons in two different ways; one "medium" item (47% correct) required interpreting the remainder after equal sharing. Cartesian Product items were difficult even though support was provided for solving two of the three (i.e., items provided the solution for smaller factors).

Finally, Table 6 presents the performance on the N = 18 multiplicative items that presented length, area, or volume/capacity quantities and within each quantity, the type of multiplicative relationship involved.

Table 6: Difficulty of Grade 4 Continuous Multiplicative Items by Type (1990-2013)

Continuous Sub-type	N	N Easy	%	N Med	%	N Hard	%	Avg %
Length	7			1		6		30.6
compare	2						27, 33	30.0
equal shares	4				47		27, 26, 23	30.8
unit convert	1						31	31
Area	6	1		1		4		36.5
compute rect	4						23, 24, 24, 19	22.5
compare	2		78		51			64.5
Volume/capacity	5	2		1		2		47.4
unit convert	3		67, 61				32	53.3
compute stack	1				56			56
compare	1						21	21
Total	18	3		3		12		37.2

Overall, the results show that multiplicative items presenting continuous quantities were generally more difficult than those with discrete quantities. Six of seven length items were "hard," as were four of six area items—even when the area items involved a single-step. However, the two items comparing areas— both presenting sectors of partitioned circles—were markedly easier (average 64.5% correct) than the corresponding discrete comparison items (n = 7; average 43.0% correct). The three volume/capacity unit conversion items were somewhat more difficult (average 53.3% correct) than the discrete unit conversion items (n = 10; average 58.3% correct). As was true for the discrete items, all three continuous items stated the conversion ratio in the item text.

Discussion

The analysis was revealing in two principal ways. First and generally, the careful examination of released NAEP items supported a finer-grained analysis of U.S. grade 4 students' successes and challenges—as a proxy measure of national understanding—than the published volumes have thus far (Klosterman & Lester [2007] and prior volumes in that series). The released item set provided greater access to the items as presented to students, their difficulty, and the details of item performance. Second and more specific to this inquiry, the analysis provided a measure of empirical support for the concern that the additive introduction of multiplication may present challenges for the growth of students' understanding beyond equal groups of discrete objects and repeated addition. However, that support was mixed and complicated by many factors outside the frame of the analysis. Since many factors other than quantity and relationship type likely contribute to item difficulty, the analysis shows the difficulty inherent in establishing what makes an item easy (or challenging) for students.

Some of the results are consistent with (a) the curricular introduction of multiplication as the replication of equal groups of discrete quantities and repeated addition and (b) the concern that that an additive foundation likely makes extension to a wider set of situations problematic. Additive items were on average easier than multiplicative items. Second, items posing multiplicative relationships among discrete quantities were much more frequent and generally easier than item involving continuous quantities. Third, situations involving Equal Groups were the most frequent of type of discrete multiplicative relationship and were easier than other discrete item types that are less amenable to interpretation as equal groups—specifically, Comparison and Cartesian Product. But this was not always the case; Unit Conversion items were easier on average than both Equal Groups and Array items. Overall, the results are consistent with and do not remove the concern that the additive introduction to multiplication and multiplicative relationships may support initial access to multiplicative relationships, but at the cost of later conceptual challenges as application extends both quantitatively and numerically (e.g., to fractions, decimals, and negative numbers).

There are numerous limitations to this analysis and more broadly to using NAEP released items to address questions about the effects of curricular approaches on student learning. Perhaps the most important is that the released item set stands in uncertain relationship to the larger corpus of items where NAEP has performance data. The conditions under which a NAEP item is released to the public are unknown. Also, where the type of multiplicative item and the type of related quantities may well influence the item difficulty, other factors do so as well, including the numerical values of the quantities (even within the set of whole numbers), the length and clarity of item prose, and the nature of support provided (e.g., stating conversion ratios or not). Third, multi-step problems present challenges for characterizing items as additive or multiplicative and for judging the sources of difficulty. Fourth, though the capacity to explain one's reasoning may be a better indicator of understanding than producing the right numerical answer, the number of released NAEP items requiring explanation (that is, both short and extended constructed-response items) have been small in number, in this target content area and likely in most others. The smaller the item set, the more perilous any conclusion drawn from such data becomes. Last, the analysis has been completed by a single person and the coding scheme must be shown to be reliable.

Despite these limitations, released NAEP items are an underused resource for mathematics education researchers who wish to address questions of learning at a national level. Where it is unlikely that any similar analysis of items selected for a given topic or response type (e.g. constructed-response) will resolve questions about student understanding, they may contribute to inquiries that draw on multiple sources of evidence. NAEP released item data, reflecting such a large and nationally-representative sample of students, is a unique source of evidence. Its analysis can provide either general support (as in this case), no support, or contradictory evidence for a given hypothesis.

A LONGITUDINAL STUDY: THE EFFECTS OF TIME AND EARLY INSTRUCTION ON STUDENTS' INTEGER LEARNING

Mahtob Aqazade	Laura Bofferding	Lizhen Chen
Purdue University	Purdue University	Purdue University
maqazade@purdue.edu	lbofferd@purdue.edu	chen1905@purdue.edu

Twenty-nine second graders received integer instruction (instruction-only) and three years later participated in our study again as fifth graders (instruction + time). In addition, we analyzed data from an additional 73 fifth graders to investigate the effect of time without having had the second-grade instruction (time-only). The findings indicate no significant difference between instruction-only and time-only groups, a significant improvement from the instruction-only to instruction + time group on integer addition and subtraction problems, and a significantly better performance for the instruction + time group on integer subtraction problems.

Keywords: Number Concepts and Operations, Cognition, Elementary School Education

The transition from a whole to negative number understanding requires conceptual change and sufficient time to process (Vosniadou, Vamvakoussi, & Skopeliti, 2008). Children as early as first grade can reason with negative numbers (e.g., Bofferding, 2014); however, they often do not learn negative number operations until seventh grade (National Governors Association Center for Best Practices [NGA] & Council of Chief State School Officers [CCSSO], 2010). Therefore, upper elementary students may generate a conception of negative numbers based on their whole number understanding (e.g., Bofferding, 2014) without getting formal feedback. For example, students may always subtract a smaller number from a larger number (e.g., Murray 1985). In fact, Aqazade (2017) found fifth graders' preconceptions limited their ability to refine their conceptions of negative numbers and achieve higher scores compared to second graders. Through the conceptual change lens, we explored the role of time and early instruction on students' performance on integer addition and subtraction problems.

1. After being exposed to integer operations in second grade (instruction-only group, Year 1 of the study), how does students' performance on integer addition and subtraction problems differ three years later as fifth graders (instruction + time group, Year 4 of the study)?
2. In Year 4, how do the fifth graders who had integer instruction in second grade (instruction + time group) perform on integer addition and subtraction problems compared to fifth graders who did not have the instruction (time-only group)?

Framework Theory Approach to Conceptual Change

The framework theory for conceptual change refers to enrichment or restructuring of children's existing knowledge to accommodate new knowledge. Consistent with this, students initially interpret integer arithmetic through a whole number lens (Bofferding, 2014; Vosniadou, Vamvakoussi, & Skopeliti, 2008).

Interpretation of the Minus Sign, Addition, and Subtraction

The minus sign holds three different meanings: binary, symmetric, and unary (Vlassis, 2004). With the binary meaning or subtraction sign, students treat the minus sign as subtraction (e.g., solving -1 + 8 as 8 – 1 = 7; Bofferding, 2010). The symmetric meaning designates taking the opposite (Vlassis, 2004); with this interpretation, students may treat negative numbers as positive and add the negative sign to their answer (e.g., solving -7 – -7 = -0; Bofferding 2010). The unary meaning indicates negative numbers, as seen when students start with the negative number and count towards negative or positive directions (Bofferding, 2010). With positive numbers, subtraction involves a decrease in magnitude (Vosniadou, Vamvakoussi, & Skopeliti, 2008), but with integers, subtraction can result in a decrease or increase (Bofferding, 2014). Students' ideas of only subtracting the smaller number from a larger one, subtraction as moving downward, and addition as moving upward are challenged with integers (e.g., Bofferding, 2014; Murray, 1985).

Methods

Participants and Setting

We have collected data for four years as part of a larger study. Twenty-nine students participated as second graders in Year 1 of the study (*instruction-only group*) and three years later as fifth graders in Year 4 of the study (*instruction + time group*). Seventy-three additional fifth graders were in Year 4 who did not have integer instruction in their second-grade year (*time-only group*). All students were recruited from two rural, elementary schools in the Midwest (about 30% were English Language Learners, and 80% qualified for reduced-price lunch).

Design and Analysis

In Year 1, second graders (instruction-only group) completed a pretest on integer addition and subtraction. Then over three sessions, groups of two to four students explored integer order and symbols and played a movement game on a number path. Next, students individually compared integers and received immediate feedback. After the sessions, students participated in a whole-class lesson on integer addition and subtraction. Then, they completed a posttest. After both tests, we interviewed 20% of the students about their strategies. In Year 4, fifth graders (time-only and instruction + time groups) took an interviewed pretest involving integer addition and subtraction problems. We focus on the data from the Year 1 posttest and Year 4 pretest.

For analysis, we used a repeated measure ANOVA to compare the instruction-only and instruction + time groups' performance on the common test items (i.e., 1 – 4, -2 – -6, -5 – -5, -1 + 8, -9 + 2, and 7 + -3), which provided information about the role of time. Afterwards, we explored students' most frequent answers and strategies on the items. We used a median test to compare students' performance in the instruction-only group from Year 1 to students' performance in the time-only group from Year 4 on the common items to investigate the role of time only versus early instruction only. Finally, we used a median test to compare time-only and instruction + time groups on all 29 integer problems from the Year 4 pretest.

Findings

Research Question One: Role of Time

Students who participated in Year 1 as second graders performed significantly better on the addition and subtraction problems when solving the same problems three years later as fifth graders (addition, $F(1, 27) = 5.32$, $p = .029$ and subtraction, $F(1, 27) = 12.385$, $p = .002$).

Instruction-only versus instruction + time, solving 1 – 4. A majority of students responded 3, incorrectly commuting the problem; the average percentage of students answering 3 remained stable over time. Moreover, 11 (37%) students answered 3 in both years, suggesting time influenced little to change this conception of subtraction. A larger percentage of students answered -3 in Year 4 than Year 1, suggesting some students changed their thinking. In fact, 6 (21%) students correctly changed their answer from -5, 3, or -2 to -3. Those who changed from -5 to -3 indicated attention to the operation, those who changed from -2 to -3 indicated more accurate counting, and those who changed from 3 to -3 indicated advances in integer subtraction.

Table 1: Most Frequent Answers on Common Integer Subtraction Problems

Groups	1 – 4			-2 – -6			-5 – -5			
	0	3	-3	4	-4	-8	0	-0	10	-10
Instruction + Time	3%	55%	38%	34%	48%	14%	86%	10%	0%	3%
Instruction-Only	3%	52%	24%	28%	17%	34%	59%	3%	10%	28%
Time-Only	0%	70%	22%	21%	47%	23%	58%	25%	0%	14%

Note. Grey cells indicate the most frequent response in each group for each problem.

Instruction-only versus instruction + time, solving -2 – -6. For students in the instruction-only group, -8 was their most common response. Students answering -8 often added the absolute values of the integers and made the answer negative, a symmetric meaning of the minus sign. Likewise, they could get -4 by solving 6 – 2 = 4 and making the answer negative. Another strategy to get -8 was to start at one number and move in the negative instead of positive direction, a unary meaning of the minus sign. Students could get the correct response using their whole number understanding and solving 6 – 2 = 4; however a correct strategy would be to start at -2 and move in a less negative direction. Among students who were in both instruction-only and instruction + time groups, 5 (17%) students changed their answer from -8 (Year 1) to -4 (Year 4), and 4 (14%) changed their answer from 4 to -4. In addition, 7 (24%) students correctly changed their answers from -4, -8, and 8 to 4. Those who changed from -4 or -8 to 4 demonstrated an understanding of the binary and unary minus signs and directed subtraction; those who changed from 8 to 4 realized the problem involved subtraction, not addition.

Instruction-only versus instruction + time, solving -5 – -5. Students in the instruction-only group more often responded -10 compared to students in the instruction + time group. Students could answer -10 based on two solution strategies: using the unary meaning of the minus sign without correct directional movement or using the symmetric meaning with an incorrect use of operation. Compared to 1 – 4 and -2 – -6, students performed higher on this problem. Among students in both instruction-only and instruction + time groups, 15 (52%) students continued to answer 0, and 10 (34%) changed their answers from -10, 10, or -0 to 0. Those who changed from 10 to 0 noticed that the problem involved subtraction. Those who changed from -10 or -0 no longer relied on the symmetric meaning of the minus sign. Even though few students responded -0 in both groups, 2 (7%) students in the instruction-only group changed their correct answer to -0 three years later. This often occurred for students who initially ignored the negatives.

Research Question Two: Role of Early Instruction

Comparing the time-only versus instruction-only group's scores on the common items with the median test indicated no significant difference between their performances. These findings suggest the effects of early instruction could play a similar role as the effects of time without early instruction. Students' performance in the instruction + time group compared to the time-only group on integer addition and subtraction problems revealed no significant difference on the integer addition problems and a significant difference favoring the instruction + time group on the subtraction problems ($X^2 = 4.254$, $p = .039$) (see Table 1).

Instruction + time versus time-only, solving 1 – 4. Students in the time-only group answered 3 more frequently than students in the instruction + time group. Further, 7% of students in the time-only group provided negative answers close to -3 (i.e., -2, -1, -4).

Instruction + time versus time-only, solving -2 – -6. Interestingly, -4 was the most regular answer among both groups. The slightly more frequent responses of -8 among students in the time-only group compared to the instruction + time group is related to their lower percentage of correct answers. However, students in the time-only group answered with -0 in two instances, indicating a symmetric meaning of the minus sign. Actually, students in the time-only group responded with negative answers more often than the instruction + time group (73% versus 55%). Students in this group also provided positive answers including 7, 6, and 2.

Instruction + time versus time-only, solving -5 – -5. Even though both groups did not have 10 as their answers, the time-only group had positive answers such as 5 and 2. An answer of 5 could result if considering one of the -5's as worth as 0 and interpreting the other one as a positive five. Similar to -2 - -6, students in the time-only group had more negative numbers compared to students in the instruction + time group. For example, students in the time-only group more frequently answered -0, representing a symmetric treatment of the minus sign.

Implications and Discussion

We investigated the effects of time and early instruction on negative number operations on students' integer addition and subtraction performance. Consistent with conceptual change theory, time played an important role (Vosniadou, Vamvakoussi, & Skopeliti, 2008). The instruction-only group shifted toward a unary conception of the minus sign and interpreting the subtraction operation as corresponding to a directional movement three years later in the instruction + time group. The significant difference between the instruction + time and time-only groups on subtraction problems suggests early integer instruction can support understanding. The time-only group provided more negative answers, which could correspond to overusing the symmetric meaning of the minus sign. Overall, an early exposure to negative numbers was beneficial for students' integer learning, which could conceptually develop through time.

SECOND AND FIFTH GRADERS' INTEGER SUBTRACTION PERFORMANCE: LEARNING FROM CONTRASTING WORKED EXAMPLES

Laura Bofferding
Purdue University

Mahtob Aqazade
Purdue University
maqazade@purdue.edu

We explored 105 second and fifth graders' performance on integer subtraction problems before and after analyzing different contrasting worked examples involving integers. The students, as part of a larger study, completed a pretest, were randomly assigned to intervention groups -- which differed in the problems they compared -- and participated in two small-group sessions, one whole-class lesson on integer subtraction, and a posttest. The students made progress in solving integer problems from pretest to posttest. In this paper, we focus on students who provided only positive or zero answers on their pretest. The trends in their posttest answers show important differences among the intervention groups concerning their use of number order and interpretations of operations in integer arithmetic.

Keywords: Number Concepts and Operations, Cognition, Elementary School Education

Theoretical Framework

Based on a framework theory view of conceptual change, children initially interpret mathematics numerical problems through a whole number lens, due to their experiences interacting with objects (Vosniadou, Vamvakoussi, & Skopeliti, 2008). Learning about negative numbers can challenge their framework theory of numbers in several ways, including their interpretation of minus signs and the meaning they ascribe to operations. Older students may refer to rules about the use of signs when solving problems with negative numbers rather than articulating conceptual justifications for their solutions (Bishop, Lamb, Philipp, Whitacre, & Schappelle, in press), possibly because they are less willing to change their prior conceptions (Aqazade, Bofferding, & Farmer, 2017). However, some research has shown that young children are willing to play with and make sense of negative numbers (Aze, 1989). We investigate how different problem contrasts might promote conceptual change with second and fifth graders.

Interpretations of Minus Signs and Operations

Using their framework theory for numbers, children's initial interpretations of the minus sign correspond to the subtraction operation, *the binary meaning* (Vlassis, 2004). With this interpretation, they often treat negatives as subtraction signs (e.g., solving 9 – -2 as 9 – 2 – 2 = 5; Bofferding, 2010) or ignore them completely. However, there are two additional meanings of the minus sign. The *symmetric* meaning of the minus sign corresponds to taking opposite of a number (Vlassis, 2004), as seen when students operate with integers as positive and make the answer negative or draw comparisons between positive and negative forms (e.g., solving -7 – - 7 = -0; Bofferding, 2010). The *unary* meaning of the minus sign designates a negative number (Vlassis, 2004), as seen when students start at a negative number and count in a correct or an incorrect direction (Bofferding, 2010).

Students learn positive number subtraction as counting down, which corresponds to a decrease in numerical magnitude (Vosniadou et al., 2008). However, with negative numbers, students need to learn that subtracting a negative number corresponds to counting up (Bofferding, 2014) and that subtraction could result in a decrease or increase in magnitude from the initial number. One way to help students distinguish the roles of the minus sign in operations involving negative numbers is through analyzing contrasting cases with worked examples.

Worked Examples and Contrasting Cases

Worked examples can help reduce the cognitive load of managing many new concepts or steps at a time so that students can focus on understanding the problems and using them to solve related problems (e.g., Hilbert, Renkl, Kessler, & Reiss, 2008). Likewise, contrasting cases can help students to notice important differences between problems to discern an underlying structure (Schwartz, Tsang, & Blair, 2016), learn new solution methods (e.g., Rittle-Johnson & Star, 2011), refine their prior understanding, and promote conceptual understanding (e.g., Namy & Gentner, 2002). With subtraction, helpful contrasts could include comparing positive minus positive problems with a) negative minus negative, b) negative minus positive, or c) positive minus negative problems. This research investigated the following questions: When learning integer subtraction, how do these contrasts and a short lesson benefit second and fifth grade students? What contrasts best help them make sense of integer subtraction problems?

Methods

Participants and Design

Participants included 95 second graders (from the larger study with 133 second graders) and 10 fifth graders (from a larger group of 74 fifth graders) from two rural, elementary schools in the Midwest (Free and reduced lunch: 30% and English Language Learners: 79%). This subset consistently answered with positive numbers or zero on the pretest (which is why the number of fifth graders in the subsample is so small). After a pretest, students were randomly assigned to a control or one of three experimental groups, participated in two small-group sessions, engaged in a whole-class lesson on integer subtraction, and took a posttest.

Data Sources and Procedure

Pretest and posttest. We focused our analysis on four, single-digit integer addition and 17 subtraction problems involving negative integers that were identical on both tests. We interviewed at least 20% of the larger sample after each test to learn more about their reasoning.

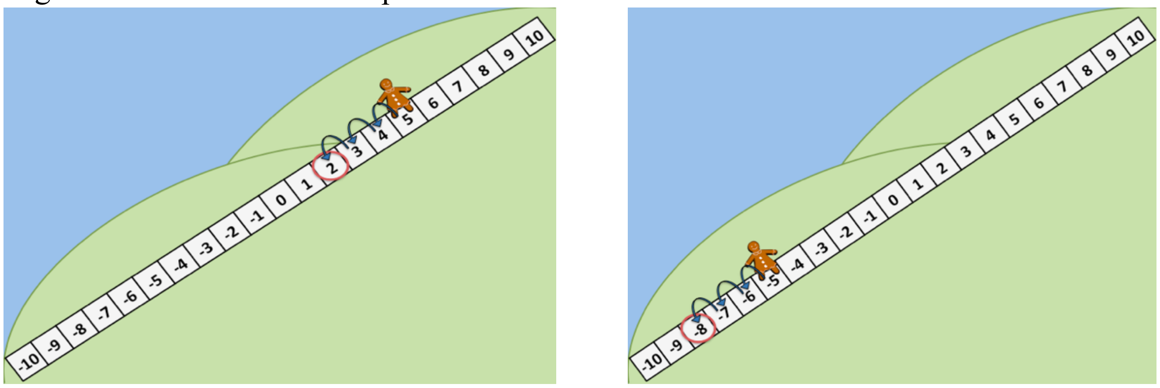
Small-group sessions. In two small-group, 20-minute sessions, groups of 2-3 students analyzed sets of contrasting integer addition problems (control group: Add) or subtraction problems (experimental groups: Negative Minus Negative, Negative Minus Positive, and Positive Minus Negative, named based on the problem type they initially saw contrasted with 5 – 3 in their first session). See Table 1 for the groups' contrasting examples seen each session.

Table 1: Examples of problems control and experimental groups compared each session

	Groups	First Session	Second Session
2nd	**Add (control)** (*n* = 25)	P + P vs. P + N	N + P vs. N + N
	Negative Minus Negative (*n* = 21)	P – P vs. N – N	N – P vs. P – N
	Negative Minus Positive (*n* = 26)	P – P vs. N – P	P – N vs. N – N
	Positive Minus Negative: (*n* = 23)	P – P vs. P – N	N – N vs. N – P
5th	**Add (control)** (*n* = 4)	P + P vs. P + N	N + P vs. N + N
	Negative Minus Positive: (*n* = 6)	P – P vs. N – P	P – N vs. N – N

Note: N = Negative number, P = Positive number

In their small-group sessions, students discussed the similarities and differences between the problems and pictures in contrasting, worked-examples (see Figure 1). Students solved related integer addition or subtraction problems at the end of each session.



Correct: 5 – 3 = 2 Correct: -5 – 3 = -8

Figure 1. Comparison of worked examples and corresponding problems that students analyzed.

Whole-class instruction. During the 30-minute lesson, students helped solve problems on a number path, where subtracting a negative number corresponded to moving in a less negative direction (or up) and subtracting a positive number corresponded to moving in a less positive direction (or down). We ordered the problems to emphasize differences (e.g., 3 – 3 then 3 – 4).

Analysis

First, we coded students' strategies based on the possible ways they could have obtained their answers. Then, we looked at their pattern of responses (e.g., Widjaja, Stacey, & Steinle, 2011) and only gave credit for correct answers if they *followed a pattern of using knowledge of negatives.* For example, a student who solved 1 – 4 = 5, -5 – 9 = 14, and 9 – -2 = 11 was classified as adding the absolute values of two integers. Therefore, we did not give credit for 9 – -2 = 11. When possible, we used our interview data to check the identified pattern of responses.

Results, Discussion, and Implications

On the pretest, based on students' overall strategies and verbal reports, the only problems students got correct happened without knowledge of negatives, so we treated all pretest scores as zero. On the posttest, based on the same analysis, students improved from the pretest. Table 2 shows students' average number correct for the posttest subtraction items.

Table 2: Overall subtraction average scores on the posttest across groups

	2nd Add (n = 25)	**2nd NMN** (n = 21)	**2nd NMP** (n = 26)	**2nd PMN** (n = 23)	**5th Add** (n = 4)	**5th NMP** (n = 6)
Overall Subtraction	0.88	0.62	**1.23**	0.43	**0.75**	0.17

Note. Add = Control group, NMN = Negative Minus Negative group, NMP = Negative Minus Positive group, PMN = Positive Minus Negative group,

Overall, second graders in the Negative Minus Positive experimental group had the highest performance across the majority of items. The performance of the groups followed an interesting pattern based on their answers. Second graders in the Positive Minus Negative group frequently reversed the order of the numbers–49% on average for the P – P problems and 35% on average for N – P problems–and subtracted the smaller absolute value from the larger, indicating a strong framework theory conception. The Add and Negative Minus Negative groups used this strategy frequently on two of the P – P problems (solving 1 – 4 with 3 and 0 – 9 with 9) and one of the four N – P problems (solving -7 – 4 with 3); otherwise, the majority of second graders answered 0, suggesting they ignored the negative sign without switching the order of the numbers. The second graders in the Negative Minus Positive group primarily answered 0 for for 1 – 4 (27%) and 4 – 5 (38%) and answered 9 for 0 – 9 (62%); overall, their performance on these items was double that of their second grade peers in other groups. Although they were most likely to answer 4 for -5 – 9 (27%), on -3 – 3, 46% answered 0, followed by 19% who correctly answered -6, and on -2 – 3, their top answers were evenly split amongst -5, 0, and 1 (each 19%). This group's initial comparisons better preserved their understanding of subtraction in terms of which direction to count when subtracting a positive number and helped them develop a better sense of the unary meaning of the minus sign. The fifth graders in the Negative Minus Positive group were most likely to reverse the numbers for 1 – 4 and 4 – 5 (42% on average) but answered 0 for 0 – 9 (50%). On -5 – 9, they were equally likely to answer 4 or -4 (33% each), and 50% answered -2 for -7 - -9, suggesting they were more likely to use the symmetric meaning of the minus sign. Even with our conservative analysis, students did make important changes from pretest to posttest in just over an hour of engagement; however, it may be worthwhile to have students participate in additional sessions, so that all problem types can be better contrasted.

COMPARISONS WITH CLOSEST AND MOST: SECOND AND FIFTH GRADERS' CONCEPTIONS OF INTEGER VALUE

Lizhen Chen

Laura Bofferding
Purdue University
lbofferd@purdue.edu

Mahtob Aqazade
Purdue University
maqazade@purdue.edu

Elementary students have difficulty learning integer values as the new knowledge conflicts with their whole number understanding. We administered a pretest and a posttest to 204 second and fifth graders and collected their answers to three types of integer comparison problems: which number is closest to 10, is most positive, and is most negative among three integers. Results showed that second and fifth graders had difficulty determining which of three negative numbers was most positive. They found it relatively easy to determine which of three positive numbers was most positive and which of three negative numbers was most negative. Students had some improvement in their integer value mental models, although their mental model shifts varied by the question phrasing.

Keywords: Number Concepts and Operations, Cognition, Elementary School Education

Traditional numerical comparison questions involving negative numbers largely test students' knowledge of convention as opposed to their conceptions of the numbers. These questions typically ask students to identify which of two integers is greater, larger, or most (e.g., Bofferding, 2014; Whitacre et al., 2017). Determining the larger of two negatives requires that students know that this question prioritizes order and not magnitude (i.e., even though -4 has a greater magnitude than -2, -2 is considered larger because it is further to the right on a number line). However, comparison questions rarely ask specifically about order (i.e., which number is closest to another number). In order to capture students' understanding of integer comparisons without forcing them to rely on convention, we explored the following research questions.

1. How do second and fifth graders' integer comparison performance differ based on the language of the comparisons (question phrasing: closest to 10, most positive, and most negative) and the numbers involved (all positive, all negative, positive or zero and negative)?
    a. In terms of number of students to correctly compare the integers?
    b. In terms of their mental models for integer values?
2. For second and fifth graders with initial value mental models on the pretest, how do their mental models change, depending on the question phrasings?

Theoretical Framework

Bofferding (2014) categorized students' mental model models of integer order and values into initial, synthetic, and formal, along with two transitional levels. Students exhibiting initial integer mental models ignore negative signs by operating with negative numbers as if they are positive. Students exhibiting a transition I mental model can differentiate between negative and positive numbers but sometimes treat the negative numbers as zero or positives. Students exhibiting synthetic integer mental models perceive the negative numbers as numbers below zero; though, they consider negative numbers with larger absolute values as greater than negative numbers with smaller absolute values (e.g., -6 > -1). In between the synthetic and formal integer mental models are transition II mental models, when students sometimes interpret negative numbers at the synthetic level but sometimes interpret them correctly. Students holding formal mental models know that positive and negative numbers are symmetric around zero and that negative numbers with bigger magnitudes have smaller values.

Students need to shift from a categorical to a continuum-based understanding of integers. With the introduction of negative numbers, the language use of more and less associated with numbers becomes challenging. Students with a categorical understanding might think that *more* corresponds to a greater absolute value (e.g., -5 > 3) and *less* corresponds to a smaller absolute value. They need to develop an understanding of directed magnitude language on a continuum where *more* has two meanings: *more positive* or *more negative* (Bofferding, 2014).

Methods

Participants and Setting

Participants came from three rural elementary schools in the midwestern United States where 74% to 87% of the students in each school received free or reduced price meals and 25% to 38% of the students were English Language Learners. Overall, 102 second graders and 102 fifth graders participated in this study to completion.

Design and Materials

The study involved a pretest, four small group sessions, a whole-class lesson, and a posttest. On the pretest, we conducted a whole-class written test including comparisons with the three question phrasings, and students chose answers from three positive numbers, three negative numbers, and a mixed set of positive or zero and negative numbers. Then students, who were randomly assigned to small groups, analyzed pairs of worked examples about integer operations. All groups saw similar problems but in different orders, and all students heard the language of *more positive* and *more negative* as part of the sessions. Next, students received a 30-minute, whole-class lesson that emphasized language use in integer operations. Finally, we conducted the posttest, which contained the same comparison problems as in the pretest.

Analysis

First, we calculated the number of students at each grade level who correctly answered each comparison problem. Next, based on each students' pattern of responses, we determined students' integer and value mental models for each question phrasing by using Bofferding's (2014) mental model framework. For example, we classified students who determined which integer was closest to 10, most positive, or most negative by selecting the largest absolute value for each question as exhibiting initial mental models. We aimed to find patterns in the shifts of students' mental models between pretest and posttest.

Results

Fifth and Second Graders' Gains from Pretest to Posttest

Both on the pretest and the posttest, second graders had difficulty determining which of three negative numbers was most positive; whereas, they had a much easier time determining which of three negative numbers was most negative. This is likely because they only had to consider the numbers' absolute values. Interestingly, they did better than chance in identifying which of three positive numbers was most negative. This required them to avoid focusing on the word "most" in the term. Their higher performance on identifying the most negative of positive numbers as opposed to the most positive of negative numbers may reflect their overall greater familiarity with positive numbers.

Second graders experienced an overall improvement from the pretest to the posttest, with the greatest improvement occurring on mixed comparison problems for the most positive question phrasing. This result suggests that students were attuned to the word *positive;* perhaps that reminder helped them avoid focusing solely on the largest absolute value, which may have been more likely if they interpreted closer to ten as closer to *a* ten.

Unsurprisingly, fifth graders had better overall performance than second graders on all integer comparisons. A similar, but slightly different, pattern was visible for fifth graders as second graders. Fifth graders did better on all positive comparisons than on all negative problems, even for the most negative question phrasing unlike second graders. They scored relatively low (71.0 on pretest and 82.6 on posttest) when choosing the most positive numbers from all-negative integers, as found with the second graders.

Mental Models on Pretest and Posttest

On the pretest, 61.8% of fifth graders, on average, exhibited formal integer value mental models while an average of 23.5% of fifth graders exhibited initial mental models. On the other hand, at the pretest, a majority of second graders did not know about negative numbers yet, so 49.3% of second graders exhibited initial integer value mental models while an average of 7.5% exhibited formal mental models.

On the pretest closest to 10 problems, 90.7% of second graders on average chose numbers with the biggest absolute values when all numbers were positive. The likelihood that students responded this way decreased for the *most positive* problems and was lowest for the *most negative* problems. These decreases indicate that those who exhibited initial mental models did not solely choose numbers with the biggest absolute values. Therefore, second graders tried to make sense of the compound meanings of *most positive* and *most negative*.

Second graders seemed to be more sensitive to *most* than *positive* or *negative* when they decided the meaning of *most positive* and *most negative*. This is consistent with Bofferding and Farmer's (2018) findings that students chose least of the cold (i.e., smallest negative) instead of least cold (i.e., warmest or biggest positive). For *most positive*, students would get similar answers if they focused on either *most* or *positive*. This is not the case for *most negative*. This mismatch could be a reason why the choices between biggest and smallest absolute values became more varied even for these comparisons. A second grader F08, for example, thought of *most negative* as most and *least negative* as less.

Mental Model Changes

Overall, we categorized both fifth and second graders as exhibiting higher integer value mental models on the posttest than on the pretest. The number of students classified as exhibiting Random, Initial, and T1 mental models decreased on the posttest while those classified as exhibiting Magnitude, T2, and Formal mental models increased. When focusing on students who started with initial mental models, the improvement took on different patterns between fifth and second graders (see Table 1).

On the posttest, fifth graders' mental models mostly shifted to Formal (with some at the Synthetic and Transition II levels). By contrast, most second graders either remained at the initial level or shifted their mental models across T1, Synthetic, and Formal, a much broader range. Interestingly, second graders who started with initial mental models had the largest percent of students exhibiting formal mental models on the posttest for the most negative question phrasing; whereas, fifth graders had the most formal mental models for the closest to 10 question phrasing. The numbers show that students did not always have the same mental model classifications for each question phrasing. Take second grader B04 as an example. This student "saw the negatives down and the rest that didn't have negatives were up" and exhibited a formal mental model for the closest to 10 phrasing. For *most positive*, though, the student chose the largest absolute values, and for *most negative*, the student chose the smallest absolute values.

Table 1: Students' Mental Model Shifts in terms of Percent for Those with Initial Mental Models on the Pretest for each Question Phrasing

Mental Model Changes	Second Graders			Fifth Graders		
	Closest to 10 (n=69)	Most Positive (n=49)	Most Negative (n=33)	Closest to 10 (n=22)	Most Positive (n=26)	Most Negative (n=29)
Initial to Random	8.7%	4.1%	0%	0%	3.8%	0%
Initial to Initial	53.6%	36.7%	51.5%	27.3%	11.5%	31.0%
Initial to Transition I	8.7%	24.5%	15.2%	4.5%	3.8%	3.4%
Initial to Synthetic	13.0%	22.4%	3.0%	4.5%	11.5%	3.4%
Initial to Transition II	5.8%	2.0%	0%	4.5%	0%	24.1%
Initial to Formal	10.1%	10.2%	30.3%	59.0%	50.0%	37.9%

Conclusions

Second graders' higher performance on the mixed questions for most positive and most negative compared to closest to 10 suggests that students do not necessarily coordinate order and value when they learn about negative integers. The implication of these results is that early integer activities need to explicitly highlight both elements of order and value to help students attend to these concepts. Moreover, regardless of their different grade levels, most students found it difficult to determine which integer was *most positive* among three negatives and which was *most negative* among three positives. This result might suggest that students need additional language support to shift from categorical to a continuum-based understanding of integers. Considering that those who started with initial mental models had different areas of improved progress, elementary teachers might consider multiple instructional ways to address students' various needs.

WHAT DOES THE LOW-ACHIEVING LABEL TELL US ABOUT STUDENTS' CONCEPTUAL UNDERSTANDING OF VARIABLES?

William DeLeeuw
Arizona State University
William.DeLeeuw@ASU.edu

This study investigated the differences in conceptions of variable among the groups of students labeled as having mathematics difficulties (MD) and typical mathematics achievement (TMA). Analysis students' responses on items involving the comparison of expressions involving generalized quantities provided data. The theoretical framework for this study was based upon the learning trajectory (LT) of the levels of sophistication of students' conceptions of variable. Data analysis included descriptive and inferential statistics. Results revealed little evidence of differences between MD and LMA students' conceptual understandings. That students labeled as MD and TMA can have similar levels of sophistication of conceptions of variables suggests that current measures of achievement provide an incomplete picture of students' understandings of algebra, and also disproportionately disadvantage those labeled as low-achieving.

Keywords: Algebra and Algebraic Thinking, Equity and Diversity, Instructional activities and practice

Algebra is often identified as an exemplar of mathematical abilities. Moses and Cobb (2001) described algebra as necessary for all students in to understand and succeed in a world with ever-increasing technological integration. Opportunities to be successful in algebra have been called equity and civil rights issues because of the limitations that low algebra achievement places upon individuals' career opportunities (Kaput, 1998; Moses & Cobb, 2001). Kaput and Blanton (2000) describe students' disappointing algebra understandings, public dislike of mathematics, and the inequity of academic tracking as problematic. These aspects can be linked to U.S. teaching practices and curricula that are focused on procedural skills instead of conceptual understanding. Kieran (2013) described the separation of procedural and conceptual understanding as a "false dichotomy" that has especially impacted the field of school algebra. She states that despite traditional instructional practices, even the symbolic aspects of algebra, have conceptual foundations that students need to develop. Since variable use is a major component of algebra and students' understanding of algebra has been identified as problematic, it is reasonable to hypothesize that students' understanding and use of variable may also be problematic. Students who see a variable as representing a single unknown value are more limited algebraic thinking, problem solving, equation solving, and making generalizations than those with a more sophisticated conception of variable. (Cai, Moyer, Wang, & Nie, 2011).

While the work done in this area is substantial, there is a gap in the research around examining specifically how the uses and conceptions of variables differ between successful algebra students and those who have difficulties in algebra. Research has suggested that students who have difficulties in mathematics differ from their typically-achieving peers in both mathematics-specific and more general characteristics. These differences have been attributed to environmental and cognitive factors. Mathematics-specific characteristics of students who have been labeled as low-achieving in mathematics are reported to include difficultly both storing and recalling basic arithmetic facts, which impact students' ability to achieve fluency in computation (Geary et al., 2012). They also experience delays in achieving accuracy and fluency in arithmetic operations and procedures and typically have a limited conceptual understanding of how and why the procedures work leading to a reliance upon less advanced solution strategies than their typically-achieving peers. I describe these students as having *mathematics difficulties* (MD).

There is not consensus about how to identify MDs from their typically-achieving peers (TMA) (Mazzocco, 2007). The "single-cutoff method", where students with MD are identified by creating one low-achieving and one typically achieving group of students based on their score on a standardize assessment is most commonly used. But this method has several draw backs including only providing a snapshot of a student's performance and typically focusing on procedural proficiency. Lewis (2014) warned the limited focus of research on MD students has resulted in low procedural fluency as a de facto defining characteristic of students with MDs. This neglects the more complex and conceptually-based aspects of mathematics. The cut-off score of 25% is most commonly used to identify students as MDs (Geary et al., 2012).

Statement of the Problem

Students are labeled as low-achieving and/or as having a MD based on the results of a single standardized and typically primarily procedural assessment. Such an assessment only provides insight into a portion of the mathematics that we want our students to know and understand. This leaves a significant gap in our understanding of specific differences between conceptions and use of variables amongst students with MD and TMA students. The purpose of this study is to investigate the differences between the responses of low- and typically-achieving students in an Algebra 1 course on items designed to assess students' ability to compare expressions involving variables.

Research Question

The general question under investigation is: Do the responses of students who are at or below the 25th percentile on the Iowa End of Course assessment (IEOC), and those of students who are above the 25th percentile differ on eight items designed to assess students' ability to compare expressions involving generalized quantities on a conceptual progress-monitoring tool at the beginning of an algebra course?

Theoretical Framework

The theoretical framework guiding this study builds on the notion that different uses of variables suggest corresponding levels of sophistication of conceptions of variable. A student's conception of variable is the student's idea of what a variable is, how it acts, and what it can represent. A student's use of variables refers to the actions that the student does in connection with this conception of variable. While we cannot know exactly what a student's conception of variable is, we can make inferences about that conception based on how the student uses variables. Blanton, Brizuela, Gardiner, Sawrey, and Newman-Owens (2015) described a progression of these conceptions and uses of variable in their learning trajectory (LT) that characterized increasingly sophisticated levels in students' thinking about variable and variable including: *Pre-Variable, Letter as Representing Variable with Deterministic Value, Letter as Representing Variable with Fixed but Arbitrarily Chosen Value, Letter as Representing Variable as Varying Unknown, and Letter as Representing Variable as Mathematical Object*.

In addition to this perspective about the connections between students' uses, misconceptions and conceptions of variables, the theoretical perspective taken with respect to students with MD is influential in the structure of my study. In this study, I view all learners as part of a normal distribution of mathematics achievement and growth as described by Geary et al. (2012). While groups of learners are not independent of each other, this does not preclude different, but overlapping, sets of characteristics. The perspective that all students are part of this distribution does not require that all students have the same factors in their mathematical achievement and growth. Specifically, I take the perspective that these MDs that students experience are the result of cognitive differences in comparison with their TMA peers (Lewis, 2014; Mazzocco, 2007). These differences are not deficits in the sense that students with MLDs are deficient in the ability, or are unable, to learn the content with which they are experiencing difficulty. Rather, students with MLDs have different connections and conceptions than their TMA peers within the foundational aspects of the content which inhibit the typical connections from these foundational topics to next level of content. Thus, these few who exhibit abnormal connections can be thought of as the left tail of the normal distribution described by Gearyet al. (2012).

Methodology

Using data collected as part of the *Algebra Screening and Progress Monitoring* project (Foegen & Dougherty, 2010), I analyzed students' responses to a subset of items on a conceptual algebra progress monitoring measure to identify and describe differences among the MD and TMA groups of students. The Project (Funding information) provided the context for my study. From the literature on students with MD (e.g., Geary et al., 2012), students were separated into two groups: TMA and MD. Students were assigned to one of these groups based on percentile rank of their Iowa End of Course (IEOC) assessment score. Students with scores at or below the 25th percentile MD. Students with scores higher than the 25th percentile were considered TMA.

Using the levels of sophistication of conceptions of variable from Blanton et al.'s (2015) LT, I coded student responses and multiple-choice options as consistent with of a specific TL level or misconception. In my study, these different descriptions of how students think of and use variables were used to classify students' responses on items designed to assess students' ability to compare expressions involving generalized quantities. These classifications were then compared across the MD and TMA groups using descriptive and inferential statistics and coded for the concepts of variable. It is important to note that letters as variables can have different roles in different situations. In all of the items that were considered for this study, the variables represented generalized quantities that were not dependent on other quantities. For example, one of the items asked students to compare the expressions "$5 + t$" and "$t + 3$".

Summary

Both the similarities and the differences identified in this study between MD and TMA student responses to items designed to assess their ability to compare expressions involving variables support the claim that most students in an algebra 1 course do not have and are not developing a conception of variable that allows for the variable to represent more than one value at a time. The few differences identified suggest that items with more complex operational, procedural, or property-based contexts are less accessible to MD students. The similarities identified support the claim that procedurally focused assessments provide incomplete descriptions of students. In both cases, MD students are disproportionately disadvantaged and these disadvantages impact not only their school experiences, but can have long-lasting impacts on career opportunities as well. These findings have implications for the classroom.

Closing Statement

In closing, this investigation revealed that the differences between MD and TMA students are limited and seem to be related to the level of complexity of the operations, procedures, and properties that are incorporated into an item. More than these differences, the similarities that were illuminated by this study impact how we perceive what successful and struggling students may look like, and what they need. The overall low proportion of students who have a sophisticated conception of variable suggests that all students need access to better conceptual instruction and experiences in algebra. The context and content of this instruction need to be appropriate for all students, which may mean that MD students required additional support than their TMA peers in developing these sophisticated conceptions of variables.

Despite the similarities that were identified in this study, students who are identified as MLD or MD may be disproportionally disadvantaged by traditional instructional practices and data-based decision making based on procedurally focused assessments and instruction these disadvantages need to be further investigated. These are the students most at risk to be "innumerate" (Geary et al., 2012, p. 206) because of the long-lasting impact that being labeled as low-achieving can have on school mathematics opportunities and on future career options. These are the students who need our help. Through experiences with and exposure to variables that represent more than just one value from a younger age, these students can begin to develop a solid foundation upon which to build their future successes, both mathematically and as a contributing member of society.

The identification of these limitations of the current ways in which we label students as provides an opportunity to reexamine how students are labeled and what we call a "successful student". This examination must lead us to consider how can we change our current instructional practices to provide more equitable access to all students, regardless of how they perform on a standardized test.

HOW QUANTITATIVE REASONING CAN SUPPORT GRAPH UNDERSTANDING IN ALGEBRA

The construction and interpretation of graphs is a key mathematical activity, particularly at the middle school level, when students' experiences form the foundation for their reasoning about functions and relations. However, research demonstrates that students experience challenges in interpreting and understanding graphs. One promising avenue is an emphasis on graphs as representations of quantities varying in tandem. We present a case of two middle-school students, one who emphasized quantities and their relationships and one who did not. We found that attention to quantities fostered ratio concepts and supported appropriate slope conceptions.

Keywords: Algebra and Algebraic Thinking, Cognition, Middle School Education

Graphing is a key aspect of mathematical understanding and represents a "critical moment" in middle school mathematics for its opportunity to foster powerful learning (Leinhardt, Zaslavsky, & Stein, 1990). However, students experience a number of challenges in constructing, interpreting and making sense of graphs (e.g., Moore & Thompson, 2015). In addressing these challenges, researchers have offered several characterizations of students' understanding of graphs. For instance, Lobato, Rhodenhamel, and Hohensee (2012) differentiated between understanding slope as a mathematical object (a relationship between quantities' values) versus a physical object (a property of visual steepness), which is similar to Zaslavsky, Sela, and Leron's (2002) two conceptions of slope, analytic and visual. Moore and Thompson (2015) distinguished between static and emergent shape thinking, in which the former involves conceiving of a graph as a shape qua shape, and the latter entails envisioning a graph as a trace of covariation. In their work, Moore and Thompson (2015) point to the need to support students' abilities to make sense of graphs emergently. This is particularly true at the middle-school level, which is when students are typically introduced to function graphs and develop graph-related conceptions that will influence their future mathematics experiences. One potentially promising way to support productive conceptions is to emphasize covariation, in which students conceive of graphs as a representation of quantities varying in tandem (Moore & Thompson, 2015). Thus, we investigate the following question: How does attending to covarying quantities affect middle-school students' construction and interpretation of graphs? In order address this question, we present a case study of two students, one who regularly referenced quantities in graph construction and interpretation and one who did not, and discuss these students' resulting conceptions and sense making.

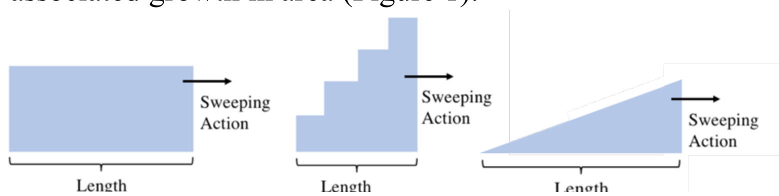
Theoretical Framework: Quantitative and Covariational Reasoning

Thompson (1994) defines a quantity as an individual's conception of the measurement of an attribute of an object. It is composed of a conception of an object, an attribute, an appropriate unit, and a process for assigning a value to the attribute. Speed, area, and length are all attributes that can be conceived as quantities. When students coordinate the variation in the values of quantities that change together, this is termed covariational reasoning (Thompson & Carlson, 2017). Covariational reasoning entails tracking either quantity's value with the explicit understanding that at every instance, the other quantity also has a corresponding value.

Researchers have characterized students' reasoning about quantities that change in tandem with respect to their graphing activities (e.g., Carlson, Jacobs, Coe, Larsen, & Hsu, 2002). This body of work indicates that students and pre-service teachers benefit from opportunities to use a covariation perspective when making sense of graph features such as slope, intercept, and root (e.g., Ayalon, Watson, & Lerman, 2015). We propose that an approach emphasizing covarying quantities can also be effective in supporting middle-school students' emerging conceptions of graphs.

Methods

We conducted a 10-day, 15-hour videotaped teaching experiment (Steffe & Thompson, 2000) with two 7th-grade pre-algebra students, Wesley and Olivia. The first author was the teacher-researcher. We developed tasks to support a conception of linear growth as a phenomenon of a constant rate of change, and quadratic growth as a constantly-changing rate of change. The tasks emphasized these ideas within the contexts of speed and area. The area tasks presented "growing rectangles", "growing stair steps", and "growing triangles" via dynamic geometry software, in which the students could manipulate the figure by extending the length and observing the associated growth in area (Figure 1).



(a) (b) (c)

Figure 1. (a) Growing rectangle, (b) stair step, and (c) triangle tasks.

Data sources included video and transcripts of each teaching session and copies of the students' work. Our analysis relied on the constant comparative method (Glaser & Strauss, 1967), and was guided by an attempt to account for the commonalities and differences in Wesley's and Olivia's graphical thinking. We developed explanatory accounts of these differences based on evidence from their written work, descriptions of their ideas, their drawings, and their gestures. We then compared and discussed these explanatory themes as a research team until we reached consensus.

Results: Quantitative Reasoning Influences Students' Ratio and Slope Conceptions

Wesley regularly referenced two quantities (area and length) when constructing and discussing his graphs, while Olivia did not. As an example, the students graphed the relationship between area with respect to the length of a growing triangle with a length to height ratio of 5 cm to 2 cm (see Figure 1.c), as well as the area of a rectangle that would sweep out the same total amount of area after a length of 5 cm (Figure 2). Both students labeled the *y*-axis "area" and the *x*-axis "length", although this is not shown in the cropped graphs in Figure 2.

Oliva discussed her graph's shape while Wesley discussed his graph's constituent quantities. When describing her graph, Olivia said, "It starts kind of low and then it gradually gets more curved and then steeper." Olivia described the visual features of the graph itself and did not reference the associated quantities of area and length in the growing triangle context. In contrast, when Wesley explained why the graph of the growing rectangle was straight, he said, "So every 1 cm in length, it's always going to be 1 cm in area." For Wesley, the graph represented a trace of the associated growth between area and length. Olivia did also at times reference the associated attributes area and length, but in a non-quantified manner, which we discuss below.

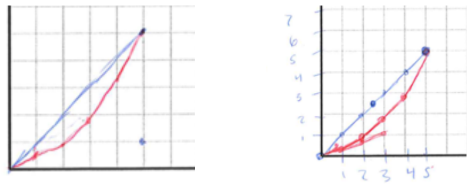


Figure 2. Wesley's (left) and Olivia's (right) graphs of the growing triangle (in red) and rectangle (in blue).

We found two major implications of an explicit attention to both quantities: (a) the development of ratio and rate, and (b) a conception of slope as a ratio. We illustrate these implications through Olivia and Wesley's approach to the "two growing rectangles" task, in which the rectangles grew in length while maintaining the same height (see Figure 1.a). The students observed one growing rectangle with an unspecified height, and then compared it to a second growing rectangle with a larger height (Figure 3).

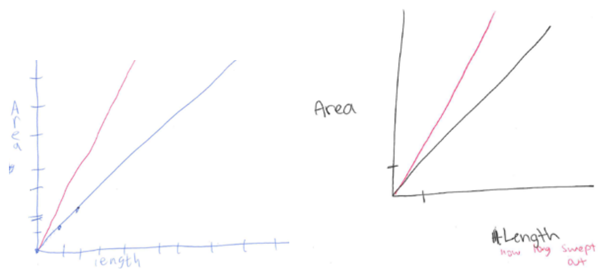

Figure 3. Wesley's (left) and Olivia's (right) graphs of the growing rectangles.

Olivia referenced the attributes length and area when explaining why her graphs were linear: "I sort of pictured it in my head…I knew it would line up because for every length that you've pulled it should be the same amount of area." Olivia mentally coordinated the two attributes, but did not quantify them. In contrast, Wesley decided to think of the height as 1 meter: "If you drag it out 1 meter, so that's the length is 1 meter and the height is 1 meter, and then to find the area you actually times the length by the height which is 1 times 1 is 1 square meter actually." When explaining why the graph of the second rectangle was steeper than the first, Wesley said, "The height is bigger than 1 meter now, then for every length that you pull it 1 meter, it gets more area [than before]." Olivia, in contrast, explained, "The steeper it is, the longer height of the wall it is", where "wall" meant the height of the rectangle.

For Olivia, the slope of her graphs represented one attribute, area, rather than a ratio of area to length. This attention to one attribute also encouraged Olivia to rely on thematic associations (Moore & Thompson, 2015) when considering a graph's slope. Namely, a feature of the graph, such as constant slope, represented a quality of the motion she observed when a rectangle grew, which she described as "consistent". For instance, Olivia justified a constant slope for a growing rectangle graph by stating, "It went consistently as like a straight line", and "The rectangle, it grew at a consistent rate." The association between "consistent" growth and a constant slope also resulted in Olivia initially graphing the area versus length of a growing triangle as a straight line rather than a curve. Her justification was similar in this case: "Mine is going up consistently." Wesley, in contrast, described slope as the ratio of two quantities: "[Slope] means the area covered in a certain length."

Both students frequently created a standard unit for length so that they could compare amounts of area across uniform intervals of length. For Olivia, this process reduced her attention to one attribute, area. In contrast, Wesley attended to both quantities, and created unit ratios. This was evident in his decision to consider the area of the rectangles from Figure 2 in relation to 1 meter of length. In another case, Wesley explained his linear graph of a growing rectangle by remarking, "The height is 1 cm. So, every time it's pulled out 1 cm, the area gets greater by 1 cm squared." Wesley could also conceive of this as a multiplicative comparison; for instance, for a 4-cm high rectangle, he explained, "To get how much the area accumulates by, you do *x* [an unknown length] times 4." When considering growing triangles, Wesley also compared amounts of area accumulated per a standard unit of length, and the unit remained explicit: "Every inch it goes it, like, it goes, it covers more area for that inch so it keeps getting steeper and steeper."

Discussion

Explicit attention to both quantities and a coordinated change in quantities offered meaningful affordances for the creation of unit ratios, the understanding of slope as a ratio, and the ability to conceive of a graph as a representation of coordinated change. Given students' difficulties in conceiving slope as a ratio-of-change (e.g., Lobato et al., 2012), the case of Wesley and Olivia suggests that an emphasis on quantitative reasoning can be a productive route towards meaningful sense-making with graphs. However, simply relying on the use of quantitatively-rich contexts is not sufficient; it does not guarantee that students will attend to both quantities or develop images of coordinated change. Teachers should therefore encourage students to attend to both quantities represented in graphs, to make that attention explicit in their language, and to ask questions that require students to coordinate variation in quantities.

FUTURE MIDDLE GRADES TEACHERS' INCREMENTAL ALIGNMENT OF KNOWLEDGE WITHIN THE MULTIPLICATIVE CONCEPTUAL FIELD

Andrew Izsák
Tufts University
Andrew.Izsak@tufts.edu

Sybilla Beckmann
University of Georgia
sybilla@uga.edu

We used interviews to examine future middle grades teachers' capacities to coordinate reasoning with quantities and with multiplication equations. Results include a mathematical analysis of multiplication as coordinated measurement and a (still emerging) psychological framework. In particular, we characterize future teachers' expanding coordination as incremental refinement and alignment of diverse knowledge resources.

Keywords: Teacher Knowledge, Teacher Education, Multiplication

Despite decades of research on topics in the multiplicative conceptual field (MCF; Vergnaud, 1983), multiplication and division with whole numbers and fractions, proportional relationships, and linear functions of the form $y = mx$ continue to pose significant challenges for many students and teachers. In contrast to research that has emphasized teachers' deficits with respect to topics in the MCF, we are investigating ways that a measurement approach to multiplication can help future teachers construct sound explanations for mathematics they will teach.

Theoretical Frame

Our framework combines mathematical and psychological perspectives. Figure 1 shows the quantitative definition of multiplication upon which we have converged. It applies to situations in which there is a quantity (the product amount) that is simultaneously measured with two different measurement units (a "base unit" and a "group"). The most important aspects of this definition are (a) writing the multiplicand and multiplier in a consistent order to highlight a common underlying structure for multiplication, division, and proportional relationships (e.g., Beckmann & Izsák, 2015) and (b) interpreting N, M, and P in Figure 1 as numbers that result from measuring quantities in terms of some designated unit (a base unit or a group).

N	$\bullet$	M	$=$	P
How many base units make one group exactly?		How many groups make the product amount exactly?		How many base units make the product amount exactly?

Figure 1. A quantitative definition for multiplication based in measurement.

The definition in Figure 1 can be used to coordinate an important swathe of the MCF—for instance, by viewing division as multiplication with an unknown factor and proportional relationships as instances where values for two of N, M, and P co-vary while the value for the third remains fixed (Beckmann & Izsák, 2015). Furthermore, the definition in Figure 1 can be used equally well with both whole numbers and with fractions. Figures like that shown in Figure 2a can support the measurement perspective on unit fractions if one asks how many of the long strip make the short strip exactly (1/3). We have found that future teachers have little problem answering such questions and can extend this measurement perspective from unit fractions to non-unit fractions, including improper fractions (Figure 2b). This appears to be a reliable

Hodges, T.E., Roy, G. J., & Tyminski, A. M. (Eds.). (2018). *Proceedings of the 40th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Greenville, SC: University of South Carolina & Clemson University.

foothold for future teachers when extending the measurement definition of multiplication shown in Figure 1 from whole numbers to fractions.

Figure 2. Interpreting fractions from a measurement perspective. (a) 1/3 of the long strip makes the short strip exactly. (b) 4/3 of the short strip (4 copies of 1/3) makes the long strip exactly.

Our psychological perspective is informed by diSessa's (2006) knowledge-in-pieces epistemology. Knowledge-in-pieces is a constructivist perspective in which learners come to know by using and refining knowledge as they construct interpretations of their interactions with the physical and social environment. The perspective characterizes the evolution from novice to expert knowledge as piecemeal construction, refinement, and reorganization of diverse fine-grained knowledge resources that are connected to varying degrees and whose use is often sensitive to context. Examples of cognitive mechanisms include refining the contexts in which resources are applied, forming new connections among resources, and loosening connections among others. In the present study, we examined the ecology of resources that future middle grades teachers used as they coordinated the definition of multiplication shown in Figure 1 with diverse problem situations that are contained in Vergnaud's (1983) MCF.

Methods

In Fall 2016, we recruited six future middle grades teachers who were enrolled in a 2-semester sequence of mathematics content courses (Number and Operations followed by Algebra). The second author taught both courses; the first author conducted semi-structured interviews. The interviews were spaced a few weeks apart and were coordinated with whole-class instruction, most often so that the interviews provided information about the future teachers' reasoning before specific topics were treated in the course. We video recorded the interviews, collected all written work generated during the interviews, and transcribed the interviews verbatim. The present report is based on analysis of talk, gesture, and inscription as captured in the interview videos, transcripts, and written work. We wrote analytic notes to capture our interpretations of how future teachers were reasoning moment-to-moment. In some cases, we took future teachers' statements as direct, reliable reports of their thinking. In other cases, we made inferences about aspects of future teachers' reasoning that they would not likely be able to report directly.

Results

All of the future teachers demonstrated some alignment between reasoning with quantities and with arithmetic computations—for instance, all connected iterating groups of units with multiplication and connected partitioning quantities into equal-sized pieces with division by a whole number. At the same time, *not* all future teachers connected partitioning quantities into equal-sized pieces with multiplication by a unit fraction. More generally, to different degrees, the future teachers experienced challenges expanding the range of situations in which they successfully aligned reasoning with quantities and with arithmetic computations (from their point of view and ours). Consistent with the knowledge-in-pieces epistemological perspective, such expanding alignment appeared to involve refinement and reorganization of a complex ecology of knowledge resources.

We organized knowledge resources we identified into four groups having to do with (a) meanings for multiplication (e.g., repeated addition, "of"), (b) meanings for the equal sign (e.g., correspondence, balance), (c) meanings for numbers (e.g., counts, measures), and (d) computation (e.g., algorithms, factor-product combinations). We make three points, first, from a knowledge resources point of view, reasoning at any given moment is supported by a set of activated resources. In some cases, those resources can be well-connected and support one another. The discussion above about connections among partitioning, division by a whole number, and multiplication by a unit fraction is one example. Second, differences in sets of resources activated by an individual helps explain variation in how that individual reasoned both within and across tasks. An individual might interpret the equal sign at one point as indicating a correspondence and, a few moments later, as stating that the numbers of units on the left and right hand sides are the same (balance). Such variation in reasoning, which was not uncommon in the interviews, can both support and constrain incremental alignment. Third, coming to perceive a common underlying structure, like the meaning of multiplication shown in Figure 1, across situations can be characterized as a gradual expansion in which one aligns thinking about quantities in those situations and about multiplication equations. Such expansion can occur through the gradual accumulation of fine-grained adjustments to the organization of knowledge resources.

We draw examples from Nina's reasoning to illustrate gradually expanding coordination. During her first interview, she demonstrated facility modeling problem situations with whole-number multiplication and connecting partitioning, division by a whole number, and multiplying by a unit fraction. At the same time, she reported that she had not thought before about a consistent interpretation of multiplication that worked both with whole numbers and with fractions. During the interview, Nina wrote equations to model word problems that described 4 cans with 3 tennis balls in each, 2 bags with 5 soccer balls in each, 1/5 of 4 ounces of tomato paste, and 1/5 of 1/3 cup of oatmeal. For the whole-number examples, Nina drew appropriate pictures to generate and explain her equations, "4 x 3 = 12" and "2 x 5 = 10." For the examples involving fractions, she again drew appropriate pictures of the situations but struggled at first to use those pictures to explain equations. She was able, however, to use her connection that "of means multiply" to calculate the correct answers of 4/5 and 1/15.

Nina was able to expand her coordination of reasoning with quantities and arithmetic computation by asking "what times 5 makes 4" and "what 5 things of equal amount will add up to 1/3." Thus, she reinterpreted situations presented with a fractional multiplier (e.g., 4 • 1/5 = ?) as one using a whole-number multiplier (e.g., ? • 5 = 4). The particular form in which Nina aligned her drawing and her computation appeared influenced by a further expectation she articulated that multiplication should make numbers larger. This incremental alignment appeared supported by her initial connection between partitioning and multiplying by a unit fraction. During her second interview, Nina continued to expand connections she made between reasoning with quantities and with arithmetic as she worked on the following problem:

> A full bottle contained 4/5 of a liter of juice. Then you drank 1/3 of the juice in the bottle. What fraction of liter [sic] of juice did you drink?

Nina began by drawing a strip diagram that showed appropriate relationships between the bottle partitioned into 4 parts (each of which was also 1/5 liter) and partitioned into 3 parts (see Figure 3a). She knew she needed further partitions to answer the question but had two competing ideas: "I don't know if I should find a common denominator between 3 and 4, because there's only 4 pieces, or if I need to find it between 3 and 5, because I want to know how much of a liter."

Faced with competing, reasonable ideas and no apparent way to prioritize one approach to partitioning over the other, Nina chose the second option.

Nina continued her work by drawing a new strip and shading 5 of 15 mini-pieces (see Figure 3b). She interpreted the shaded region: “So this is 1/3 of the juice. Also 5/15 a liter, I think.” When the first author asked if she had other ways of thinking about the task, Nina explained “1/3 of 4/5” meant to multiply and computed “1/3 x 4/5 = 4/15.” She recognized that she had two different answers but did not understand how to reconcile them. After Nina spent approximately 3 minutes trying to diagnose her inconsistent answers, the interviewer moved on to other tasks.

Nina took a fresh pass at the Juice problem 25 minutes later at the end of the second interview and this time accomplished greater coordination between her reasoning with drawn quantities and with computations. She considered the equivalent fractions 4/5 and 12/15, saw that she should partition the bottle into 12 parts, and created a new drawing that coordinated the liter, the juice bottle, partitioning, and her calculated answer of 4/15. Nina’s final comment suggested that she perceived new alignment that had eluded her during her first attempt: “That makes me feel better.” Although Nina did not make any specific comment, she might have learned that partitions in drawings (4 parts and 3 parts in this case) can be a reliable guide for partitioning. Such an adjustment is a further example of refinement in her ecology of resources that supported alignment of reasoning with quantities and with arithmetic computation.

Conclusion

Future teachers entered our courses with initial capacities to coordinate reasoning with quantities and with arithmetic; and, we examined the knowledge resources that they used and transformed to achieve alignment across a wider range of situations in the MCF.

A COVARIATIONAL UNDERSTANDING OF FUNCTION: PUTTING A HORSE BEFORE THE CART

Teo Paoletti
Montclair State University

Kevin C. Moore
University of Georgia
kvcmoore@uga.edu

Supporting students developing understandings of function has been a notoriously elusive task. In this report, we present Thompson and Carlson's (2017) description of a covariational meaning of function and provide an empirical example of a student who maintains meanings compatible with this description. We use this students' activity to illustrate nuances in Thompson and Carlson's description and to highlight how such meanings can be powerful.

Keywords: Function, Cognition, Teaching Experiments

Several researchers have examined teachers' and students' understandings of univalence and arbitrariness, key mathematical properties typical to a formal function definition. Univalence is the property that for each element in the domain there is a unique element in the range. Arbitrariness refers to a function needing not be defined by a known correspondence rule. Researchers have shown that students and teachers do not perceive a need for the univalence and arbitrariness properties of function (e.g., Breidenbach, Dubinsky, Hawks, & Nichols, 1992). Addressing the property of univalence, Even (1990) noted, "some serious questions are raised by the fact that, without prompting, none of the subjects could come up with a reasonable explanation for the need for the property of univalence" (p. 531). In an effort to re-conceptualize the notion of function in school mathematics, Thompson and Carlson (2017) presented a covariational meaning of function, which we elaborate on in the next section. We include an example of student activity to highlight nuances in Thompson and Carlson's (2017) description of a covariational meaning of function and illustrate how such a meaning can be productive for a student. Our goal is to show how a student who has developed such a meaning has the horse (i.e. foundational understandings) needed to pull a cart (i.e. the formal definition of function).

Theoretical Perspective: A Covariational Understanding of Function

Drawing on their body of work and the growing body of literature highlighting the importance of students reasoning about quantities that change in tandem, Thompson and Carlson (2017) proposed a definition of function rooted in covariational reasoning. They described, "A function, covariationally, is a conception of two quantities varying simultaneously such that there is an invariant relationship between their values that has the property that…every value of one quantity determines exactly one value of the other" (p. 444). Rather than foregrounding univalance, Thompson and Carlson (2017) foregrounded an individual *constructing* an invariant relationship; once an individual has conceived of such a relationship, she can begin to investigate properties of that relationship. Hence univalence becomes a particular property of this invariant relationship. Thompson and Carlson (2017) avoid including dependent and independent variables in their definition. They explained, "What is independent and what is dependent will depend entirely on the person's conception of the situation and which way they envision dependence, if they envision dependence at all" (p. 444). Thompson and Carlson highlighted, however, a conceived function entails some cognitive sense of dependency of one quantity to another, as an individual must think of one quantity before the other. Thompson and Carlson (2017) added, "it is through covariation that the dependency becomes crystalized in her thinking as being invariant across quantities' values" (p. 444). However, the extent to which students absolutely maintain a dependency of one quantity in relation to another when conceiving of an invariant relationship between two quantities remains an open question.

Data Sources and Results

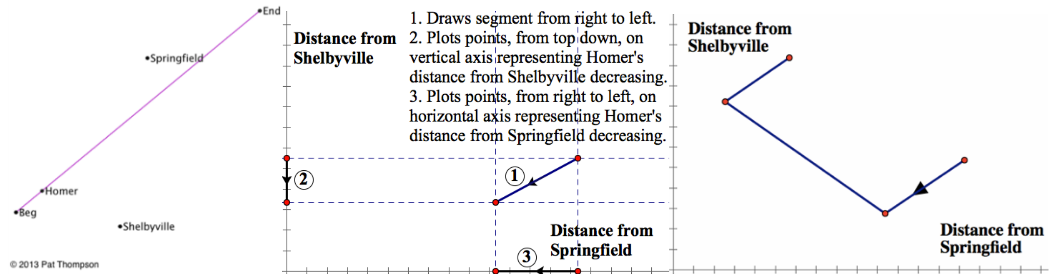
To provide an example of a student who maintained meanings consistent with those described by Thompson and Carlson (2017), we draw from data collected during a semester-long teaching experiment (Steffe & Thompson, 2000) with an undergraduate student, Arya. Throughout the semester, Arya repeatedly conceived of and constructed relationships between covarying quantities in dynamic situations and represented these covariational relationships graphically. During these activities we intentionally gave little to no focus on univalence and arbitrariness. In what follows, we focus on Arya's activity towards the end of the teaching experiment that is particular to Thompson and Carlson's (2017) description of a covariational meaning of function and refer the reader to Paoletti (2015) for detail on her specific activities.

Conceiving of an invariant relationship in the *Car Problem*

Arya addressed an adaptation of the *Car Problem* designed by Saldanha and Thompson (1998). Consistent with Saldanha and Thompson's use of the task, we asked Arya to represent the relationship between an individual's (Homer's) distances from two cities (Shelbyville and Springfield) as he travels back-and-forth on a road (Figure 1a). We adapted the task by asking about "function" after Arya constructed her graph. Because the relationship is such that neither represented distance is a function of the other distance, we conjectured Arya may spontaneously consider other quantities in the situation that were not directly represented in the graph.

Arya's activity suggests she conceived of "two quantities varying simultaneously such that there is an invariant relationship between their values" (Thompson & Carlson, 2017, p. 444). Arya consistently focused on the relationship between Homer's distances from the two cities through constructing the relationship in the situation and then representing her conceived relationship graphically. To illustrate, she first described the directional covariation of Homer's distance from each city (e.g., as Homer moves from the beginning of his trip, the distance from each city decreases), and then drew a segment from right to left corresponding to decreasing ordinate and abscissa magnitudes (indicated by (1) in Figure 1b). Arya pointed to the applet and described, "We start off... far from Springfield and pretty close to Shelbyville [*pointing to Beg. on computer screen then traces along road*]. Then... you're getting closer to Shelbyville for a little ways and closer to Springfield as we're moving along the road". With respect to her graph, Arya marked horizontal and vertical dashed lines from each graphed point to the vertical and horizontal axes, respectively, to verify that she represented distances from Shelbyville and Springfield each decreasing (indicated by (2) and (3) in Figure 1b). Arya continued such actions to construct and justify the other two segments in her graph (Figure 1c).

Consistent with claims by Piaget et al. (1977) and Thompson and Carlson (2017), Arya did conceive of one quantity first when constructing a relationship in the situation and graph; however, Arya's actions did not imply she conceived an explicit dependent-independent relationship of either distance to the other. Arya first described how Homer's *distance from Springfield* varied. Before drawing her second segment (seen in Figure 1c), Arya first described how Homer's *distance from Shelbyville* varied . Finally, before drawing the third segment, Arya again first described how Homer's *distance from Springfield* varied. Arya maintained a focus on two quantities simultaneously covarying whilst alternating which quantity she considered first in order to accurately construct and represent the relationship she conceived.



(a) (b) (c)

Figure 1. (a) The Car Problem applet, (b) a recreation of Arya's initial work, and (c) a recreation of Arya's final graph.

Addressing questions about "function" in the *Car Problem*

We next asked Arya if she could "talk about anything in this situation in terms of things being functions?" Arya first determined that neither graphed quantity was a function of the other graphed quantity, stating, "If you take either like the distance from Springfield or the distance from Shelby[ville] as your input you're going to have more than one output in some places." A researcher then asked, "Is there anything else we could have asked you about that may or may not have represented a function?" Arya considered either distance from a city "and how it travels over total distance." Specifically, she considered using either Homer's distance from a city or total distance as the input quantity to make conclusions regarding the 'function-ness' of each possiblw input-output pair (e.g., she concluded that Homer's distance from Springfield is a function of his total distance traveled, see Table 1). Notably, Arya referred only to the dynamic image of the situation as she considered if each distance from a city corresponded to exactly one total distance traveled and vice versa; Arya did not use a graph, equation, or table.

Because Arya added an arrow to her completed graph (Figure 1c), we conjectured she may reason about the trace of her graph as being defined parametrically. A researcher asked, "What if your input was total distance traveled and your output was… like a pair of values. Where that pair is your distance from Springfield and your distance from Shelbyville... What do you think about that case?" Arya discussed two possible total distances: (1) Homer making one trip from Beg. to End and (2) Homer traveling back and forth along the road accumulating total distance. Arya stated that in either case the relationship represented a function if she considered total distance as the input but the inverse relationship only represented a function in the first case.

We use Arya's activity to highlight how a student who conceives of an invariant relationship between quantities consistent with Thompson and Carlson's (2017) description can use this understanding to determine if there was a "relationship between their values that has the property that… every value of one quantity determines exactly one value of the other" (Thompson & Carlson, 2017 p. 444). In total, Arya's image of the situation enabled her to consider 10 different possible functional relationships (see Table 1), regardless if the relationship was explicitly represented by a graph, equation, or table.

Table 1: The relationships Arya considered as possibly representing functions

Input	Output	Function?
Distance from Springfield	Distance from Shelbyville	No
Distance from Shelbyville	Distance from Springfield	No
Total distance traveled	Distance from Springfield	Yes
Distance from Springfield	Total distance traveled	No

Total distance traveled	Distance from Shelbyville	Yes
Distance from Shelbyville	Total distance traveled	No
Total distance traveled (one trip)	(Distance from Shelbyville, Distance from Springfield)	Yes
Total distance traveled (accumulated)	(Distance from Shelbyville, Distance from Springfield)	Yes
(D. from Shelbyville, D. from Springfield)	Total distance traveled (one trip)	Yes
(D. from Shelbyville, D. from Springfield)	Total distance traveled (accumulated)	No

Discussion

Arya's activity highlights how a student who understands "two quantities varying simultaneously such that there is an invariant relationship between their values" can leverage this understanding to determine if "every value of one quantity determines exactly one value of the other" (Thompson & Carlson, 2017 p. 444). Further, Arya's activity highlights how a conceived relationship between covarying quantities can serve as the *something* that students are reasoning about when discussing 'function' in various representations (e.g., Thompson, 1994).

Arya's activity addressing the *Car Problem* allowed us to clarify Thompson and Carlson's (2017) elaboration of Piaget et al.'s (1977) notion that an individual must conceive of one quantity varying first, but this does not imply necessary dependency. We note that the quantity Arya considered first switched throughout her activity, illustrating that a student can move flexibly between considering either of two quantities first as she conceives of and represents a relationship between these quantities. Returning to the opening analogy, we posit that supporting students in constructing invariant relationships between quantities has the potential to provide them with the horse to pull the cart that is the definition of function in school mathematics.

Because functions cut across many areas within mathematics, they are especially important for mathematical understanding. Yet research shows that students struggle to develop the functional representation fluency needed for more sophisticated mathematics. This pilot study examines how students use multiple representations of functions in a unit that incorporates functions to program the movement of a robot. Preliminary results indicate that students conceptualize a bidirectional relationship between the algebraic and robotic representations of a function but that the relationships between the other representations remain unidirectional or disconnected. We hypothesize that students' strong connection between the algebraic and robotic representations can be leveraged to facilitate increased understanding of the relationship between the other representations.

Keywords: Algebra and Algebraic Thinking, High School Education, Middle School Education

The concept of a function is essential to the study of mathematics. While students might be most comfortable with one representation of a function, they need the competency to compare, relate, select, use, and flexibly convert between the multiple representations (National Council of Teachers of Mathematics, 2000). The functional representation fluency expected by the NCTM Standards and needed for more sophisticated mathematics has been shown to be difficult for students (Knuth, 2000; Leinhardt, Zaslavsky, & Stein, 1990; Pérez, 2014; Van Dyke & Craine, 1997; Van Dyke & White, 2004). Students have trouble making the connections between different representations even when they contain the same information (Knuth, 2000). In studying 12th grade students' performance on function questions in the 2009 National Assessment of Educational Progress (NAEP) mathematics assessment, Pérez (2014) found that students had more difficulty with function items that involved identifying the appropriate graphs and equations in real-world contexts. This pilot study looks at learner engagement with multiple representations of functions in the context offered by using functions to program robots.

Background

This study in progress is part of a larger National Science Foundation study on integrating computational thinking practices and dispositions in the mathematics curriculum. Following an initial engagement with modeling and programming, several participating teachers have expanded on the project's original conception to develop a unit on functions, programming, and robots. The teachers created a unit where students would apply their knowledge of a velocity-time function of the form $\boxed{y = mx + b}$ within a programming script to control the velocity of a small robot's physical movement. In the equation, the y-value represents the velocity at which the robot travels, the m-value represents the acceleration, the x-value is the time in seconds, and the b-value represents the initial velocity of the robot.

The robots were built using Arduino microcontrollers and students were exposed to programming through the Arduino language. Within the programming script, students manipulated a linear equation by changing the slope and y-intercept (Figure 1, Line 33) to control their robot's velocity. The domain, incrementing from 0 to 5, was manipulated in the for-loop (Figure 1, Line 30).

```
29
30      for(float x=0; x<=5; x++) {
31
32
33       float y=(0*x+0);
34
```

Figure 2. Linear Equation and Domain Conveyed in the Arduino Code

Data Collection

The unit was implemented in 8th grade mathematics classes at a public middle school and 11th grade mathematics classes at a career-technical public high school. One lead teacher taught all 8th grade classes and another lead teacher taught all 11th grade classes. The middle school unit lasted 7 days, while the high school unit lasted 10 days. Each class was video and audio recorded during the unit. There was also a research assistant present to observe, take field notes, and interact with the students and teachers during the sessions.

Representations of Functions: Challenges and Opportunities for Students

The three common representations of functions engaged in classroom settings are algebraic equations, tables, and graphs. The relationships are represented in Figure 2 (see also Leinhardt, Zaslavsky, & Stein, 1990; Van Dyke & Craine, 1997). The double arrows indicate bidirectional fluency between those representations for information and the ability to create those representations in either direction.

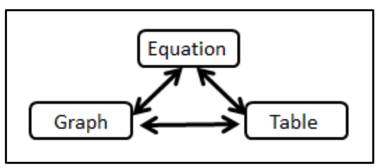

Figure 2. Ideal Configuration of Three Representation Fluency

In the context of the programming robots unit, where the robot's velocity is controlled by a linear function, a fourth physical representation of the robot's movement is conceptualized. The relationships between the four representations are represented in Figure 3.

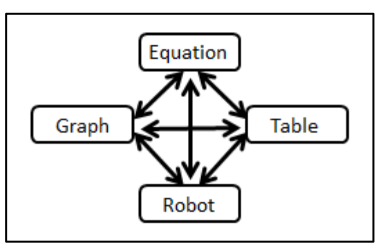

Figure 3. Ideal Configuration of Four Representation Fluency

During initial activities, students discovered how the slope and y-intercept in the linear equation affected the robot's velocity and movement over a fixed interval of time. This created an equation-to-robot relational connection. The students were then confronted with a series of challenges to further develop these connections and their reasoning with functions. For example, one challenge was to drive the robot forward past a target, stop, reverse, and then finally stop on the target. To achieve these goals, students programmed the robot by modifying a linear equation (Figure 1, Line 33) and its domain (Figure 1, Line 30).

One goal of the unit was for students to develop and reinforce fluency in the different functional representations. The meaningfulness of tables and graphs as functional representations was enhanced by their role as tools for inferring the robot's behaviors and the appropriateness of the equation for a given task. For example, the tables and graphs offered salient representations for the behavior of the robot in moving forward, stopping, and then reversing back to its original position. In this task, the robot's behavior represented in tabular form would translate to an equal number of positive and negative velocities that sum to zero over the domain. Understanding this representation can guide students' selection of appropriate slope and y-intercept values in the equation to satisfy the required outcome.

Expected Findings

Preliminary data show that students conceptualized a bidirectional relationship between the equation and robot. However, the relationship between the equation, table, and graph were unidirectional. In other words, most students only completed the table and drew the graph after they determined an appropriate equation for the robot to complete the challenge. In this scenario, tables and graphs served as documents for record of occurrence. They were not used to make predictions. This supports the idea that students did not yet recognize that the tables and graphs offered salient information to help them identify an appropriate equation for the task. This also suggests that, for many learners, there was not a connection between the robot's movement representation and the tabular or graphical representations since those representations were considered last and created from the equation. Thus, based on whole class observations, a general preliminary conception of the students' understanding of the relationships between the four functional representations is expressed in Figure 4.

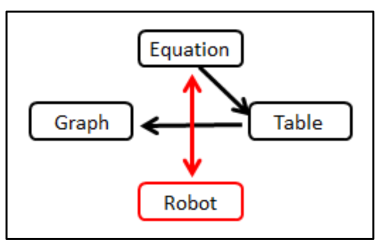

Figure 4. Observed Configuration of Students' Four Representation Fluency

Discussion

Students' strong understanding of the behavior of the robot in relation to the equation is an opportunity to leverage more fluency between all the representations. This bidirectional equation-to-robot connection can be used to build fluency between the robot's movement representation and the tabular and graphical representations. When tables and graphs are readily displayed at the time the robot moves, then there is opportunity for the robot's behavior to be related to these representations. The representation of the robot's movement constrains and grounds the more abstract functional representations (Ainsworth, 2008). The robot's movement is a familiar action to the students that can be used to support their understanding and reconcile any misconceptions regarding the information displayed through algebraic, tabular, and graphical representations (Figure 5a → Figure 5b). Then those developed connections with the robot could be used to mediate the bidirectional relationships between the equation, table and, graph.

A possible trajectory in using a fourth representation – which is contextualized here with the robot's movement – is displayed in Figure 5. A focused look at this trajectory hypothesis will happen during future iterations of the design experiment. Our goal is developing students' proficiency with mathematics to operationalize functions in all their representations and in real world situations. This is an important area for our nation's students to show growth (Pérez, 2014).

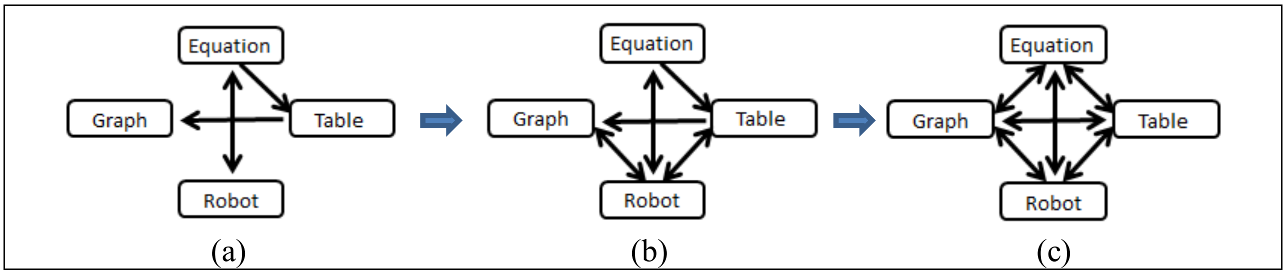

Figure 5. A Hypothesized Trajectory to the Ideal Configuration of Four Representation Fluency

Presentation Overview

The presentation will provide an overview and background of the pilot study. This will be followed by a discussion of the opportunities for student growth in functional representation fluency. The presentation will conclude with how the findings will inform future iterations of the design experiment.

EXPLORING FACTORS RELATED TO HIGH SCHOOLERS' ALGEBRA ACHIEVEMENT: A REVIEW OF DISSERTATIONS USING HSLS:09 DATA

Sheree T. Sharpe
University of New Hampshire
sheree.sharpe@unh.edu

Dalton Marsh
University of New Hampshire
ddm1002@wildcats.unh.edu

The difficulty that students demonstrate when it comes to learning algebra in secondary school has been long documented and researched. The authors conducted a research synthesis of the literature that uses data from the High School Longitudinal Study of 2009 with a focus on algebra achievement. We've summarized the results of 13 dissertations across 2 outcome variables (9th and 11th grade algebra achievement). We employed optimal resource theory (ORT) as a research framework to inform best-practices for improving student outcomes. Our findings reveal that several malleable factors at the student-, teacher-, school-, and parent-level were found to be related to algebra achievement.

Keywords: HSLS:09 Data, Algebra Achievement, High School, and Dissertation Review

Given the importance of high school students' performance in algebra and the role of algebra as a gatekeeper to higher level mathematics and the pursuit of a career in Science, Technology, Engineering, and Mathematics (STEM) fields, it is imperative we have a clear understanding of the factors that are related to high schoolers' algebra achievement. The purpose of this paper is to summarize the results of dissertations using the nationally representative High School Longitudinal Study of 2009 (HSLS:09) to investigate the malleable student-, teacher-, school-, and parent-level characteristics that are associated with algebra achievement.

Theoretical Framework

This study employs optimal resource theory (ORT) introduced by Anderson (2015) as a research framework to inform best-practices for improving student outcomes. Positive student achievement is among the main interests of ORT. Five principles governing this growth advise to: (1) account for the multiplicity and complexity of factors that influence student development, (2) account for externally controlled factors where practicable, (3) examine manipulable factors that may be internally controlled, (4) focus on incremental progress or reasonable outcomes rather than on comprehensive change, and (5) focus on maximizing progress with available resources, despite external circumstances. Therefore, to advise schools on improving student achievement, ORT would target influential factors that are within school control (such as teaching practices, course offerings, etc.) while taking into account available resources and external factors beyond school-based control that also affect student achievement (such as race, gender, socioeconomic status, etc.). ORT was chosen for this study because the nature of HSLS:09 allowed the dissertations we reviewed to examine a multitude of factors associated with student achievement in algebra while controlling for various external circumstances. Furthermore, our research synthesizes the findings of these studies with a focus on malleable factors. Guided by ORT framework, this synthesis should help to inform teachers, schools, and parents' decisions regarding how best to improve their students' mathematics achievement. Our research question was: What are the student, teacher, school, and parent level factors that are related to high school students' algebra achievement in the U.S.?

Method

In this study, we conducted a synthesis of research literature that used data from the High School Longitudinal Study of 2009 (HSLS:09) and focused on mathematics achievement as the outcome variable. The HSLS:09 is an ongoing nationally representative study consisting of about 24,000 9th-graders from 944 schools in fall 2009. The first follow-up was of 11th graders in spring 2012. The surveys were completed by students, parents, math and science teachers, administrators, and counselors. The students also took a cognitive mathematical assessment, which was designed to provide a measure of student achievement in algebraic reasoning at two points in time (9th and 11th grade). The test framework was designed to assess a cross-section of understandings representative of the major domains of algebra and the key processes of algebra. The test and item specifications describe six domains of algebraic content (the language of algebra; proportional relationships and change; linear equations, inequalities, and functions; nonlinear equations, inequalities, and functions; systems of equations; sequences and recursive relationships) and four algebraic processes (demonstrating algebraic skills; using representations of algebraic ideas; performing algebraic reasoning; solving algebraic problems) (Ingels, et al, 2011, p. v).

Data Sources

We performed a search of the literature through June 2017 that used data from the HSLS:09 and related to mathematics. We excluded all reports and executive summaries from our search, and focused on journals, dissertations, research briefs, conference proceedings, and books. Data collection occurred in 4 stages: (1) Identification: identify records through database searching using variations of the search terms HSLS:09 and math; (2) Screening: screen the records' abstracts for HSLS:09 and Mathematics; (3) Eligibility: screen the methods section for algebra achievement as an outcome variable; and (4) Inclusion: determine the number of studies included in the qualitative synthesis. We searched the following databases: Google Scholar, ERIC, PsycINFO, Education Source, Academic Search Complete, Mental Measurements Yearbook with Tests in Print, JSTOR, Project MUSE, Sociological Abstract, and ProQuest Dissertation and Thesis A&I. We used *RefWorks* to eliminate duplicate records. The number of records remaining after duplicates were removed was 70. Out of the 70 records, we found 28 articles, one research brief, 35 dissertations, 5 conference proceedings, and one book. Preliminary results from a focus on the articles were presented at the 2018 National Council of Teachers of Mathematics (NCTM) Research conference. This study will focus on the dissertations. The methods and results section of each dissertation was reviewed to screen for the use of either 9th or 11th grade algebra achievement as the outcome or dependent variable. After this screening, we were left with 13 dissertations to review. Data was extracted from each dissertation that met our inclusion criteria. The studies were categorized based on the two primary outcome variables; 9th grade algebra achievement (Amar, 2016; Briggs, 2014; Cope, 2013; He, 2014; Kim-Choi, 2015; Larrain, 2015; Onsongo, 2015; & Rochmes, 2014) and 11th grade algebra achievement (Alexander, 2015; Howard, 2015, John, 2017; Maldonado, 2016; & Saw, 2016). Across the 13 dissertations, we classified the level of the factors/predictors/independent variables (IV) as either parent, school, teacher, or student. The factors were then cross tabulated and classified within the four levels and two outcomes with the reported significance level.

Results

The results of the systematic review included both non-malleable and malleable variables at the student, teacher, parent, and school levels that were related to high school students' algebra achievement. Since socio-economic status (SES) was defined as a composite of parent/guardian education, occupation, and family income status, we classified SES as a parent level variable. The significant ($p < .05$) non-malleable factors found were related to SES, region/location of school, race/ethnicity, gender, prior achievement or previous coursework, disability status, first language, and nationality. Next, we will focus on the significant ($p < .05$) malleable IV variables, since these are variables that can be influenced directly.

Parent Level

Parent involvement (as reported by the parents) was found to be positively associated with 11th grade algebra achievement (Howard, 2015).

School Level

Percentage of Advanced Placement (AP) enrollment was found to be positively associated with both 9th and 11th grade algebra achievement (Larrain, 2015; Saw, 2016).

Teacher Level

Class achievement (math teacher perception of the average level of achievement of students in their class) was found to be positively associated with both 9th and 11th grade algebra achievement (Cope, 2013; John, 2017). Also, math literacy (conceptual teaching emphasized by the teacher) was found to be positively associated with 11th grade algebra achievement (Maldonado, 2016). Cope (2013) found that heavy emphasis on teaching math concepts, effectively explaining math ideas, and performing computations with speed and accuracy were positively associated with 9th grade algebra achievement, while heavy emphasis on developing computational skills, the nature and history of math, and reasoning mathematical were negatively associated with 9th grade algebra achievement. In addition, teaching experience (the number of years taught) was positively associated with 9th grade algebra achievement (Cope, 2013).

Student Level

Math identity (students see themselves as a “math person” and believe others do too), math self-efficacy (students’ confidence in their ability to do math), and school engagement (arriving on time and bringing proper materials for class) were found to be positively associated with both 9th and 11th grade algebra achievement (Alexander, 2015; Briggs, 2014: Cope, 2013; Howard, 2015; John, 2017; Kim-Choi, 2015; Larrain, 2015; Onsongo, 2015). Math interest (math is the student’s favorite course and they enjoy it) was found to be positively associated with 9th grade algebra achievement, but negatively associated with 11th grade algebra achievement (Howard, 2015; Kim-Choi, 2015). The number of hours spent per day on homework and math utility (perception of the usefulness of math) were found to be negatively associated with 9th grade algebra achievement (Kim-Choi, 2015; Larrain, 2015). However, student-teacher relationship (students’ perceptions of whether they were treated fairly and with respect) and educational aspiration (highest level of education students expects to attain) were positively associated with 9th grade algebra achievement (Kim-Choi, 2015; Onsongo, 2015). Math effort (how often students pay attention in class, turn in assignments, or keep trying in class) and Peer network (peer academic orientation and peer communication) were found to be positively associated with 11th grade algebra achievement (Alexander, 2015; John, 2017).

Discussion

Based on the ORT theoretical framework and summary of the 13 dissertations that used a nationally representative dataset, we found that one-third of the significant factors affecting algebra achievement were external (non-malleable) factors beyond school-based control (such as race/ethnicity, gender, socioeconomic status, etc.). The remaining factors (that are within school control) were represented at the parent-, school-, teacher-, and student-level, noting that most of these factors explored by researchers were at the student level (approximately 68%). In accordance with ORT principle (1), the dissertations included several factors that may influence algebra achievement. Principle (2) recognizes that these factors likely operate differently depending on external circumstances, thus, race/ethnicity and socioeconomic status—factors out of the student or high school's control—were included as controls. Principle (3) stipulates a focus on malleable factors, so parent involvement, advanced placement course enrollment, and teaching emphasis—something that schools, teachers, or parents could look to change—were included as the main factors of interest. Based on these findings, researchers may provide practical recommendations for schools by considering ORT principles (4) and (5) which respect that progress may be gradual and that schools have finite resources.

CONCEPTUAL ANALYSIS OF STUDENTS' SOLVING EQUAL SHARING PROBLEMS

Jaehong Shin

Soo Jin Lee
Korea National University of Education
sjlee@knue.ac.kr

In the present study, we conduct conceptual analysis based on schemes and operations to explain how students with different mathematical levels would solve equal sharing problems. We suggest two distinctive schemes (distributive sharing scheme and splitting scheme for composite units) as the key schemes each of which independently supports the students' solving equal sharing problems.

Keywords: Number Concepts and Operations, Rational Numbers

Equal sharing problems provide students with an opportunity to conceive fraction as a complex entity of multiplication, division, and ratio (Empson, 1999; Empson, Junk, Dominguez, & Turner, 2006). As Kieren (1988) notes, to support students' development of more advanced fraction knowledge, students are to reason with partitive quotient construct as well as part-whole construct. Abstraction of the partitive quotient notion of fraction could be established when students engage in equal sharing activities (Charles & Nason, 2000). The purpose of this study is to present our conceptual analysis of students' schemes and operations to solve equal sharing problems. In particular, we suggest the two distinctive schemes – distributive sharing scheme and splitting scheme for composite units – as the schemes, each of which supports students solving equal sharing problems.

Distributive Sharing Scheme with Partitioning

Young students construct what it means to share fairly based on their prior experiences of dealing out collections to establish fair shares (Wilson, Edgington, Nguyen, Pescosolido, & Confrey, 2011). Thus, students can spontaneously develop, what we named, *distributive sharing schemes* (DS schemes) from their very early age. The situation of a DS scheme is to share a whole number, p units of quantity among a whole number, q persons and the goal is to equally share the quantity among the people. The activities of the scheme consist of *distributing* operations. The student with the DS scheme distributes a unit or multiple units of the to-be-shared quantity to each of the sharing people in turn and the result is one person's share accumulated by repeating the distributing activities. The scheme is closed when the quantity is exhausted by the distribution and each person has an equal share. Quantifying the result of the sharing activity (i.e., measuring the accumulated amount gaining from the distributing activities) is not part of the DS scheme. For instance, for sharing 20 cookies among five people, which is normatively called a partitive division problem, a student whose DS scheme activates for the situation distributes 20 cookies one by one to each person until all the cookies are allotted to the people. She might not realize that one person gets to have four cookies until reflecting on her activities and results upon a teacher's request. One reason for implementing a DS scheme in partitive whole number division is spontaneity of its development from young students' daily life experiences, and another reason would be their lack of operating with a three-levels-of-units structure. In this case, they are to construct a composite unit, 20, as a unit of five units each containing four units so that they can take one part (four cookies) from the equally partitioned five-part whole (20 cookies). As students' multiplicative concepts deepen enough to construct such a three-levels-of-units structure, they are unlikely to use a DS scheme for the partitive whole number division due to its inefficiency.

However, when those students encounter a situation of equally sharing some number of same-sized objects among some number of people, where the result is a fractional quantity, because it requires more than their whole number knowledge, they may feel challenged in figuring out the quantity for one person's share. When establishing a goal of sharing, say, three pizzas among five people, they might attempt to partition the three pizzas into five equal parts at one go. As they realize there is no easy or practical way of cutting the three pizzas into five pieces, the students may go back to use their DS scheme, which would let them attend to sharing subsets of the whole rather than partitioning the whole at once. On the other hand, as students start to learn fractions and thus diverse partitioning operations are ready at hand for their mathematical activities, they should be able to use them as assimilating operations of their DS schemes for solving equal sharing problems. For the problem situation stated above, sharing three pizzas among five people, they can give one-half pizza to each person by halving each of the three pizzas and then partition the remaining one-half pizza into five equal shares. Especially, when students understand sharing multiple units as "multiple instances of sharing a single unit" (Wilson et al., 2011, p. 233), we judge that the students engage in *distributive partitioning operations* (Steffe & Olive, 2010). As reported in previous literature (e.g., Charles & Nason, 2000; Empson et al., 2006; Lamon, 1996; Hackenberg & Lee, 2016), the levels of sophistication in students' use of partitioning strategies increase as their understandings of fraction become more mature. However, one common characteristic of the partitioning strategies derived from students' use of DS schemes is to partition subsets (one or more items) of the whole at a time at their convenience, rather than the whole multiple items at once. In terms of three hierarchical multiplicative concepts based on the ways by which students generate and coordinate composite units (Hackenberg & Tillema, 2009; Steffe, 1992), we conjecture students with the *second multiplicative concept* (MC2) can construct distributive partitioning operation for sharing p items among q people, where q does not evenly divide p. However, a deficiency in the distributive partitioning operation by a DS scheme at the MC2 level is its inability to switch a referent unit in naming the resulting share. For example, even if an MC2 student succeeds to find one person's share by partitioning each of three pizzas into five, taking one part from each pizza, and combining them, she might not know the sharing result is both $\frac{3}{5}$ of a pizza and $\frac{1}{5}$ of the whole three pizzas. To view the result in relation to the two referent units requires "being able to switch between three-levels-of-units structures, which is outside of MC2 students' ways of operating." (Hackenberg & Lee, 2016, p. 260)

Splitting Scheme for Composite Units

A splitting operation for composite units "simultaneously splits each unit in a composite unit containing the units into an equal but unknown number of subunits" (Steffe & Olive, 2010, p. 320). The assimilating operations of the splitting scheme for composite units (SCU scheme) are the operations that produce the *generalized number sequence* whose operations "entail coordinating the basic units of two number sequences, such as the unit of three of a sequence of such units and a unit of four of a sequence of such units, prior to engaging in activity" (Steffe & Olive, 2010, p. 320). Such coordinating ability, considered as a functional accommodation of the splitting operation for composite units (Hackenberg, 2010), plays a critical role in transforming equal sharing problems into the situations for an SCU scheme. For example, for the sharing problem of four bars among 10 people, a student may want to *split* four units of a bar into 10 parts at once. Then the student would attempt to partition each of the four units into some number of parts to generate enough number of parts in total with a goal that the generated number of parts could be evenly divided by the number of people. To find an appropriate number that serves the goal prior to partitioning activities, the student should be able to coordinate two three-levels-of-units structures. In other words, she needs to implement the following steps simultaneously at the level of mental representation: 1) to distribute some number of parts, say, 10 parts to each of the four bars and form a composite unit, 40 as a unit of four units each containing 10 units, 2) to view the composite unit, 40 as a unit of 10 units each of which contains four units. Such coordinating operation enables her to transform an equal sharing problem into a situation for her SCU scheme so that the student can take a fractional part of the same-sized multiple items, which turns into the situation of whole number partitive division. Thus, from the perspective of the student with SCU scheme, to solve an equal sharing problem is equivalent to taking a fractional part of the whole*,* of which the student is explicitly aware throughout the problem solving process. Moreover, given that construction of the SCU scheme is predicated on the construction of the *third multiplicative concept* (MC3), we hypothesize that the student potentially construct flexibility in viewing the sharing result in relation to two referent units (a bar and the whole four bars) without much difficulty. Behavioral distinction between the splitting operation in an SCU scheme from the distributive partitioning operation in a DS scheme is the way to take one person's share. To make one person's share with four bars each of which is partitioned into 10 parts, a student using distributive partitioning operation gathers one part from each of the four bars because each part is the result of sharing each bar. In contrast, a student whose SCU scheme activates for the problem takes a chunk of four parts (maybe the leftmost four parts) of 40 parts because four is $\frac{1}{10}$ of 40.

Our conceptual analysis of schemes and operations in solving equal sharing problems informs that *distributive partitioning scheme* (Steffe & Olive, 2010) develops as the most sophisticated form of DS scheme when splitting operations for composite units are available for the DS scheme as assimilating operations. Despite that, a student who can solve the above problem using her SCU scheme might not feel the necessity to activate her DS scheme with distributive partitioning operation. The SCU scheme with the coordinating ability of two three-levels-of-units structures is enough to find one person's share by splitting the to-be-shared quantity by the number of people at once.

Conclusions and Implications

In this paper, we suggest DS scheme and SCU scheme as the schemes, each of which have its own developmental path and independently supports students' problem solving in equal sharing situations. We separated the two schemes for their distinctive characteristics in nature. DS scheme, itself, is a non-measuring scheme constructed from a very early age of young students, and its main activity (operation) is *distribution* which is directly linked to kinetic motion of sharing even though partitioning operations can be embedded in the assimilatory structure. SCU scheme is a quantitative scheme, and its main operations are various partitioning operations including a splitting operation for composite units. Thus, the activities implemented by the scheme entail quantification process of the sharing result. The results of our conceptual analysis are aligned with previous research findings that even lower grade students could successfully find one person's share (using DS scheme from our perspective) but were challenged when they were to name the amount of share in terms of referent units due to the lack of other mathematical resources such as multiplicative reasoning and fractional knowledge (Empson et al., 2006;

Hackenberg & Lee, 2016; Lamon, 1996, Steffe & Olive, 2010). Our results also complement the study of Hackenberg & Lee (2016) by explaining why four out of the six MC2 students, in their clinical interview, showed distributive partitioning operations, but not distributive partitioning schemes, and only one of the MC3 students used the distributive partitioning operation. We conjecture that the four MC2 students might have implemented distributive partitioning operations as parts of their DS schemes. Five other MC3 students, ironically due to their matured multiplicative reasoning, might not have felt logical necessity to activate their DS schemes with distributive partitioning operations. In this study, we argue that the required partitioning schemes and operations for solving equal sharing problems (and naming one person's share) are on a par with MC3, which is a highly advanced multiplicative concept at the elementary school level. Thus, mathematics teachers are advised to be sensitive to students' level of multiplicative concepts and partitioning operations. Hasty introduction of various partitioning strategies to students at the level of 2nd multiplicative concept or lower might produce an unexpected result that they adopt the partitioning solutions only as efficient, algorithmic strategies for finding one person's share, ignoring quantification process of the share in relation to relevant referent units.

Reasoning about fraction division is difficult for children and adults. We examined the relative effectiveness of three types of diagrams, number line, rectangular area, and circular area diagrams, for increasing children's accuracy and conceptual understanding of fraction division as compared to no diagram at all. Children who used number line and circular area diagrams to solve fraction division problems had the highest rates of accuracy. Children rated problems presented with circular area diagrams as the least difficult. Children who completed fraction division problems with number lines were most likely to consistently reason with conceptually sound, quotitive division models.

Keywords: Number Concepts and Operations, Problem Solving, Rational Numbers, Cognition

Reasoning about fraction operations is a critical aspect of the development of children's mathematics understanding (e.g., National Mathematics Advisory Panel, 2008, p. xviii). Despite its importance, fraction division is difficult for children (e.g., Mack, 2001; Siegler, Thompson, & Schneider, 2011) and teachers (e.g., Luo, Lo, & Leu, 2011). The Common Core State Standards for Mathematics (CCSSM) places an emphasis on using visual models (especially, the number line) to learn the effects of fraction operations and to represent them in a variety of situations, with visual models for fraction magnitudes introduced in first and second grade and visual models for fraction multiplication and division in fourth and fifth grade (CCSSM Writing Team, 2013). In practice, empirical studies demonstrate that area models are particularly common during classroom instruction (e.g., Webel & DeLeeuw, 2016). However, there has been no systematic investigation of the relative benefits and limitations of area models and number lines.

Across the fields of mathematics education, psychology, and mathematics, as well as among practitioners, there is considerable disagreement over which models best support students' fraction reasoning. For example, U.S. preservice teachers appear to be most accurate when reasoning in area contexts (Luo et al., 2011). However, reasoning with number lines may prevent common misconceptions that stem from the whole number bias (e.g., Ni & Zhou, 2005). *Looking back*, there is a wealth of research on visual models and models for division, but little is known about how differences in visual models affect children's fraction division understanding. *Looking ahead*, we hope our collaboration across Psychology and Mathematics Education fosters new perspectives, increased collaboration, and *crosstalk between these disciplines*.

We propose that number lines are more effective at supporting children's deep understanding of fraction operations than commonly-used area models. Our work is guided by a prominent psychological theory of numerical development, the *integrated theory of whole number and fractions development* (Siegler et al., 2011), which suggests the centrality of number lines as a tool for understanding the magnitude of all rational numbers. Number lines may better support children's fraction operation understanding because they better support children's fraction magnitude understanding (e.g., Hamdan & Gunderson, 2017; Siegler et al., 2011). Also, given that number lines support children's understanding of both fraction and whole number magnitudes, they are theorized to facilitate transfer and integration across whole number and fraction concepts (e.g., Siegler at al., 2011). Additionally, a number line allows students to represent more than one numerical magnitude on a single, common scale, which may better serve to highlight the multiplicative structure of fractions. Among area models, Wu (2011) notes the inflexible and limited nature of circular over rectangular models.

We investigated which types of diagrams best support children's accuracy, and elicit sound conceptual models of division, when solving fraction division problems. We hypothesized that any diagram would be beneficial in comparison to no diagram. However, we expected that children who completed problems with number line diagrams would have higher *accuracy rates* and show greater *conceptual understanding* than those who completed problems with circular area diagrams. We expected that rectangular area diagrams would elicit similar performance to number line diagrams, due to their linear nature. However, it is possible that children are more familiar with area models, and therefore more accurate on them.

Method

Participants

Participants were 62 children in late Spring of 5th grade or Fall of 6th grade (*M* age = 11.6*y*, *SD* = 1.4*y*; 45.6% girls; 75.0% White) from one public school in Northeast Ohio. Ohio state standards for mathematics education are aligned with the CCSSM, with fraction division first introduced in 5th grade. At this school, 18.30% of children qualify for the free and reduced price lunch program. Data collection occurred in two phases. Phase 2 included an additional 70 children.

Tasks

Children were randomly assigned to one of four between-subjects diagram conditions (see Figure 1) as they solved 18 fraction division problems: (a) *circular* area diagrams (n = 17), (b) *rectangular* area diagrams (n = 14), (c) *number line* diagrams (n = 16), and (d) *no diagrams* provided (n = 15). Problems varied by divisor and dividend type, including unit fractions, proper fractions, mixed numbers, and whole numbers (e.g., 1/3 ÷ 1/9 = ?, 2 1/4 ÷ 1/4 = ?, 2/5 ÷ 4 = ?). Each provided diagram represented six whole units (e.g., six circles). Whole units were partitioned into the denominator units of the smaller operand. Each problem was presented on a separate page in a random order. Children received no feedback. After solving each problem, children rated their confidence (0% to 100%) and perceived difficulty (*not difficult at all* [1] to *very difficult* [4]).

Procedure

Participants were tested individually in their school by the first author or an undergraduate researcher. We introduced the task by telling children that we were interested in the strategies they used to solve "*new kinds of math problems*", and asking children to show their work for each problem. Then, the researcher demonstrated "*how you can show your work*" using a whole number division example (6 ÷ 2). The researcher spoke about making "*a group of six*" and showing or thinking about "*how big six is*", making "*a group of two*" and showing or thinking about "*how big two is*", and finding "*how many times a group of two goes into a group of six*". In the diagram conditions, the researcher drew a diagram, matching that child's randomly-assigned diagram condition, to demonstrate a quotitive relationship between six, two, and three. In the *no diagram* condition, the experimenter simply wrote the numerals '6' and '2'. Instructions were scripted, and apart from instructions to "*show*" (diagram conditions) or "*think about*" (no diagram condition) the numbers, the script was identical in all conditions. We chose to model whole number division given previous research suggesting that children are more likely to successfully model fraction division immediately after modeling whole number division (Sidney & Alibali, 2017). We chose to model quotitive division given that children favor quotitive models for fraction division (e.g., Fischbein, Deri, Nello, & Marino, 1985).

Results & Discussion

Accuracy

We coded accuracy as whether or not the children wrote the correct answer to each problem somewhere on its page. For each child, we calculated the percentage of correctly answered problems out of the total number of problems attempted. All but six children attempted all 18 problems; data from all children were included in the analyses. Children were more accurate with fraction divisors (43% accuracy) than whole number divisors (25%), $t(56) = 3.30$, $p < .01$. This may be unsurprising given the nature of the quotitive example we provided; division of a fraction by a whole number may be better understood through a partitive model of division. Note that we did not observe this striking difference in accuracy by divisor type in the *no diagram* condition, $t(56) = 0.15$, $p = 0.88$. This may be indirect evidence that, in contrast to the children in the diagram conditions, children given no diagrams were not thinking about the conceptual structure of fraction division (either partitive or quotitive); reasoning with a diagram may invite children to reason conceptually. Furthermore, children in the *number line* condition had the highest overall rate of accuracy (48%), followed by children in the *circular* condition (43%), *no diagram* condition (33%), and *rectangular* condition (31%). However, in an ANCOVA on children's average accuracy, with diagram condition as the independent variable and problem order as a covariate, the overall effect of condition did not differ from zero, $F(3, 57) = 0.90$, $p = .45$. The pattern of accuracy suggests that there may be advantages to both number lines and circular area diagrams.

Conceptual Models

We examined children's conceptual models in each condition by coding children's written work on each problem based on a coding scheme (see Sidney & Alibali, 2017) aimed at categorizing children's overt strategies for fraction division. Critically, children's work on each problem was categorized as reflecting quotitive division, partitive division, or neither. In the number line condition, 12 out of 16 children demonstrated a quotitive or partitive divison model on at least 50% of problems. In contrast, children in either area diagram condition, *circular* (35%) or *rectangular* (43%), demonstrated quotitive or partitive division less often: 12 out of 16 children *vs*. *area* diagrams: 12 out of 31 children, $p = .01$, Fisher's exact probability test. In the *no diagram* condition, students' work rarely reflected a conceptual model. Thus, number line diagrams were most likely to elicit sound conceptual models of fraction division.

Difficulty

Finally, we examined children's difficulty ratings. Children in the *circular* condition rated problems as being less difficult ($M = 1.52$) than children in the *rectangular* ($M = 2.01$), *number line* ($M = 1.92$), and *no diagram* conditions ($M = 1.90$), $t(57) = -2.73$, $p < .01$. Looking across our analyses of accuracy and difficulty, children in the *number line* and *circular* conditions had similar levels of accuracy, and yet children in the *circular* condition reported less difficulty. If these findings are replicated in our full sample, it may be important for teachers and students to know that number lines may be challenging to reason with, but the benefits in conceptual understanding are "worth" the difficulty.

Conclusion

Overall, our findings suggest that diagrams support children's thinking about the *conceptual structure* of division, and that number lines in particular may elicit sound conceptual models of division. Both circular area models and number line models were beneficial for problem solving *accuracy*. Finally, because we reminded children of quotitive whole number division, our findings may provide evidence that children who reasoned with number lines were more likely to *transfer* across whole number and fraction division problems. In the full study, we hope to more closely examine this idea.

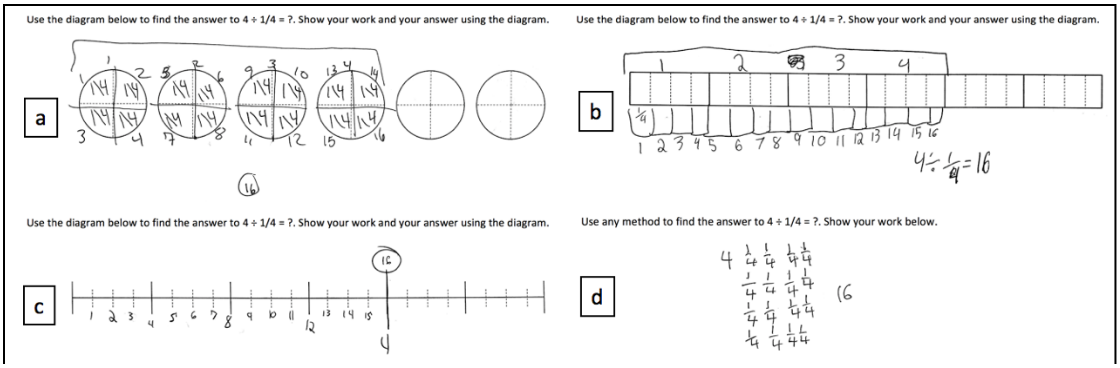

Figure 1. Solved fraction division problems, by condition. An example of correct student work from each condition is shown: circular (a), rectangular (b), number line (c), and no diagram (d).

CONNECTIONS AMONG CURRICULUM, TASKS, AND LINGUISTICALLY DIVERSE SECONDARY STUDENTS' UNDERSTANDINGS OF RATES OF CHANGE

Lynda Wynn
San Diego State University
lwynn@sdsu.edu

William Zahner
San Diego State University
bzahner@sdsu.edu

We examine how two 9th grade integrated mathematics teachers from a linguistically diverse school introduced linear and exponential rates of change, and we describe how their students demonstrated learning on a written assessment and a set of clinical interviews. The teachers collaborated on some aspects of their lesson planning, but used different curriculum materials. We found evidence that students in these two classes learned different concepts. Our preliminary analysis, using Lobato et al.'s (2013) focusing framework, indicates that students' performance can be traced back to the teachers' use of particular curricularly-influenced tools in the instructional environment such as "ratio tables."

Keywords: Algebra, Rate of Change, Curriculum

How does a teacher's use of curriculum materials shape student learning in linguistically diverse classrooms? This paper grows from a five-year design-based research study investigating how secondary mathematics teachers can design learning environments in which English Learners (ELs) develop robust understandings of critical concepts. Our study is conducted in a linguistically diverse school and is focused on the content area of linear and exponential rates of change. The first phase of the design research included an analysis of student assessments and interview tasks. In this analysis, we noticed that the students in two different teachers' classes answered both interview and assessment questions in consistent, but different ways. For example, students in one class used the general formulas for linear and exponential functions more frequently than students in the other class, yet they struggled more so than the students in the other class to use the formulas in a contextualized problem. The teachers had used different curriculum materials to teach the exponential rate of change unit. These observations lead to the following research question: What connections can be found among the curriculum, tasks, and student understandings of concepts related to exponential rates of change? More specifically, what were the different foci of the classroom activities that may have supported the students' interpretations of the tasks involving exponential rates of change? Given the use of two different curricula, what different concepts were in evidence in the students' learning?

Theoretical Framework

This study is rooted in a sociocultural approach to researching the mathematics learning of linguistically diverse students (Moschkovich, 2015), connecting students' opportunity to learn to broader dimensions of the learning environment such as curriculum and assessment (Zahner, 2015). Our analytical approach is informed by Lobato, Hohensee, and Rhodehamel's (2013) focusing framework for students' mathematical noticing, based on the notion that "what students notice mathematically has consequences for their subsequent reasoning" (p. 809). Lobato et al. described that what students notice is shaped by social interactions in the classroom, their interactions with mathematical tasks or curricular materials, and the nature of the mathematical activity in which they participate. The framework has four components. First, *centers of focus* are the mathematical features of a task that individual students notice that can be inferred through their written work, what they say, or through their gestures. The next three components, focusing interactions, mathematical tasks, and the nature of mathematical activity, all contribute to the emergence of the centers of focus. To illustrate the use of this focusing framework, Lobato et al. discussed the mathematical activities of two classrooms both focused on learning about slope as a rate of change, but with different types of activities. As they hypothesized, the students in each class developed different ways of reasoning about slope, influenced by the nature of the mathematical activities, tasks, and social interactions in their respective classes.

Although we adopt a focus on the appropriation of mathematical discourse (Moschkovich, 2015), we noticed a phenomenon similar to Lobato et al.'s (2013) in our study. Specifically, we noted that students in one teacher's class tended to use the equation, both recursive and explicit, as a resource for reasoning about exponential functions. At the same time, students in the other class were fairly adept at using the ratio / difference table to identify and build exponential / linear functions. We hypothesized that both of these trends could be traced back to the instructional environment and the centers of focus that emerged in each class (Lobato et al., 2013).

Methods

Setting

Our study was conducted at City High School (a pseudonym), a linguistically diverse comprehensive high school in California. We observed two Integrated Mathematics 1 (IM1) classes with two different teachers. The IM1 students at City High are primarily in the ninth grade. In the 2016-2017 school year when we collected this data, about 30% of the 9th grade students at City High were classified as English Learners (ELs) and about 56% of the 9th graders were formerly classified as ELs. The classes we observed for our study had similar proportions of ELs and former ELs as the overall ninth grade population.

Participants

We worked with two IM1 teachers, whom we call Mr. S and Ms. G. We observed their classes as they taught both the linear and exponential rates of change units in the fall and spring, respectively, but we focus on the results of the spring classroom observations, student interviews, and student assessments that reflected the introduction of exponential rates of change and a comparison of linear and exponential rates. Mr. S, who had taught at City High for eight years, was in his third consecutive year of teaching IM1. He has a mathematics degree and speaks both English and Spanish. Ms. G had 12 years of experience teaching at City High School and was teaching IM1 for the second year. She has a chemistry degree and holds a credential in mathematics. She is a monolingual English speaker. The IM1 students in their classes also participated in our study. All students were asked to take a pre- and post-assessment. Forty-nine students completed the assessments and 20 students volunteered to participate in problem-based interviews.

Data Sources

The data for this report came from three sources: classroom observations, pre- and post-assessments, and student interviews. The classroom observations coincided with the main instructional days during one unit on linear and exponential functions. These observations were video recorded, and the observer took structured field notes. We spent eight days observing in Mr. S's class and 10 days in Ms. G's class. The assessments consisted of four questions consisting of three problems from the IM1 textbook adopted at the school and one problem from map.mathshell.org. A total of 49 students completed both the pre- and the post-assessment. The student interviews were 45-minute long problem-based interviews using tasks from the IM1 textbook. The interviews were conducted in English and Spanish depending on the students' language preference. A total of 20 students participated in the 17 interviews we conducted. Three interviews were conducted with pairs of students.

Data Analysis

After observations, each researcher wrote reflections about the observation noting interesting mathematical and linguistic moments in the class as well as highlighting notes most pertinent to our study and questions that arose that we may wish to investigate at a later time. A high-level overview of each teacher's unit was created, consisting of the number of days in the unit, a basic outline of topics covered, and notable moments that highlighted the relationship between mathematics and language. Next, a detailed summary of each day of the unit was written, noting what mathematical content was covered, the types of contexts and activities used, unexpected or salient student contributions, and the ways the teachers supported language access and development.

The student assessments were scored using a researcher-created rubric, and all student responses were recorded in a database for further analysis. Statistical analyses showed that there were no significant differences between Mr. S's and Ms. G's classes before or after instruction, but the pre-post gain for the classes was statistically significant ($t(48)=5.7509$, $p<0.001$, using a paired t-test). Overall, about 78% of the students earned a higher score on the post-assessment, with an average gain of 20.5%. We then analyzed the database for patterns in the data. While the overall class performances were not statistically different from each other, we found interesting patterns in the data revealing a difference in foci.

Each of the student interviews were transcribed and coded. Each researcher created a summary of each interview by question and recorded overall impressions of the interview as well as any questions that arose for future interviews or analysis. We created content-analytic summary tables (Miles, Huberman, & Saldaña, 2014) for each question to summarize responses across all student interviews in order to find any patterns that emerged in the data.

Results

As we observed the teachers, we noticed differences in their presentations of the exponential rates of change units and we linked these to the different curriculum resources they were using. Table 1 below summarizes some of these differences. Note the use of multiple representations and multiple contexts in Ms. G's presentation compared to the primary use of tables and bank accounts in Mr. S's presentation of the material.

Table 1: Comparison of Features of the Exponential Rates of Change Units

Teacher	Days	Curriculum	Representations Emphasized	Task Contexts	Common Difference & Common Ratio
Mr. S	10	CME	Tables	Bank accounts	Delta column in table (1st day) Ratio column in table (4th day)
Ms. G	8	MVP	Multiple representations (tables, graphs, equations)	Allowance Filling/draining a pool Book shipments Repeatedly cutting paper into equal pieces Growing dot patterns	Arithmetic & Geometric Sequences (Delta and ratio columns were not introduced until the 8th day.)

Our analysis of the assessments led to several observations, and, in the interest of brevity, we will share two. First, of the students who could correctly identify an exponential function written in recursive function notation (36.7%) and explain why it was exponential (18.4%), all of these students were in Ms. G's class. We traced this difference in student answers back to the more frequent use of function notation and the focus on arithmetic and geometric sequences in Ms. G's class. Ms. G's emphasis on using phrases such as "multiply by three to get to the next term" instead of "multiply by three each time" was reflected in the student's explanations. Second, the majority of the students who could correctly fill in the output and "ratio" columns of a table for a given exponential equation (68.4%) were in Mr. S's class. As shown in the table above, this difference in student performance can be traced back to the earlier introduction of and continued emphasis on using a ratio column in a function table in Mr. S's class.

During the student interviews, the students were asked to describe, in their own words, what it means to be a linear function and what it means to be an exponential function. The students gave a variety of descriptions including graphical descriptions, recursive descriptions, and general equations in explicit or recursive forms. Of the students who gave the explicit forms of the equations (20%), all of these students were in Ms. G's class. Of those who referenced delta and ratio columns (20%), all were in Mr. S's class. Ms. G introduced the explicit forms on the 4th day of her unit and emphasized their use throughout the rest of the unit (7 days), whereas Mr. S emphasized the use of delta and ratio columns in tables throughout his unit (7 days). Additionally, on a question involving a comparison of banks offering simple interest versus compound interest, of the students who could correctly identify which offer would be the best in the long run and explain why, 83.3% were in Mr. S's class. As shown in the table above, Mr. S focused on a similar context (bank accounts) during his unit, while Ms. G's unit consisted of multiple contexts.

Discussion

Although we found differences in students' understanding of concepts related to exponential rates of change, it is important to recall that there were no significant differences in the post-assessment results of the two classes and that both classes had significant gains on the post-assessment. However, it is clear that what happens in the classroom, what emerges as centers of focus, impacts student learning. Our results don't clearly indicate that one approach is better than the other, only that the differing approaches yielded different profiles of student understandings. These results led us to consider the following question. What are the affordances of having an equation-centric view versus a table-centric view? An equation-centric view more easily suggests the existence of continuous covarying quantities, whereas the table-centric view points to the structure of the invariant ratio, which is a nice parallel to the collinear points conception (i.e., invariant slope).

RELATIONSHIPS BETWEEN UNITS COORDINATION AND UNDERSTANDING CALCULUS CONCEPTS

We report on data from a 14-session paired-student constructivist teaching experiment investigating relationships between calculus students' *levels of units* and their understandings of differential and integral calculus concepts. We describe our initial assessments of students' units coordination (Norton, Boyce, Phillips, Anwyll, Ulrich, & Wilkins, 2015), students' reasoning during subsequent video-recorded teaching experiment activities, and conjectures of connections between students' levels of units and reasoning about graphs, including their covariational reasoning (Thompson & Carlson, 2017).

Methods, Results, Discussion

In Summer 2017 we conducted clinical interviews with students enrolled in Calculus I at a public university to assess their levels of units. Debbie was assessed as assimilating with two levels of units, and Trevor was assessed as assimilating with three levels of units. Our learning goals for students in a follow-up paired-student teaching experiment were for them to construct (a) more powerful ways of reasoning about functions, (b) connections between different contexts of the derivative, concavity of its graph, and second differences of average rates of change over intervals of uniform width, and (c) the accumulation function and fundamental theorem of calculus (Thompson & Silverman, 2008). Our goal was understanding affordances and constraints in students' constructions. We noticed persistent differences in students' reasoning about rates of change of linear functions, particularly through the ways the students reasoned with tables and graphs. Debbie reasoned more often with coordination of values; Trevor had a greater propensity for engaging in continuous covariational reasoning. Assimilating with three levels of units does not explain the plethora of differences noticed in their schemes, however, as Trevor's lack of imagery for trigonometric functions constrained his understanding of the integral $\boxed{\int_0^{\pi} \sin t \, dt}$. Future work may explore both how to support students' construction of covariational reasoning before they get to calculus and to continue to support conceptual understandings of calculus for students who assimilate with two levels of units.

EVOLUTION OF DEVELOPMENTAL STUDENTS' MATHEMATICS BACKGROUND KNOWLEDGE

Eyob Demeke
California State University

Far too many students began their postsecondary mathematics education in remedial mathematics (Bailey, 2009, Schwartz, 2007). In the California State University (CSU) system, approximately a third of their incoming freshmen are considered unprepared for college level mathematics courses (CSU, 2012). For some students in the CSU, a year will elapse before they can enroll in a college level mathematics course. Across the CSU, unless exempted, every admitted student is required to take the Entry Level Mathematics (ELM) test, which aims to measure proficiency in basic skills need to succeed in a college level mathematics course. 50 on the ELM is a cutoff score that determines whether a student needs mathematics remediation or not.

It is important to note that the ELM is not a diagnostic test; as such, it does not shed light on specific contents that students are struggling with. To that end, in this study, we used Second Year Algebra Readiness Test (SYART) to understand the mathematical background knowledge of 1100 students who received a score below 50 on their ELM test. These students were enrolled in a two, four-week courses designed to prepare them for a college math course: beginning algebra and intermediate algebra. In both classes, students met their instructor five times a week, and every class, except exam days, they would spend approximately 30 minutes in cooperative learning that utilizes active learning strategies such as *think-pair share, peer lesson,* and *wait time*. A pre/posttest analysis of SYART showed that students' overall score improved significantly. On average, beginning algebra students' SYART score improved by approximately 39.5%. Using a two-sample t-test, session one witnessed a statistically significant growth with a *p-value of* $\boxed{3.3 * 10^{-63}}$.

To summarize, students improved their performance in several topics of the test. However, the biggest growth were observed in the following topics: Exponents and square roots; Scientific notation, Linear equations and inequalities, Polynomial and quadratic equations. However, several students were still below a critical level in some topics. Specifically, students continue to struggle in graphical representation of solution of equations and inequalities. Still, there is a strong evidence to conclude that the four-week intervention in math remediation has a considerable impact.

SEEING THE MATH IN PATTERNS: CHILDREN'S ATTENTION TO NUMERICAL INFORMATION IN A REPEATING PATTERN TASK

Emily R. Fyfe
Indiana University
efyfe@indiana.edu

Martha W. Alibali
University of Wisconsin-Madison
mwalibali@wisc.edu

Introduction

A growing body of research has established associations between children's early patterning skills and their formal mathematics knowledge (e.g., Rittle-Johnson, Fyfe, Hofer, & Farran, 2017). To better understand these associations, we sought to assess whether children "see the mathematics" in repeating patterns – that is, whether they spontaneously attend to mathematical information in patterns, such as the number of items in the part that repeats (e.g., the pattern is two circles followed by one square, then it repeats). Research in cognitive development suggests there is high variability in how often children attend to this type of precise quantitative information—referred to as children's "spontaneous focusing on numerosity" or SFON—and that individual differences in SFON predict later mathematics performance (Hannula, Lepola, & Lehtinen, 2010). In this study, we assess children's spontaneous attention to numerical information in a repeating pattern task and examine how this relates to their mathematics skills.

Method and Results

Participants were 36 children ranging from 5 to 13 years old. The same sample was studied in Fyfe, Evans, Matz, Hunt, and Alibali (2017), but for a different set of research questions. Children completed 24 pattern extension problems (e.g., ● ● ■ ● ● ■ ● __) by predicting the next item in the sequence and explaining their selection. We categorized these explanations based on whether they focused explicitly on numerical information in the pattern (i.e., the quantity of specific elements in the unit of repeat, such as "the pattern goes two-one, then two-one") or focused solely on the feature information (i.e., the concrete characteristics of the elements in the unit of repeat including size and shape, such as "it goes circle circle square then a circle"). Children also solved 9 arithmetic problems (e.g., $2 + 4 + 5 + 2 =$ __, $4 + 7 – 7 =$ __).

Children provided number explanations on close to 20% of pattern items, with 58% of children providing a number explanation at least once. The frequency of providing number explanations was not correlated with total pattern scores, $r(34) = .08$, $p = .65$; thus, attention to numerical information was not related to success on the pattern task. However, attention to numerical information was predictive of children's calculation skills. The frequency of providing number explanations was a significant, positive predictor of children's total score on the arithmetic problems, $\beta = .28$, $p = .04$, even after controlling for total pattern scores, nonverbal IQ, and verbal working memory capacity. In contrast, the frequency of providing feature explanations was not a predictor of children's scores on the arithmetic problems, $\beta = .06$, $p = .68$. These results provide a window into how children "see the mathematics" in patterns.

Introduction/Theoretical Framing

Students sometimes experience success in school mathematics if they learn to reason with three levels of units *in activity*, which means they "build" an ephemeral third level of units as part of their way of reasoning rather than assimilating situations with a units (of units (of units)) structure—this difference has implications for the development of multiplicative and algebraic reasoning in the middle grades (Ulrich, 2015). Some students pursue STEM majors in college assimilating with two levels of units, and research suggests connections between students' ways of coordinating units and their ways of understanding rates of change in Calculus (Byerley, 2016). What connections exist, if any, between students' units coordination and their readiness for Calculus? One measure of student readiness for Calculus is The Precalculus Concept Assessment [PCA] (Carlson, Oehrtman, & Engelke, 2010). Past results suggest that a 50% score on the 25-item assessment differentiates student success in calculus: 77% of students scoring more than 12 passed their introductory calculus course, while 60% of students scoring less than 13 received a grade of D or F, or withdrew from the course.

Methods/Results

We assessed the units coordination and calculus readiness of 32 students enrolled in first-term Calculus at a university in United States. Each student completed the PCA and participated in a 15-minute clinical interview, conducted by the second author using the methods and descriptors described in Norton, Boyce, Phillips, Anwyll, Ulrich, & Wilkins (2015). Each student was assessed as either assimilating with three levels of units [S3] (14 students) or as assimilating with two or fewer levels of units [S2] (18 students). A Wilcoxon Signed-Ranks Test indicated that mean PCA scores for students in group S3 ($M = 15.71$) and students in group S2 ($M = 9.78$) were significantly different ($Z = 4.94$, $p < 0.001$). Additionally, 71% of students in group S3 scored more than 12 on the PCA compared to 33% of students in group S2. These results suggest a connection between students' units coordination and Calculus readiness. Implications for attending to students' units coordination and teaching and learning Calculus are discussed.

MODELING COGNITIVE DEMAND ACROSS MATHEMATICAL DOMAINS

Sarah Kerrigan
Virginia Tech
stk123@vt.edu

norton3@vt.edu

Katy Ulrich
Virginia Tech
culrich@vt.edu

Keywords: Cognition, Modeling

M-capacity is an age-dependent construct (ranging from 2 to 5 among middle school students) describing the number of schemes or actions one can simultaneously hold in working memory at a time (Pascual-Leone, Johnson, & Agostino, 2010). We present a model that uses M-capacity to explain and predict students' performance on tasks across different mathematical domains (multiplicative reasoning, fractions, algebraic reasoning), integrating schemes and actions from units coordination research. Units coordination (Steffe, 1992) describes students' engagement with various levels of units in mathematical tasks. Students can assimilate up to three levels of units at a time and account for additional levels of units through activity. Students are able to solve tasks with different levels of cognitive demand depending on their stage of units coordination and their M-capacity.

In the model, circles, boxes, and triangles represent schemes for assimilating one, two, and three levels of units, respectively; arrows represent mental actions. A uni-directional arrow represents a mental action carried out in activity; a bi-directional arrow represents a reversible action interiorized as part of a scheme. Figures 1(a)-(c) illustrate theoretical capacities for students at each of three stages of units coordination to reason through a multiplicative task: 8x3.

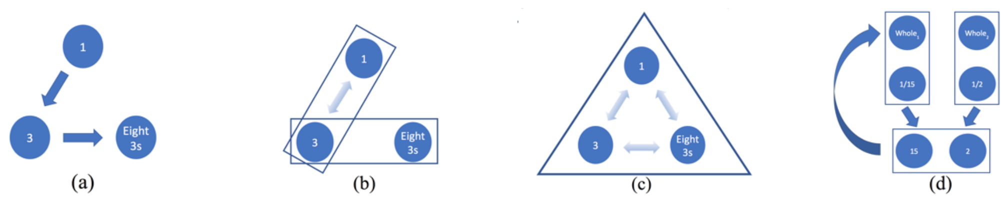

Figure 1: (a)-(c) Stage 1-3 unit coordination; (d) Stage 2 student solving a fractions task.

Figure 1(d) is our model applied to a students' work found in the literature (Hackenberg & Tillema, 2009). Sara was solving the task: "You decide to share that piece (one-fifteenth) of cake between two people. How much of the cake would one person get?" (page 7). The task involved six levels of units for the student to coordinate (circles). As a Stage 2 student, Sara could assimilate the units into three two-level schemes (boxes). Assuming a middle school student M-capacity of 5, she could carry out mental actions for coordinating the first two schemes with the third, through activity (short arrows). However, limited to five schemes/actions, she would not be able to coordinate results from the third scheme (30) back to the whole (long arrow) without relying on figurative material, which fits Hackenberg and Tillema's (2009) descriptions.

PRELIMINARY GENETIC DECOMPOSITION FOR QUADRATIC RELATIONSHIPS IN REAL-WORLD CONTEXTS

Tiffany J. LaCroix
Virginia Tech
tlacroix@vt.edu

Keywords: algebra & algebraic thinking, learning trajectories (progressions), cognition

Review of Literature & Conceptual Framework

Students struggle to solve quadratic functions in authentic contexts (Didis & Erbas, 2015), due in part to reading comprehension (Pape, 2004). This paper therefore outlines a preliminary genetic decomposition (Dubinsky & McDonald, 2001) of the mental constructions that support student's conceptions of introductory-level authentic quadratic relationships including function, covariation, and reading comprehension.

Methods & Results

APOS Theory suggests students construct increasingly sophisticated mental structures (Action, Process, Object, and Schema) to understand mathematical concepts. The function strand is from Arnon et al. (2014), and the covariation strand is based on Carlson, Jacobs, Coe, Larsen, and Hsu (2002). For covariation, an Action conception constitutes students identifying how changes in one variable relate to changes in the other, and a Process conception involves students explaining the directionality of related values. An Object conception describes students recognizing that different coefficients cause the relationship between the x- and y-values to differ in measurable ways, and a Schema conception shows students can differentiate between quadratic relationships based on the relationships between the x- and y-values.

Interpreting Pape's (2004) work to coincide with the stages of APOS finds students have a Direct Translation Approach (DTA) approach to reading comprehension at the Action and Process levels, meaning they cannot translate the text, context, units, or mathematical relationships to a problem solution. Meaning-Based Approach (MBA) full-context reading comprehension occurs at the Object level when students can translate the text to mathematical symbols and justify their choices based on context. An MBA-justification approach occurs at the Schema level when students can comprehend at the MBA full-context level while justifying their choices mathematically.

COVARIATION GRAPHING PRACTICES: THE CHANGE TRIANGLE

Konda Luckau

Keywords: Algebra and Algebraic Thinking

Creating and interpreting graphs in algebra remains challenging for many students. Past research has identified important ideas and common misconceptions related to graphing (Leinhardt, Zaslavsky, & Stein, 1990). Roth and Bowen (2001) challenge this work by noting that experts in science sometimes demonstrate misconceptions in their interpretation of graphs common in science but not directly related to their research. Roth and Bowen suggest that competent interpretation of graphs requires knowing graphing practices that are associated with specific types of graphs and the social contexts in which they are situated. In this study, we identified a family of practices associated with the use of the *change triangle* (see Figure 1) in a function-based algebra class (Carlson, 2016). We recorded instances of an experienced function-based algebra teacher using the change triangle while teaching, and then analyzed those instances to create descriptions of the ways the instructor attended to and reasoned about different elements of the change triangle.

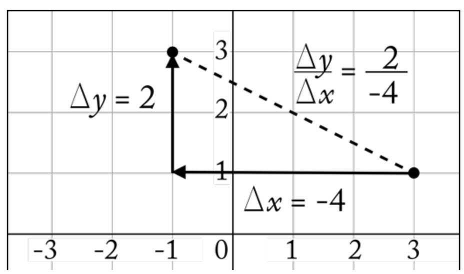

Figure 1. Change Triangle. Elements include a starting point, horizontal and vertical vectors, an ending point, and a dotted or solid line or line segment connecting the two points.

The change triangle is superimposed on graphs to invoke and support covariational reasoning (Thompson & Carlson, 2017) while solving a variety of problems (e.g., finding the vertical intercept of a line given a constant rate of change and an ordered pair). Different elements and multiple copies of the change triangle are attended to and coordinated in different ways to support a variety of quantitative comparisons and achieve multiple purposes. By making these practices more explicit to students, we not only support students in creating and using change triangles to identify and reason about covariation, but also allow for discussions about the norms and strategies for creating and using diagrams to support mathematical thinking.

BORROW, TRADE, REGROUP, OR UNPACK? INSTRUCTIONAL METAPHORS CURRICULAR RESOURCES INSTILL AS FOUNDATIONS FOR BASE-TEN NUMBER

Julie Nurnberger-Haag

Given that analogical reasoning is a cognitive mechanism that humans use to understand new ideas (Gentner & Bowdle, 2008), instructional metaphors have their place in mathematics education and specifically base-ten number instruction (English, 2013; Pimm, 1981). Metaphors used while learning base-ten number require still more nuanced investigation (Nurnberger-Haag, 2018). The term *trade*, for example, has been treated in practice and research as though it is the target mathematical idea (e.g., Fuson & Briars, 1990; Saxton & Cakir, 2006); however, this is an instructional metaphor that arose due to Dienes blocks (Nurnberger-Haag, 2018). Thus, this study asked: What instructional metaphors do elementary textbooks use for base-ten number?

A preliminary analysis of base-ten number in the second through fourth-grade teachers' editions of 12 U.S. textbook series were coded for metaphors expressed in words (verbal metaphors; Nurnberger-Haag, 2018; see poster for list of textbooks). Ten series expressed more than one metaphor. Metaphors such as *grouping*, *composing/decomposing,* and *bundling* reflect crucial early number concepts (CCSSI, 2010), yet these insufficiently represent base-ten number because these terms imply these processes occur within same unit levels, rather than building the crucial base-ten number concept of composite units (Nurnberger-Haag, 2018; Steffe & Cobb, 1988). Nevertheless, these were the most common metaphors, occurring in 92% of the textbook series. Despite trade metaphors violating base-ten number concepts by failing to communicate the idea of units within units, modeling unintended operations, and opening what should be a closed problem system (Nurnberger-Haag, 2018), 75% used a trade metaphor. Four series used *carry/borrow* along with other metaphors. The packing/unpacking metaphors theoretically predicted to best represent base-ten number operations and concepts (Nurnberger-Haag, 2018) were found in the teacher, but not student pages, of a single series. This analysis combined with future research on how students learn with specific metaphors could inform revisions of textbooks for improved base-ten number understanding for all learners in elementary classrooms.

HOW BENCHMARKS AFFECT THE NATURAL NUMBER BIAS AND STRATEGY USE IN FRACTION COMPARISON

Andreas Obersteiner, Freiburg University of Education, andreas.obersteiner@ph-freiburg.de
Vijay Marupudi, U. of Wisconsin-Madison, vijay.marupudi
Martha W. Alibali, U. of Wisconsin-Madison, martha.alibali@wisc.edu

Keywords: natural number bias, strategy use, fraction comparison

Fractions are difficult for many people. One source of difficulty is people's tendency to overextend natural number reasoning to fractions. For example, when people are asked to choose the larger of two fractions, natural number components can interfere with reasoning about magnitudes, yielding a "natural number bias" (Ni & Zhou, 2005). However, not all studies reveal the bias, and some studies have revealed a reverse bias (e.g., DeWolf & Vosniadou, 2015). In this study, we investigated whether encouraging people to use benchmarks (reference numbers, e.g., ½) in fraction comparisons would help them to activate fraction magnitudes and overcome a potential bias. We also examined patterns of strategy use.

Adults solved complex fraction comparison problems and reported their strategies on a trial-by-trial basis. All fractions were smaller than 1, and none of the pairs had common numerators or denominators. Half of the pairs were congruent (i.e., the larger fraction had the larger components) and half were incongruent (i.e., the larger fraction had the smaller components). The congruent and incongruent sets were balanced in terms of the fractions' magnitudes relative to common "benchmarks" (i.e., reference points, specifically, ¼, ½, or ¾). In "straddling" problems, one fraction was smaller and the other larger than one of these benchmarks. In "in-between" problems, both fractions were in between two adjacent benchmarks. In a special subcategory of "in-between" problems, both fractions were either smaller than ¼ or larger than ¾; in these problems, one fraction was close to 0 or 1, which may be especially salient benchmarks. Some participants also received a tip that benchmarks could be useful.

Overall, we found a reverse "smaller components—larger fraction" bias. Participants varied in their strategy use across problem types, indicating that they used strategies adaptively. On problems in which one fraction was close to 0 or 1, they used generally incorrect, component-based strategies much more often than on other problems. For the other two problem types, participants used component-based strategies less often, and used benchmark strategies somewhat more often. The tip about using benchmarks had little effect.

Participants used strategies adaptively in ways that made good use of the affordances of different problems (Alibali & Sidney, 2015), including the fractions' relative positions to benchmarks. Thus, patterns of strategy use may at least partially explain the occurrence and the direction of the natural number bias in fraction comparison. To better understand the natural number bias and why it varies across studies and across samples, it will be critical to understand the strategies people use in making specific fraction comparisons.

ASSESSMENT OF K-2 RELATIONAL REASONING SKILLS: STRENGTHS AND LIMITATIONS OF ITEM TYPES AND FORMATS

Lindsey Perry
Southern Methodist University
leperry@smu.edu

Leanne Ketterlin-Geller
Southern Methodist University
lkgeller@smu.edu

Keywords: Assessment and Evaluation, Number Concepts and Operations, Reasoning and Proof, Elementary School Education

Numeric relational reasoning is often defined as the ability to recognize and analyze relationships between numbers or expressions (Baroody, Purpura, Eiland, Reid, & Paliwal, 2016; Jacobs, Franke, Carpenter, Levi, & Battey, 2007). Students using numeric relational reasoning can use known facts to derive new facts (e.g., using 5 + 5 to solve 6 + 5), solve complex equations by transforming expressions using composition and properties of operations (6 + 5 = ☐ + 4), and recognize when calculations aren't necessary (e.g., 5 + 8 = ☐ + 5). Due to the predictive relationship between numeric relational reasoning and mathematics achievement (Aunio & Niemvirta, 2010; Nunes et al., 2007), it is important to understand how numeric relational reasoning can be assessed so that instruction can be modified to improve students' competence with this construct.

The purpose of this literature synthesis was to (1) identify what instruments currently exist that assess K-2 students' numeric relational reasoning competence, (2) determine different item types and formats for assessing this construct, and (3) determine the depth of reasoning needed by students for each item type.

After an extensive search, seven assessments were found that include items to assess K-2 students' numeric relational reasoning skills. These assessments include differing levels of content representation for numeric relational reasoning and its main components. Three main item types were utilized on these assessments: items with concrete or visual representations, word problems, and items with abstract notation only. The depth of reasoning elicited by these items varied, in part because the item formats did not make the students' reasoning visible. It is recommended that items focus not only on the correct answer but also evaluate students' reasoning strategies to better capture whether students are reasoning relationally.

This paper reports on a project aimed at developing a system of professional support for the improvement of the Geometry for Teachers course that mathematics departments teach to preservice secondary teachers. We share data from interviews with 20 instructors to report on how they perceive their position of geometry instructors and the work they do in the course. To inspect this set of interviews, we use the framework of professional obligations to the discipline, to individual students, to the institution, and to the classroom community. We share how references to these professional obligations emerged in the interview data.

Keywords: Geometry and Geometrical and Spatial Thinking, Post-Secondary Education, Teacher Education-Preservice

Introduction

This paper reports on a study of instruction at the college level, specifically focused on the geometry course that many universities offer and is taken by prospective secondary teachers (Geometry for Teachers, or GeT hereafter). We report how GeT instructors perceive their position and the work they do in the GeT course in relation to institutional stakeholders. The literature on instruction at the college level is emerging (Mesa, Wladis, & Watkins, 2014) and in order to frame our focus, we can profit from considering as background the literature on K-12.

The study of mathematics instruction at the K-12 level has often considered the classroom as a container within which interactions among teacher, students, and content unfold. The influence of institutional context on instruction has not always been part of that consideration. Cohen et al.'s (2003) instructional triangle calls attention to the environments in which instruction is situated but most studies of instruction pay little attention to how those environments influence instruction. Some of that is justified on the received wisdom that instruction is "loosely coupled" with administration (Weick, 1976). Awareness in our field of the importance to look at the relationships between institutional and instructional issues has been brewing, particularly from research focused on systemic reform (e.g., Cobb, Jackson, Smith, Sorum, & Henrick, 2013) and on equity (e.g., Lubienski, 2002; Walker, 2007). The realization, particularly from the latter research, is that some of the phenomena that happen at the classroom level (e.g., little access to good mathematics) owes to issues that are structural (e.g., tracking, teacher placement, school climate). As the era of accountability starts to affect also higher education (Levine, 2017), there is reason to consider how environments affect instruction also at the college level. On this matter the K-12 literature can provides some theoretical resources.

Chazan, Herbst, and Clark (2016) describe the position of the teacher as one that connects the institution and its stakeholders with the roles and relationships at play in instruction. Attempts to improve instruction have often relied on the agency of teachers. Chazan et al. (2016) contend that such attention to agency needs to be complemented with attention to structural issues at play in educational institutions and in society at large if we are to understand how instruction can be improved. This paper argues that the GeT course is one that could benefit from instructional improvement and asks the question of how instructors of this course experience the influence of institutional issues that might support or hinder that improvement.

We inscribe the paper within an improvement effort that tries to follow the approach described Bryk, Gómez, Grunow, and Le Mahieu (2015), which challenges the usual improvement paradigm of diffusion of innovation. Rather than conceiving a solution to a problem and seeking to implement it with fidelity and evaluate its results, the approach described by Bryk et al. (2015) starts from creating a *networked improvement community* (NIC). Using an organizational learning perspective, this approach engages the whole network in designing, monitoring, and continuously developing solutions that might improve the system, particularly by attending to variation in performance. This methodology for improvement starts from understanding the system that produces the outcomes that need to be improved. Our attention to how instructors perceive their institutional positions, at the hinge between the institution and classroom instruction, is key in understanding the system in question.

The Need for Improving the Geometry Course for Teachers

A geometry course (HSG, hereafter) has been part of the US high school curriculum for more than 100 years (Sinclair, 2008) and it has traditionally been key in inducting students into mathematical practices such as conjecturing and proving. The changes proposed by the Common Core (Common Core State Standards Initiative, 2010), and the corresponding state assessments have substantial impacts on the HSG curriculum (Wu, 2014). These changes have been accompanied by an increase in the use of students' achievement for individual teachers' accountability (Roth McDuffie et al., 2015). Likewise, the description of "highly qualified teachers" ushered in by the No Child Left Behind [NCLB] legislation (Bush, 2002) suggests the need for teachers to have substantial content preparation in the disciplines they will teach. This suggests an institutional pressure on those who prepare teachers, to align what they teach preservice teachers with what the latter will need to teach their own students. This pressure can be seen in the CAEP standards adopted by 33 states through partnership with NCATE which state that teacher education provider programs must "ensure that candidates demonstrate skills and commitment that afford all P-12 students access to rigorous college- and career-ready standards (e.g., […] Common Core State Standards)." The pressure can also be understood by examining the MET II documents that call secondary teacher preparation programs to offer courses specifically designed to focus on mathematics at the high school level from an advanced perspective, including "address[ing] the CCSS approach to Euclidean geometry based upon translations, rotations, reflections and dilations" (CBMS, 2012, p. 7). But, are GeT courses providing teacher candidates with the knowledge they need in order to teach HSG? Grover and Connor (2000) surveyed the content and instructional practices of geometry courses at 108 randomly selected U.S. colleges and universities and found that GeT course content varies greatly: From a review of middle and high school topics to the development of elementary axioms or a study of non-Euclidean and projective geometries using alternative transformational and analytic approaches. A comparison of the textbooks used for GeT courses produced similar differences. Grover and Connor (2000) concluded that there is no typical curriculum for GeT. This variability in GeT courses prompts questioning their usefulness for teachers (Wu, 2011).

It seems that institutions should have reason to be interested in improving the GeT course by better aligning what is taught to future teachers with the knowledge they need to teach HSG.

However, because Euclidean geometry is no longer an area of active mathematical research, the geometry content high school students study has few stewards in university mathematics departments (Steen, 1988; see also Atiyah, 2001). With the GeT course being a service course for fewer students than other service courses (such as calculus or linear algebra), it is hard for mathematics departments to create local communities to steward the GeT course. Improvement is needed but it may need more than local attention; it could use a network approach.

We are interested in improving the GeT course using the approach described by Bryk et al. (2015), which requires us to start from understanding the system in need of improvement. The GeT course is one where environmental influences (e.g., instructors need to prepare PSTs to teach geometry) could connect with the outcomes of the course (viz., better mathematical knowledge for teaching geometry of preservice teachers). As some research has shown connections between MKT and the mathematical quality of instruction as well as K-12 student outcomes (Hill, Rowan, & Ball, 2005; Hill et al., 2008), increasing MKT would be desirable. Based on performance data, Clements (2003) suggested that students' knowledge of geometry could use improvement. Increasing MKT in geometry might be one lever. Given that the need for improvement in HS geometry instruction points to the possibility to improve the GeT course, a question that can be asked is whether a process of continuous improvement based on principles of organizational learning can be used productively to improve geometry for teachers.

Our project has started developing a networked improvement community by bringing individuals together. We began by locating institutions with large teacher preparation programs—as we are interested in the undergraduate geometry course serving future teachers, rather than geometry courses in general. Within those institutions, we looked at mathematics departments for geometry courses serving secondary mathematics pre-service teachers and identified instructors of those courses as the natural candidates to be members of this community. We are also incorporating other stakeholders, including high school geometry teachers and mathematics supervisors who influence certification policies at state levels. Our first step has been to do a set of initial interviews of instructors of the GeT course. The interviews help us describe members of this group in terms of their professional position as instructors of college students.

Theoretical Framework: Practical Rationality of GeT Instructors

As we consider the effort involved in improving GeT, we are keen to note that like the case in K-12 instructional improvement, the improvement of curriculum and instruction for GeT is likely to need more than resources and networks: It needs know-how, anchored in an understanding of what instructional practice is like in its institutional context (Halverson, 2003). In a review of the research literature on collegiate mathematics, Speer, Smith, and Horvath (2010) reported that there exists "very little research [that] has focused directly on teaching practice—what teachers do and think daily, in class and out, as they perform their teaching work" (p. 99). Further, they argue that "the community's efforts to support instructors as they learn to teach college mathematics is often not informed by data and research on what is involved in teaching college mathematics" and recommend conducting research in this area to guide the professional development efforts designed to improve collegiate mathematics (p. 111). Specifically, in considering what is involved in the improvement of GeT, it would be helpful to understand how GeT instructors negotiate the multiple demands of their role preparing HSG teachers. How do faculty relate to the dual expectation that GeT be a university mathematics class and prepare students to teach high school geometry?

In their account of the practical rationality of mathematics teaching, Herbst and Chazan (2012; see also Chazan, Herbst, & Clark, 2016) identify sources of justification that instructors might use to make their actions reasonable or sensible. Many actions in teaching mathematics go without saying, they don't call for justification but rather are habitual or normative. But quite often instructors deviate from the norm—e.g., instead of correcting a mistaken response, an instructor might ask his or her class to consider whether the response makes sense. Herbst and Chazan (2012) propose that such departures from the norm might be perceived as justifiable by a professional if they help meet one or more of four professional obligations: An obligation to the discipline of mathematics, an obligation to students as individuals, an obligation to the class as a community, and an obligation to the institutions that make room for instruction.

The obligations framework has important implications for the ways we think about supporting GeT instructors in improving their instructional practice. In particular, we can use this framework to unpack the tensions that they perceive as undergirding GeT instruction. For example, the institutional obligation (to the Teacher Education program and State certification agency calling for mathematics departments to offer GeT courses) might compel the GeT instructor to cover the content that his or her students would need to teach in schools, while the instructor's obligation to the discipline of mathematics might compel them to bring in considerations that are more general (e.g., that Euclidean geometry is only one geometry, but different choices of postulates might give rise to different geometries) in order to better represent the discipline. Because time is limited, instructors can't just avoid these tensions, they need to manage them. We see the many tensions that might exist among the professional obligations of undergraduate instructors as fertile places where to start an inquiry toward the systemic improvement of the GeT course. In this paper, we begin that work by sharing what we've learned from GeT instructors through a set of initial interviews. Our research questions are: (1) How does the framework of professional obligations help us understand the professional position of geometry instructors? and (2) How does such understanding help us move toward alignment between the GeT course and the HSG course?

Methods

We recruited 20 participants (8 men and 12 women) from 17 universities across the U.S., all of whom were identified as mathematics department faculty, hold doctoral degrees in mathematics or mathematics education, and have recently taught a geometry course aimed at serving pre-service teachers in large teacher preparation programs. We developed a semi-structured interview protocol to learn about the instructor, their context, and their dispositions toward improving the GeT course. The protocol had three sections: 16 questions about the GeT course and the challenges that come with teaching it, 3 questions (with follow-ups) about the various forms of content covered in the course, and 3 questions about the background of the participant. In this paper we focus responses to the first section, and questions such as: "What experiences do you aim for your students to have in the geometry course for teachers?" and "What are the expectations that shape the geometry course for teachers that you teach?"

We piloted the interview with two non-participants who are experienced instructors of the GeT course before administering it to the rest of the participants. We conducted the interviews using online video-conferencing software that allowed us to capture audio and video records of the interaction. The analysis of the interview data was a multi-step process. We began by taking field notes during the interview and then improving those notes with one or two reviews of the video after the fact. Using the professional obligations framework, we individually coded participants' contributions across the first section's interview questions, meeting together to compare, discuss, and reconcile our understanding of each category as well as identify emerging themes.

Results

In this section, we use the professional obligations of mathematics teaching to organize initial gleanings from the interviews. We share the various ways that each of the professional obligations emerged in the data, illustrating each theme with examples from the data. Lastly, because part of what we aim to do is to understand how well the obligations framework helps us account for instructors' perceptions of their position as instructors of the GeT course, we also share data that did not fall neatly within any of the four professional obligations framework.

Instructors Dispositions toward the Disciplinary Obligation

We had hypothesized that that GeT instructors would relate to their professional position by recognizing an obligation to the discipline of mathematics. Unsurprisingly, we observed a plethora of responses that illustrated various dispositions toward the disciplinary obligation. Three themes emerged from that analysis; a disposition to attend to (1) geometry as a body of confirmed and correct knowledge that GeT students need to know; (2) mathematics as a practice of inquiry, discovery, invention, or knowledge development that people need to engage in; (3) geometry as a set of models which are useful for solving problems. In Figure 1 we illustrate these themes with participants' responses:

Mathematics as ...	Participant Response
A body of confirmed and correct knowledge	"I do think it's important for mathematicians to teach this course… it's a surprisingly mathematically sophisticated course. I think that it's mathematically sophisticated enough that mathematicians should be teaching it" (MV).
A practice of inquiry, discovery, invention, or knowledge development	"High school teachers were definitely as good as I was in recognizing patterns or solving problems. But when they found an answer, they were happy to move on. They didn't seem to me to need to have a rigorous argument about why this pattern worked or why things were the way they were...that's something that I want to convey to my students" (RR).
Providing models useful for solving problems	"[Community members such as businesses] want their people to be problem solvers and have the ability to deal with an unfamiliar situation. ... I think that that's the main value of the class to the society as a whole" (SA).

Figure 1. Examples of data coded as evidence of GeT instructors' disciplinary obligation. Note: Two letters are used to refer to each of the different participants.

Instructors Dispositions toward the Individual Obligation

We hypothesized that GeT instructors would relate to their professional position through a recognition of their obligation to the individual student. While not as prevalent as the evidence for instructors' disciplinary obligation, we observed many participant responses that we agreed would be categorized under the individual obligation. We share two themes that emerged from that analysis: the obligation to attend to the individual as: (1) a cognitive being (who can think, process mentally, etc.); (2) an emotional being (who can feel anger, joy, fear, disgust, sadness, etc.). Figure 2 illustrates these themes with participants' responses:

Individual as	Participant Response
A cognitive being	"[The mathematical experience is] a good thing for a person's spirit…to be challenged and succeed" (IL).
An emotional being	"So I've definitely have gotten some good feedback about people who were scared about, or nervous about teaching geometry at the high school level and after they took the college geometry course at our university they felt like they were ready, or maybe even excited about teaching geometry" (RL).

Figure 2. Examples of data coded as evidence of GeT instructors' individual obligation.

Instructors Dispositions toward the Institutional Obligation

We hypothesized that GeT instructors would relate to their professional position through a recognition of their obligation to the institution. Three themes emerged from that analysis: the obligation to attend to the institution as: (1) a place that provides service to young members of society; (2) a place that has external accountability (teacher preparation programs and certification agencies); (3) an organization that has rules, policies, etc. We illustrate these themes (see Figure 3) with participants' responses to various interview questions:

Institution as ...	Participant Response
A place that provides service to young members of society	"[T]he content in the course and the student work in the course is related to how well they do on things like Praxis tests as well as how it relates to how they actually teach in the classroom two years later" (IF).
A place that has external accountability	"We redesigned it based on the MET II document, actually based on the MET and then revised again with the MET II, and also focusing on the um Common Core Stand—State Standards as to what geometry the teachers are going to have to teach. And so we have totally revamped the course so the focus is on those aspects of geometry" (IF).
An organization that has rules, budgets, etc	"The catalogue affects me - the description talks about axiomatics and finite geometries. While finite geometry is a nice playground, because they can build the models and see everything, I wouldn't have to do that. That course description constrains me" (SL).

Figure 3. Examples of data coded as evidence of GeT instructors' institutional obligation.

Instructors' Dispositions toward the Interpersonal Obligation

We hypothesized that GeT instructors would relate to their professional position through a recognition of their obligation to the interpersonal collective of the classroom. Unlike the previous three obligations, we found few of the instructors' responses that could be filed under the interpersonal obligation. Thus, here we have just one theme that emerged from our analysis:

the obligation to attend to the group of students as a discourse community, that needs to partake of communicative exchanges (Figure 4).

Group of students as ...	Participant Response
A discourse community, that needs to partake of communicative exchanges	"So I want them to collaborate mathematically in and outside of class, I want them to get experience communicating mathematics both in person, we do a lot of presentations at the board, a lot" (MV).

Figure 4. Examples of data coded as evidence of GeT instructors' institutional obligation.

Those Responses Falling Outside the Four Professional Obligations

Prior to closing this section, we take a moment to review some of the instructor responses that felt important to describe how GeT instructors relate to their professional position but were not captured by the professional obligations. These exceptions are rare in the data, as we have only found two instances. These instances can be attributed to instructor's personal resources, including knowledge, experience, beliefs, and identity. One of the responses came in the context of discussing whether or not GeT instructors held any responsibility for teaching students how to engage in work that was specific to the work of teaching, like creating questions for a geometry exam or understanding students' difficulties with geometric proof. RR's response serves as an example of how an individual's knowledge or experiences can elevate the tensions that one experiences in teaching the GeT course:

> I was trained as a mathematician, I was not given any formal training on student teaching/learning - anything I know about student teaching/learning is something that I've read or picked up from [a mathematics education colleague] but there are other [mathematicians] who don't have [mathematics education colleagues] who come at these courses - geometry, or upper level algebra/analysis course who don't have any of that experience. (RR)

Conclusion

The professional obligations framework is useful to understand the professional position of GeT instructors, positions toward the GeT course, though the data speaks also about the importance to attend to personal resources. The interviews suggest that efforts to improve the course by developing a networked improvement community may need collective awareness of the variety of ways in which individuals relate to their positions as instructors.

DEVELOPING AND USING DEFINITIONS FOR PRISMS AND PYRAMIDS

dana.cox@miamioh.edu

Teaching geometry courses for preservice elementary teachers, we observed that difficulty with classifying shapes (and, in particular, composite 3-D shapes) persists even after work with simple shapes to support the writing of accurate and unambiguous definitions. We conducted a self-study of our teaching of 3-D concepts to uncover the concept images of pyramid and prism that emerge. We sought to understand the nature of those observed difficulties. We found that using both simple and composite shapes in classification activity exposed more nuanced and complex concept imagery than simple shapes alone. Opportunities to articulate assumptions create a space for all learners to make the language more precise and to create concept definitions that are more resilient.

Keywords: Geometry and Geometrical and Spatial Thinking, Instructional Activities and Practices, Teacher Education-Preservice

Background

Human perceptions of the physical world are primarily made up of 3-D shapes. Many curricula around the world provide opportunities to identify and name three-dimensional solids in early grades (Sinclair, Cirillo, & de Villiers, 2017). However, only a few studies on learners' definitions and conceptions of 3-D solids were discussed in the review conducted by Sinclair, Cirillo, and de Villiers (2017). Bozkurt and Koc (2012) reported that many of the first-year Turkish pre-service elementary teachers (PSETs) in their study found it difficult to define prism; 60% of them either could not provide a definition for prism or could not go beyond stating the fact that it was a term for 3-D shape. Another study identified a variety of concept images that Turkish PSETs hold about the base of 3-D shapes. Many were limited and/or contradictory in nature (Horzum & Ertekin, 2017). Tanguay and Grenier (2010) found that preservice secondary teachers had difficulty defining and describing regular polyhedra, which hindered their later attempts to develop a proof for the existence of only five possible regular polyhedra.

In our geometry courses for PSETs, we have observed the difficulty that our students have in classifying shapes, and, in particular, composite 3-D shapes. This difficulty persists even after significant work with simple pyramids and prisms to support the writing of accurate and unambiguous definitions. Initially, we speculated that this difficulty was related to our PSETs' ability to write and apply formal definitions, but wondered if it was also related to unarticulated concept imagery. The challenge was to create opportunities to articulate problematic concept images and expose the hidden contradictions that make classification difficult. Our analyses have uncovered layers of complexity in PSETs' conceptions of prism and pyramid.

We will provide findings related to two research questions:

1. What concept images of pyramid and prism emerged from in-class activities that focused on defining and classifying 3-D solids?
2. What is the nature of PSETs' difficulty in using established concept definitions and images to classify composite 3-D shapes as pyramids, prisms, or neither?

Theoretical Framework

In our work to help PSETs understand prisms, pyramids, and related concepts, we strive to create opportunities for PSETs to experience cognitive disequilibrium (Piaget, 1985). This is the moment when there is an imbalance between prior knowledge (schema) and experiences that cannot (yet) be explained by it. The process of engaging students in the act of defining is one of iteration and revision; we move back and forth between examining concrete shapes built from wooden models or other commercially made building materials, and writing and revising emerging concept definitions. The activity described later in this paper, *Prism, Pyramid or Neither?* is one of our attempts to perturb the equilibrium of our students in the hopes that they are able to articulate deeply held concept imagery about these shapes and to demonstrate how resilient their conceptions have become.

We used Tall and Vinner's (1981) framework of concept definition and concept image to frame our PSETs' experiences with classification activity. Tall and Vinner describe a *concept image* as "the total cognitive structure that is associated with the concept which includes all the mental pictures and associated properties and processes" (p. 152). These authors distinguish this from a *concept definition* or "a form of words used to specify that concept" (p. 152). For example, one of our students described a pyramid as having "a tippy or pointed top, a base opposite to the top, and triangles around the top point." Individual concept definitions may be different from the "formal concept definition," which is a definition accepted by the mathematical community.

Data Collection and Analysis

This study followed the *Self-study of Teacher Education Practices* as we undertook action research to systematically study our own practices and to make our knowledge and beliefs, along with the dilemmas, decisions, and reflections, explicit (Vanassche & Kelchtermans, 2015). Self-study research makes it possible to share what we have learned from our practices so that it can be examined and transformed by other teacher educators (Bullough & Pinnegar 2001). We adopted an "inquiry as a stance" approach and acknowledged that self-study is an ongoing and complex process (Cochran-Smith, 2003).

We collected data in a geometry course required for all PSETs in a Midwest university including lesson plans and observation notes of about 100 minutes of lessons, lesson stories written by assigned students spanning the first two lessons of the semester, as well as written work from 58 students from three different sections taught by the same instructor on classifying composite polyhedrons.

We will present three stories, built from our data. First, we will use collected data to describe two episodes of classroom instruction related to classifying polyhedra and creating concept definitions for prisms and pyramids. Data collected at the classroom level were analyzed in order to examine existing and emergent concept imagery as the class worked to construct concept definitions for prism and pyramid. Once these definitions had been constructed, we used the quantitative results of the *Prism, Pyramid or Neither?* assignment to determine areas of both success and struggle for individuals involving classifying polyhedra using those classroom-constructed concept definitions. In this activity, we showed PSETs composite polyhedra built by composing pyramids and prisms in different ways. We asked them to identify each as a prism, pyramid, or neither. We were able to interpret their written justifications and identify specific concept images that interfered with classification activity.

Findings and Discussion

Emergent Images and Definitions

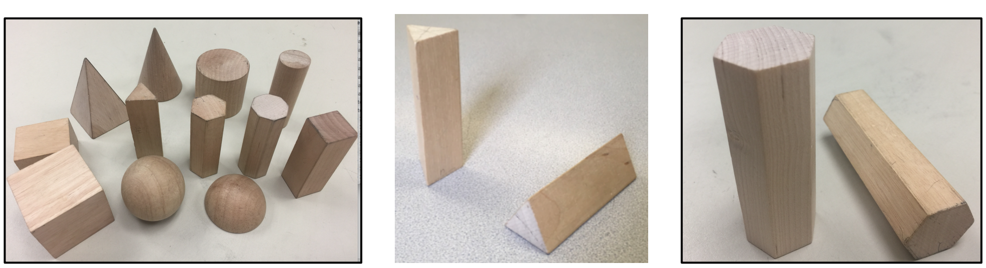
In this section, we discuss two classroom episodes. These episodes are amalgams of data from three separate teachings of the same content. They are written to represent the depth and breadth of conversations that occurred, even if each varied in minor ways from the others.

Episode 1. Working in small groups of 3 to 4, preservice elementary teachers were asked to come up with different ways to categorize a set of 15 wooden 3-D shapes that included both polyhedra (e.g., triangular prism, rectangular pyramid) and non-polyhedra (e.g., cylinder, sphere) as seen in Figure 1a. They were asked to record their thoughts on the question, "How are items in a category like one another and how are they different from other shapes?" A variety of categories was proposed and discussed during the follow-up whole-class discussion.

Many issues emerged during this part of the lesson that gave rise to the need for more precise definitions. For example, students had different meanings for the word *face*. Some considered *flatness* as part of their definitions of *face*; thus, a hemisphere would have only one face. Others argued that a hemisphere had two faces—a flat one and a curved one. The word *side* was also problematic. Some used the word *side* to refer to the *faces* of a prism, while others used that word to refer to the *edges* of a prism.

These discussions led to a classification scheme that separated polyhedra from non-polyhedra, with polyhedra being 3-D shapes that had only straight edges and flat faces. The instructor then assigned students to learn more about polyhedra, prisms, and pyramids by visiting the interactive 3-D shapes by Annenberg Learner (https://www.learner.org/interactives/geometry/3d.html).

Episode 2. To begin the second lesson, PSETs shared what they had learned from the website about the definitions as well as their current thoughts on the similarities and differences between pyramids and prisms. Initially, many students had a limited conception of *base*, similar to their Turkish counterparts (Horzum & Ertekin, 2017). The instructor helped students to transcend orientation-dependent conceptions of *base* by drawing attention to identical triangular and hexagonal prisms placed in different orientations (Figure 1b, 1c).



a b c

Figure 1. Classifying wooden models.

Our definition for the base of a prism as a special type of paired, opposite, congruent, and parallel faces required more clarification. When exposed to the hexagonal prisms in Figure 1c, PSETs encountered multiple pairings that fit this description. Introducing the idea of congruent *cross-sections* encouraged the distinction between base and lateral faces (non-base face). Similar discussions explored the idea of *apex* in pyramids as a special kind of vertex where all the edges from the base connected. Finally, the PSETs arrived at the class definitions: prisms are polyhedra with two congruent, parallel bases and all lateral faces are rectangles; and pyramids are polyhedra with a base, an apex opposite to the base, and all lateral faces triangles.

To further solidify the concept definitions and images, the instructors passed out to each group two composite shapes that were made up of two prisms, two pyramids, or one of each and asked the students to name the two shapes that made up the composite shape, describe the way they were connected, and decide whether the composite shape was a prism, pyramid, or neither.

This proved to be a challenging task for many students. For example, one group of students was not sure if the composite shape in Figure 2 was a pyramid. They could identify that this composite shape was made by connecting the base of a square pyramid with a lateral face from a hexagonal prism. They thought it could be named a pyramid because there were an apex and a base, but they admitted it didn't quite look like a typical pyramid. The instructor reminded students to justify their decision using the definition of pyramid that the class had agreed upon. Finally, students examined the shape further and noticed that some of the lateral faces weren't triangles, thus confirming that this composite shape was not a pyramid.

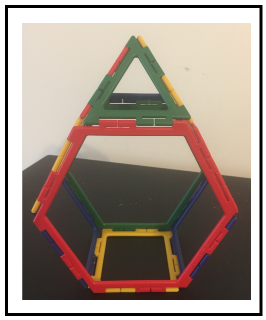


Figure 2. Is this composite shape a pyramid?

Classification Difficulty

We were also able to document our PSETs' difficulties in using established concept definitions and images to classify composite 3-D shapes. After the class activities described above, PSETs were asked to complete an online quiz. The online quiz had two components. The first component asked them to determine if each of 12 composite shapes was a prism, pyramid, or neither. The second part asked them to "write a careful justification to explain whether a composite shape shown is a prism, pyramid, or neither" for three composite shapes selected at random from a subset of 4 of the original 12 shapes.

Because of space limitations, we included here results from only six items: two from the items with the highest percentage of correct responses and four from the items of lowest percentage to provide insights into PSETs' overall performance. We use bold print to indicate correct responses. While the majority of PSETs were able to correctly identify that Figure 3a was a prism and 3b a pyramid, the other shapes were not so easily classified. The quantitative data alone are evidence of the difficulty our students faced in applying definitions to classify 3-D shapes. However, the justifications for these classifications (provided in the next section) illustrate strongly held concept images that might help explain the nature of these difficulties. Below, we describe several concept definitions and images strongly held by some PSETs when classifying composite shapes. We drew support from both the analysis of the quantitative data summarized above and the analysis of the written work.

Difficulties associated with pyramid. Despite the class discussion tending to the classification of the composite shape in Figure 2, about a quarter of PSETs still classified the shape in Figure 3c as a pyramid because it had an apex, a base, and triangular lateral faces. For example, Dakota (mistaking the hexagon for an octagon) wrote, “The composite shape is a pyramid because it has an octagonal prism with another octagon pyramid on top. The definition of a pyramid includes a polygonal base—an octagon, and lateral faces that are triangles that run into one vertex.” She and many PSETs still ignored the fact that some lateral faces on Figure 3c were not triangles; thus, it could not be a pyramid.

	(a) 	(b) 	(c) Prism	**94.83%**	5.17%	6.90%
Pyramid	0.00%	**84.48%**	25.86%
Neither	5.17%	10.34%	**67.26%**
	(d) 	(e) 	(f) 
Prism	32.76%	3.45%	**41.38%**
Pyramid	1.72%	48.48%	6.90%
Neither	**65.52%**	**48.48%**	51.72%

Figure 3. Classification of composite shapes by PSETs (N = 58).

Shape 3e was another difficult one to classify. It was made up of a hexagonal pyramid and a triangular prism connecting through their lateral triangular faces. Half of the PSETs judged it to be a pyramid and half of them judged it to be neither. Our analyses of the written justifications revealed that the class definition of pyramid as “polyhedra with a base, an apex opposite to the base, and all lateral faces are triangles” might not be explicit enough to help PSETs to correctly classify Figure 3e. For example, Ryann wrote, “Pyramid. Because it has one face that is a polygon and all the other lateral faces are triangles they also come to a point.” Ryann’s concept definition of pyramid was previously sufficient to classify all of the wood blocks in Figure 1a, but it was not sufficient to tackle the complexity of this composite figure.

Some PSETs did recognize that there seemed to be odd faces disconnected from the apex that were not bases. This was a moment of disequilibrium (Piaget, 1985) that proved important. Some decided to modify their concept definition to accommodate the new type of face. Katelyn wrote,

> The composite shape is a pyramid because even though it has an extension on one of the lateral faces, all lateral faces are triangles and both bases are polygons. It is a combination of a triangular pyramid and a hexagonal pyramid. It fits the definition of a pyramid, which is a polyhedron where the base is a polygon and all lateral faces are triangles. It breaks no rules and meets all the requirements to be considered a pyramid.

Our analysis uncovered additional concept images and definitions of pyramid that were useful in helping the PSETs to make the correct classification. For example, some PSETs decided that Figure 3e was not a pyramid because "it had a side stick out." Alex stated that for a shape to be classified as a prism or pyramid, "The shape would have to be able to lay on any one of its sides." Jasmin said this is not a pyramid because it is "capable of rocking back and forth." The concept image of a pyramid that could lay stable on each of its many faces was a strong one. Others had included in their concept definitions of pyramid the requirement of having only one base. As Anjou reasons, Figure 3e isn't a pyramid because it has two bases:

> Our definition for pyramid is—a polyhedron where the lateral faces are triangles, has one base which is a polygon. Now. Although all the lateral faces meet at a common point, this shape has more than one base so it has more than one base so it can't be a pyramid either.

Difficulties associated with prism. About 51.72% of the students declared that Figure 3f was neither a prism nor a pyramid. Most justified eliminating pyramid as a choice due to the lack of an apex. However, the fixed orientation impacted PSET's ability to see it as a prism. As Jessica says, "This shape is not a prism because all of the lateral faces are not rectangles, some are triangles and also this shape does not have two congruent bases."

Just like Jessica, many PSETs had the concept image of a base as a face on which the whole 3-D shape sits. So if a student assumes the square as the base, the octagons become lateral faces and it is impossible to find another congruent square parallel to that square base. The idea that shapes retain their form as they are rotating in space (or, for 2-D, on a plane) is a critical conceptual understanding that students need to develop in making sense of both 2-D and 3-D shapes. Some were able to overlook the orientation and identified this shape as a prism, as Jamal wrote, "This composite shape is a prism because it has two congruent bases when I flip the shapes sideways (yellow shapes at the bottom) and the rest of the lateral faces are rectangles which fits in the definition of a prism."

What is it about the shown orientation that renders it unrecognizable? The answer is to return to concept imagery around the term *base*. When classifying simple polyhedra in class, students always oriented their prisms so that they were resting on one of the bases. By doing so, it became a habit to define *base* as a face on which the whole 3-D shape "sits." The singular case is also described as "the bottom" (as in a basement) and the pair of bases as "the bottom and top" of a prism. Jessica explains: "This shape is not a prism because all of the lateral faces are not rectangles, some are triangles and also this shape does not have two congruent bases."

The case of overgeneralization. As seen in Figure 3a and 3b, the majority of the PSETs were able to recognize the composite shape in 3a as a 9-gonal prism made by connecting a hexagonal prism and a pentagonal prism at a congruent lateral face. Also, they recognized the shape in 3b as a pyramid made by connecting two triangular pyramids at a congruent lateral face. Unfortunately, that led some students to believe that the overall shape of a 3-D composite is a prism if it is made up of two prisms, and is a pyramid if it is made up of two pyramids, and is neither if it is made up of a prism and a pyramid.

The statement is obviously false but the challenge is to recognize what parts of this statement contain some truth. It is true that composing a prism and a pyramid will always result in a shape that is neither a prism nor a pyramid. Figure 3c is one example. In the composition process, the figure cannot retain the property of having two congruent parallel bases (thus, not a prism) nor can it cannot retain the property that all lateral faces are triangles (thus, not a pyramid).

The first two parts of the generalization, however, are not always true. In Figure 3e we see a counterexample of a composite shape, made up of two pyramids, that is not a pyramid. The two shapes were connected via a lateral face such that their bases did not create a composed pyramid; their bases are not in the same plane as in Figure 3b. Another counterexample is shown in Figure 3d, which was composed of the same two prisms in Figure 3a by matching the same lateral faces, but twisted so that their original bases would not lie on the same plane.

The composite polyhedra were selected for this activity because they had the potential to bring a variety of concept imagery to the surface related to the terminology used to define prisms and pyramids. However, this last discussion indicates that this activity has the potential to generate even more false generalizations if we do not recognize the complexity of this topic.

Conclusions and Implications

We have chosen to closely examine our instruction related to prisms and pyramids partly because of the difficulties we observed PSETs having with classification activity related to both 3-D and 2-D shapes. However, we were surprised at the depth to which we were able to take our analysis, indicating that composing, decomposing, and classifying 3-D shapes is far more complex than we previously thought. The power of self-study is to uncover assumptions, and we feel that the methodology was successful in that regard.

From this experience, we find that it's not enough to use simple ready-made solids such as wooden blocks when exploring 3-D concepts with PSETs. While they are sufficient to sort polyhedra from non-polyhedra, they lack the complexity necessary to lead to a deep discussion about related concepts (e.g., base, lateral face, edge, side, and apex) to make the properties of prisms and pyramids clear. Using simple polyhedra allows for ambiguity and assumption.

Composite shapes and complex polyhedra (including platonic solids) have the power to cause disequilibrium (Piaget, 1985) and perturb the concept imagery that PSETs take for granted. The concept images that PSETs have of prisms and pyramids as well as related concepts are myriad and rich, but often go unarticulated. Opportunities to articulate assumptions create a space to make the language more precise and to create concept definitions that are more resilient.

Supporting students in their examination and classification of polyhedrons has long-term implications at all levels. The act of composing and decomposing are central to the development of measurement concepts (Feikes, Schwingendorf, & Gregg, 2008). A robust understanding of prism and pyramid is important to the future study of measurement concepts such as volume and surface area. Many concept images are formed throughout the teaching episodes presented here. Specifically, using cross sections to make distinctions between bases and lateral faces on prisms has great promise when it comes time to develop formulas for volume.

Furthermore, teaching the act of defining rather than a memorized definition (de Villiers, 1998) creates a space to challenge and refine concept imagery that conflicts with more formal concept definitions. This, in turn, supports a more robust understanding of the concepts we are trying to define. Providing a myriad of activities that help students assimilate increasingly complex shapes into their schema for polyhedra, prisms, and pyramids challenges assumptions and opens up opportunities for nuance and precision in the way we are all able to collectively negotiate meaning and shared understanding.

Both the theoretical frameworks by Piaget and Tall and Vinner have supported the design and analyses of numerous mathematics education research projects in the last 40 years. In this study, we found them also to be helpful in illuminating our quest for understanding the nature of difficulties behind 3-D classification. One area for future research is to continue to explore the use of their constructs to understand the nature of student difficulty with other challenging topics related to 3-D solids, such as surface area and volume, for both PSETs and K-12 learners. Another study could focus more on the general conceptions of definition held by PSETs and the impact of curricular moves on those conceptions. Leikin and Zazkis (2010), looking across multiple research studies, argued that teachers' concept images and their understanding of the notion of definition influence the ways in which teachers introduce mathematical content to their students. Working in conjunction with methods instruction, it would be important to extend the study into a field experience where PSETs were tasked with designing and/or implementing lessons on 3-D shapes with elementary students.

EVALUATING GEOMETRIC DEFINITIONS

Mark A Creager

Definitions are fundamental to the work of geometry, but many students struggle with understanding terms, and fail to learn the role of definitions in mathematics. We explore how ten college-level students created and evaluated definitions for common geometric terms. Using the idea of concept image and definition, we hoped to learn about the links between how students think about geometric terms, how they define them, and how they evaluate definitions. We found that despite demonstrating strengths in their understanding, none of them evaluated definitions by constructing a biconditional argument. We suggest ways of addressing the issue.

Keywords: Geometry and Geometrical and Spatial Thinking, Reasoning and Proof

Definitions play an essential role in teaching and learning mathematics (Vinner, 2002; Zazkis & Leikin, 2008). They shape the relationship between a concept image and a concept definition and form an essential part of one's knowledge structure that affects their thinking processes (Tall & Vinner, 1981). However, research has demonstrated that students experience difficulties in constructing and evaluating definitions (e.g., Zazkis & Leikin, 2008). The definitions that learners generate mirror their understanding of particular mathematical concepts (Zazkis & Leikin, 2008), and serve as a lens for examining their understanding of what a mathematical definition entails. Examples are illustrations of concepts and principles, and we view the act of defining and evaluating definitions similarly, which allows us to draw inferences about the participants' knowledge of the concepts involved in the definitions. The purpose of this study is threefold: (1) to investigate the process of constructing and evaluating definitions for basic geometrical concepts, (2) to investigate concept images of college students for these concepts, and (3) to analyze the relationship between college students' concept images with how they construct and evaluate definitions.

Theoretical Framework

Three tools framed our research; concept image, concept definition, and proof schemes. Hershkowitz (1990) described types of behaviors that explain the quality of the concept images an individual has. We used two in this study, limited and complete concept image. Individuals with a limited concept image make judgments based on a few prototypical examples plus some properties drawn from those examples. Whereas, individuals who can provide a wide variety of examples and all the important properties of these examples are considered to have a complete concept image. Images can either be static or dynamic. To have a dynamic image of rectangle, for example, would mean to have an image of all the possible variations in rectangle that still maintain the defining properties. Whereas having a static image includes only few examples of the figure and being unaware of how changes to one image might lead to another. We consider this type of image to be related to Harel and Sowder's (1998) transformational reasoning.

Only definitions by property are discussed because they were the only types of definitions the participants created. Zaskis and Leikin (2008) evaluated participants' definitions using a framework, with three criteria: accessibility and correctness, richness, and generality. We adopted these criteria except accessibility. The correctness of a definition means that the definition includes a set of necessary and sufficient conditions. Richness addresses whether the definitions include properties other than the well-known properties (i.e. sides and angles), and targets whether the definition shows signs of a robust understanding. Generality refers to whether the definition relates to general objects of the concepts being defined rather than specific ones, and is similar to de Villiers's and colleagues (2009) meaning for economical definitions.

Definitions are arbitrary, and it is valuable to have a diversity of equivalent definitions because one can chose which definition best suits their problem solving interests (Borsai, 1992; Sinclair, et al., 2012). Having a rigid understanding of definitions might imply that the individual sees definitions as given a priori and fails to see the role that humans play in creating them. By equivalent definitions, we mean logically equivalent where one must show that a biconditional relationship exists. However, we examined the types of reasons the participants gave using Harel and Sowder's (1998) taxonomy of proof schemes, where a proof scheme is a way of thinking about how to ascertain or persuade for an individual or a community.

Methodology

In this section we describe the participants, data sources, and the analysis of the data. Ten college students participated in the study. Nine were secondary mathematics education or mathematics majors, one was an accounting major with a minor in mathematics. They were given between four and five geometry terms and asked the following questions in sequence. Can you draw an example of the term? They were continually asked for a new, different example until they described aspects of the image they were changing. We hoped by asking these questions we would get a sense of the images that students had for the terms, how diverse those images were, and whether or not their images were dynamic. Next, we asked them to define the term in as many ways as they could. This was followed by asking them if are there any properties they felt were important for someone to know about that were not included in their definition(s). With these questions we hoped to get a sense of the types of definitions they had for the terms in regards to the definitions correctness, richness, and generality. Finally, they were presented definitions and asked to decide if the definitions were valid or not and to explain their reasoning. The interviews were recorded with one camera capturing the participant's work and another camera capturing the interaction. Any work that was performed was scanned, and thick descriptions were created that included, transcripts, work, drawings, gestures, and tone.

To analyze the data, we independently watched each participant's video, collecting all the images they created for each term and their names. Each definition the participant gave was coded for correctness, richness, and generality. This gave us a sense of their concept image. Finally, we coded the participants' reasons for accepting or rejecting the alternative definitions using proof schemes. We met to discuss the summaries of our work and resolved disagreements collaboratively. After doing this for all of the participants' videos, we met to discuss key themes. After elaborating our meaning for these themes we went back through and again watched one participant's interview at a time to categorize their work by these themes.

Results

In this section, we describe the participants' concept images and definitions as well as how they evaluated definitions in the sections that follow.

Participants' Concept Images

All of the participants had a complete concept image for the majority of the terms. However, we noted four relevant features. First, all the participants were consistently able to create an example of each figure in the class with one exception explained below. Second, almost all demonstrated evidence of thinking hierarchically and transformational reasoning (Harel &

Sowder, 1998). For example, Sally drew the black parallelogram in Figure 1(a), marked the angle and said she could continually draw new, different examples by changing the angle, but keeping the sides the same length. When asked to draw an example of what she meant, she drew the red parallelogram. The subtle, but important, distinction between what Sally claimed to be doing and the image she drew is captured in Figure 1(b). Similarly, many participants had difficulties creating the images they described, and when they did create the images in their minds, the images did not behave the way they drew them. So, although they demonstrated transformational reasoning, their images could misrepresent their thinking.

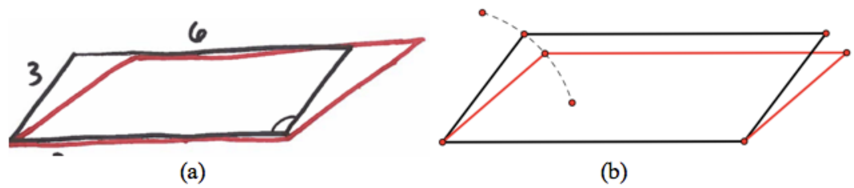

Figure 1. (a) Sally's drawing to demonstrate how to dynamically change angle measure while maintaining side lengths in a parallelogram. (b) Researchers' construction of Sally's description.

The exception described above came when the participants were asked to draw a generic term like quadrilateral. Almost all participants consistently drew a special case as their first image, and continued to draw special cases. As Sally put it, "when I'm asked to draw a triangle, I always just draw a right triangle." Because the participants regularly reasoned empirically, their specialized images left them open to verifying false claims, and making false claims. For example, it was not uncommon for them to claim a median of a triangle is also perpendicular to the opposite side because the shapes they reasoned with were specialized.

Participants' Concept Definitions

We asked the participants for several definitions, but only three participants were able to create multiple definitions. And in these cases, the definitions were not different. For example, James originally defined a rectangle as a quadrilateral with four right angles. When asked for another, different definition, he simply swapped quadrilateral for parallelogram. In total, 50 definitions were created and only four were invalid. Another fifteen definitions failed to meet necessary conditions because the participants used terms like shape or figure instead of polygon or quadrilateral. We considered these omissions to be minor. While evaluating the following definition for triangle – a triangle has 3 sides and 3 angles – Cameron said, "It would help if there was some other information … like it's a polygon … but that's probably understood." We felt that the participants were quite skilled at creating at least one definition. Eighteen of them not only meet necessary and sufficient conditions, but were also economical.

Evaluating Researcher-Generated Definitions

Given their rich concept images and ability to create definitions, we felt the participants would do well at evaluating definitions. They evaluated 38 definitions in total, seven incorrectly, and three correct justifications used invalid reasons. Thus, the participants were inaccurate when evaluating definitions over 25% of the time. Given their success in the other areas, we wondered what the cause was.

The participants evaluated definitions three ways, using non-examples, examples, and arguments. To use non-examples, the participants tried to imagine a figure that was a non-example of the term that fit the properties used in the researcher-generated definition. There were two different ways that they evaluated definitions using examples. For the first way, they imagined examples and checked whether the term had the properties in the researcher-generated definition. James, for instance, was evaluating the definition, a parallelogram is a quadrilateral with diagonals that bisect each other, when he said, “Yeah, I think so. I’m just thinking by looking at these [pointing to the pictures of parallelograms he had drawn]. Yeah, they bisect each other”. For the second way, they imagined what figure(s) could be created if they drew an example with the properties in the researcher-generated definition and checked to see if those examples matched their concept image. For example, Eve drew several examples that fit the following definition: a parallelogram is a quadrilateral that has a pair of opposite sides that are parallel and equal in length. Then said, “Anything you could give would fit the description of a parallelogram.” Interestingly, none of the participants used both methods when evaluating the definitions. Had they done so, they would have, at least empirically, proved the biconditional nature of the definition. The participants’ arguments additionally only proved the conditions in the researcher-generated definition produced the conditions in their definition. Again, not proving the biconditional nature of the definition. We explore the potential reasons for this next.

Discussion

Students need to take a greater role in the process of creating and evaluating definitions (Borsai, 1992; Vinner, 2002). Kobiela and Lehrer (2015) showed that when 6th-grade students were given these opportunities they learned about the concepts and about the process of creating a definition. Evaluating definitions, valid and not, presents an opportunity for valuable and difficult mathematical work. By examining non-definitions, students get the opportunity to learn about how definitions are created. Examining alternative definitions provides students with an opportunity to work in an authentic mathematical environment, and see that some, but not all, properties meet necessary and sufficient conditions. Moreover, it provides students with an authentic opportunity to use proof; something the participants did spontaneously and regularly. Finally, students will have the opportunity to sharpen their own understanding of the terms as alternative definitions help students make connections between terms they see as distinct, and to see distinctions between terms that are similar.

EXPLORING TRIGONOMETRIC RELATIONSHIPS: IS IT A FUNCTION?

Craig J. Cullen
Illinois State University
cjculle@ilstu.edu

Tami S. Martin
Illinois State University
tsmartin@ilstu.edu

We examined conceptual understandings of preservice secondary mathematics teachers as they reasoned about chord length and arc length in a directed-length representation related to the sine function. We characterized the ways in which our participants understood the functional relationship between the geometric objects by describing various aspects of their concept images, and the progression of the images over time. Concept image components progressed from less useful to more useful, eventually aligning with components of a standard definition of function and key features of the sine function.

Keywords: Reasoning and Proof, Geometry and Geometrical and Spatial Thinking, Teacher Education-Preservice

Understanding trigonometric functions is important as that understanding is "a pre-requisite for understanding topics in Newtonian physics, architecture, surveying, and many branches of engineering" (Weber, 2005, p. 91). However, practices for teaching trigonometry have led to difficulties including "underdeveloped angle measure understandings" (Moore, 2014, p. 103) as well as poor connections to the unit circle (Moore, LaForest, & Kim, 2016). Even with a knowledge of right-triangle trigonometry, students may not be able to define function, a foundational concept in mathematics, nor know how to describe sine as a function (Weber, 2005). Clement (2001) described common perceptions of function including: (a) a relation that passes the vertical line test; (b) a machine that gives an output for an input; and (c) a correspondence following a clear pattern, rather than arbitrarily matched values. Many believe functions should be: (a) given by a rule, (b) continuous, and (c) one-to-one (Clement, 2001).

Weber (2005) and Moore (2014) concluded that using quantitative reasoning was a promising avenue for learners to make sense of and articulate properties of the sine function. However, in Weber's study, students used measurements, rather than focusing on quantities. Hertel and Cullen (2011) found that preservice teachers (PSTs) were able to make sense of trigonometric relationships when using a directed-length representation of the basic functions. In a directed-length representation, a vector (i.e., with direction and length), related to a circle arc, represents a trigonometric function. We build on the work of Hertel and Cullen by considering PSTs' sense making using directed lengths as objects or quantities about which to reason.

This study focused on the first in a sequence of learning activities in which PSTs reasoned quantitatively about two dynamically changing objects in a circle, and whether those objects could be considered inputs and outputs of a function. Our work was guided by the research question: Which aspects of PSTs' conceptual understanding are activated when exploring directed-length representations related to the sine function?

Theoretical Perspectives

The design of our instruction was informed by quantitative reasoning. Thompson (1990) defined a quantity as "a quality of something that one has conceived as admitting some measurement process. Part of conceiving a quality as a quantity is to explicitly or implicitly conceive of an appropriate unit" (p. 5). Quantities in our study were related in a single diagram, implying the presence of a common unit. In our analysis, we distinguished between PSTs' concept images and the concept definition (Moore, 1994; Tall & Vinner, 1981; Vinner & Hershkowitz, 1980). One's *concept image* "refers to the set of all mental pictures that one associates with the concept, together with all the properties characterizing them" (Moore, 1994, p. 252). *Concept definition* "refers to a formal verbal definition that accurately explains the concept in a non-circular way, as might be found in a mathematics textbook" (Moore, 1994, p. 252).

Methods

The participants in this study were 23 PSTs, working in groups, who had completed at least 60 hours toward a degree in mathematics with a focus on secondary education. The context of the study was a semester-long course focused on technology in mathematics education. In this report, we discuss data from the first week of a 6-week instructional sequence on trigonometry.

The instructor displayed an arc and a chord, in *Geogebra* (see Figure 1). Both objects changed as point C rotated counterclockwise around the circle. The instructor gestured to the animated model and asked "Is this a function?"

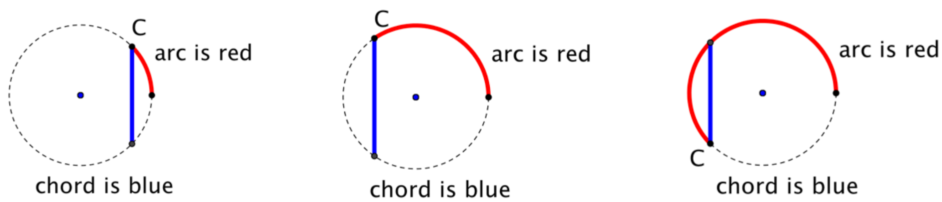

Figure 1: Covarying quantities as point C varies.

Results

All groups traversed a similar path in which the following aspects of their concept images were activated: (a) the vertical line test, (b) function matching, (c) independent and dependent variables, (d) univalence, and, finally (e) function matching revisited: the sine function. PSTs are identified by their group. For example, StudentA-1 is person number 1 in group A. Text in parentheses, describes gestures or tone; text in brackets offers contextual clarification.

The Vertical Line Test

PSTs in groups A and C initially attempted to use the vertical line test to determine whether the relationship constituted a function, indicating that this test was part of their concept image of "function." However, in this situation, it was not reasonable to use the vertical line test, which would require interpreting the dynamically changing components of the circle as "graphs" on a coordinate plane. StudentC-3 claimed the chord isn't a function because "the vertical line goes through the whole thing." Eventually, StudentC-2 said the vertical line test cannot be used as a criterion for determining whether the quantities are related by a function "because we're not dealing with a coordinate plane. You can only use vertical lines for a coordinate plane."

A Collection of Known Functions

Students in groups B and C seemed to reason that if they could map the situation they were investigating to a known function, then they could conclude that the situation they were discussing must represent a function. For example, StudentB-1 described the behavior of the dynamic diagram components as a parabola, noting "…as the length of that's increasing it gets bigger and then smaller and bigger again…"

The next concept image components, discussed by all three groups, were independent aspects of the concept definition: the identification of independent and dependent variables and the univalence requirement, that is, the requirement of one unique output for any input (Even, 1993).

Independent and Dependent Variables: Quantifying Length and Angle

To identify the independent and dependent variables, PSTs considered the length of the blue chord and length or angle of the red arc as quantities. StudentC-1 asked, "What is your output when you're talking about the chord?" To which StudentC-2 stated "It could be the length of the chord. Because the length of the chord depends on the position." StudentC-1 noted a connection between the position of point C and the length of the arc, "So given the length of the arc is the length of the chord?" and later clarified "Well, that place (pointing to animated diagram) is also in reference to the length of the arc and then it repeats as soon as you hit 360 (rotated his finger in a circle). StudentC-2 also made reference to an angle of 360˚, but it was not clear whether the PST was referring to the arc angle or the measure of the associated central angle.

Univalence

While clarifying independent and dependent variables, PSTs explored ramifications of repeated value situations. In so doing, PSTs focused on univalence and struggled to distinguish a function from a one-to-one function. StudentC-2 wanted to "restrict it to an interval" from 0 to π/2 to ensure the relationship was a function. StudentC-1 challenged the limitation, implying repeated outputs are allowed, by asking "Why isn't it a function all the way to π?" StudentC-2 responded "Because once we go all the way to π [past π/2] the chord starts shrinking again and we go back to the lengths that we've already had." StudentC-1 pointed out that "it's a different position on the circle" and StudentC-4 then explained "it would still be a function. It won't be one-to-one, but it will be a function."

After deeming the relationship a function on [0,π], the group considered whether more than two of the same outputs was acceptable, as when point C was more than halfway around the circle. To avoid dealing with additional repeated outputs, StudentC-1 proposed the idea of directed length, "Oh yeah, you're technically doing negatives. Like an opposite. You could interpret it [the blue chord's repeated length] as the opposite 'cause that length would be like flipped over."

Function Matching Revisited: The Sine Function

StudentB-1 claimed the relationship between objects constituted a sine function. This conclusion followed mention of oscillation, unit circle, and key ordered pairs. StudentB-1 said each key input value (0, π/2, π, 3π/2, and 2π) and stated or nodded for the corresponding output values. Likewise, StudentC-1 followed up on his earlier conjecture that the chord could be signed (i.e., positive when the arc was between 0 and π and negative when the arc was between π and 2π). StudentC-1 concluded "This is like (moved his finger counterclockwise around an imaginary circle)… Right?...Wait a second.... Hold up, this is like the sine function? You start at zero and the length gets longer up to π/2… and then it goes back down. This is like sine!"

PSTs concluded that the relationship between the arc and chord could be conceived of as a function by considering quantities (i.e., the length of the arc and chord) and labeling them as independent and dependent variables. Their work sorting independent and dependent variables also resulted in articulating differences between the univalence requirement for functions and the criteria for one-to-one functions. However, most PSTs had not yet recognized that unless they only considered directed length, they were dealing with an absolute value. And no PST had realized that the function based on the full chord was actually twice the sine function.

Discussion

As PSTs explored quantitative relationships we noted two conclusions. First, PSTs engaged in reasoning and sense making. Like PSTs in Even's study (1993), our PSTs had a preference for the vertical line test. But our PSTs identified limitations of this test, the importance of dependent and independent variables, as well as differences between one-to-one and univalence. Second, as we tracked concept image components activated as PSTs determined whether or not a situation could be a function, we noted a path that lead them away from a less helpful aspect of a concept image (i.e., vertical line test) toward more effective components linked to a concept definition.

Throughout this exploration, PSTs determined the relationship between the arc and the chord could be conceived of as a function by considering each as quantities and noting that length was the quality of the object (Thompson, 1990) that was relevant. We see this move toward precision as important in the PSTs' development of more robust conceptual understanding of trigonometric functions and functions in general.

Although we hoped that representing the angle as an arc of a circle would help PSTs negotiate a geometric definition of sine, it was clear PSTs still struggled with representations of angle (Akkoc, 2008), using radian and degree measure interchangeably. Likewise, they appear to have conflated central angle, arc angle, and arc length, without noting the need to consider the magnitude of the circle's radius.

After the PSTs reached consensus that the relationship between the arc and the chord was indeed a function, some PSTs conjectured it was the sine function. For those PSTs, the recognition of familiar aspects of their concept images of sine (e.g., embedded in circle, oscillating behavior, known ordered pairs), may have led to the conjecture. In that moment, those PSTs may have added to their concept image of sine as they encountered a function defined by a relationship between a circle's arc and related chord. Having reorganized their concept image of the sine functions in this way, perhaps the PSTs were more ready to consider a directed-length definition of sine, build connections among this definition, the right triangle definition, and the unit circle definition, and use that connected understanding as a potent tool for making sense of all trigonometric functions.

EXPLORING GENDER DIFFERENCES IN A SYMMETRY SOFTWARE INTERVENTION FOR YOUNG CHILDREN

Nicole Fletcher

ginsburg@tc.edu

Symmetry is a foundational geometric concept that receives minimal attention in early childhood mathematics. Differing informal play experiences involving symmetry exploration may contribute to gender differences in symmetry understanding. This study sought to explore whether boys' and girls' performance on symmetry tasks differs after a symmetry software intervention. A significant gender effect benefiting boys was found on post-test rotation tasks but not on reflection or translation tasks, controlling for pre-test scores. A gender effect was also not significant for identifying or explaining symmetric transformations at post-test. The findings have implications for learning opportunities and modes of assessment for all children.

Keywords: Gender, Geometry and Spatial Thinking, Early Childhood Education, Technology

Symmetry is present in everyday life and is a theme in children's play and creative activities. Despite children's natural interest in symmetry, learning standards addressing symmetry do not appear in the Common Core State Standards until grade four (NGACBP, 2010). A software program was developed to expand young children's understanding of three symmetric transformations—reflection, translation, and rotation. The purpose of this study is to explore whether there were differences between boys' and girls' symmetry understanding following the symmetry software intervention. This study sought to answer the following questions: (1) Do boys and girls differ in their ability to accurately create symmetric transformations after the intervention when controlling for pre-intervention symmetry aptitude (measured by the Symmetry Graphical Assessment) and treatment status? (2) Are there differences between boys and girls in their identification and explanations of symmetric transformations, as measured by the Video Transformation Task, after the intervention when controlling for treatment status?

Theoretical Perspectives

This research is based on the theoretical perspectives of constructivism, socio-cultural theory, and, to a lesser extent, the idea of intellectual honesty. The software and study design were informed by constructivism—the theory of learning that posits that learners do not simply absorb information but instead actively construct knowledge from their experiences (e.g., Piaget, 1970). The software functions as a "phenomenaria" (Perkins, 1991), intentionally designed to allow children to manipulate and explore symmetric transformations. Vygotsky's (1978) socio-cultural theory, especially the idea that social interaction is key to learning, was embedded into the study design with a research assistant (RA) facilitating exploration and prompting the child to verbalize observations. The software served as the "more knowledgeable other" (Vygotsky, 1978) by providing definitions and examples and offering feedback and solution strategies. The introduction of the mathematically complex topic of symmetric transformations to young children was influenced by Bruner's (1960) idea that "any subject can be taught effectively in some intellectually honest form to any child at any stage of development" (p. 33).

Because geometry is often taught in a cursory manner in early childhood (Clements, 2004), children's symmetry experiences often occur in informal contexts. Gender differences benefiting boys in symmetry-related spatial tasks such as mental rotation have been documented (e.g., Maeda & Yoon, 2013), but gender differences may be attributable to socio-cultural or experiential factors (e.g., Fennema & Sherman, 1977). For example, symmetry is a recurring characteristic of children's block building (Seo and Ginsburg, 2004), but boys engage in block play more frequently than girls (Kersh, Casey, & Young, 2008). Though certain play experiences may help children develop symmetry understanding, gender differences in engagement in these types of play may contribute to gender differences in symmetry understanding.

Methods

Materials: Symmetry Software

A computer program was designed to teach reflection, translation, and rotation to young children. Cognitive principles for the design of mathematics software for young children guided software development (Ginsburg, Jamalian, and Creighan, 2013). Visual and audio feedback identify mistakes and provide solution strategies to the users.

Research Design and Procedure

The study was conducted using a pre- and post-test between-subjects randomized experimental design with two conditions: the treatment condition, which consisted of nine symmetry software sessions (three each for reflection, translation, and rotation), and the control condition, which consisted of nine sessions using a non-symmetry-focused mathematics software. Experimental group software activities included guided explorations (during which an RA prompted the child to verbalize observations), viewing instructional videos with real world examples, and completing tasks that involved placing shapes on the screen to create the specified symmetric transformation and receiving feedback from the software.

Setting and Participants

The study was conducted in an urban public elementary school in the Northeastern US. The participants included 86 children from the school's first and second grade classrooms—43 were randomly assigned to the experimental group (24 girls and 19 boys) and 43 were assigned to the control group (21 girls and 22 boys). Participants' ages ranged from 5.8 to 7.8 years.

Measures

Symmetry Graphical Assessment. The Symmetry Graphical Assessment, a paper-and-pencil instrument designed by the primary investigator (PI) to measure students' ability to generate reflections, translations, and rotations, was administered at pre- and post-test. The instrument included explanations and examples for the symmetries to ensure that it assessed symmetry concept understanding rather than familiarity with relevant vocabulary. Two RAs were trained to implement the pre-/post-test scoring scheme. Inter-rater reliability, estimated using Cohen's kappa, was equal to 0.878.

Video Transformation Task. The Video Transformation Task was designed by the PI to measure participants' ability to identify and explain reflection, translation, and rotation and was implemented at post-test. Participants watched six short videos of symmetric transformations and were asked to identify the symmetry and explain their reasoning. Identification of the symmetric transformation in each video was scored for accuracy (0 or 1). Explanations were coded for the presence of words or phrases indicating conceptual understanding of the symmetries. Explanations were assigned a score of 1 for indicating conceptual understanding or 0 for not indicating conceptual understanding of the symmetry. One RA coded students' explanations for indicating conceptual understanding of the symmetric transformation. Inter-rater reliability between the coding by the RA and master coding by the PI, estimated using Cohen's kappa, was equal to .90.

Results

Post-Test Outcomes

Treatment group girls achieved, on average, higher reflection task scores than boys in the same group; however, treatment group boys achieved higher average scores on translation and rotation tasks than girls in the same group. Similar gender patterns on post-test reflection, translation, and rotation tasks were observed in the control group (see Table 1).

Table 1: Descriptive Statistics on the Post-Test Outcomes by Group

Post-test outcome	Treatment group		Control group	
	Boys (N = 19) Mean (*SD*)	Girls (N = 24) Mean (*SD*)	Boys (N = 22) Mean (*SD*)	Girls (N = 21) Mean (*SD*)
Reflection	53.57 (*16.99*)	56.93 (*18.68*)	49.19 (*19.40*)	51.43 (*16.82*)
Translation	60.28 (*20.37*)	55.49 (*25.36*)	47.10 (*19.00*)	45.02 (*21.31*)
Rotation	58.70 (*12.87*)	51.60 (*16.11*)	61.53 (*13.84*)	53.11 (*19.59*)

A MANCOVA model was estimated to test for the joint effect of treatment condition and gender on the three outcomes, controlling for pre-existing abilities in the outcomes as measured at pre-test. MANCOVA model assumptions for multivariate normality of the outcomes and homogeneity of variance covariance of the outcomes among groups were met. A statistically significant effect for treatment condition (Pillai=0.17, F=5.39, p=.002) and gender (Pillai=0.09, F=2.73, p=0.049) on the three outcomes was observed, controlling for pre-test score. On average, boys' scores were 1.24% higher on reflection tasks, 5.38% higher on translation tasks, and 10.19% higher on rotation tasks than girls. Separate ANCOVA models on each outcome showed a significant gender effect on rotation tasks [F(1, 82)=4.56, p=0.035], but not reflection [F(1, 82)=2.64, p=0.108] or translation tasks [F(1, 82)=0.09, p=0.76].

Video Transformation Task Outcomes

Descriptive statistics showed that girls in the treatment group achieved, on average, higher scores in the identification and explanation of symmetries than boys in the same group on the Video Transformation Task (see Table 5). For control group participants, boys achieved higher average scores on accurate symmetry identification than girls, but girls achieved higher average scores on explanations of symmetries than boys.

A MANOVA model was estimated to test the joint effect of treatment condition and gender on accuracy and explanations in the video transformation task. MANOVA model assumptions for multivariate normality of the outcomes and homogeneity of the variance covariance matrix among groups were met. There was a statistically significant treatment effect on accuracy and explanations [Pillai=0.27, F(1, 81)=14.90, p<0.001,], but a gender effect was not significant [Pillai=0.04, F(1, 81)=1.56, p=.22]. Separate ANOVA models were estimated for accuracy and explanations. The results show a significant effect on accuracy scores for treatment [F(1, 82)=17.86, p <0.001] but not for gender [F(1, 82)=0.03, p =.86.]. Similarly, the results show a significant treatment effect on explanation scores [F(1, 82)=27.71, p<0.001] but not a gender effect [F(1, 82)=1.88, p=.17].

Table 2: Descriptive Statistics on the Video Transformation Task Outcomes by Group

	Treatment group		Control group	
	Boys (N = 19) Mean (*SD*)	Girls (N = 24) Mean (*SD*)	Boys (N = 21) Mean (*SD*)	Girls (N = 21) Mean (*SD*)
Accuracy	4.63 (*1.26*)	4.75 (*1.54*)	3.41 (*1.74*)	3.19 (*1.44*)
Explanations	3.95 (*0.97*)	4.42 (*1.21*)	2.62 (*1.32*)	2.90 (*1.51*)

Discussion and Scholarly Significance

After a symmetry software intervention, a significant gender effect benefiting boys was found on post-test rotation tasks but not on reflection or translation tasks, controlling for pre-test scores. A gender effect was not significant for identifying or explaining symmetries. Boys' more accurate performance on rotation tasks at post-test is in line with existing literature (Maeda & Yoon, 2013). However, even though boys have more play experiences that lend themselves to symmetry exploration than girls, boys and girls were similar in their identification and explanation of reflection, translation, and rotation and in their performance on reflection and translation tasks. Boys' and girls' similar performance on certain symmetry tasks indicates the importance of testing for aptitude in different types of symmetry content.

The presence of a significant gender effect on post-test rotation items, and the absence of a significant gender effect on accuracy and explanations on the video transformation tasks, points to the importance of multiple means of assessment for young children. While some children may feel confident taking a paper-and-pencil task, others may feel less comfortable with the written format. Including verbal tasks in assessments for children provides an important opportunity to reveal understanding not observed in traditional written assessments.

The absence of significant gender differences on almost every measure in the study indicate that teaching symmetry concepts to young children has the opportunity to benefit both girls and boys—building on their natural interest in symmetry and preparing them for success in higher level mathematics and career opportunities both in and out of mathematics.

MEASUREMENT AND CONSERVATION OF LENGTH: A TEACHING EXPERIMENT WITH TONY AND SAM

Sara Brooke Mullins

The way measurement is taught in elementary school differs from the Piagetian concept of operational measurement and conservation of length. The purpose of this study is to investigate how two first grade students conceptualize measurement and conservation of length. Results show that although both students began at the same Piagetian stage, one student progressed further and achieved operational measurement and conservation of length. Differences in each student's thinking are analyzed and insights to future research are offered.

Keywords: Elementary School Education, Measurement, Learning Trajectories, Standards

The concept of *measurement* and the process of *measuring* are connected, but different. When students construct operational *measurement*, they internalize how to coordinate sub-division and change of position (Piaget, Inhelder, & Szeminska, 1960/1981). *Measuring* however occurs when students compare objects to see which one is longer or taller; examples of *measuring* include directly comparing objects, relating object lengths with nonstandard items, or reporting standardized units from a ruler (VDOE, 2016). This examination mirrors Lamon's (2007) findings that demonstrate that some students are not being taught the concept of *measurement*, but rather the process of *measuring*. This inhibits students from learning that some objects cannot be measured, which stunts their conceptual understanding of *measurement* and rational numbers. National standards, however, have kindergarteners measure by comparing objects before first-graders iterate a tool the length of an object (CCSSI, 2018; NCTM, 2000). This suggests a focus on sub-division and change of position which helps students develop *measurement*. The purpose of this paper is to investigate how two first-grade students conceptualize measurement and conservation of length.

Conceptual Framework

When a student coordinates sub-division and change of position, Piaget et al. (1960/1981) believe conservation of length is attained, resulting in operational measurement. Three stages precede operational measurement. In Stage 1, four to five-year olds compare objects with visual and perceptual estimates. Students five to six years old manually transfer objects side by side for comparisons in Stage II. More sophisticated students at this stage use their body (e.g., hand) to compare objects. Between Stage II and III, six to seven-year olds compare lengths intuitively with tools, but can only compare the tool to each object, not between both objects. Finally, in Stage III students seven and older develop conservation through operational measurement and can use tools to compare between objects. These stages suggest students in first grade may develop operational measurement and conservation of length. National standards (e.g., CCSSI, 2018; NCTM, 2000) support this argument, but some state standards (e.g., VDOE, 2016) fail to address the development of conservation of length through operational measurement, implying students may learn *measuring* without learning *measurement*.

Methods

Sam and Tony (pseudonyms) were two first grade boys who attended a public elementary school and had similar demographics. Three, fifteen-minute clinical interviews (Clement, 2000) using tasks from Piaget et al. (1960/1981) were conducted to determine how Sam and Tony each conceptualized measurement, conservation of length, and their zones of potential construction (ZPC; Norton & D'Ambrosio, 2008). From this data, individual constructivist teaching experiments (Steffe & Thompson, 2000) were designed consisting of six, fifteen-minute teaching episodes during which hypotheses were made and later tested. Tasks from *Everyday Mathematics, Grade 1* (McGraw Hill, 2014) were chosen based on their ZPC and research hypotheses. Sam's and Tony's responses were compared against Piaget et al.'s (1960/1981) stages to build a second-order model of conceptualization of measurement and conservation of length. Each teaching episode was recorded, transcribed, and coded for observations according to Piaget et al.'s stages. Conceptual analysis was used to determine what mental structures Sam and Tony used while performing each task (Thompson, 2008), which afforded a refined second-order model of how Sam and Tony conceptualized measurement and conservation of length.

Results

Sam

The preliminary second-order model proposed during Sam's clinical interviews was consistent with Stage IIA for conservation (Piaget et al., 1960/1981). He could compare endpoints of objects visually or in activity with his fingers, but never realigned the moved objects to show length was conserved, and could not explain curves have length. He did manually move a tower he built next to another tower to compare their heights. He could not use a common measure to compare the lengths of objects. Sam also showed no desire to sub-divide a whole or change a tool's position along the whole, counting the moves between endpoints.

Sam began the first teaching episode using manual transfer to measure a table side with a string of Unifix cubes. He could not however measure his toys with tools that were shorter or longer than the toy because the tools were "too long" or "too short." If the tools did not exactly align with the toy's length, Sam rounded his measure up. For example, when a pencil was longer than his transformer, Sam reverted to visual transfer and guessed the length of the transformer was one pencil long. During another episode, Sam measured the perimeter of a table with a pencil, but repeatedly lost count and ignored when the pencil was longer or shorter than the table's edge. Subsequent episodes were used to practice counting and the motor skills involved in change of position. Sam still struggled to count by ones while pointing to each count, and consistently lost his count on tasks. Because he regularly did not align his countable unit with the endpoint of the measured object and put his finger between units without noticing it took up space, episodes three and four focused on sub-division. After much practice, he accurately measured the height of a table and sofa with a marker, and did not lose count. Since Sam improved in counting, motor skills, and sub-division, episode five entailed comparative length tasks. Sam again reverted to visual transfer to relate the lengths of objects, and only used a paperclip to measure when prompted. Sam ended the teaching episodes being intuitively able to state that a pen moved to a different location would not change length.

Sam's re-assessment of Piaget et al.'s (1960/1981) tasks from the clinical interviews, showed his behaviors were slightly more sophisticated than Stage IIA. He inconsistently accounted for the lengths of curves between a straight and curvy pipe cleaner using visual transfer. He claimed the lengths were the same even though "one is bent and curled around so it's shorter." Similarly, he knew two parallel rows of toothpicks had the same length because he counted them, but when one row was zig-zagged he said the straight row was longer without counting. When assessing the lengths of two identical parallel pipe cleaners with one moved forward, Sam tried measuring the lengths with a paperclip, but lost count and concluded one was longer. He then ignored this finding and noticed the moved pipe cleaner was “longer” on one side than the unmoved pipe cleaner. Finally, when comparing the heights of a tower he built to one prebuilt on a higher surface, he used manual transfer to compare the towers until satisfied their heights were equal. He knew the uneven surfaces made a difference in the tower heights, but when his tower was moved back to the lower surface, he added blocks to make the heights “equal.”

Tony

The preliminary second-order model proposed during Tony’s clinical interviews was consistent with Stage IIA for conservation (Piaget et al., 1960/1981). He based measurements on visual estimates, focused on the endpoints of objects and used his fingers to compare lengths. He also used manual transfer to relate objects, but his explanations suggested he was beginning to see measurement as the intervals between two endpoints.

During the first episode, Tony measured his shoe with his hand, reporting it as seven hands long, but recognized this was incorrect and used eight Unifix cubes instead. This suggested he was transitioning to Stage IIB. Tony consequently practiced iterating a tool to determine lengths and compared objects using paperclips. He struggled at first using a shorter or longer tool but improved. When asked to measure a paper strip, Tony resisted using a longer pencil as his unit, but then decided the paper strip was half a pencil. Tony needed support with fractions since he independently noticed tools either did not exhaust the whole or surpassed it. It was hypothesized that part-whole relationships (Norton & McCloskey, 2008; Steffe, 2010) were in his ZPC.

Tony had no prior knowledge of fractions at this point in the year. Using Cuisenaire rods, he developed an understanding of halves, thirds, and fourths, as exemplified by his explanation: “1/3 is like if there’s one whole piece and there’s 3 pieces and these are the same, that’s 1/3.” In another task, he showed that four individual units made up the whole, demonstrating a part-whole fraction scheme (Norton & McCloskey, 2008; Steffe, 2010). Tony was also able to partition a whole into units, and understood unit pieces needed to be equal in size. For example, Tony made two approximate “cuts” to a pencil, but then realized the pieces were not equal and adjusted his cuts. Tony verified each piece was identical to the others, indicating he was able to equipartition a whole to determine an iterable unit (Steffe, 2010), and knew he could iterate any one of them to recreate the whole (Norton & McCloskey, 2008). Tony further demonstrated his fraction scheme by drawing lines to segment a paper strip into thirds on one side and fourths on the other. This indicated partitioning, disembedding, and iterating, giving way to an equipartitioning fractional scheme in activity (Norton & McCloskey, 2008; Steffe, 2010). Tony applied this knowledge to iterate a tool, and then partition the tool in the last iteration to determine what fractional piece of the tool was left over. When measuring a pencil with paperclips, he estimated six, then determined it was five and one third paperclips. This suggested Tony had progressed to Stage IIB. Through explorations, Tony learned curves have length, making curved objects longer than straight ones. For example, he measured a straight path of 6.5 paperclips and a curved path of 9.5, and knew, “9.5 is bigger than 6.5 so it [the curved path] is longer.” He also learned that once objects have a measurement, length is conserved.

Tony’s re-assessment of Piaget et al.’s (1960/1981) tasks, showed he progressed beyond Stage IIA. He knew a curved pipe cleaner would be longer than a straight one due to the curves, and justified his answer with a paperclip. He understood the length of the pipe cleaner would not change despite its shape, and that two equivalent pipe cleaners would be the same length, no matter how they were arranged. Tony then counted the number of toothpicks to determine the two rows were equal and knew zig-zagging made no difference. He was initially confused when one toothpick was broken in half, but then demonstrated that two halves completed a whole, making the rows the same. In the final task, he used a paperclip to measure the heights of two towers, and knew the difference in table heights affected that of the towers. Tony's behaviors therefore supported operational conservation of length indicative of Stage III.

Conclusions

This study shows that although students may begin in the same developmental stage, each student needs different supports to cultivate more sophisticated ways of thinking. Both students, however, were able to progress in their conceptualization of measurement. Sam progressed from Stage IIA to transitioning between Stage IIA to IIB, whereas Tony progressed from Stage IIA to Stage III, reaching operational measurement and conservation of length (Piaget et al., 1960/1981). In the teaching experiment, Tony needed support to use fractions, a concept Sam never entertained. This is supported by Lamon's (2007) findings that measurement is directly related to fraction concepts. However, it is unclear why Tony was able to make conceptual strides while Sam was unsuccessful. Addressing this is beyond the scope of this paper, so future research is needed to explore the factor that may have caused a difference in each student's development of operational measurement and conservation of length. Overall, this study also shows that the way measurement is being taught in some schools hinders the development of operational measurement and conservation of length, at least in the case of Sam.

INVESTIGATING VOLUME AS BASE TIMES HEIGHT THROUGH DYNAMIC TASK DESIGN

This study aims to engage students in dynamic tasks of extruding surfaces on a certain heights and reasoning about volume as a continuous quantity that depends on the size of the base and the height of extrusion, what we call as Dynamic Measurement for Volume (DYME-V). This paper describes two of our DYME-V tasks and presents data from a design experiment with one pair of fifth grade students showing DYME-V's potential for developing students' conceptual understanding of volume as a multiplicative relationship of base times height.

Keywords: volume, capacity, technology, dynamic measurement

The different 'faces' of Volume

In school mathematics, volume measurement focuses on packing the space within a three-dimensional object with a two-dimensional array of cubic units iterated in the third dimension (Curry & Outhred, 2005) and quantifying that packing in terms of the total number of cubic units used. In other words, students need to develop a mental picture of a unit structure, find the number of units required to cover the base of the 3-D shape and multiply that number by the number of layers (Curry, Mitchelmore, & Outhred, 2006). This approach of volume measurement is called *volume as packing* (Clements & Sarama, 2009, Curry & Outhred, 2005).

The literature presents several difficulties that students experience while packing a 3-D space by unit cubes. Examples include students just counting the number of cubes that are visible to them ignoring the other cubes, or counting the number of squares on the cubic units shown on the visible two faces and double that count (Figure 1), ignoring in that way the three dimensions of the object (Ben-Haim, Lappan &Houang, 1985). Similarly, Battista and Clements (1996) argued that students struggle in coordinating the separate views of arrays and integrate them to form a coherent mental model. This struggle is also present even when students are given a real 3D objects and are asked to use real cubes to measure it. Curry and Outhred (2005) found that students have difficulty in packing a bigger cuboid by enumerating smaller cubes, because students cannot always determine the successive positions of the cubes while iterating. As a result, students leave gaps and overlaps in the empty space.

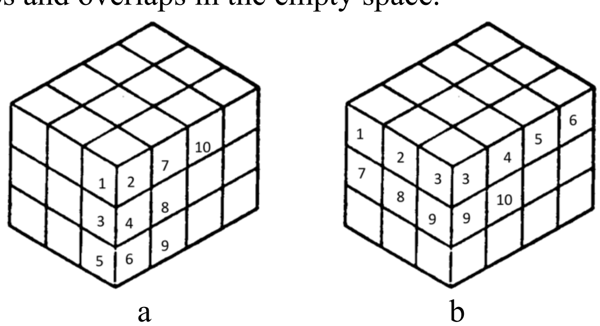

Figure 1. Students count (a) the faces of the cubic units and (b) the visible cubic units

The literature on volume measurement in math education distinguishes between *Volume as packing*) versus *Volume as filling.* Volume as filling is about filling a 3-dimensional space with iterations of a fluid unit that takes up the space of the container (Clements & Sarama, 2009, Curry & Outhred, 2005), an approach that seems to be a more continuous approach towards measuring the volume of an object over *volume as packing*. According to Piaget (1960), in order for students to understand the multiplicative relationship of volume, they need to conceptualize it as a continuous quantity, therefore the volume as filling approach seems promising for developing a conceptual understanding of the volume formula.

While exploring volume as filling, Curry and Outhred (2005) asked students to find the number of cups of rice that would fit into a jug after one cup was poured in the jug. They found that students treated the height of the rice in the cups as a unit length, which they iterated to fill the jug, ignoring the other dimensions of the jug. Similarly, while studying students' conceptions of volume, Piaget and his colleagues (Piaget, 1968; Piaget, Inhelder & Szeminska, 1960) found that elementary school students thought that the volume had been reduced when the liquid was poured into a wider glass. This predominant use of a single dimension to make three-dimensional judgments was termed by Piaget as 'centration hypothesis' and it is found to occur even when adults perceive volume in boxes at the grocery store (Raghubir, 1999).

Exploring volume dynamically

The literature above comes in contrast with research stating that students already have a dynamic sense of volume that we may use to develop students' conceptual understanding of this concept. While exploring similarity, Lehrer, Strom and Confrey (2002) discussed how students visualized volume "like pulling" the area through the height of the cylinder, in other words looking at three-dimensional objects as 2-D unfoldings (Lehrer, Strom & Confrey, 2002). The same study reported that students were able to find the volumes of cylinders by estimating the surface area of the base and then calculating the volume as the product of area and height.

The idea of "pulling" an area through a height is conceptually different than filling a jar with cups of liquid. In exploring students' thinking of dimensions in geometry, Panorkou & Pratt (2016) discussed the dual nature of capacity stating that "one can see the space as incorporating objects; in this sense, the space contains the objects. At the same time, the space can be thought of as generated by the objects" (p. 213). The generation component of volume is also described by Lehrer, Slovin, Dougherty and Zbiek (2014) who discussed how we can generate attributes through motion and gave the example of a volume being generated by sweeping an area through a length. To illustrate this generation, imagine extruding a two-dimensional rectangular surface of area '*ab*' for a height or depth of '*c*' to generate a space of '*abc*' (Figure 2).

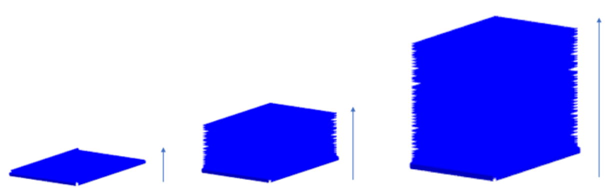

Figure 2. Volume as a continuous structure

The difference between this approach and the filling/packing approaches lies in the distinction between a matrix which is made up of a limited number of elements [a certain number of blocks/cups] and "one which is thought of as a continuous structure with an infinite number of elements" (Piaget et al. 1960, p. 350). We call this approach to measurement *Dynamic Measurement for Volume (DYME-V)*, and it involves extruding surfaces on a certain height and reasoning about volume as a continuous quantity that depends on the size of the base and the height of extrusion. DYME-V seems promising not only for developing a meaning of volume for rectangular cuboids but also for other 3-D objects, such as triangular prisms and cylinders.

Consequently, our goal was to test the conjecture that it is possible for children to visualize volume as a dynamic continuous structure and as a product of the area of base and height through careful task design. More specifically we explored: a) What type of tasks and tools may be used for developing students' DYME-V? b) What forms of DYME-V reasoning are made visible and can be seen to develop as a result of students' systemic engagement in these tasks?

We used a design-based research methodology to engineer particular forms of learning and study how those forms of learning develop with the particular context of volume measurement (Cobb et al., 2003). For our task design, we used the dynamic feature of extrusion and tracing of Geogebra to enable students to generate 3-D objects by extruding 2-D surfaces and reason about volume. This paper presents two tasks that we implemented with one pair of fifth grade students, Ashley and Maggie, and discuss the generalizations they made about volume during their interaction with the specific tasks. We met with Ashley and Maggie for 8 one-period sessions (45-50 min). The students represented various abilities according to their teacher and the prior knowledge they had on measuring volume was by water displacement from their science class.

The Case of Ashley and Maggie

In the first task, we asked students to extrude surfaces in different planes and reason about what they observe (Figure 3). As they dragged the surfaces, students reasoned that, *'it spreads out and looks like it is layering itself.'* When we asked them if they could count the number of layers they stated, '*there are millions of layers and together they make a 3D cube,'* claiming that the size of the shape *'depends on how far you stretch them out.'*

Figure 3. Extruding rectangular surfaces to create 3D shapes

Building on the students' notion of *layers* and *stretching*, the next task aimed to shift their attention to the value of base in order to make judgements about volume. We presented two surfaces of different area to students and asked them to stretch them for 1-inch each (Figure 4).

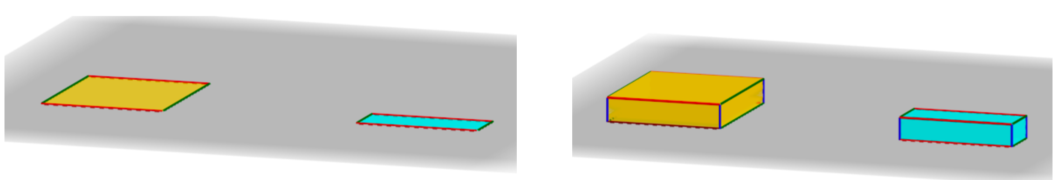

Figure 4. Stretching a 5 x 6 inches^2 and a 5 x 2 inches^2 surfaces by 1-inch height.

Researcher:	What is the size of each box?
Ashley:	This one is 10 [right] and this one is 30 [left].
Researcher:	How much space will each one fit? How much space is the first one and how much is the second one?
Maggie:	The same amount?

Ashley: I don't think so. It cannot be, because if this one [yellow on the left] is bigger, then it has to have more space.

Researcher: How much more though?

Ashley: This one is 5 times 6 which is 30 and times 1 is 30. That's for the yellow one. And that one is 5 times 2 which is 10 and 10 times 1 is 10. So 30 minus 10 is 20.

As we prompted the students to say more about why they multiplied, Maggie responded, *'because it just added on to another one. So like a second one, which means multiplying by 2'* [describing how two stretches of 1-inch are equal to one 2-inch stretch]. It appeared that they considered composites of 1-inch stretches and could realize volume as filling and continuous. In subsequent tasks, when we asked the students to state how they can find the space covered they responded, *'by multiplying the height and area, well, area is typically the base.'*

Concluding remarks

DYME-V is an exploratory study which examines how students reason about volume as a continuous quantity when they are exposed to technological tasks developed in Geogebra. Our results suggest that the approach of dynamic measurement has the potential to engage students in dynamic tasks that foster the development of volume as a continuous construct to ultimately reasoning about volume as base *times* height. Moving forward we plan to conduct more design experiments for exploring the progression of students' DYME-V reasoning as they interact with the tasks, and examine patterns and difference between different pairs of students.

INVESTIGATING STUDENTS' PROOF REASONING AS THEY TRANSITION FROM VERBAL PLANNING TO WRITTEN PROOF

Michael L. Winer
Eastern Washington University
mwiner@ewu.edu

Michael T. Battista
The Ohio State University
battista.23@osu.edu

The importance of doing formal axiomatic proofs and students' difficulties with proof have been well documented in research. This paper focuses on formal proofs that use triangle congruence postulates, which students create in high school geometry. Examining student work with proofs in an clinical interview setting, we analyzed students' transition from planning their proofs to writing their formal proofs using a two-column format. We found that much of the reasoning students described in their planning did not match the reasoning they used in their written proofs. Using a lens of spatial/logical structuring, we illustrate this finding by providing an illustrative example in which a student's planning does not match the deductions that she wrote in her formal proof.

Keywords: Geometry and Geometrical and Spatial Thinking, Reasoning and Proof, Cognition

It has been well documented in research that the majority of students struggle to construct valid proofs in high school geometry (Chazan, 1993; McCrone & Martin, 2004; Senk, 1985). This paper focuses on formal proofs that use triangle congruence postulates, which students create in high school geometry. It takes a psychological constructivist perspective (Battista, 2001) to investigate how students transition from orally planning their proofs to writing their proofs formally using the two-column format. It illustrates how the reasoning students convey during the planning of their proofs many times does not match the reasoning conveyed in their written formal proofs, and how this mismatch provides researchers insights into students' proof reasoning.

Conceptual Framework

The reasoning involved in constructing geometric proofs is quite complex and involves using four types of structuring: spatial, geometric, logical, and axiomatic (Battista, 2008). *Spatial structuring* is the cognitive operation of constructing a spatial organization or form for an object or set of objects (Battista, 2008). Battista (2008) defined *geometric structuring* as using formal geometric concepts and properties (e.g., congruence, parallelism, slope, length etc.) to describe a geometric shape's spatial structure. For a geometric structuring of a shape to make sense to a person, it must evoke an appropriate interiorized spatial structuring of the shape as well as interiorized formal geometric concepts used to describe the shape (Battista, 2008). Both spatial and geometric structuring are needed to begin constructing a geometric proof as students view/draw a diagram in terms of both its visual-spatial properties and the geometric conceptualizations that are given to describe it.

However, to construct a geometric proof, not only does an individual need a linked spatial and geometric structuring, but he/she must also be able to integrate this linked spatial and geometric structuring to the third and fourth types of structuring—logical and axiomatic structuring. *Logical structuring* is the process of making a series of deductions assumed to be consistent with the rules of logic in an attempt to prove the desired conclusion from the given premises. In the two-column proof format, logical structuring is the set of conclusions that one deduces and writes in the left-hand column. One major error that can occur in a proof's logical structure is when the argument has a logical gap in it. A logical *gap* occurs between two deductions when students deduce a conclusion by applying an axiom or theorem whose premises have not been established by the given conditions or prior deduced conclusions in their proof. *Axiomatic structuring* is the process of situating and justifying deductions and logical structuring within a given axiomatic system. In the two-column proof format, axiomatic structuring can be thought of as the sequence of deductions in the left-hand column coupled with the required justifications in the right-hand column. A two-column proof exhibits a correct logical structure if the sequence of conclusions in the left-hand column is correct in that each conclusion can be justified with one axiom or previously proved theorem in the axiomatic system. A two-column proof exhibits a correct axiomatic structure if every conclusion exhibits a logically valid deduction (correct logical structuring) and each conclusion is correctly justified in the right-hand column by a relevant axiom or theorem.

Method

The data was collected by conducting a series of one-on-one semi-structured task-based interviews to seven high school geometry students who were asked to complete a series of proof problems. All participants were volunteers who were currently enrolled in a proof-based geometry course in which they had already completed a unit on triangle congruence proofs. Students were interviewed for five one-hour sessions in which they "thought aloud" as they worked on twelve proof problems. For each proof problem, students were first asked to verbally (orally) plan their proof and only after they had described their proof plan verbally were they asked to write out their formal proof. All interviews were video recorded, transcribed, and later analyzed using the constant comparative method and retrospective analysis.

Sample Results and Discussion

In this paper, we discuss how students transitioned from verbally planning their proofs to writing their proofs formally using the two-column format, along with difficulties they faced, and differences between their plans and written proofs. When evaluating a written proof with a gap, the proof itself typically provides little to no insight as to the reason(s) why the students might have skipped/missed deductions. In contrast, in this interview setting, many students demonstrated important proof reasoning in their verbal explanations that was not explicitly conveyed in their written deductions for proof. Therefore, the present study found that students' verbal explanations many times provided critical insight into the reasons why some students missed or skipped deductions in their written proofs. Due to space limitations, we only present one example of student work to illustrate that what many students said during their verbal proof planning did not always match what they wrote later in their formal proofs and how this mismatch affected their proofs' logical and axiomatic structuring.

Rose's Verbal Plan for Problem M {See Figure 1 below for Problem M}

Rose: So, DE is perpendicular to EG is down here [marks $\angle DEF$ as a right angle]. And then the same thing with BF [marks $\angle BFG$ as a right angle]. …

IN: And how did you know they were right angles?

Rose: I was marking for perpendicular. *If it is perpendicular it has to be a right angle.* So, F is the midpoint of EG, which means that since it is the midpoint these [points to $\overline{EF}$ and $\overline{FG}$] have to be the same length. [Rose marks $\overline{EF}$ and $\overline{FG}$ congruent]. And then DF is parallel to BG. So [marks $\overline{DF}$ and $\overline{BG}$ parallel] I drew parallel signs. And [Triangles] DEF and BFG; so, proving that those two triangles [are congruent]. So, since this [points at $\overline{EG}$] is a straight line and these [outlines $\overline{DF}$ and $\overline{BG}$] are parallel they intersect *at the same angle* [make X gesture with her arms] which makes these [marks $\angle DFE$ and $\angle BGF$ congruent] Corresponding Angles. And I just proved that the triangles because Angle-Side-Angle [*points to* $\angle BGF$, $\overline{FG}$, *and* $\angle BFG$]. **[Later in the episode, after Rose has completed her written proof for Problem M**].

IN: These ones right here [points to $\angle BFG$ and $\angle DEF$] you said were 90-degree angles. Is that right?
Rose: Yeah. I feel like it is a self-explanatory given that they are perpendicular they would have to be right angles.

Rose's Formal Written Proof for Problem M

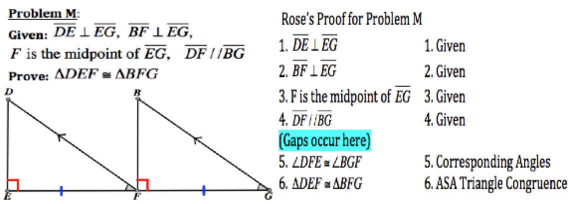

Figure 1

Correct Formal Proof for Problem M

1. $\overline{DE} \perp \overline{EG}$	1. Given
2. $\overline{BF} \perp \overline{EG}$	2. Given
3. F is the midpoint of $\overline{EG}$	3. Given
4. $\overline{DF} // \overline{BG}$	4. Given
4a. $\angle E$ and $\angle BFG$ are right angles	4a. Def. of $\perp$ lines
4b. $\angle E \cong \angle BFG$	4b. Right Angles are Congruent Theorem
4c. $\overline{EF} \cong \overline{FG}$	4c. Def. of midpoint
5. $\angle DFE \cong \angle BGF$	5. Corresponding Angles
6. $\Delta DEF \cong \Delta BFG$	6. ASA Postulate

Figure 2

Rose had three errors in her formal proof's logical structure due to missing deductions that were relevant and critical to the validity of her formal proof. First, Rose never explicitly wrote a deduction in her proof that stated that Angles E and BFG are right angles by the definition of perpendicular segments. From her oral description (in particular her statement about "self-explanatory"), we infer that Rose did not write this deduction because she assumed that the argument was intuitively obvious, therefore there was no need to write it out. Although Rose had clearly demarcated these right angles (in red) on the diagram (see Figure 1), since she did not write it as a deduction there is no explicit evidence in her written proof on how this conclusion was justified within the axiomatic system. If Rose's proof was evaluated solely from what she had written, one would have to make presumptions about whether Rose understood that these angles are right angles by definition of perpendicular segments, which might or might not be reflective of Rose's reasoning. Since it is not clear from only reading Rose's written proof that she understood this issue, the missing deduction would need to be classified as a gap in her written proof's logical structure. However, when considering her oral explanations with her written proof, it is clear that Rose had the correct intuitive reasoning about the missing deduction, but failed to formalize it in her written proof.

Second, Rose did not explicitly state a second deduction about the two right angles being congruent in either her verbal explanations or her written proof. This missing deduction was critical to the proof's logical structure because it was used later to draw the last deduction that Triangles DEF and BFG congruent by the ASA Postulate. This is evidenced in her verbal planning when Rose explicitly pointed to Angle BGF, Segment FG, and Angle BFG on the diagram to represent the congruent parts from Triangle BFG when explaining why the two triangles, BFG and DEF, were congruent. From her gesture to Angle BFG, which she had demarcated as a right angle on the diagram (see Figure 1), it can be inferred that Rose used the notion that the two right angles were congruent to satisfy the premise for a second pair of congruent angles needed to apply the ASA Postulate. However, Rose had not explicitly established that these two angles are right angles nor that they are congruent in her written proof. From reading her written proof, it is not clear how Rose was applying the ASA Postulate when she only had one pair of congruent angles (see line 5 in Figure 1) explicitly established in her proof. As a result, this is a gap in her formal proof's logical structure.

The third error that Rose made in her written proof was that she needed to explicitly write a deduction that stated that Segments EF and FG are congruent by the definition of midpoint. This missing deduction was also critical to her proof's logical structure because she used it as the corresponding congruent sides premise to apply the ASA Postulate in line 6 of her written proof (see Figure 1). This was exhibited when Rose pointed to Segment FG as her congruent side in

Triangle BFG as she was explaining why she could deduce the triangles congruent by the ASA Postulate. Importantly, Rose verbally stated that Segments FG and EF have the same length by definition of midpoint during her verbal planning of the proof, indicating that Rose had the conceptual understanding of the premises of this deduction, but she did not explicitly convey this understanding in her written proof. This illustrates again that students can have gaps in their written proofs even when they actually have correct reasoning about missing deductions. So, it is not so much a gap in logical structuring but one of axiomatic structuring, misconceiving the level of detail needed for a written formal proof.

Concluding Remarks and Implications

Findings from all the clinical interviews suggest that most of the proofs that students wrote were not formally correct, but that many students wrote proofs that were not reflective of the sound proof reasoning evidenced in their oral plans. In many instances, students had developed sound intuitive ideas for proofs, but they did not write proofs that were rigorous enough to stand up to scrutiny due to gaps/omissions in their written proofs' logical and/or axiomatic structures. Most of the time, teachers and researchers assess students' proof reasoning only by evaluating their written proofs. The present study shows that in many instances there is more going on with students' proof reasoning than what is reflected in their writing. A two-column proof provides only so much information about what the student was thinking when he or she drew a deduction, especially in flawed proofs. Many times, when students make errors or omissions in their written proofs, it is not clear or evident from simply reading their proof what student reasoning was behind these errors. For example, when students are missing deductions in their written proofs, the teacher or researcher usually cannot distinguish between students who did so intentionally because they thought the deductions were obvious from students who did it because of faulty reasoning.

In contrast, as the present study illustrates, evaluating students' proofs using both their verbal explanations and their written proofs can provide teachers and researchers with deeper insight into students' reasoning. This insight not only helps teachers and researchers better understand students' proof reasoning difficulties, but also helps them diagnose students' errors and misconceptions so they can develop more effective curriculum and instructional interventions to remedy the difficulties. Additionally, this paper illustrates that having students verbally plan their proofs before writing them reveals that some students have correct intuitive reasoning about some deductions absent from their written proofs. Due to the deeper insight gained into students' reasoning, it is recommended here that when possible, teachers and researchers should evaluate students' proofs using both their verbal explanations and their written proofs.

THE EFFICACY OF AN ALTERNATIVE HIGH SCHOOL GEOMETRY CURRICULUM ON STUDENT ACHIEVEMENT WITH PROOFS

Wayne Nirode
Miami University
nirodew@miamioh.edu

Keywords: Geometry, Reasoning and Proof, Curriculum, High School Education

Over the last 30 years, professional organizations (e.g., NCTM, 1989; NCTM, 2000) and policy makers (CCSSI, 2010) have continued to make recommendations that high school geometry students should learn proof, but students have continued to struggle with it (McCrone & Martin, 2009; Senk 1985). Furthermore, some geometry teachers have claimed that they do not have any instructional strategies to scaffold the learning of proof and that students must either "sink or swim" when learning it (Cai & Cirillo, 2014).

In response to the continued struggles, the present study established baseline data on achievement on proof for students who learned geometry using a recently developed curriculum that emphasizes a semester of making conjectures through investigations followed by a five-part proof progression. For a detailed description of the proof progression, see Nirode (2018).

Out of 78 students in four classes at a single high school, 56 students enrolled in the study. Near the end of the third quarter, students took an 8-question test. Questions 1 and 2 asked students to put a proof in order given all the statements and reasons. Questions 3 and 4 had students filling in blanks for a partially completed proof. For questions 5 and 6, students wrote a proof after being provided with a diagram, the given, and what to prove. For questions 7 and 8, students wrote a complete proof from a conditional statement.

The researcher scored the tests. The proof puzzles both had 8 statements and 8 reasons for students to put in order for a total of 16 points. The next two questions both had 6 blanks in the proof for students to complete for a total of 6 points. Then, the researcher scored questions 5–8 using Senk's (1985) four-point rubric. Also, like Senk's study, for questions 5–8, a proof with a score of 3 or 4 was classified as correct.

Students did exceptionally well with both proof puzzles ($M = 15.25$, $SD = 1.08$ and $M = 15.39$, $SD = 1.89$). Next, students did well on filling in the blanks ($M = 3.91$, $SD = 1.40$ and $M = 4.34$, $SD = 1.40$). For the two proofs where students were provided with a diagram, the given, and what to prove, the means for both proofs were essentially correct scores ($M = 3.25$, $SD = 1.22$ and $M = 2.93$, $SD = 1.42$). Finally, students struggled when writing a proof from a given conditional statement ($M = 1.29$, $SD = 1.29$ and $M = 1.29$, $SD = 1.29$).

YOUNG CHILDREN'S RESOURCES FOR DEFINING ASPECTS OF 3D SHAPE

Megan Wongkamalasai
Vanderbilt University
megan.j.wongkamalasai@vanderbilt.edu

Keywords: early childhood education; geometry and geometrical and spatial thinking

Studies of young children highlight relations between their cognitive development and experiences moving in space (Oudgenoeg-Paz et. al., 2015). Yet, current early mathematics instruction often ignores the resources children have to make sense of foundational properties of space. Recent programs highlight the accessibility of geometric concept for young children (Hawe et al., 2017), but less is known about how early experiences of space can also support their engagement in mathematical practices. Expanding attention to young children's development of mathematical practice aligns with sociocultural views of mathematics as situated in the everyday activity and evolving practices of local communities (Lave et al.,1984). I present a design study conducted in a rural 1st grade classroom aimed at co-developing children's concepts of 3D shape and defining practices to answer these research question: What resources from children's everyday experiences with 3D shape and space help them define and conceptualize properties of 3D shape? How do children's resources support the development of a new classroom practice of defining?

Using grounded theory, I analyzed video and field notes from eight days of instruction. I first categorized ways students described, built, and interacted with 3D structures. Then, I traced how these different categories supported episodes of collective defining practices using Kobiela and Lehrer's (2015) framework of aspects of defining. I found four themes in students' engagement with 3D structures. These included judgements about a structure's smoothness (i.e., sliding a hand around a structure; ability to roll; stability in relation to properties of closure; and height versus width. These four themes also proved consequential to the classroom's development of a practice of defining. In particular, the teacher's press on students to articulate what properties of structures they used to make judgement corresponding to these themes helped establish definitions for properties and classes of 3D shapes. For example, when comparing examples of right prisms, students noted each could roll around their rectangular faces but some rolled better. By exploring what impacted the structures ability to roll, students coordinated rolling to the number of sides on the bases. Students then generated a generalization that these bases needed to match and that they played an important structural role of holding all the rectangles or squares together. This final generalization was later positioned as a definition for prisms.

OPENING SPACE FOR CHANGE AND EMPOWERMENT THROUGH PHILOSOPHICAL AND STRUCTURAL CONTEMPLATION IN TEACHER PROFESSIONAL DEVELOPMENT

David M. Bowers
Michigan State University
bowersd2@msu.edu

In this theoretical article, I examine the norms of teacher professional development with an eye towards modifying them to allow for genuine systemic change. I first argue that current norms restrict professional development practice to "pseudo-activity" which necessarily operates within rather than against larger societal structures. I then propose philosophical and structural contemplation of mathematics as an example of a currently non-normed practice that has the potential to effect substantive change.

Keywords: Equity and Diversity, Teacher Education-Inservice/Professional Development

> In our frenetic academic life, it is not easy to find the time and the will to contemplate. Partly because one of the necessary requisites for contemplation is the absence of a concern with the applicability of our thoughts, in these days in which time is money, some will ask: why lose money with all this philosophical/contemplative waste of time? The ethos of scientific research today makes plain that empty words are not enough; we must set to work, do it instead of just talking about it. What we need, some say, is engagement in action, quick solutions ready to be implemented, evaluated and, eventually, discarded, so that the entire process can start again. (Pais, 2012, p. 82)

> The threat today is not passivity but pseudo-activity, the urge to 'be active', to 'participate', to mask the Nothingness of what goes on. (Žižek, 2006, p. 334)

The 40th annual North American Conference of Psychology in Mathematics Education invites us to consider the enduring challenges of the last 40 years as well as ways to enact change moving forward. With that in mind, my goal in this article is to lay out an argument that current teacher professional development norms preclude the opportunity for genuine systemic change, and to suggest a path forward that would allow for such change. Specifically, I argue for a widening of the norms of acceptable mathematics teacher professional development in the United States to allow for philosophical and structural contemplation. To that end, the purpose of this article is twofold: (1) to provide a critical analysis of the ways professional development opportunities systematically privilege forms of professional development that focus on "pseudo-activity," activity that has here-and-now implications for the classroom but preserves the hegemony of school mathematics, and (2) to illustrate a discouraged form of professional development and the power it could have to enable critique of the hegemony of school mathematics and open space for empowerment. I will first argue that current professional development practice focuses on activities that might have immediate or directly visible impacts on teaching practice, and that such practices preserve the hegemony of mathematics and narrow space for empowering the students and teachers who interact with mathematics (Pais, 2012). I will then outline how structural and philosophical consideration of mathematics could have powerful implications for teachers and students, since such consideration exposes the discipline to critical interaction while opening space for the empowerment of the people who interact with it. In essence, the former argument is meant to establish that the norms of teacher professional practice are narrow in some way, while the latter is an existence proof of a potentially valuable practice that currently lies outside the realm of normed practice.

Throughout this paper, I will use the phrase "structural and philosophical contemplation of mathematics" to refer to thinking about the epistemological and ontological assumptions on which the discipline is built as well as to considering the ways the discipline acts as a framing or scaffolding device that shapes how we think of other aspects of our world. The former contemplation I would call philosophical and the latter structural. The lines between these two types of contemplation are fuzzy, but since I use them in tandem as a single construct throughout this article, this fuzziness should not be problematic.

Critical Analysis of Constraints on Teacher Professional Development

> I often experience it firsthand when I am asked to speak with teachers and administrators regarding mathematics achievement and persistence among African American students. Despite insisting on the complexity of these issues, some version of the following is inevitably asked: 'What you have said is fine, but tell me, specifically, what I should do today when I go back to my school or classroom to work more successfully with African American students?' In most cases, this is a sincere request. (Martin, 2009, p. 304)

Professional development is commonly taken to refer to the learning opportunities that teachers engage in to improve their professional practice (Feiman-Nemser, 2001). Professional development thus includes, but is not limited to, mandated staff development offered by districts, reading professional journals, and attending professional conferences.

In order to argue that the norms of acceptable mathematics teacher professional development should be widened, I first contend that the current norms of practice presently exclude certain types of professional practice. In brief, I contend that teachers have limited time to devote to professional development activities, and that professional structures restrict the sorts of professional development that might be considered acceptable. None of this should be taken as a critique of teachers; instead, it is a critique of larger forces that shape the decisions that teachers might reasonably make.

Teachers work long hours during the schoolyear. The OECD's large-scale international study found that teachers in the United States work an average of roughly 1,900 hours per year, more than 30 of the 32 other countries included in the dataset (OECD, 2017, p. 388). Assuming the majority of this workload occurs during the school year rather than over breaks, it is not out of the question that many teachers in the United States might average 50 or more hours per workweek during the school year, 25% more than the prototypical 40 hour workweek. This finding is echoed by the 2011-2012 Schools and Staffing Survey which reported that public school teachers in the United States average 52.2 hours of work per workweek (SASS, 2012) as well as by numerous smaller-scale non-scientific surveys (e.g. Banning-Lover, 2016).

Given the long hours teachers work, they must use their time strategically. Teachers have many obligations, including but not limited to: (1) teaching, (2) planning and preparation of lessons, (3) review and marking of student work, (4) communication with parents and guardians, (5) supervision of students outside of teaching time, (6) teamwork with colleagues, (7) participation in mentoring or support groups, and (8) other managerial or extracurricular obligations such as serving as department head or running academic clubs (OECD, 2017, pp. 390-391). Along with all of these obligations, teachers are expected to find time for professional development. Given the limited time remaining for such activities, teachers are pressured to make the most efficient use of professional development time possible.

What strategic choice of how to use limited professional development time might a teacher reasonably make? As is suggested by Martin's (2009) quote at the beginning of this section, one enticing choice is to focus on activities with immediate or directly visible implications for the classroom. In many cases, this choice is made for teachers by districts, in the form of full- or half-day sessions which focus on the dissemination of teaching techniques or strategies coupled with "inspirational" lectures (Feiman-Nemser, 2001). Such mandatory professional development informs norms of teacher professional development, suggesting that it should center on activities with immediate or directly visible implications for the classroom. This norm is further reified by the professional structures that provide additional professional development opportunities for teachers.

The National Council of Teachers of Mathematics (NCTM) is perhaps the largest professional institution devoted to mathematics education and teaching, boasting more than 60,000 members and 230 affiliates (NCTM, 2017a). NCTM offers a variety of journals and meetings devoted to the professional development of practitioners as well as the practical dissemination of research (or implications thereof) to practitioners. Given the size and pervasiveness of this institution, looking at its journals and meeting schedules can offer some insight into the norms of mathematics teacher professional development practice in the United States.

In reviewing the feature articles from the most recent (as of the time of this writing) issues of every NCTM journal dedicated to K-12 teachers (see *table 1*), I found that *every* feature article

***Table 1*: NCTM practitioner journal feature articles reviewed by the author**

Journal	Teaching Children Mathematics	Mathematics Teaching in the Middle School	The Mathematics Teacher
Articles	Bleiler-Baxter, Stephens, Baxter, & Barlow (2017) Bray & Blais (2017) Earnest, Radtke, & Scott (2017) Firmbender, Casa, & Colennese (2017) Lambert, Imm, & Williams (2017) Lomax, Alfonzo, Dietz, Kleyman, & Kaxemi (2017) McCormick, & Essex (2017) Perry, & Lewis (2017) Shumway, & Pace (2017) Turrou, Franke & Johnson (2017)	Banes, López, Skubal, & Perfecto (2017) Groth, Jones, & Knaub (2017) Matsuura, Sword, & Finkelstein (2017) McNamara (2017) Oslund, & Barton (2017) Roy, Bush, Hodges, & Safi (2017)	Beigie (2017) Borkovitz, & Haferd, (2017) Dougherty, Bush, & Karp (2017) Gerver, Santucci, & Leventhal (2017) Goldenberg, & Carter (2017) Jaqua (2017) Lommatsch (2017) McCaffrey, & Matthews (2017) Samuels (2017) Taff (2017)

focused on immediate or directly visible implications for classroom practice. This review covered 10 articles from *Teaching Children Mathematics*, 6 from *Mathematics Teaching in the Middle School*, and 10 from *The Mathematics Teacher*. All of these articles either: (1) described an exemplar lesson or course (e.g. Earnest, Radtke, & Scott, 2017), (2) describe a pedagogical technique (Oslund & Barton, 2017), or (3) offer some guiding principles for a certain style of teaching (e.g. Roy, Bush, Hodges, & Safi, 2017). Provided the reader is teaching the relevant course, every article in here contains ideas that could be immediately implemented in class and that could be pointed out to observers as teacher practice responding to professional development. Cursory analysis of additional articles spanning the years 2013-2017 echoes this finding.

Reviewing the proceedings of the annual meeting and exposition of NCTM (2017b) produces analogous results. Reviewing all 708 scheduled talks suggests that all, save for the administrative meetings, focus on topics with immediate or directly visible implications for the classroom which could be classified under the same three broad headings mentioned above.

Taken together, I claim these results suggest that a strong, though sometimes implicit, message is being sent to teachers: professional development time should be spent on activities with immediate or directly visible implications for practice. One might propose to counter this claim by arguing that teachers simply prefer professional development activities of this sort, and school districts and NCTM are acting to meet their needs. The truth or falsity of this counter-claim, however, is irrelevant to my claim. Regardless of whether or not the counter-claim is true, the current state of district mandated professional development and NCTM's professional offerings nonetheless send a message about what type of professional development is acceptable, thus informing the norms of teacher professional practice.

Focusing on professional development with immediate implications can be very valuable. However, maintaining such a focus to the point of excluding other sorts of professional development is potentially problematic, as it restricts the ways that teachers might think about solving problems (Putnam & Borko, 2000) and risks locking us into larger structures that are themselves destructive (Pais, 2012). In particular, I note that mathematics learning is itself a destructive force when not exposed to critique (Ernest, 2016), and that "here-and-now" professional development works within the discipline rather than subjecting it to critique. Thus, if there are valuable types of professional development currently excluded from the norms of professional development that might respond to this weakness, then we should make efforts to widen those norms.

Structural and Philosophical Consideration of Mathematics as Productive Professional Development

> If mathematics is objective, it makes no sense to be concerned with learners' cultures and lived experiences. If mathematical achievement can be accurately and fairly measured with standardized tests of routinized items, it makes no sense to develop more "subjective" assessments of mathematical understanding. And if mathematics is inherently too difficult for many to master, it makes no sense to try to teach all students rigorous aspects of the discipline. (Ellis & Berry III, 2005)

> Often these processes operate at a level below consciousness; they remain unexamined or even unnoticed, in which case the task at hand is to render them visible and expose them to critique. (Greer & Mukhopadhyay, 2012)

In order to argue that the norms of acceptable teacher professional development should be widened, I now contend that there exist potentially powerful forms of professional development that are currently excluded from the norms of acceptable professional development evidenced previously. In particular, this existence proof focuses on the potential power of structural and philosophical consideration of mathematics as a means to disempower the discipline while opening space for the empowerment of the people who interact with it, such as students and teachers. Noting at the outset that such contemplation falls outside of the normed space of professional development with immediate or directly visible implications for practice, my argument is structured as follows: (1) mathematics plays a large and widespread role in our lives, (2) perception of mathematics as objective and value-free empowers the discipline in potentially destructive ways, (3) substantial evidence conflicts with this perception, and (4) adopting a view of mathematics as fallible and value-full better reflects this evidence and opens space to empower people while disempowering the discipline.

Mathematics plays a powerful and pervasive role in our lives. Mathematics coursework is expected of us for a minimum of twelve or thirteen years of our lives, and many more years are required for many of jobs popularly labeled as the "best" jobs available to us (Ward, 2017). Mathematics underlies much of modern technology which has become so deeply integrated into our everyday lives. The tools of mathematics are utilized by statisticians whose work, in turn, informs policy at all levels of the government. Mathematics is everywhere, not just in the sense that anything can potentially be mathematized, but in the sense that mathematics has played some role in almost every facet of our lives.

Perhaps even more so than science (Gould, 1981/1996), mathematics is often perceived as objective and value-free (Ernest, 1991). This hegemonic perception gives power to the discipline while taking power away from those who interact with it (Ernest, 2016; Greer & Mukhopadhyay, 2012). For example, if one holds the belief that mathematics is objective and value-free, then one might take the persistent "racial gap" in academic achievement as evidence that people of color are intellectually inferior to whites (e.g. Herrnstein & Murray, 1994; Jensen, 1969), reinforcing hegemonic positioning and reifying white supremacy through appeal to the assumed nature of mathematics (Greer & Mukhopadhyay, 2012).

Mathematics is neither objective nor value-free. Focusing first on the former, Ernest (1991) identified and refuted several assumptions required for an absolutist view of mathematics, the view that mathematics is certain and unchallengeable. Without recreating the entirety of Ernest's argument, I will highlight several key take-aways in support of the opposing fallibilist view of mathematics: (1) The informal proofs that mathematicians publish are commonly flawed, (2) there now exist proofs that cannot be checked by humans for correctness, and (3) we cannot know that any but the most trivial of axiomatic mathematical systems are secure.

I focus now on the latter, that mathematics is not value-free. To that end, I make the following non-exhaustive list of some ways in which mathematics is value-full:

- Aesthetics drives all aspects of mathematics, from what mathematical questions people ask to the ways they construct argument and proof for inspection by others (Burton, 1999; Sinclair, 2009; Wells, 1990).
- Mathematics and mathematical meaning-making vary from culture to culture, indicating that mathematics itself is a cultural product (D'Ambrosio, 1985; Lipka, Wong, Andrew-Ihrke, & Yanez, 2012; Meaney, Trinick, & Fairhall, 2013; Thomas, 1996).
- Mathematics is socially-mediated and mathematical proofs are discursively constructed (Burton, 1999; Lakatos, 1976).
- The version of mathematics taught in schools and practiced by mathematicians is Eurocentric (Joseph, 1987).

- People of marginalized backgrounds have different experiences with mathematics than white males for reasons that cannot be explained by effort or ability (Martin, 2009; Stinson, 2013)

Note that these arguments that mathematics is not value-free can be taken as further support of the fallible nature of mathematics, since these values will influence what sorts of mathematical questions are asked, what can be taken as evidence in favor of mathematical claims, and generally what counts as mathematics or mathematical knowledge (e.g. Thomas, 1996).

Adopting a view of mathematics as fallible and value-full more accurately reflects this evidence and also serves to open space for the empowerment of people who interact directly or indirectly with the discipline. Recalling the earlier example of the "racial gap" in academic and mathematics achievement, this view of mathematics allows one to ask questions such as: (1) Whose brand of mathematics is being named "mathematics," (2) what value judgements and assumptions underlie the metrics used to measure achievement in this brand of mathematics, and (3) how does the culture of the test-takers interact with the cultures and values of this brand of mathematics and the measures of achievement? Thus, rather than mathematics being empowered to marginalize people, people are empowered to critically interact with mathematics (Greer & Mukhopadhyay, 2012).

Adopting such a view of mathematics requires opportunities for structural and philosophical contemplation of the discipline itself, with no concern for immediate or directly visible actions to be taken in the classroom. Opportunities for such critical analysis of and interaction with mathematics as a structure in our lives and society can be empowering (Greer & Mukhopadhyay, 2012) and might even be necessary for the construction of a more just society (Pais, 2012), but are currently excluded from the norms of acceptable professional practice for teachers. Consequently, I conclude that the norms of teacher professional development need to be widened to allow for such contemplation.

Conclusion

In this article, I have argued for a widening of the norms of acceptable teacher professional development in the United States to allow for structural and philosophical contemplation of mathematics. I began by providing evidence that the norms of professional development for mathematics teachers currently exclude professional development activities that lack immediate or directly visible implications for practice. I then argued that such "pseudo-activity" reinforces the hegemony of mathematics in destructive ways, and illustrated how structural and philosophical contemplation of mathematics could enable productive critique of the discipline if (re)introduced into the realm of acceptable professional development practice. Taken together, I conclude that the norms of teacher professional practice should be widened to allow for such structural and philosophical contemplation.

The machinery through which these norms could be widened is nontrivial, and I make no specific recommendations for how it should be accomplished; my goal here has been to invite conversation, not dictate prescription. It could be that some individual or group in a position of appropriate influence might push school districts, NCTM, or other professional institutions to make room for structural and philosophical contemplation. It could be that teacher-educators, as individuals or as a group, might take it upon themselves to adopt discourse patterns that validate such practice. It could be the culmination of a million small acts of agency, conspiring to change our professional world.

Given the immensity of the challenge, it would be tempting to take no action at all. In trying to do what is right, it seems rational to start with the set of things that are possible, and look within that for the things that are right; if the task of normalizing structural and philosophical contemplation is impossible, then it is discarded at the outset. However, when we are ourselves linked tightly into the structures that influence our lives, it can be hard to distinguish what is genuinely impossible and what is impossible only within the current system (Pais, 2012; Putnam & Borko, 2000). Thus, I suggest instead that we start with the set of things that are right, and find ways to make those things possible.

SUPPORTING A MATHEMATICIANS' INSTRUCTIONAL CHANGE IN UNDERGRADUATE MATHEMATICS THROUGH FACULTY COLLABORATION

Nicholas Fortune
Western Kentucky University
nicholas.fortune@wku.edu

Karen Keene
North Carolina State University
kakeene@ncsu.edu

To reform instruction by moving towards student-centered approaches, research has shown that faculty benefit from support and collaboration (Henderson, Beach, & Finkelstein, 2011; Speer & Wagner, 2009). In this study, we examined the ways in which a mathematician's instruction unfolded during his participation in a faculty collaboration geared towards reforming instruction and aligning it with inquiry oriented instruction (IOI) (Kuster, Johnson, Andrews-Larson, & Keene, 2017). Results indicate the participant's mathematics background and research interests influenced how he used student thinking in his instruction. Further, there existed a tension between IOI and anticipating student thinking. Lastly, results highlight the importance of active participation in faculty collaboration to support instructional change.

Keywords: Post-Secondary Education, Teacher Education-Inservice/Professional Development

Over the last decade there have been numerous calls for reform in undergraduate mathematics education (e.g., President's Council of Advisors on Science and Technology [PCAST], 2012). These calls for reform draw on research that has shown the benefits of student-centered instruction (e.g., Freeman et al., 2014). To address these calls, change is needed in the instruction of undergraduate mathematics. For example, *A Common Vision* gave a general call that instruction should move away from traditional lecture as the sole instructional method in undergraduate mathematics (Mathematics Association of America [MAA], 2015).

Given these calls for instructional reform, faculty want to make changes to their instruction. However, research has shown that even when working with research-supported curricular materials, mathematics faculty are often unprepared to undertake the challenge of changing their instruction (Henderson et al., 2011; Wagner, Speer, & Rosa, 2007). Current research is providing mathematics faculty with support needed to change their instruction.

There are also calls for departments and faculty members to collaborate specifically on the pedagogy (MAA, 2011). One research-based method of support is faculty collaborations geared towards collectively improving instruction (e.g., Nadelson, Shadle, & Hettinger, 2013). In particular, researchers are studying how mathematics faulty come to use research-based instructional strategies in their classrooms in the context of faculty collaboration. This study explored the experiences of a mathematician who participated in one such faculty collaboration that addresses the numerous calls for reform in undergraduate mathematics education and instruction. The study addressed the following overarching research question: *1) In what ways does one mathematician's experiences in an online faculty collaboration on inquiry oriented differential equations relate to his instructional practice?* And the following sub research questions: *a) How does his instructional practice unfold over his first implementation of inquiry oriented differential equations and in what ways does it align with inquiry oriented instruction? b) How does his participation unfold in the online faculty collaboration?*

Literature Review

In this section, we briefly describe the instruction that the faculty collaboration sought to support. Following this we briefly discuss relevant research on instructional change.

Inquiry Oriented Mathematics

The faculty collaboration focused on inquiry oriented mathematics and instruction. Rasmussen and Kwon (2007) defined inquiry oriented (IO) environments as teaching where students are inquiring into the mathematics, while the teachers are inquiring into the students' mathematical thinking. In this study, we focused on inquiry oriented differential equations (IODE) which has been shown effective for student understanding of differential equations (Kwon, Rasmussen, & Allen, 2005; Rasmussen, Kwon, Allen, Marrongelle, & Butch, 2006).

Inquiry oriented instruction. In inquiry oriented mathematics, it is clear that the role the teacher plays is important for advancing the mathematical agenda. Kuster et al. (2017) recently defined four focal components of inquiry oriented instruction (IOI): generating student ways of reasoning, building on student contributions, developing a shared understanding, and connecting to standard mathematical language and notation. The focal components of instruction are guiding principles of IOI. It is important to note that the four focal components very rarely occur independently; oftentimes, these components overlap and occur in the complexities of an IO classroom. Further, there are local practices of IOI. The local practices of IOI (see Table 1) are an elaboration on the four focal components of IOI. While the focal components are guiding principles of IOI (i.e., ways of composing and discussing IOI), the local practices are specific actions that instructors do in an IO classroom.

Table 1: Inquiry oriented instructional local practices (Kuster et al., 2017)

Local Practice	**Description**
1	Teachers facilitate student engagement in meaningful tasks and mathematical activity related to an important mathematical point.
2	Teachers elicit student reasoning and contributions.
3	Teachers actively inquire into student thinking.
4	Teachers are responsive to student contributions, using student contributions to inform the lesson.
5	Students are engaged in one another's thinking or reasoning.
6	Teachers guide and manage the development of the mathematical agenda.
7	Teachers introduce language and notation when appropriate and support formalizing of student ideas/contributions.

Overview of Instructional Change

Here we first describe barriers to instructional change and then what the research community knows about facilitating and sustaining instructional change.

Barriers to instructional change. One barrier to instructional change is faculty's knowledge for teaching with student-centered instructional strategies. Research has shown that some faculty lack the necessary skills to enact student-center instruction (Hayward, Kogan, & Laursen, 2015), sometimes because they lack specialized content knowledge relating to instruction and being prepared to respond to student questions productively (Wagner et al., 2007). Further, faculty have stated that student resistance, lack of student buy-in, and student attitudes of school are reasons why they do not use student-centered instruction (DeLong & Winter, 1998). The most often cited environmental reason by faculty to not use student-centered instruction is how much more time it takes than teacher-centered instruction (Henderson & Dancy, 2017). Likewise, faculty say they stray away from student-centered instruction because they have a certain amount of material that needs to be covered over the course of one semester (Hayward et al., 2015).

Facilitating and sustaining instructional change. Henderson et al. (2011) outlined four categories of instructional change strategies that are elaborated on in this section: disseminating curricula and pedagogy, developing reflective faculty, enacting policy, and developing a shared vision. Borrego and Henderson (2014) elaborated on these four categories of change by defining eight change strategies that fit within the framework. This study considered two of these change categories that we discuss here: scholarly teaching and faculty learning communities. Scholarly teaching is when "individual faculty reflect critically on their teaching in an effort to improve" and faculty learning communities are when a group of faculty come together and "support each other in improving teaching" (Borrego & Henderson, 2014, p. 227). These two strategies can work together to improve undergraduate mathematics instruction.

Methods

This study focused on one participant from an IODE online faculty collaboration (OFC). This qualitative instrumental case study (Stake, 1995) was bounded by the participant's participation in the OFC and his classroom teaching. This work comes from the TIMES project, which supported university mathematics faculty in shifting their practice towards an IO practice. TIMES offered three supports: the IO materials (in this case IODE), a summer workshop, and the weekly OFC. Here we first highlight pertinent details on the OFC.

Online Faculty Collaborations

The IODE OFC met weekly during the semester they are teaching IODE, virtually via Google Hangouts to conduct lesson studies that were modified Japanese lesson studies (Demir, Czerniak, & Hart, 2013) led by a facilitator. The main goals of the OFC were to: 1) aid teachers in making sense of the instructional IODE materials, 2) thinking through the sequences of tasks, how students might approach the tasks, how to structure instruction around the tasks to support student learning, and 3) assist teachers in developing and enhancing their instructional practice.

Participant

The focus of this study is one participant from the IODE OFC, Dr. DM. The OFC consisted of the facilitator (Dr. KK), two graduate research assistants (GRA1 and GRA2), five faculty teaching the materials for the first time (Drs. DM, AB, PR, CD, ST). The sampling of Dr. DM was purposeful in nature (Yin, 2013) and there were several reasons for that choice. First, he was and is passionate about his participation in TIMES and to this day continues with IOI in his IODE classroom. Second, he became a facilitator for the project in future semesters following his participant experience. Furthermore, Dr. DM filmed every class of the semester, which was more than was expected of the other TIMES participants, affording a plethora of possible data sources and a semester-long look at instruction.

Data Collection and Analysis

Classroom data. Video data from Dr. DM's classroom were collected. Classroom video was chosen to match the units covered in the OFC lesson studies. The OFC discussed Unit 6 and Unit 9. In addition to those units, Unit 1-2 as an introductory unit and Unit 12 were analyzed. All units lasted a different amount of time. The IOI framework discussed above (Kuster et al., 2017) was designed to capture IOI in action. Consequently, we used the framework as an a priori analytical framework for coding Dr. DM's classroom instructional practice to answer research question 1a. In particular, we used the local practices (LP) of IOI. The IOI framework also contained "evidences," not shown above, of each LP; these evidences served as codes that were collapsed to each LP. LP1 was not coded for unique observable instances in the data. After the first round of coding, we went back again and revisited analysis logs and made adjustments to the coding as necessary. In this step, we looked for emergent themes from the data.

OFC data. Each OFC was screencast recorded. All weeks of the OFC were analyzed except week 6 because the data was corrupted and week 8 because Dr. DM was unable to attend that week (in total 9 OFCs were analyzed). Weeks 1 and 2 were introductory weeks. Lesson study 1 took place over weeks 3-5 and lesson study 2 took place over weeks 6-10. Lastly, a debrief OFC occurred during week 11. All videos were transcribed. To analyze Dr. DM's participation in the OFC we coded the transcripts with specific a priori codes and frameworks: the role of the speaker (production design from Krummheuer, 2007), the role of the listener (reception design from Krummheuer, 2011), and conversation categories (Keene, Fortune, & Hall, under review). These frameworks were adapted to fit the context of this study and are discussed in the results. In a broad sense, we considered Dr. DM's active versus passive participation.

Interview data. The interview data served as a third data source to relate Dr. DM's experiences in the faculty collaboration to his instructional practice. Furthermore, this data offered Dr. DM's personal perspective on being part of a faculty collaboration. Entrance and exit semi-structured interviews were conducted. All interviews were audio recorded and transcribed. Transcripts of both interviews were open coded (Yin, 2013).

Results

Instructional Practice

Central to IOI is the facilitation of mathematics where students are actively inquiring into the mathematics while the teacher is actively inquiring into the students' mathematical thinking (Rasmussen & Kwon, 2007). Dr. DM's instruction focused predominantly on LP2, eliciting student ways of reasoning and contributions (see Table 2). Dr. DM less often actively inquired into why his students were making such contributions (LP3), less often used those contributions to push the agenda forward (LP4), and less often had students engage in one another's thinking (LP5; although this happened frequently in Unit 1-2). Note that frequencies were scaled and rounded to represent the same amount of class time; each unit lasted a different number of days.

Table 2: Frequencies of Dr. DM's Local Practices of Inquiry Oriented Instruction

Practice	Unit 1-2	Unit 6	Unit 9	Unit 12
2	58	52	66	26
3	17	24	16	4
4	17	16	15	8
5	42	26	14	2
6	14	16	6	4
7	3	14	8	2

Table 2 is very telling of Dr. DM's instruction. He was very interested in generating student contributions. While some of the questions asked were ones from the IODE tasks themselves, he often would ask his own questions in his own way as a means to address something that he wanted to focus on or have his students think about. While students had opportunities to engage in others' contributions as they were written on the board, they less often had opportunities to engage in others' thinking, as Dr. DM did not tend to follow up with questions to have students elaborate on their thinking. Essentially, after students made contributions, Dr. DM would more often move on. We cannot know for sure if Dr. DM was so in tune with the students in his class and the mathematics itself, that he did actually know why his students were thinking along certain lines. However, LP3 and LP4 are about making explicit to the rest of the class such thinking and thus Dr. DM's LP frequencies were reflective of the fact that he didn't often make public his inquiring into student thinking.

Dr. DM's instruction did not necessarily change from the beginning of the semester to the end of the semester. As discussed across the totality of Dr. DM's instruction his most frequent LP was LP2, eliciting student ways of reasoning and contributions. However, when comparing the four units of analyzed instruction there were contrasts between the unit instructional portraits. Namely, the way Dr. DM's instruction unfolded was tied to 1) how and when he used student thinking in his class, 2) the mathematical task itself, and 3) his mathematical beliefs, rooted in his mathematical research arena.

First, in Unit 1-2, Dr. DM frequently (more often than any other unit when comparing across scaled time) engaged students in one another's thinking. In particular, this unit was the unit where his students' thinking was most at the forefront of the class and he oftentimes used that thinking to advance the mathematical agenda. When student thinking was made prevalent to the rest of the class, Dr. DM's instructional portrait reflected that.

Second, it was observed that Dr. DM's instruction was influenced by the mathematical task. Specifically, if a unit was a more scaffolded unit with limited options for student exploration (e.g., Unit 12), the questions that Dr. DM would ask were limited in scope and thus he used less IOI LPs in those units. In this particular case, Unit 12 was a very algebraic unit where students, being led by the teacher, develop an understanding of how to find the eigenvalues of a system of differential equation and use that information to find the associated eigenvectors and in turn the solution to the system of differential equations. Consequently, the questions Dr. DM could ask and the probing he could do was significantly impacted and all IOI LPs occurred less often.

Third, when the mathematics of the unit was associated with Dr. DM's mathematical research interests he would focus on getting students to get to "the way [he] view[s] the mathematics" rather than having his students' work or ideas at the center of the development of the mathematical agenda. Unit 9 dealt with the development of the phase plane which was a crucial tool in Dr. DM's research. The instructional portrait of that unit had the highest amount of eliciting student ways of reasoning and contributions (LP2) and in comparison, a very low frequency of LP3-5 (the other practices associated with student thinking). Many of the questions that Dr. DM asked were of his own accord and not generated from the whole class discussion. Because he knew the mathematics so intimately, he was most interested in getting students to see the mathematics the way he does, rather than letting the mathematics emerge from the students.

Participation in OFC

Recall the goal of the OFC was to support cohorts of mathematicians as they came to learn about IOI and IODE. Table 3 highlights the participation frequencies based on role and conversation. For the purposes of space, we only discuss active and passive participation here rather than all the more specific roles adapted from Krummheuer (2007, 2011). Additionally, we adapted frameworks from our previous work (Keene et al., under review) but here only include four broad conversation categories rather than each individual conversation topic.

Rather than growth throughout the semester, Dr. DM immediately jumped into the active role in the OFC and that active role was consistent throughout the semester. Similar to his classroom instruction there was not a change but rather how his role looked depended on the content of each OFC. For example, if the week focused on doing mathematics, he rarely authored topics because he simply was partaking in the conversation, however, he was very active in those weeks as he has a real passion for mathematics. Additionally, when the OFC focused on sharing of his videos, he authored frequently those weeks and the conversation focused on pedagogy as he sought advice on, for example, how to speed up his class because he was running out of time at the end. Table 3 highlights Dr. DM's most active role related to pedagogical issues.

Table 3: Frequencies of Speaker / Listener Codes by Participation / Conversation Category

Conversation Category	Speaker		Listener	
	Active	Passive	Active	Passive
Pedagogical Issues	137	16	82	55
Mathematical Issues	70	6	72	40
Student Issues	63	2	20	23
OFC Issues	97	24	91	156

Discussion

In this section, we provide an answer to the overall research question.

Mathematics Background

Dr. DM's mathematics background played a role in how his instruction panned out throughout the semester and how he participated in the OFC. In both cases his mathematical content knowledge (rooted in his background and research interests) was placed on top of his interest in enhancing his pedagogical practice. By that we mean, in his teaching his view of mathematics sometimes was the view of mathematics that he was guiding his students towards. Likewise, in his participation in the OFC, his mathematical understanding was one of the driving factors for his interest in enhancing his pedagogical practice. Namely, he sought support on how he can get his students to that same level of awe and understanding.

This conclusion supports previous work from Speer, Wagner, and colleagues (Speer & Wagner, 2009; Wagner et al., 2007). However, there are important distinctions that shed light on this topic and provides discussion for faculty collaborations going forward. Most importantly, that is the subtle notions of what a mathematician's mathematical content knowledge is. In their work, Speer and Wagner noted that their participant had a strong understanding of the mathematical content but that did not help in terms of his analytic scaffolding (i.e., meaning facilitation of discussion). Similarly, Dr. DM also had a strong understanding of the mathematical content across all units. However, the difference lies in the fact that in some units he was able to provide analytic scaffolding, namely, he was able to use his students' ideas in the class (LP3: actively inquiring into student thinking, LP4: being responsive to student contributions, LP5: engaging students' in one another's thinking, LP6: guide the mathematical agenda). Yet, he was more likely to do that when the mathematical content wasn't his specific research interest. Consequently, we concur with Speer and Wagner and posit that one's mathematics background is not sufficient to successfully use student thinking in one's class, however, the level to which one understands that content makes a difference in their instruction.

Tension Between Agenda and Inquiry

This first relationship translates into a second one, as there is a tension between what a mathematician wants to do in his/her class and IOI. In the case of Dr. DM, his focus, for some of the content from the course, was to get his students to his view of the mathematics. This ultimately leads to a tension between one's teaching agenda and inquiry. If in inquiry, student thoughts are central to the development of the mathematical agenda (Kuster et al., 2017), then imposing one's own view of mathematics does not align with an inquiry perspective. The reason this causes a tension is because being passionate about your research inherently is not a bad thing, nor trying to get your students to see the beauty of mathematics. However, in so doing, one privileges their understanding over that of their students.

Anticipating Student Thinking

A third relationship that relates Dr. DM's instruction to his participation in the OFC considers how one anticipates student thinking and how student thinking is used in instruction. We know from extant literature that mathematicians often struggle to implement novel teaching (if it is new to them) and in particular struggle with how to respond to and deal with student contributions in a productive and successful way (Wagner et al., 2007). However, this was not an issue for Dr. DM as he was in an OFC supporting his instruction. He never noted that he was unsure what his students were going to do. Yet, he seldom actively inquired into his students thinking. This indicates he either knew what his students were thinking or simply did not probe into their thinking; we cannot know which one.

We also know from extant literature on the possible successes of anticipating student thinking in professional development settings (e.g., Demir et al., 2013). In the OFC, participants spent 1-2 weeks for each lesson study doing the mathematics of the units of focus and then anticipating how their students may approach the tasks. This model was based off of the Japanese lesson study (Demir et al., 2013). Ultimately, we conjecture there is a tension between anticipating student thinking and inquiry oriented instruction. By that we mean that because a critical component of inquiry oriented instruction is inquiring into student thinking and engaging with unexpected contributions, if student contributions are overwhelmingly "anticipated," mathematics faculty may struggle to engage with those unexpected contributions if they spend a large amount of time anticipating what their students will do.

Active Participation in Faculty Collaborations

The fourth relationship centers around active participation in the OFC positively impacting instruction. As discussed, Dr. DM was an active participant in the OFC. Additionally, his goals were clear in that he was there to enhance his pedagogical practice. Dr. DM's passion for IODE and IOI bled into both his instruction and participation in the OFC. This OFC was an example of what Borrego and Henderson (2014) defined as a faculty learning community. "STEM undergraduate instruction will be changed by groups of instructors who support and sustain each other's interest, learning, and reflection on their teaching" (Borrego & Henderson, 2014, p. 233). Dr. DM was supported by and supported his fellow colleagues in learning about and reflecting on inquiry oriented instruction. This indicates that for successful instructional change, faculty learning communities or faculty collaborations needs to be designed with ensuring active participation from all involved.

Conclusion

This area of research is ripe for future research directions. The instruction of undergraduate mathematics courses is a hot button item in undergraduate mathematics education research today. More importantly, the research community still needs to know more about how we can support endeavors to reform instruction, how can they be scaled up, and how do we measure success? In this qualitative instrumental case study, while not generalizable, we can conclude that the OFC supported Dr. DM's desire to reform his instruction. This work has highlighted how those faculty collaborations can be improved moving forward and most importantly highlights that instructional change is possible if the time and effort are put into it.

BEGINNING TEACHER FEEDBACK IN THE CONTEXT OF A CO-TAUGHT INCLUSION MATH COURSE

Corinne Glenwerks
Tufts University
corinne.glenwerks@tufts.edu

As schools turn towards co-teaching models to implement inclusion practices (US Department of Education, 2010), teachers are increasingly being asked to operate with a co-teacher (Scruggs et al., 2007). However, most research on co-teaching remains at the survey level; it does not examine factors that may influence co-teaching relationships over time (Scruggs et al., 2007). This paper seeks to address that gap by examining the feedback a first and second year co-teacher give one another as they teach a high school mathematics course. The question under consideration is: what kinds of feedback may beginning co-teachers offer one another and how may it influence their classroom practice over time? The results of this work contribute to the broader body of co-teaching research by offering insights into a specific case of teacher collaboration.

Keywords: Teacher Education- Inservice/Professional Development; Equity and Diversity; Affect, Emotion, Beliefs, and Attitudes

Inclusion, the practice of blending students with and without documented special needs in one classroom, has become increasingly supported in schools across United States by adopting a co-teaching model where one teacher has content knowledge and the other teacher, knowledge of special education practices (US Department of Education, 2010). When implemented well, co-teaching has been shown to be an effective way to teach all students (Cook & Friend, 1995). However, research indicates that teachers often do not have adequate supports, such as common planning time, resources, and training, and that without these advantages, these co-teaching relationships are not nearly as successful (Bouck, 2010; Dieker & Murawski, 2003; Scruggs, Masteropieri, & McDuffie, 2007). Because under-resourced, beginning co-teacher situations are common, they should be explored in greater depth to better understand how to support educators in this position.

The current body of co-teaching research is primarily limited to teacher perception studies that provide snapshot insights into co-teacher relationships (Scruggs et al., 2007). A 2012 study by Rytivaara and Kershner is an exception; their case study of two social studies co-teachers suggests that co-teachers may shift towards more student-centered practices when they collaborate effectively. This is an exciting prospect because not all teachers have access to more traditional professional development (PD) programs to improve their practices; therefore, if co-teachers can offer productive feedback towards one another, co-teaching might offer an alternative form of PD to foster productive changes in teacher pedagogy over time. Indeed, Rytivaara and Kershner (2012) emphasize the importance of "social and collaborative" (p. 1001) reflection as key to successful professional learning and note that in theory, co-teaching gives participant teachers the opportunity to engage in a "peer-learning relationship" (p. 1001).

The purpose of this paper is to consider the role of feedback given by two co-teachers, myself and my co-teacher, "Peter," in our "peer-learning relationship" (Rytivaara & Kershner, 2012, p. 1001) and examine whether and how our classroom practice changed over time. The study was conducted using action-research methodology (e.g. Chazen, 2000; Lampert, 1990; Townsend, 2014). The feedback Peter and I exchanged as we worked together for the first time to teach an Algebra II and Trigonometry course are analyzed to address the following research question: what feedback may beginning co-teachers offer one another and in what ways may it influence their classroom practice over time?

Theoretical Framework

This work was conducted based on the belief that learning is situated (Greeno, 1991; Lave & Wegner, 1991) and that teachers and students are "elements or aspects of an encompassing system of social practices" (Cobb & Bowers, 1999, p. 5). Therefore, this study's intention is not to strive for generalization to other contexts, but instead to seek initial patterns from the data themselves and produce context-dependent insight into a specific case, as opposed to producing "high level theory" (Flyvbjerg, 2006, p. 223). As Flyvbjerg (2006) argues, it is essential to consider a breadth of cases before developing more general theory, and that the cases themselves are useful for producing a more "nuanced view of reality" (p. 223). This study will contribute to the literature by illustrating the case of two beginning co-teachers, Peter and myself, as we collaborate together for the first time.

Research Methods

Study Context and Participants

I started teaching high school mathematics in an urban district in the Northeastern U.S. during the 2014-2015 school year. Prior to teaching, I spent two years working on a PD research project that sought to increase teachers' ability to attend and respond to their students' mathematical ideas. Based on this background, I hoped that Peter and I could work together towards developing a more responsive classroom environment for all of our students (Hammer & Shifter, 2001), where we would build our lessons on students' ideas and craft an environment where students shared and discussed one another's mathematical thinking.

Peter had taught for one year in a resource room in another district before moving to the research site, which is a relatively high-performing urban high school with approximately 1,700 students. He often reported that he loved math in high school, but found it difficult in college and changed his major to Spanish. Although he did not take many college-level mathematics courses, from our experience together it was clear that he was quite proficient in the topics we taught.

Peter and I co-taught one course together, from January to June 2015, but he taught two other classes with two other teachers that semester as well. His planning time did not align with any of the teachers he was assigned to work with, so most planning occurred via email or after school. Hence, Peter and I had little common planning time and had received no co-teacher training before teaching together. This situation is representative of many other co-teachers across the U.S. (Bouck, 2010; Dieker & Murawski, 2003; Scruggs et al., 2007).

As stated previously, Peter and I taught an Algebra II and Trigonometry course. The curriculum covered a review of polynomials, linear and quadratic functions and their transformations, and then introduced exponential and logarithmic functions, rational functions, limits, the unit circle, solving trigonometric equations, proving identities, and finally, graphing trig functions and trig function application problems.

Study Design

This study was designed as action research (Adelman, 1975; Lampert, 1990; Townsend, 2014), as I occupied the dual role of teacher and researcher whose goal was to foster a more responsive environment with my co-teacher. While some researchers have argued that the primary purpose of action research is to change practice, rather than to produce research (Elliott, 1991; Kemmis & McTaggart, 1982), I sought to design a study where the results could be similar to other situations with broader research implications. Hence, I strove for it to be as authentic to a traditional co-teaching experience as possible, only intending to give feedback and argue for responsive teaching practices when the moment arose organically in conversation, rather than overtly pushing my agenda. Therefore, while I hoped that our practices would become more responsive to our students' needs, I did not explicitly communicate that to Peter.

Data Collection and Analysis

The data were collected from late January to late June 2015. I recorded 26 of the approximate 40 conversations we had we planned together. These conversations were of varying length (5 minutes to 1.5 hours) and occurred almost entirely after school. I also made daily field notes that summarized the day's class and my impressions from that day, and collected my 123 email correspondences and the assignments Peter and I developed for our students.

The data were first coded line-by-line using grounded theory methods (Charmaz, 2014). For instance, in the transcript below (Figure 1), Peter and I discussed how to address low student test scores. The lines on the right indicate the presence of some of the codes given to each piece of transcript. Peter says "part of me is like, we spent two weeks on that, but it was very choppy because of all of the other stuff…" This was coded as "blaming students for poor performance," as he says "we spent two weeks on that" and the second part, "But it was very choppy because of all of the other stuff," was coded as "taking responsibility for student performance." This entire segment was coded as "exploring why students did not do well on an assessment," because Peter discussed how time, student motivation, and instruction may have influenced the test scores. Over 200 codes were developed after analyzing all transcripts.

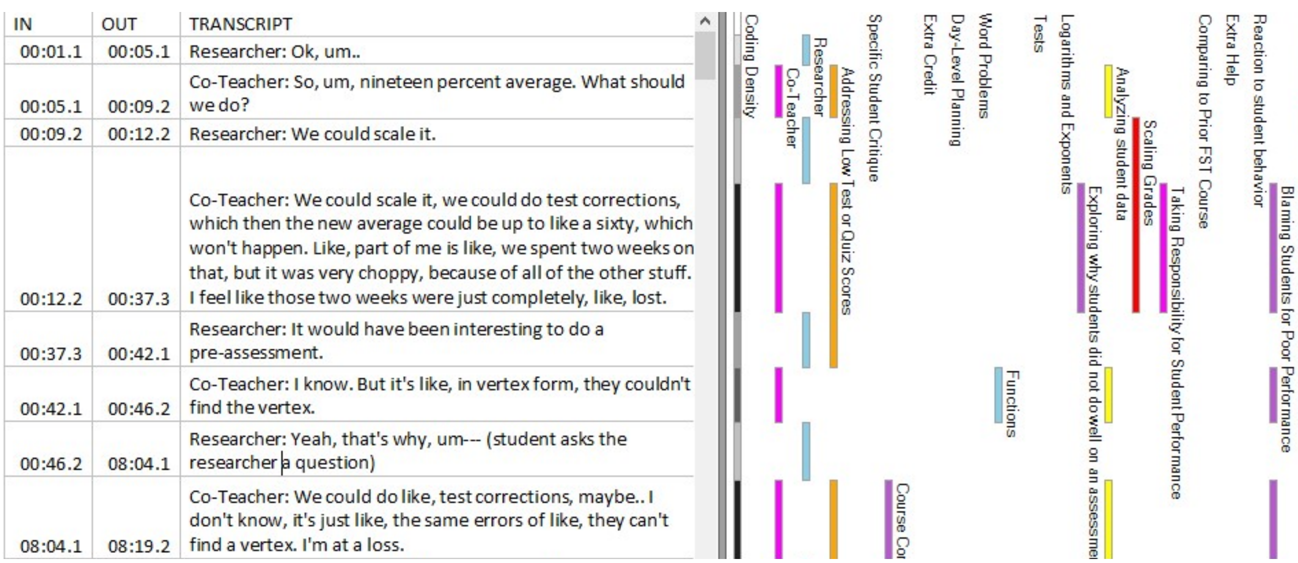

Figure 1. Example of the initial coding process using Nvivo software.

Next, the 200 codes were sorted into 43 broader categories (Charmaz, 2014) to identify larger themes in the data. After this initial analysis was completed, I returned to the research question to examine the feedback more directly. All moments of feedback were classified based on their degree of specificity, as specificity is considered a hallmark of quality feedback (Gan & Hattie, 2014; Hattie & Timperley, 2007). Three codes were developed based on this premise:

Vague: Feedback that is merely positive or negative and does not appear to add any advice or insight or explain our reasoning. For instance, "That packet is awesome" and "That looks great!" are examples of vague feedback because we do not explain why the subject at hand is "awesome" or "great."

Moderately Specific: Feedback that provides some level of detail as to the strengths or weaknesses of the subject. For example, "I think it's a little long but the questions are great!" In this quote, I validate Peter's hard work ("the questions are great!") but provide the feedback that I believe the assessment he developed is too long. However, I does not explain why I believe it is too long or provide suggestions to address the issue.

Specific*:* Feedback that is detailed and explains the feedback-giver's reasoning. This feedback should also include propositions for changes. Following Peter's development of a quiz, I replied with the following:

> Overall, I really like the structure of the quiz and I think the questions are great, but I think that the graphs are <u>really</u> hard—I think that in order for us to determine what they understand and what they don't, some of them should just have a phase shift, some should just have amplitude, some should just have a vertical shift, and some could have a combination to see what they're capable of. I think it's a little much to have all three shifts in most problems.

In this example, I give the feedback that I think the quiz is "really hard," but then grow more specific: I delve into why I believe this is the case and offers suggestions to remedy the situation.

Results

The purpose of this paper is to describe the types of feedback we gave one another and how it may have changed our classroom practice. Therefore, the results are organized by first giving an overview of the feedback we gave one another, and then examining the ways in which our class changed over time.

Feedback Exchanged

There were two instances of feedback in the 26 recorded conversations between Peter and me and both occurred near the end of the semester in June. In the first instance, I followed up on a discussion Peter had with one of our students, Jalen. I recorded the events that transpired the day Peter talked with Jalen in my field notes:

> Peter stopped by my class after school and helped Jalen, one of our students who passed first quarter and then started to slack. He worked on revisions from our Limits test, but had essentially forgotten what limits were so Peter was reteaching him. Early on, Peter asked Jalen what he planned to study after graduating. Jalen said he was interested in music and in the medical field, and so Peter told him that if he was interested in studying medicine he might need to take calculus. Because limits are a 'calculus-y' concept, understanding them is very important and kind of a preview to what he'd be learning in calculus. I thought it was a good approach for Peter to relate the content to Jalen's interests, but the tone kind of (unintentionally, I think) implied that if he didn't master limits, calculus would be really hard. I don't think that Peter meant to give Jalen that message, but I'm afraid that Jalen left with a fear that he couldn't succeed in what he hoped to pursue. Also, Peter was trying to encourage Jalen, 'See, you're getting it, this stuff is easy.' But I don't think that Jalen was understanding the material to the degree that Peter thought he was, and Jalen seemed a little upset by his assertion-- he didn't want to protest, I don't think, [or] contradict what Peter was saying by pointing out that no, he didn't understand, but it was a little uncomfortable. I didn't really know how to help, either, but I probably should have said something (June 4th, 2015).

This quote contains an important reflection. I wrote, “I didn’t really know how to help.” Not knowing how to approach areas of disagreement with Peter was common in the field notes; there are a few instances where I wrote notes such as, “I don’t really know how to talk about that with him,” especially early and mid-semester. In this case however, I was so bothered that I decided to discuss it with Peter the next time we were both after school:

Me: Yeah, I think that... I wasn't sure... like, the other day, when you were saying, um, like, ‘You got it! You got it!’ to him, I was like, ‘I don't-- I dunno if he has it yet.’

Peter: No, but like, maybe he doesn't have it, but at least if he's taking a step in the right direction? Sometimes positive reinforcement. I think sometimes I might do that a little to much. Like a sine graph, I sometimes may go way overboard with praise, sometimes I may be like, ‘screw you.’

Me: Yeah, I guess it's just making sure it's the right kind of praise too. I just remember some of my math professors, when they were trying to make us feel better about what we were learning, they would be like, ‘This is so easy! You shouldn't feel bad about this. This is so easy!’ And then I would be like, ‘No, it's not easy! Now I just feel dumb.’ And until I was that student. I was like, ‘Oh, I should make sure I don't call something ‘easy.” Sometimes I use the euphemism of ‘straightforward,’ which doesn't really…

Peter: I definitely called limits easy, because it's like, we're looking at two things. They either come together or they go in different directions (June 6th, 2015).

I tried to provide feedback on the type of praise that Peter offered, that it may have been premature to assert that Jalen understood the material. Peter countered, saying that he gave “positive reinforcement” to Jalen’s work. I then attempted to argue by connecting to my own personal experience, citing that when I was told by a well-intended professor that the content was “easy,” it made me feel worse. Peter disagreed, saying that the material was “easy.” In this example, Peter did not appear to accept my feedback to adjust the way he discussed content with students. He continued to argue that the content was “easy” and that he did provide appropriate praise.

The second instance of feedback occurred later that same day. In class, Peter had tried to “cold-call” students to hold them accountable for paying attention. As the co-teachers reflected on how class went that day, the following discussion took place:

Peter: I'm happy. I think today some people made sense of things. I feel like today was somewhat of a success.

Me: Well it was funny how many people you called upon to ask for a definition and how many people still just like, weren't listening.

Peter: Yeah, weren't even listening to the group. And like, it's sad but I think it's something that we have to keep doing.

Me: Yeah, I think it's good to do that. You probably could have kept it up a bit longer too.

Peter: Yeah.

Me: But it's hard when there are so many people who are sitting and you can only call on them some of the time (June 6th, 2015).

This small piece of my feedback, that “you probably could have kept it up a bit longer too,” is the one piece of pedagogical feedback given over the course of the semester. However, I wrote in my field notes that “I think that if we were friends it might be easier for us to give each other feedback on curriculum materials, etc.” It appears that I felt uncomfortable giving Peter feedback because we were not friends. Yet, my feedback that Peter could have “kept it up a bit longer too,” along with my critique of his conversation with Jalen, both may indicate that by the end of the semester I felt that our relationship was strong enough to offer small pieces of pedagogically-based feedback face-to-face with Peter.

While there was little feedback given during face-to-face conversations, there were 19 instances of feedback given via email between Peter and me, significantly more than the 2 instances given in-person.

Table 1: Number of specific, moderately specific, and vague pieces of feedback per month given via email.

Month	Specific	Moderately Specific	Vague
January	0	1	4
February	0	1	0
March	2	0	0
April	1	1	0
May	3	2	1
June	3	0	0

As Table 1 shows, as the semester progressed, there was an increase in the frequency of specific feedback and a decrease in vague feedback. Again, this may indicate that as we grew more comfortable with one another, we felt that we could give more specific critiques. All feedback related to developing course materials and assessments. For example, after grading a test on the unit circle, I wrote in an email:

> The kids bombed the test. The highest grade was in the 40s… I like the idea of having a revisions/make-up day at some point before the end of the semester, but I was thinking that we give them advanced warning and give them a group test on Tuesday or Wednesday, then average the scores… I wonder whether it makes sense to just forget about the sum/difference formulas and focus on graphing and mastering what they do know... what do you think? (May 31st, 2015).

Peter replied:

> I agree about tomorrow. I feel like the multiple representations are important. Perhaps we could use desmos or have them extend the graph to show the two graphs, or we could [ask] them [to] compare a sine graph shifted to the cosine graph (y = sin(x + pi/2) vs. y = cos(x)) so they can see the similarity between the graphs (June 1st, 2015).

This quote conversation is representative of the types of conversations Peter and I had. Here, I proposed omitting the sum and difference formulas moving forward, although it would be on the final, and instead continue work on graphing. Peter gave the feedback that he agreed with my suggestion, and then built on my comments by proposing multiple representations using technology. We often acknowledged one another’s ideas about content, discussing order of topics, material development, and assessing student understanding, and agreed or pushed back accordingly.

Changes in Classroom Practice

When Peter and I began our class in January 2015, we often opened with a "Do Now" warm-up problem for students to try, followed by direct instruction and then individual or group work. We often alternated between providing direct instruction and circulating the room to ensure that the students were on-task. A similar structure prevailed in the end of the semester. Hence, our overall classroom structure did not appear to change from the beginning to end of the course and we did not shift towards using the responsive teaching practices to the extent I had hoped for. This is perhaps representative of the lack of feedback and conversation around making our classroom more student-centered; there were only two pieces of feedback about student interactions and they occurred in June.

Peter and I did change how we delivered material to students. Initially we developed large packets of problems and notes per unit, but as the semester progressed we transitioned to daily assignments based on our perception of our students' understandings from the day before. Peter and I often alternated between making the next day's assignment and would share our lesson through email to get feedback. This shift could perhaps reflect our focus on students' understanding of content through the assignments and assessments we created, as opposed to the mathematical ideas students shared in class. This focus was especially prevalent in the feedback we gave one-another via email. While our daily structure remained the same, that our assignments became more attentive to students' mathematical knowledge raises the possibility that given more time and experience, Peter and I may have learned to practice more responsive teaching methods as well, not just more responsive assignments.

Discussion and Implications

The results show that we gave each other pedagogical feedback face-to-face only once, at the end of the semester, and otherwise gave no feedback in-person. However, we gave each other content-based feedback much more frequently over email, and this feedback increased in specificity as the semester progressed. This is an important indication of quality feedback (Hattie & Timperley, 2007; Shute, 2008). The late increase in feedback may indicate that we grew more comfortable with one another as the semester progressed and suggest that for co-teachers to give one-another feedback, they need to know one-another first. This builds upon prior research, which has found that for a co-teaching relationship to be successful, it needs to be like a marriage: "requiring effort, flexibility, and compromise for success" (Scruggs et al., 2007, p. 14). Therefore, future research should examine structures that could be put in place to help teachers develop stronger relationships, therefore fostering an environment more conducive to giving and receiving feedback.

Peter and my feedback was quite substantive as well at times, suggesting that even beginning co-teachers can give feedback to improve the content presented to a course. However, our lack of feedback towards other aspects of teaching highlights that we were not good sources of feedback for improving pedagogy, and could explain why there were no shifts in classroom practice over the semester while there were changes in how we created and delivered course material. This builds upon current feedback research, which primarily focuses on feedback given by teachers to students or from administrators to teachers (Khachatryan, 2015), by illustrating that even beginning teachers can offer suggestions for improvement.

While more co-teaching relationships should be examined to see the greater variety of the ways in which co-teachers may provide feedback and shift their practices, schools might consider using all, not simply veteran, teachers when implementing feedback protocols. This is because even beginning teachers may have important contributions to make to improving school experiences for students.

FRAMING ELEMENTARY SCHOOL TEACHERS' CONSIDERATIONS WHEN ENGAGING WITH THEIR OWN STUDENT WRITTEN WORK

Naomi Allen Jessup
Georgia State University
njessup@gsu.edu

Professional development (PD) is widely used to aid teacher development and improve student learning outcomes. In PD, skilled facilitators use research-based frameworks to support and provide a lens for teachers' engagement with artifacts of practices (e.g., student written work). However, often what is unaccounted for in PD design is the use of teachers' insider knowledge of their students. This study explored considerations that arose when teachers engaged with written work from their classes outside PD. Results identify the range and prevalence of considerations used in teachers' conversations. Also discussed are implications for professional developers and those who support teacher learning through the analysis of written work.

Keywords: professional development, frames, student written work, elementary school teachers

Professional development (PD) is widely used to support teacher development and improve learning outcomes. In PD, the complex work of teaching is decomposed into manageable parts, and teacher learning is often supported through engagement with artifacts of practices (e.g., student written work) led by experienced facilitators (Kazemi & Franke, 2004). In addition, the use of research-based frameworks (Carpenter, Fennema, Franke, Levi, & Empson, 2014) and protocols of instruction (Krebs, 2005; Little, 2003) provides a lens to support teachers' engagement with classroom artifacts in PD with the intent that the same lens is used in their classrooms. However, what is often unaccounted for in most PD is the potential role of teachers' insider knowledge of their children and the influence of their engagement with artifacts of practice.

Take for example the task of examining written work, which is a prevalent activity inside and outside PD. In PD, teachers are asked to bring in samples of written work from their own class as they utilize research-based frameworks to understand their children's thinking. Facilitators and collaborative groups play a role in co-constructing what to consider as teachers engage with their written work with the hope those considerations will remain the same once teachers leave the PD. Outside of PD, teachers engage with written work individually in their classrooms and sometimes collaboratively with their peers (e.g., within grade level meetings). When teachers are in their classrooms, engaging with written work is typically constructed by the individual teacher's insider knowledge of their children and is guided by the need to make decisions in the moment or in preparation for the next day. Considerations are influenced by goals set for each child, the class as a whole, or curricular expectations. When teachers work collaboratively with their peers, considerations for engaging in the written work are driven by school-level expectations, standards, accountability, and curriculum (Little, 2003). In collaborative settings, the goal of analyzing the written work is often not closely linked to the teachers' individual child but related to understanding classroom performance, more generally. The different settings in which teachers examine written work—in PD contexts, teachers' individual classrooms, or school-based teacher groups—position written work differently, and teachers draw upon different relationships in their analyses. These differences highlight the use of teachers' knowledge and beliefs but also the context of teaching should be considered when trying to understand teachers' engagement (Webel & Platt, 2015).

Conceptual Framework

In this study, I chose to think about teachers' considerations as "frames" to look beyond what teachers say as they work with written work, and instead focus on the nature of the engagement. Framing or frame analysis was theorized by sociologist Erving Goffman to explain how individuals structure information for sense-making. Goffman (1974) argued that we all actively classify, organize, and interpret our life experiences to make sense of them by filtering relevant information and discarding what is not needed depending on the situation. Individuals, whether aware or unaware, construct frames on a day to day basis to make sense of the world around them. I argue framing is a broad construct that includes knowledge, beliefs, dispositions, and experiences. In the case of engaging with written work, the frames used by the PD facilitator, the individual teacher, or grade level teams could shape individual teachers' engagement. For example, in schools and PD settings, the framing of written work could include making sense of children's mathematical thinking (Kazemi & Franke, 2004; Little, 2003), understanding misconceptions (Krebs, 2005), or checking for correct answers (Horn, 2007).

Researchers in mathematics education have applied framing in PD to understand teachers' noticing in video clubs (Sherin & Russ, 2014) and in schools to investigate teachers' conversations when categorizing students (Horn, 2007) and in teacher learning through collaborative groups (Bannister, 2015; Louie, 2016). Across these studies, framing served as an analytical approach to provide the meaning of teachers' conversations. For example, Bannister (2015) noted individual teachers expressed different conceptions of how to classify a "struggling student" based on the needs of their own students. However, the framing of "struggling students" was co-constructed by the group's collective interpretation which was not representative of every teacher's interpretation.

In PD settings, facilitators guide teachers through the use of research-based frameworks that frame ways to structure meaning of written work. For example, Kazemi and Franke (2004) used a research-based children's mathematical thinking framework (Carpenter et al., 2014) to promote elementary school teachers' analysis of written work in professional development. During the PD, teachers shared written work samples from their classrooms while the facilitator questioned teachers to attend to and make sense of strategies according to the children's mathematical thinking framework. Findings showed that, over time, teachers learned to frame how they attended to and made sense of children's mathematical thinking in ways that were reflective of the framework used in the PD. In essence, the design of the PD guided teachers' framing of the written work as intended.

The Kazemi and Franke (2004) study is representative of studies that have provided evidence that teachers can learn to use a *children's thinking* frame as they engage with written work during PD, which is a controlled setting. There is also some evidence that teachers who have adopted a children's thinking frame in PD, continue to use this frame in their own classrooms (Sherin & van Es, 2009). However, we do not know if there were other frames that arose as teachers engaged with written work because that was not the focus of these types of studies. Looking beyond the *children's thinking* frame used in PD to examine written work can provide insight into other frames that were not addressed in PD. Further, by looking at the frames that arise outside the context of PD when teachers engage with written work after having taught a lesson, we can better understand the issues that could emerge in a more naturalistic and applied setting.

In this study, I chose to explore frames outside of a *children's thinking* frame and outside of PD. I draw heavily upon Sherin and Russ's (2014) conception of *interpretative* frames, which were defined as structures that described the way teachers' attention grows out of and informs their reasoning. Sherin and Russ (2014) used interpretative frames to understand the relationship between teachers' reasoning about classroom events and the role of reasoning used in teachers' noticing of short video excerpts. Analysis of teachers' conversations in video clubs identified 13 interpretative frames that characterized the network of ideas teachers used to reason when analyzing video excerpts from their own classrooms during PD. My study is similar to the work of Sherin and Russ (2014) because I investigated the frames used when engaging with children's ideas, but there are some important differences. Sherin and Russ (2014) worked with middle and high school teachers who were analyzing video of classroom events. I chose to focus on elementary teachers' individual engagement with their own written work after a classroom lesson.

Research Focus and Questions

The focus of this study was to explore considerations elementary school teachers used when examining their own students' written work. Specifically, I addressed the following questions: What considerations arose in elementary school teachers' conversations when engaging with written work from their classrooms? More specifically, what frames were utilized (outside the *children's thinking* frame provided in the PD) when teachers engaged with written work from their classrooms?

Methods

Participants

This study involved 42 grades 3–5 teachers who were a subset of teachers who participated in the Responsive Teaching in Elementary Mathematics (RTEM) study — a professional development design study focused on research-based knowledge of children's fraction thinking and how teachers can use this knowledge to be responsive to children's thinking in their classrooms. The 42 participants were teachers whose classrooms were observed solving an equal sharing fraction problem (Empson & Levi, 2011), completed 1, 2, or 3 years of PD in the RTEM study, reflected a range in years of teaching experience and prior experiences with research on children's thinking. They were drawn from three school districts in the southern region of the United States, and these districts included not only a diversity of ethnicities and achievement levels but also purposeful variations in instructional supports and constraints, which could influence teachers' engagement with written work.

Professional Development

The 3-year PD consisted of 8.5 total days each calendar year, including the summer and academic school year. Teachers engaged in numerous activities focused on using research-based frameworks for children's thinking of whole-number concepts and fractions to support responsiveness to children's thinking. Additionally, teachers participated in practices (e.g., questioning and noticing) that built on children's mathematical thinking. Equal sharing problems were a type of problem widely used in the PD to support building children's foundational understanding of fractions and conceptual knowledge of working with fractions. An example of an equal sharing problem is: *Six children want to share ten brownies so that everyone gets the same amount. How much brownie can each child have?*

Data Sources and Analysis

Data Sources. Data included 42 audio-recorded, semi-structured teacher interviews that took place following an observation of each teacher's classroom instruction. Teachers were asked to pose an equal sharing problem during their instruction that they considered appropriate for their class. After the lesson, teachers were immediately interviewed. I am focused on the portion of the interview in which teachers were asked to identify a student's written work that was interesting to them and then discusses what stood out about that child's thinking. Additional questions asked teachers to describe the details of the child's strategy, their understandings, and next instructional steps.

Data Analysis. The analysis of teachers' conversations occurred in multiple steps and was guided by the question: "What frames beyond children's thinking do teachers typically draw upon when making sense of their own students' written work?" Again, the focus for looking beyond children's thinking was to look for what teachers considered beyond what was addressed in the PD. The first analysis stage focused on segmenting the interview transcripts into idea units when a single topic was discussed. In the second stage, I determined the focus of each idea unit. During the third stage, I used an iterative process looking across the idea units to generate five frames for conversations about the teachers' own written work. I was inspired by the approach of Sherin and Russ (2014) but did not begin with their 13 *interpretative* frames for teachers' engagement with video. Instead, I generated frames that emerged from the data. Finally, in stage four, I used the five frames identified in the third stage to code the entire data set. In this final phase of analysis, I identified themes across frames to create categories and noted how many teachers used each of the five frames.

Results

The main result of the analysis of teachers' conversations was the identification of five frames used in the teachers' conversations. These five frames fell within two broad categories: non-mathematical or mathematical performance comparisons. Non-mathematical frames highlighted affective aspects or personal aspects of the child and their sense making. Mathematical performance comparison frames highlighted the child's mathematical performance in comparison to the child's performance in previous problems, the performance of others in the class on this problem or previous problems, or curricular or testing goals for that grade level. Table 1 describes each of the frames that emerged and includes the number of teachers who used for each frame.

Non-Mathematical frames

Confidence, behavior. This first category consisted of two frames in which teachers focused on some non-mathematical or personal aspects of the child in a discussion of the written work and sense-making. Non-mathematical frames were used to highlight the progress the child has made despite certain issues or as a way of making excuses for what the child was unable to accomplish. In the *confidence* frame, the teachers highlighted a child's mathematical confidence concerning their mathematical thinking. For example, when asked to describe the details of the child's strategy, Teacher 1 noted, "At first they did nothing. I had to walk them through the problem. They have the knowledge to solve the problem, but does not have the confidence to do it on their own without assistance." In this excerpt, Teacher 1 did not attend to the details of the child's strategy but excused the child's inability to solve the problem independently due to a lack of confidence when additional support was not provided. The confidence frame was used by 24% of the teachers.

Behavior was another non-mathematical frame in which teachers identified specific behaviors of a child and related that to their written work. In these instances, teachers' statements suggested that a child's behavior had a causal relationship to what was represented in the written work. For example, in response to the question, "What stood out to you in the child's work?" Teacher 2 stated, "I could not understand why they chose to draw so many lines. They were on the right track, but struggles with attention and gets side-tracked easily and probably started to draw a lot of elaborate lines and arrows." A closer look at the child's strategy indicated the lines and arrows were used to purposefully denote passing out to the sharers. Teacher 2 attributed the details in the child's representation to his difficulty focusing on the problem. Only two teachers used the behavior frame, but this frame was included because it speaks to ways others have found that teachers categorize students (Horn, 2007).

Mathematical Performance Comparison Frames

Past performance, class performance, broader scope. This second category included three frames that highlighted the mathematical performance of the individual child in comparison to that individual child, the class, or curricular goals. Teachers discussed the child's work in a descriptive or evaluative manner regarding its consistency with the teacher's knowledge and experiences from previous involvement with that specific child, children in the classroom, research, curriculum, etc. In the *past performance* frame, teachers highlighted how the child's performance on the problem compared with prior work from that child and often mentioned typical strategies used by the child or his or her progress over time. For instance, in a description of a child who solved the problem using a valid strategy but had an incorrect answer, Teacher 3 said, "They drew two rectangles and split each into 6 pieces, but no answer was written. I was surprised because yesterday, they had an invalid strategy. They might know more than I thought." These statements indicated the teacher originally expected the child to solve the problem using an invalid strategy based on their work on the previous day. The teacher was surprised the child used a valid strategy and acknowledged a potential underestimation of the child's understandings. The *past performance* frame was widely used by 60% of the teachers.

Related to the *past performance* frame was the *class performance* frame in which teachers highlighted how this child's performance on the problem compared with the performance of the rest of the class on this problem or previous similar problems. For example, when probed about a child's understandings for a problem about 20 cookies being shared by 8 friends, Teacher 4 stated "They understand that if there are 20 [items], you have 2 groups of 8 with a remainder of 4. They did the division in their head, while everyone else first passed out wholes individually. In some ways, they are more advanced than the others." This statement shows the teacher's comparison of the child's strategy and level of understanding to the majority of the class. Teachers also used the *class performance* frame as a way to consider how the child might offer support to others in the class or for others to help the child in their thinking and was also widely used by 67% of the teachers.

The third frame in the mathematical performance comparison category, the *broader scope* frame, drew on teachers' expectations from goals that were beyond the performance of the specific children in the teachers' class. In this frame, teachers highlighted how a child's performance on this problem compared with the broader curricular or testing goals for the grade level. Teacher 5 provided an example of the *broader scope* frame when asked to share next steps for the selected child: "I want [the class] to start notating their thinking more since on their [state standardized test] they have to write out everything. They cannot draw to show their work." Here, the teacher framed her analysis to focus on the use of notation for the child and the entire class based on their knowledge of testing expectations. The *broader scope* frame was used by 29% of the teachers.

Table 1: Frames Used to Discuss Teachers' Own Student's Written Work

	Written Work Frames	Definition	No. (%) of teachers using frame *N = 42*
Non-Mathematical	Confidence	Teacher highlights a child's confidence related to his or her problem-solving performance	10 (24%)
	Behavior	Teacher highlights a child's behavior related to his or her problem-solving performance	2 (5%)
Mathematical Performance Comparison	Past Performance	Teacher highlights how a child's performance on this problem compares with prior work from this ***child***	25 (60%)
	Class Performance	Teacher highlights how a child's performance on this problem compares with the performance of the rest of the ***class***	28 (67%)
	Broader Scope	Teacher highlights how a child's performance on this problem compares with the ***broader curriculum goals*** or testing for the grade level	12 (29%)

Extended Example of Frames in Use

When teachers talked about their written work, they often used multiple frames or the same frames multiple times throughout the conversation. The following example shows the use of various frames in a conversation with Ms. Young and written work from Jordan (pseudonyms were used). Ms. Young posed the following problem to the class: *10 friends want to share 19 brownies equally. How much brownie will each friend get?* Jordan solved the problem by drawing 19 rectangles to represent the brownies. She numbered the first ten brownies to give each friend one brownie. Jordan then split the next five brownies into halves and gave 1/2 to each friend. Finally, Jordan split the remaining four brownies into fifths and gave each person 1/5 from every two brownies, totaling 2/5. Jordan combined 1, 1/2, and 2/5 incorrectly and wrote 1 7/10 as her final answer.

Interviewer: What stood out to you about Jordan's work?

Ms. Young: Jordan's answer did not match her work. It's okay, but she is just not confident in her work. That is why she added them altogether. However, the rest of the class did what I expected them to do. Most of the class broke up the brownies into tenths, like I expected. Jordan did not do what I expected her to do.

Ms. Young was surprised that Jordan responded to the problem incorrectly despite having a valid strategy. Ms. Young used the *confidence frame* as a rationale for Jordan's mistake of adding the fraction pieces incorrectly. According to Ms. Young, Jordan's overall lack of confidence in her work was the reason for adding incorrectly. Ms. Young compared Jordan's difference in partitioning to the class, using the *class performance* frame. Ms. Young expected most of the class including Jordan to solve the problem by partitioning based on the number of sharers (10) and Jordan did not partition as anticipated, which was a reason her work stood out.

Later in the conversation, Ms. Young used the *past performance* frame to discuss Jordan's understandings:

Interviewer: Based on Jordan's work, what do you think she understands?
*Ms. Young***:** I think she can be flexible with her fractions. It's just interesting that she broke it up into halves first and then fifths. Usually, she does division and writes out the answer (without drawing a picture), so I don't know why she ended up drawing a picture today.

Ms. Young expected Jordan to solve the problem with a more advanced strategy than using a picture because according to Ms. Young, Jordan typically partitioned mentally and used symbols. Additionally, Jordan typically solved the problem by partitioning based on the number of sharers, but for this problem used halves and fifths. Jordan's variation in partitioning demonstrated flexibility with fractions for Ms. Young. In sum, Ms. Young's interview reflected a use of multiple frames to position her thinking about written work produced by a single child.

Discussion

This study investigated considerations drawn upon by elementary school teachers who examined written work from their classrooms. Findings suggest that teachers used their insider knowledge to think about the specific moment, past experiences, and their vision for the individual child and the class. The broad category of frames, non-mathematical and mathematical performance comparisons highlights topics that are typically overlooked or not foregrounded in the design of PD.

It is important to note that all teachers in this study used a *children's thinking* frame in their engagement with written work, but also included additional frames. The five frames identified suggest teachers often acknowledged an individual child's learning while considering the learning of others in the classroom (Webel & Platt, 2015). The use of multiple frames provided insight into how teachers coordinated what was shared in PD along with many other ideas of how to support student learning.

Table 1 summarized each of the frames found in the teachers' conversations and indicated some frames were used more by teachers than others. Overwhelmingly, teachers used more frames in the mathematical performance comparison category. This finding was not surprising given the task occurred during teachers' math lessons and the design of the PD was focused on children's mathematical thinking. It was somewhat surprising that the *past performance* frame was used as frequently as the *class performance* frame given the task was centered on the discussion of an individual child's work. The *past performance* and *class performance* frames were used by 60% and 67% of the teachers, respectively.

Conclusion

A closer look into the use of *frames* highlighted ways a single piece of written work came in and out of focus in teachers' discussion. Sometimes teachers only attended to aspects within the child's written work. Other times, teachers demonstrated an ability to maintain focus on the individual child's written work while comparing that work to others in the class or the class as a whole. Additionally, teachers exhibited foresight by thinking beyond the work of the individual child or the entire class to consider other curricular expectations. The different ways teachers attended to the child's written work linked to certain frames but highlighted another important feature to consider. These findings suggest the need for PD to afford opportunities for teachers to think about the complexity of honoring the individual child's thinking while keeping in mind thinking of the entire class and the connection to broader curriculum goals.

In PD, teachers are provided with a *children's thinking* frame that shapes their interaction with artifacts of practice (e.g., written work). In this study, teachers used the *children's thinking* frame but also other frames when engaging with written work. As the analysis of written work continues as a widespread practice in PD, those who design PD should consider how the use of frames–beyond those shared in PD–shapes teachers' engagement. Teachers in this study grappled with considering goals related to individual child, the class, and curricular expectations. The identification of the five frames used in teachers' conversations of written work can provide professional developers with ways to address contextual aspects of teaching. Further research is needed to understand the interplay of multiple frames and the overall nature of teachers' engagement with written work in the context of PD and in the classroom.

An important decision that professional development (PD) facilitators must make when preparing for activities with teachers is to select an appropriate tool for the intended learning goals of the PD (Sztajn, Borko, & Smith, 2017). One important and prevalent tool is artifacts of student thinking (e.g. Jacobs & Philipp, 2004). In this paper we add to the literature on artifact selection for professional development by discussing the affordances and constraints of different written artifacts of student thinking. Through a professional noticing assessment, we examine the interpretive frames (Sherin & Russ, 2014) that were invoked by 72 secondary teachers regarding 6 students' written strategies to proportional reasoning tasks. We characterize different ways teachers might make sense of different artifacts of student thinking, and discuss for what purposes PD facilitators might select particular written solutions.

Keywords: Written Artifacts of Student Thinking, Secondary Teachers, Interpretive Frames, Professional Development

In their review of research about professional development (PD) of mathematics teachers, Sztajn, Borko, and Smith (2017) found two striking similarities across the programs illustrated in the research. First, there was a similar vision for effective mathematics teaching across the programs, namely that teaching should include facilitation of interactions among students as they engage in rich mathematical tasks, that teachers should elicit and use students' emerging ideas to reach a mathematical goal, and that an overarching goal should be advancing understanding for all students. Second, the PDs were structured in similar ways; leaders *actively engaged* teachers in activities (as opposed to lecturing) about mathematics content and the teaching and learning of said content, and programs spanned many months and included many hours of work. Additionally, many PD programs focus on students' mathematical ideas as a way to support teacher learning, through the use of video artifacts (e.g. Sherin & van Es, 2005) or written artifacts (e.g. Jacobs & Philipp, 2004; Kazemi & Franke, 2004). Herein, we focus on written student work, given its prominent use in PD and its accessibility for teachers. To support PD leaders, we investigate the affordances and constraints of different features of written student work and how they might influence what teachers notice.

There are many ways teachers might interact with written student work. For example, National School Reform Faculty (2014) has over 200 different protocols that teachers and PD leaders can use to engage with students' written work, each supporting different discussions about a variety of pedagogical topics. However, little is known about *which* strategies teachers might be interested in analyzing and discussing (for selection criteria for videos of student thinking, see Sherin, Linsenmeier, & van Es, 2009). Hence, we investigated teachers' perceptions of six different written solution strategies, with the aim of informing future PD leaders as they select particular strategies to engage their teachers.

Conceptual Framework

In order to understand teachers' perceptions of the different artifacts, we draw upon the construct of *interpretive frames* (Sherin & Russ, 2014). Sherin and Russ defined interpretive frames as "structures that describe the ways in which a teacher's selective attention both grows out of and informs a teacher's knowledge-based reasoning, and vice-versa" (p. 3). In particular, what teachers notice is both contextual and interdependent. That is, what teachers notice depends on what they noticed previously, and is influenced by their beliefs, values, and/or knowledge. Teachers actively (yet tacitly) create particular frames through which they view their surroundings in order to make sense of their surroundings.

In their chapter, Sherin and Russ (2014) identified 13 different types of interpretive frames that teachers' created while making sense of videos of classroom lessons. Consider the following examples. In a video of a student loudly tapping their pen on a desk, a teacher viewing the event through an *evaluative* frame might claim the student is off task, and must be a bad student. Alternatively, a teacher viewing the event through an *affective* frame might express an emotional reaction to the event, and talk about how pen tapping irritates him/her. As another example, a teacher viewing the event through a *principle* frame might see the pen tapping as evidence the student is off-task, and describe this instance by citing a principle such as "students tend to act disruptively when they don't have access to the task." Importantly, each frame supported a different *way* of noticing the event, and teachers' perceptions of the event provide evidence of the creation of particular frames. In this study we focus on investigating two types of frames teachers create: *narrative* frames and *personal* frames. Narrative frames refer to when teachers simply describe what they notice, which may or may not include identifying causal relations. Personal frames refer to when teachers experience a personal connection to what they notice, which may include emotional reactions to what they notice, or desires to interact with the student/strategy in some way. We focus on these two frames because we believe they have much potential to influence the depth at which teachers engage with students' ideas.

Methods

To understand how different pieces of written student work influence what teachers notice, 72 practicing and prospective secondary teachers completed a survey. In the survey teachers responded to prompts about six different strategies for solving two proportional reasoning tasks. We then analyzed teachers' responses by identifying *when* teachers created particular interpretive frames, and *for which strategies* teachers created these frames (Sherin & Russ, 2014). In the next four sections we describe the participants, survey, strategies, and our analysis.

Participants

The secondary teachers in this study come from two teacher populations in the southwestern United States. First, 30 prospective secondary mathematics teachers were recruited from a large urban university. All intended to become secondary teachers, and none had begun the post-baccalaureate credential program offered at that university, nor student teaching. Second, 42 experienced practicing teachers (grades 6 - 12) were recruited from the southwestern region of the United States. All teachers had at least 4 years of experience teaching, and an average of 13.1 years of teaching experience.

We recognize that there are important differences among the two teacher groups that may influence what the teachers notice; however, parsing out these differences is beyond the scope of this paper. Our purpose in this paper is to investigate and discuss some of the ways different artifacts of student thinking pique secondary teachers' curiosity. For that reason, in the rest of the paper the term "teacher" will refer to both prospective and practicing teachers.

Survey

The survey consisted of three parts. In part 1, teachers first solved a missing-value proportional reasoning task, and then considered three student's written strategies for solving that task (see table 1). Next, teachers responded to three professional noticing prompts about the

Table 1: Tasks, Students, Strategies, and Descriptions

Student	Strategy	Our Description of the Strategy
	Task: Each day, 6 mice eat 18 food pellets. How many food pellets do 24 mice eat?	
A	$6\overline{)18}$ 3 24 × 3 62 food pellets	Student divides 18 pellets by 6 to find a unit rate of 3 pellets per mouse. Student multiplies unit rate by 24 mice. Student makes a mistake when multiplying 24x3.
B	$\frac{18}{6} = \frac{x}{24}$ $\frac{432}{6} = \frac{6x}{6}$ $\boxed{72 = x}$	Student uses the traditional cross-multiplication strategy, setting up pellets on top and mice on bottom of the fraction. Student manipulates equation correctly.
C	24 ÷ 6 = 4 18 × 4 = 72	Student divides 24 mice by 6 mice to find the number of groups of 6 mice in 24. There are 4 groups of 6 mice, so there should be 4 groups of 18 pellets.
	Task: Each day, 8 caterpillars eat 12 leaves. How many leaves do 20 caterpillars eat?	
D	8÷12=1½ 8÷8=1 12−8=4=½ of 8 1½×20=X 30 leaves 1×20=20 20×1=20 20/2=10 20+10=30	Student divides 12 leaves by 8 caterpillars (mistakenly writes 8 divided by 12), to find each caterpillar eats 1.5 leaves. The student divides in a non-standard way. The student then multiplies 1.5 leaves x 20 caterpillars, using the distributive property to help with the multiplication.
E	8 caterpillars × 3 = 24 caterpillars 12 × 3 = 36 leaves 36 − 4 = 32 24 − 4 = 20 Caterpillars | leaves 20 — 32	Student multiplies both 8 caterpillars and 12 leaves by 3, apparently scaling up the ratio to 24 caterpillars and 36 leaves. The student subtracts 4 from both quantities to obtain the 20 caterpillars, and arrives at 32 leaves. This last part exhibits additive reasoning, and is not correct.
F	8×3= 24 24 − 4 = 20 12÷2=6 12×3= 36 −6 30 30 leves	Student multiplies 8 caterpillars by 3 to get 24 caterpillars, then subtracts 4 to get 20 caterpillars. Student likely recognized that 4 caterpillars is half of 8 caterpillars, because next the student finds half of 12 leaves (6 leaves). The student then multiplies 12 leaves by 3, and subtracts a "half group of leaves" from 36 to get 30 leaves

students' mathematical thinking (Jacobs, Lamb, & Philipp, 2010). Part 2 was similar to part 1, except with a different task and with different strategies (table 1). In this paper, we discuss responses to the first two prompts: (a) Describe in detail what these students did in response to the task, and (b) What did you learn about these students' mathematical understandings? Hence,

we collected data on both what the teachers attended to and interpreted in the students' strategies, and consequently the narrative frames teachers created with respect to the strategies.
In the third part of the survey, teachers revisited all six of the strategies they had previously considered, and responded to four prompts. In this paper, we discuss the analysis of the first two prompts: (a) Is there a student you would like to talk to further? If yes, which student would you like to talk to further, and why? (b) Would you be interested in discussing a particular solution with other teachers? If yes, which solution would you discuss with other teachers, and why? Hence, we collected data on whether teachers wanted to interact with a specific student or strategy, and consequently the personal frames teachers created with respect to the strategies.

Written Artifacts of Student Thinking

The mathematical tasks and written artifacts can be seen in Table 1. To differentiate among the strategies, we focus on 6 characteristics: (a) strategy type, (b) integer/non-integer ratios, (c) exhibits non-standard calculation strategies, (d) conceptually correct/incorrect, (e) correct/incorrect calculations, and (f) work includes all steps/work or is missing steps. For strategy type, we identified what type of strategy the student used according to the literature on proportional reasoning (Carney et al., 2015; Lobato & Ellis, 2010). Strategies A and D employ a unit rate strategy, in which the student finds how many pellets (or leaves) one mouse (or caterpillar) eats, and then multiplies this number by the new number of mice (or caterpillars). Strategy B employs a cross-multiplication strategy, which provides little evidence of the degree to which the student has a conceptual understanding of proportions (Cramer, Post, & Currier, 1993). Strategies C, E, and F employ different scaling strategies, where the student scales up the original ratio (strategy C), scales up and adds equal amounts (strategy E), or scales up and adds proportional amounts (strategy F).

For integer ratios, we identify whether the student used a scalar or unit rate multiplicative relationship (Carney et al., 2015), and whether that relationship was an integer ratio or non-integer ratio (Tourniaire & Pulos, 1985). For strategies A and C, the scalar and functional multiplicative relationships are integer ratios, and for strategies D and F they are non-integer ratios. We did not include strategies B or E, because strategy B does not use either the scalar or unit rate multiplicative relationship when solving, and strategy E includes additive reasoning. For the other four categories, we simply looked for whether there was evidence the strategy exhibited that characteristic or not. For example, strategy D exhibits non-standard calculations, while the others do not. Table 2 summarizes the characteristics we identified for each strategy.

Table 2: Characteristics of Strategies

Student	Strategy Type	Integer Ratios?	Correct Calc's?	Standard Calc's?	Correct Concept?	All Steps?
A	Unit Rate	Yes	No	Yes	Yes	Yes
B	Cross-Multiplication		Yes	Yes		Yes
C	Scale Up	Yes	Yes	Yes	Yes	Yes
D	Unit Rate	No	No	No	Yes	Yes
E	Scale Up w/ Adding Equal Parts		Yes	Yes	No	Yes
F	Scale Up w/ Adding Prop. Parts	No	Yes	Yes	Yes	No

Analysis

Analysis was conducted by the first author. In parts 1 and 2, teachers described the students' strategies and understandings. Hence, all teachers created narrative frames in some form as they noticed the student's work and described what the student did. Consequently, the first author focused solely on whether the teacher's description got the gist of the strategy, or the key underlying reasoning of the strategy. Examples include descriptions similar to our own, or descriptions of the strategy we identified (e.g. "Student A found the unit rate and solved for 24 mice"). Non-examples include identifying a strategy other than the one we identified, claiming the student was confused when evidence existed that the student was not, or admitting confusion about what the student did (e.g. "I have no idea what this student did"). More than 20% of the data was double coded by another researcher, and interrater reliability was 87%.

In part 3, teachers had a choice of talking or not talking to/about a student. However, it turned out that 100% of the teachers chose to talk to/about at least one student. The first author coded for *which* student a teacher selected, and *what* they wanted to talk about. Responses fell into four categories: (a) learn more about the strategy, (b) help the student, (c) share the strategy with the class or with other teachers, or (d) discuss other mathematical topics. More than 20% of the data was double coded by another researcher, and interrater reliability was 91%.

Finally, the first author also looked for instances when teachers spontaneously expressed excitement toward a strategy (e.g. "Love it," "This student is a genius," "Student F is my favorite"), which we took as evidence that the teacher created a personal connection with the strategy (i.e. a personal frame). Even though we did not actively seek to collect data on teachers' emotions, 24% of the teachers spontaneously expressed excitement for at least one strategy at some point in the survey. More than 20% of the data was double coded by another researcher, and interrater reliability was 93%.

Results

For narrative frames, we counted instances when the teacher's response captured the gist of the strategy. Percentages of teachers that that captured the gist of the strategy can be seen in Table 3. Almost every teacher captured the gist of strategy B, which was the cross-multiplication strategy. Comparing the correct unit rate strategies (i.e. A & D) with the correct scaling strategies (i.e. C & F), we see that the scaling strategies were more challenging for teachers to capture the gist of the strategy. Additionally, within these four conceptually correct strategies, it appears the non-integer ratio strategies (i.e. D & F) were more challenging than the integer ratio strategies (A & C), respectively, but only marginally more challenging than their counterparts. Strategy E, which included additive reasoning, was more challenging than the unit rate and cross multiplication strategies, but less challenging than the other two scalar strategies. For personal frames, we counted instances when a teacher wanted to talk to/about a particular student, and then categorized responses based on what they wanted to talk about. We also looked for evidence that a teacher enjoyed a particular strategy. Percentages can be seen in Table 3. When considering the conceptually correct scalar and unit rate strategies (i.e. A, C, D,

Table 3: Percentages of teachers capturing gist, wanting to talk to/about a student, and expressing emotion

N = 72	A	B	C	D	E	F
% of teachers that captured gist of the strategy	89%	97%	63%	83%	69%	57%
% of teachers who want to talk to/about a student	8%	15%	25%	33%	60%	75%
% of teachers expressing excitement	0%	3%	3%	11%	4%	18%

& F), scalar strategies elicited more teachers wanting to talk to/about the student than the unit rate strategies, and the strategies with non-integer ratios were more intriguing to the teachers than the integer-ratio strategies. Strategy F (which was the most challenging, included non-integer ratios, used a scaling up strategy, and appeared to not show all steps) elicited the largest percentage of teachers wanting to talk to/about the student, as well the largest percentage of teachers expressing excitement. Strategy E, which had the conceptual error, elicited the second highest percentage of teachers wanting to talk to/about the student. Strategy D, which had the non-standard algorithms, elicited the second highest percentage of teachers expressing excitement. Looking at what excited the teachers for strategy D, ¾ of the teachers who expressed excitement specifically mentioned the non-standard algorithms.

The percentages of which students teachers wanted to talk to/about and why can be seen in table 4[1]. Notice that almost half of the teachers wanted to learn more about strategy F, which supports the notion that strategy F was the most challenging and intriguing to teachers. Strategy F also elicited the highest percentage of teachers who wanted to share the strategy, either with their class or with other teachers.

Looking at strategy E, which had the conceptual error, we see that this strategy elicited the highest percentage of teachers (38%) wanting to help the student. In contrast, less than 10% of the teachers wanted to help students A and D (respectively), who exhibited calculational errors in their work. (The teachers who wanted to help students C and F assumed they were confused.)

When considering the conceptually correct scalar and unit rate strategies (i.e. A, C, D, & F), we see two more pieces of evidence that scalar strategies and strategies with non-integer ratios are more interesting than their counter-parts. First, more teachers wanted to learn about scalar strategies than unit-rate strategies, and more teachers wanted to learn more about the strategies with non-integer ratios than the strategies with integer ratios. Second, more teachers wanted to share the scalar strategies with others than the unit rate strategies, and more teachers wanted to share the strategies with non-integer ratios than the strategies with integer ratios. When sharing strategies, teachers often either expressed excitement for the strategy, or valued the different ways of thinking exhibited in the work.

Finally, teachers wanted to discuss a variety of other things with their peers. This included learning about some new mathematics, anticipating other solutions, discussing the importance of multiple solutions, discussing pedagogical strategies for teaching proportional reasoning, and assessment strategies. Notice that the cross multiplication strategy had a large number of teachers wanting to discuss other mathematical ideas. All of these teachers wanted to discuss whether the cross-multiplication strategy exhibited a high level of understanding, or not. This

Table 4: Percentages of teachers wanting to talk to/about a student and why

N = 72	A	B	C	D	E	F
Want to learn about strategy	3%	4%	14%	18%	22%	46%
Want to help student	4%	1%	4%	6%	38%	8%
Want to share strategy		4%	7%	4%	6%	18%
Want to discuss other topics	1%	6%	1%	7%	1%	8%
Total wanting to talk to/about student	8%	15%	25%	33%	60%	75%

means that not only did these teachers recognize that this student might have used a memorized procedure, but they were also interested in discussing such implications with other teachers.

[1] In table 4, the columns do not sum to the totals because some teachers created multiple different personal connections for the same student. Additionally, the totals do not sum to 100% because some teachers chose to talk to/about multiple students.

Discussion

To summarize, we found that some strategies elicited teachers' desire for discussions more often than others, albeit for different reasons and in different ways. In this section we discuss the strategies and the interpretive frames teachers created, and for what purposes PD leaders might select particular strategies.

Strategy F was clearly the most exciting, interesting, and challenging for teachers. We conjecture that this strategy was difficult and interesting for four reasons. First, the scalar strategy type appears to be less familiar to teachers than the unit rate or cross multiplication strategy. Second, the non-integer ratios afforded certain complexities that would not have been available in a task structure with integer ratios. In particular, this student has to both iterate and partition the ratio, and then subtract a partitioned ratio from the larger ratio (Lobato & Ellis, 2010). In strategy C, the student need only multiply the 18 pellets by a whole number; there is no need to partition the original ratio. Third, the missing step was a challenging step for many teachers to notice, but also an important part of the strategy. Finally, the computations are all quite simple at first glance. We wonder if the simple computations created a slight misdirection in teachers' expectations as they considered the student's strategy. Perhaps the excitement teachers expressed arose from prevailing in understanding a challenging strategy.

Student E was also often chosen by teachers, but for different reasons than for student F. Many of those who wanted to talk to/about student E wanted to help student E fix the error, or develop a stronger understanding. Contrasting this with the other two strategies that exhibited errors, strategy A and strategy D, we see that the conceptual error in strategy E was more interesting to teachers than the calculational errors in strategies A and D. Hence, it appears conceptual errors intrigue teachers more than calculational errors.

Strategies D and F elicited the most excitement from teachers. For strategy D, ¾ of the teachers who exhibited excitement specifically cited the non-standard division and/or multiplication algorithms as exciting. Strategy F appeared to be exciting in general. Considering the two strategies, we highlight four similarities that may have supported such excitement. In particular, strategy F and the non-standard algorithms of strategy D were correct, based on underlying concepts, complex, and unfamiliar to teachers. We conjecture that other strategies with these qualities may also elicit excitement from teachers.

Another idea that emerged from the data was that 6% of the teachers wanted to discuss the underlying mathematics of strategy B, and whether it counted as a deep conceptual understanding or not. It appears that these teachers recognized that the student might have been following a memorized procedure, and wanted to discuss with other teachers what this might mean with respect to learning and teaching. We believe that conversations like the one these teachers wanted to have could be productive for teachers. Perhaps other more traditional strategies, when surrounded by non-standard or conceptually-based strategies, could spark conversations among teachers about the underlying mathematics.

In their study of video artifacts of student thinking, Sherin, et al. (2009) rated videos based on three particular characteristics, and looked for which types of videos supported conversations among teachers. They concluded that there wasn't a particular characteristic that was more important than others, but rather certain combinations of characteristics supported better discussions. Our results seem to support this idea, that no single characteristic makes a solution interesting, but rather a combination of characteristics.

Earlier we mentioned that we recognized there were important differences between the two teacher groups from which we collected our data. In our analysis we noticed that there were indeed differences among the teacher groups. For example, the four teachers who wanted to discuss whether the cross multiplication strategy exhibited a deep conceptual understanding were all practicing teachers. In contrast, the two teachers who wanted to show off the cross multiplication strategy (because they valued the strategy) to other teachers were prospective teachers. However, due to the scope of this paper we did not aim to parse out these differences, and instead focused on investigating what interpretive frames our teachers invoked and how they were invoked across the different strategies. In future work we will disaggregate our data and investigate differences in interpretive frames among the teacher groups.

We end by emphasizing that different artifacts serve different purposes. Each strategy seemed to have its own unique set of challenges, and teachers wanted to respond to different ideas based on the different strategies. In our work we only looked at 6 different strategies and the qualities associated with these strategies, and aggregated data from a diverse group of secondary teachers. We wonder what other kinds of strategies researchers might consider, what other combinations of qualities might pique teachers' interest, and how teachers' interests differ across different populations of teachers.

PROFESSIONAL DEVELOPMENT AND KNOWLEDGE GAINS FOR HIGH SCHOOL MATHEMATICS TEACHERS

Kristi Martin
North Carolina State University
kmartin8@ncsu.edu

This study examined the effects of the Local Systemic Change Through Teacher Enhancement Initiative (LSC) on 1,596 in-service high school mathematics teachers' knowledge. Because data are clustered by schools, a hierarchical linear model was calculated. It was found that five of the characteristics of the professional development, time to reflect, support to implement, hours attended, assistance to implement from LSC, and participation in message boards, had statistically significant effects on increasing teacher knowledge, but time to work with other teachers, race, educational background, and years taught did not have a statistically significant effect.

Keywords: High School Education, Teacher Knowledge

Introduction

There are many different ideas about what makes professional development effective, but there is some agreement on what key features are important (Borko, 2004; Darling-Hammond, Wei, Andree, Richardson, & Orphanos, 2009; Desimone, 2009; Garet, Porter, Desimone, Birman, & Yoon, 2001; Heck, Banilower, Weiss, & Rosenberg, 2008). Desimone (2009) argues for her Core Conceptual Framework with five key features of professional development that are content focus, active learning, coherence, duration, and collective participation, and that these key features lead to an increase in teacher knowledge. In the Eisenhower professional development programs, Garet et al. (2001) found that focus on content knowledge, active learning, and coherence were all statistically significant predictors of enhanced knowledge and skills when controlling for sponsor, traditional or reform, span, and contact hours.

Between 1997 and 2006, the National Science Foundation funded 86 professional development projects, 48 of which were for math teachers, across the country through the Local Systemic Change Through Teacher Enhancement Initiative (LSC) (Heck et al., 2008). According to Heck et al. (2008), the main goals of the LSC projects were to include all teachers in targeted schools with a minimum of 130 hours of professional development and to implement LSC-designed curriculum materials in the teachers' classrooms. The individual projects were designed to include key features of effective professional development, but the main focus was to increase teachers' content knowledge, pedagogical content knowledge, and the use of investigative pedagogical strategies (Heck et al., 2008). To assess these outcomes, teachers were expected to complete a questionnaire at the end of a year of participation in the LSC project (Heck et al., 2008).

Research Question

What factors of an LSC professional development for high school math teachers predict perceived increase in knowledge by the teacher?

Method

Data

The data was collected from the National Science Foundation's Local Systemic Change through Teacher Enhancement Initiative (LSC). This project offered professional development for K-8 and 6-12 teachers in mathematics and science over the school years 1996-97 to 2005-06 (Banilower, Heck, & Weiss, 2007; Heck et al., 2008). Each year of the project, principals and teachers were required to complete a Principal Questionnaire or Teacher Questionnaire, with a response rate of 80% expected for the teachers and 90% expected for the principals (Heck et al., 2008). Several of the questions in the questionnaires changed in the initial two years, but the questions stabilized by the third year (Heck et al., 2008). For questions that were changed, data from later questionnaires were both recoded to the original scale and included in the new scale with missing values for the original questionnaires. The data set is available by request from Horizon Research.

Participants

The full data set included over 80,000 participants' responses to the four teacher questionnaires, K-8 math, 6-12 math, K-8 science, and 6-12 science, but the data were filtered to focus just on the 9-12 math teachers which left 3,064 of the full data set. Removing any participants who were missing data for the variables of interest left 1,596 teachers in the sample data to be analyzed.

The participants are all 9-12 mathematics teachers who took part in LSC professional development. The participants are split almost evenly between males (45%) and females (55%). The participants are primarily white (80%), with other races under 10% (black). For educational background, the majority had an undergraduate major in mathematics or mathematics education (60%) and certification to teach (60%). Additionally, a large percentage held a graduate degree in mathematics or mathematics education (38%). On average, the participants had 12.30 years of teaching experience.

Table 1: Descriptive Statistics of Teacher Control Variables by Sample and Original Data

	Sample Data						Original Data				
	M	SD	Min	Max	N		M	SD	Min	Max	N
Male	.43	.50	0	1	1,596		.45	.50	0	1	3,023
Hispanic	.03	.17	0	1	1,596		.03	.18	0	1	3,064
Indian	.01	.11	0	1	1,596		.01	.11	0	1	3,064
Asian	.02	.15	0	1	1,596		.03	.17	0	1	3,064
Black	.09	.29	0	1	1,596		.10	.31	0	1	3,064
Pacific Islander	.00	.04	0	1	1,596		.00	.03	0	1	3,064
White	.83	.37	0	1	1,596		.80	.40	0	1	3,064
No Race Indicated	.02	.14	0	1	1,596		.03	.17	0	1	3,064
Undergraduate Major	.61	.49	0	1	1,596		.60	.49	0	1	3,020
Undergraduate Minor	.10	.30	0	1	1,596		.10	.30	0	1	3,020
Graduate Major or Minor	.38	.49	0	1	1,596		.38	.49	0	1	3,020
Teaching Certificate	.63	.48	0	1	1,596		.60	.49	0	1	3,020
None of the Above Education	.07	.26	0	1	1,596		.08	.27	0	1	3,020
Years Taught	11.86	7.67	1	21	1,596		12.30	7.79	1	21	3,038

Note. $N = 3{,}064$ for the original data and $N = 1{,}596$ for the sample data. Years taught is on a scale of 1 to 21+ years, with the maximum coded as 21. For all other variables, 0 indicates "no" and 1 indicates "yes."

For the original data set, the data are nested within 19 professional development projects with a range of 1 to 400 participants in each project. There mean number of teachers per project is 161.26 with a standard deviation of 117.94. For the sample data, the data are nested within 18 professional development projects with a range of 3 to 223 participants in each project. There are a mean number of 88.67 teachers per project with a standard deviation of 61.74.

Table 2: Descriptive Statistics by Project ID by Sample and Original Data

	Sample Data			Original Data	
Project ID	Count	Percent		Count	Percent
04	56	3.51		98	3.20
09	77	4.82		153	4.99
10	93	5.83		188	6.14
18	223	13.97		400	13.05
19	13	.81		16	.52
28	0	.00		1	.03
31	51	3.20		124	4.05
36	98	6.14		195	6.36

73	4	.25		11	.36
74	120	7.52		219	7.15
78	28	1.75		58	1.89

Note. $N = 3{,}064$ for the original data and $N = 1{,}596$ for the sample data.

Measures

The control teacher variables come primarily from the teacher questionnaire. The variables for gender and race are dummy variables created from participants choosing one of a list of choices, as seen in Table 1. Participants also chose from a list of educational backgrounds, but were allowed to choose all choices that applied to them, as seen in Table 1. For years taught, participants chose from a list with ranges of years taught (0-2, 3-5, 6-10, 11-15, 16-20, 21-25, 26 or more). These were initially coded as dummy variables, but were operationalized as the mean of each range to turn them into more meaningful continuous variables.

Most of the covariate measures also come directly from the teacher questionnaire. These include the amount of time to work with other teachers during the professional development, time to reflect during professional development, and support to implement what was learned in the professional development. All three of these variables came directly from the questionnaire, with a rank of 1 to 5, with 1 labeled as "Not at all" and 5 labeled as "To a great extent." The number of hours of professional development attended was listed in 11 categories on the questionnaire (0, 1-9, 10-19, 20-39, 40-59, 60-79, 80-99, 100-129, 130-159, 160-199, and 200 or greater). These were initially coded as dummy variables from 1 to 11, but were operationalized as the mean of each range to change them into continuous variables with more meaning in the context of the research question.

The final three professional development variables, assistance to implement the professional development from LSC, participation in the LSC message boards, and increase in knowledge from professional development, are each means of multiple questions from the questionnaire. All of the original questions for these measures are on the same scale as the number of times participants did each activity (0, 1-2, 3-4, 5-6, and 7 or more). Assistance to implement the professional development is the average of four sources of assistance, coaching by LSC staff based on observations, LSC teacher leaders, LSC district staff, or LSC mathematicians or mathematics educators, with $\alpha = .7247$ with all four measures included. Participation with message boards was the average of three sources of participation, reading messages, posting messages, and discussion groups, but the $\alpha = .5107$ with all three sources and $\alpha = .6440$ with just reading messages and posting messages. Thus, participation is only the average of the two sources that leave the highest α, reading and posting on message boards. Perceived increase in knowledge was initially the average of three sources of knowledge, mathematics content knowledge, understanding of how children think/learn about mathematics, and ability to implement high-quality mathematics instructional materials, with $\alpha = .8887$. However, $\alpha = .8907$ by removing mathematics content knowledge, so perceived increase in knowledge is just the average of the two measures of teaching knowledge.

Table 3: Descriptive Statistics of Professional Development Variables by Sample and Original Data

	Sample Data						Original Data				
	M	SD	Min	Max	N		M	SD	Min	Max	N
Amount of time to work with other teachers	2.84	1.23	1	5	1,596		2.81	1.22	1	5	1,962
Level of time to reflect	2.76	1.19	1	5	1,596		2.73	1.18	1	5	1,957
Level of support to implement what was learned	3.42	1.15	1	5	1,596		3.39	1.15	1	5	1,952
Hours attended	93.78	67.04	5	200	1,596		62.07	69.32	0	200	2,843
Level of assistance to implement from LSC	1.43	1.62	0	7	1,596		1.40	1.60	0	7	1,908
Amount of participation in message boards	1.25	1.40	1	6	1,596		1.25	1.40	0	7	1,919
Perceived increase in knowledge	3.32	1.09	1	5	1,596		3.32	1.10	1	5	1,941

Note. $N = 3{,}064$ for the original data and $N = 1{,}596$ for the sample data.

Analysis

Given that the original analysis was concerned with how the teachers were able to implement the LSC curriculum materials in their classrooms, the possible covariates and control variables were limited by the data collected in the teacher questionnaire. The covariates used were amount of time to work with other teachers during professional development, level of time to reflect during professional development, level of support to implement what was learned in professional development, hours of professional development attended, level of assistance to implement professional development from LSC, and amount of participation in LSC message boards. Research has shown collective participation (Desimone, 2009; Franke, Carpenter, Levi, & Fennema, 2001; Garet et al., 2001) and duration (Banilower, Heck, & Weiss, 2007; Garet et al., 2001; Heck et al., 2008) are both predictors of teachers' gains in knowledge from professional development. Other research has shown that aid to implement what is learned in professional development is related to teachers' long term use of what was learned in the professional development (Carpenter, Fennema, & Franke, 1996; Fennema et al., 1996; Franke et al., 2001). Participation in online forms of professional development has also been shown to be effective in helping teachers to gain knowledge (Boling & Martin, 2005; Dede, Breit, Ketelhut, McCloskey, & Whitehouse, 2005; Herrington, Herrington, Hoban, & Reid, 2009). The possible teacher control variables were gender, race, educational background, and number of years teaching. All were included, because it is likely that each will have an influence on how teachers view what they have learned from the professional development projects.

Results

The sample data are nested in 18 LSC professional development projects, so a hierarchical linear regression model was calculated. This model produced similar results to the multiple regression model, with the same professional development covariates being statistically significant predictors of perceived increase in knowledge from the professional development. In model 2, these variables include time to reflect on what was learned in the professional development, support to implement what was learned in the professional development, hours of professional development attended, assistance to implement what was learned in the professional development from LSC, and participation in LSC message boards; all were statistically significant at $p < .001$. Unlike the multiple regression however, the only statistically significant teacher control variable was gender ($t(1595) = -6.00$; $p < .001$).

Table 4: Hierarchal Linear Model of Increase in Knowledge on Professional Development Variables and Teacher Control Variables

	Model 1	Model 2
	Perceived increase in knowledge	Perceived increase in knowledge
Time to work with other teachers	.0147	.0101
Time to reflect	.0958***	.1081***

Note. t statistics in parentheses, $*** \; p < .001$, $** \; p < .01$, $* \; p < .05$. Reference group is white for race and no education in mathematics or mathematics education.

Discussion

Both the multiple regression and the hierarchical linear model agree on the factors of the LSC professional development that related to the teachers' perceived increase in knowledge. The number of hours of professional development attended has the greatest standardized coefficient, so it has the greatest impact on the projected increase in knowledge. Specifically, for every one standard deviation increase in number of hours attended by a teacher, there is a projected .2889 standard deviation increase in knowledge. This agrees with the research findings that say that the duration of a professional development is one of its key features (Desimone, 2009; Garet et al., 2001; Heck et al., 2008). Another result that agrees with research is that the support and the assistance to implement the professional development is related to the increase in knowledge. Franke et al. (2001) found that the teachers felt the support of the professional development team was a critical factor in their ability to sustain what they learned in the professional development.

Finally, participation in the message board was also a statistically significant predictor of the teachers' increase in knowledge, which agrees with research that online professional development can help teachers increase their knowledge (Boling & Martin, 2005; Dede et al., 2005; Herrington et al., 2009).

One result that does not agree with research is about the time to work with other teachers. Research shows that collective participation is a key feature of professional development (Desimone, 2009) with a positive relationship to increased knowledge (Garet et al., 2001). However, the multiple regression found working with other teachers to have a negative relationship that was not a statistically significant predictor of increase in knowledge.

Limitations

These results are based on self-reported survey data from the participants about their views on the professional development project and what they learned from the professional development project. However, Desimone (2009) argues that surveys are a reliable data source for behavior-based constructs about frequencies of events, such as teachers' experiences in professional development and experiences implementing the professional development. This data is a mix of behavior-based questions and evaluative questions, so using a survey may not be the most reliable source of data collection. Another limitation is that the teachers are rating their own perceived increase in knowledge, rather than using a pretest and posttest of knowledge to quantify how much teachers learned. This makes it difficult to know how much the teachers actually learned from attending the professional development.

Next Steps

This analysis focused on teacher knowledge, but not on how teacher knowledge affects teaching practices or student achievement. Research has shown that teacher knowledge has an impact on both practice in the classroom and on students' achievement (Ball, Thames, & Phelps, 2008; Hill, Rowan, & Ball, 2005; Kennedy, 1999). Although data is not available about student achievement for the LSC projects, the teacher questionnaire included questions about teaching practice. Thus, a next step would be to analyze whether the change in knowledge predicts teaching practice, as was found in other research on professional development (Desimone, 2009; Garet et al., 2001; Heck et al., 2008).

WHERE'S THE MATH? A STUDY OF COACH-TEACHER TALK DURING MODELING AND CO-TEACHING

Sarah Theule Lubienski
Indiana University
stlubien@iu.edu

Evthokia Stephanie Saclarides
University of Alabama
stephanie.saclarides@gmail.com

This study explores how two instructional coaches enacted modeling and co-teaching cycles with five elementary teachers during mathematics instruction. A content analysis of the coach-teacher talk from 11 planning meetings and 23 lessons reveals that the coaches and teachers seldom engaged in mathematical conversations. Instead, they primarily had low-depth discussions about curriculum, other instructional materials, and assessment. Implications for school districts with instructional coaching models are discussed.

Keywords: Teacher Education-Inservice/Professional Development

Introduction

Recent reforms promote an ambitious vision of high-quality math instruction for all students (Martin & Herrera 2007; NCTM, 2014; Common Core State Standards Initiative, 2011). As this vision represents a significant shift from how many teachers learned and taught math (Hiebert, 1999), enacting this type of instruction requires much support (Ball & Cohen, 1999). To address this challenge, many schools are enlisting the help of instructional coaches, as their intensive, one-on-one support can embody many facets of effective professional development (Desimone & Pak, 2017). Given the significant financial investment coaching requires (Knight, 2012) it is critical that we understand its enactment, including emergent challenges and supports that can make it successful.

Literature and Research Questions

To impact classroom teachers' knowledge and instruction, both *individual* and *group* settings are important places of learning (Campbell & Griffin, 2017; Cobb & Jackson, 2015). However, research on *one-on-one* activities has received relatively little attention (Cobb & Jackson, 2011; Gibbons & Cobb, 2017).

In their conceptual analysis, Gibbons and Cobb (2017) identified two potentially productive coaching activities for individual teachers: *modeling* and *co-teaching*. According to the authors, these activities are potentially productive as they meet the standards of high-quality professional development, and have demonstrated a positive impact on teachers.

Despite the popularity of these two strategies, there is a surprising lack of research describing how modeling and co-teaching can be used effectively with experienced, practicing teachers. Most studies examining modeling and co-teaching have focused on pre-service teachers (Clarke et al., 2014; Scantlebury et al., 2008) or mentoring programs aimed to support novice in-service teachers (Feiman-Nemser, 2001). While a few studies have explored modeling or co-teaching with practicing teachers, they have primarily focused on literacy coaches (Bean et al., 2010; Vanderburg & Stephens, 2010). A small handful of math education studies with school-based coaches have touched on the practices of modeling and co-teaching, although that was not the main focus of their work (Campbell & Griffin, 2017; Ellington et al., 2017).

To address this gap, this study looks in-depth at the modeling and co-teaching cycles enacted by two coaches and five teachers during math instruction. Specifically, the following research question is addressed: What is the nature of coach-teacher talk during modeling and co-teaching cycles?

Framework

Prior literature suggests that two elements are important for teacher learning during professional development: (1) high-depth interactions; and a (2) focus on mathematics content.

High-Depth Interactions

In her 2003 paper, Coburn called upon education researchers to rethink how they conceptualize scale when talking about education reform. According to the author, scale has traditionally been operationalized in a quantitative sense, with the goal of increasing the number of schools and teachers involved in a reform. Coburn (2003), however, argues that this is a superficial way to measure scale-up, and that careful attention must be given to the four dimensions of depth, sustainability, spread and shift.

The dimension of depth is applicable to this study as it has been conceptualized as one way to demonstrate the opportunities teachers have to learn when engaged in social interactions (Coburn & Russell, 2008). Specifically, Coburn and Russell (2008) distinguish between low- and high-depth interactions, with low-depth focusing on "surface structures and procedures, such as sharing materials, classroom organization, pacing, and how to use the curriculum" (p. 212) and high-depth addressing "underlying pedagogical principles of the approach, the nature of the mathematics, and how students learn" (p. 212). Thus, it can be argued that teachers have limited opportunity to engage in meaningful learning if they are primarily exposed to low-depth interactions. We apply Coburn's (2003) concept of low- and high-depth interactions to understand teachers' opportunities to engage in meaningful learning experiences during modeling and co-teaching cycles.

Focus on Mathematics Content

Current research on effective professional development reflects a consensus that there must be a content focus (Desimone, 2009; Desimone & Pak, 2017). Furthermore, current literature on high-quality mathematics instruction states that teachers must possess a deep understanding of the math they teach (Martin, 2007; NCTM, 2014). Thus, in addition to engaging in high-depth interactions, teachers must also be provided with opportunities to deepen their understanding of the math content they teach during professional development.

Methods

Participants and Context

The participants included two elementary instructional coaches, Meg and Claire. Meg was in her second year as a coach and had spent 21 years prior as a teacher, and Claire was in her third year as a coach and had previously been a teacher for 10 years. During this study Meg modeled instruction for Teachers Michelle and Mackenzie (grades 3 and 4), while Claire co-taught with Teachers Cathy, Caroline and Cecilia (grades 5, 1, and 4). All teachers were rather experienced (range of 9-23 years of teaching), and all teachers and coaches were white females.

Data Collection

Primary data collection methods included observations and resulting field notes (Bogdan & Biklen, 2011), as well as transcripts generated from audio recordings of 11 planning meetings and 23 modeled or co-taught lessons (see Table 1).

Table 1: Observation Data for All Coach-Teacher Pairs

	Modeling		Co-Teaching		
Coach	Meg		Claire		
Teacher	Michelle	Mackenzie	Caroline	Cecilia	Cathy
Grade Level	3rd	4th	1st	4th	5th
Lessons Observed	7	6	4	3	3
Planning Meetings	1	1	2	4	3

Data Analysis

All audio recordings were first transcribed using InqScribe software. The primary author then carefully read each lesson transcript and searched for places where the coach and teacher *directly engaged* with one another, typically through conversations and singular comments.

To look at coach-teacher engagement across the planning meetings and lessons, it was helpful to have a set of common codes. The authors primarily engaged in a process of open coding (Creswell, 2013) to develop two levels of emergent codes: (1) Level-1 Parent Codes; and (2) Level-2 Codes. Table 2 presents the Level-1 and -2 codes and how they are clustered.

Table 2: Level-1 and Level-2 Codes

Level-1 Codes	Management	Pedagogy	Content	Planning and Logistics	Contextual Factors	Other
Level-2 Codes	1) Classroom Composition and Attendance 2) Classroom Management	1) Grouping 2) Assessment 3) General Pedagogy	1) Curriculum, Activities, and Materials 2) Mathematics	1) Technology 2) General Plans for Coaching Cycle 3) Facilitator's Role 4) Time and Schedule	1) Relationship Building 2) External Requirements	1) External Individuals 2) Other

During the coding process, all codes were mutually exclusive and assigned at either the sentence (planning meeting data) or exchange (lesson data) level. After coding, we noticed a lack of talk directly focused on math, but there were many instances in which math-related terms were at least mentioned. To better capture all math-related talk (beyond the math-focused talk that was coded as Mathematics), we used a "Mathematics Indicator" to flag instances when the coaches and teachers used math words and phrases while discussing other topics, such as the curriculum, without attending to the mathematical meaning of those words and phrases.

The primary author coded all data and engaged in a reliability process with two independent coders trained in mathematics education research. During the reliability process, random subsets of data were independently coded by the both the primary author and an independent coder. Then, the two individuals met to reconcile differences. After talking through all areas of disagreement, overall, the coders agreed on over 97% of all assigned codes.

Last, to better understand the depth of the coach-teacher talk, the authors used Coburn and Russell's (2008) definitions of low-, medium- and high- depth and mapped their Level-2 Codes onto these three categories. Some of the Level-2 Codes closely mapped onto the definitions. For example, the exchanges coded as Curriculum, Activities and Materials mapped onto the low-depth category, as Coburn and Russell considered talk about "materials" and "how to use the curriculum" as low-depth. Other Level-2 Codes, such as General Pedagogy, did not cleanly fit with a single depth level, and such codes were divided into sub-codes and placed in the appropriate category. After the coding process, the authors tabulated frequencies and percentages for all sets of codes to better understand the substance of the coach-teacher talk. For the planning conversations, percentages were tabulated at the character-level using NVivo software, while for the lesson-level data, percentages were calculated at the exchange-level.

Results

We begin by illustrating what was typical regarding the coach-teacher talk, including the most prevalent topics with examples. Given space constraints, we report data for the practices of modeling and co-teaching without details for each coach-teacher pair. We then explore the prevalence and examples of the Mathematics code, as well as the Mathematics Indicator. Last, we discuss the depth of all coach-teacher talk.

Modeling

Here, we describe typical coach-teacher talk for Coach Meg and Teachers Michelle and Mackenzie during their modeling cycles, which were focused on implementing Calendar Math. We were invited to observe one planning meeting for each pair, as well as 13 total modeled lessons. Transcripts from the planning conversations and modeled lessons were coded with the set of 15 Level-2 codes noted above.

Overall, the coach and teachers most frequently discussed: (1) Curriculum, Activities and Materials (25%); (2) Assessment (14%); and (3) Classroom Management (12%) (see Table 3). Each topic is discussed in more detail below.

Table 3: Coach-Teacher Talk for Modeling and Co-Teaching Cycles

	Modeling			**Co-Teaching**		
	Planning Meetings	Modeled Lessons	Overall	Planning Meetings	Co-Taught Lessons	Overall
	n=2	n=13		n=9	n=10	
Content						
Curriculum, Activities and Materials	26%	24%	25%	16%	23%	20%

Total	4%	17%	11%	8%	10%	9%
Other	13%	4%	9%	12%	4%	8%

Curriculum, Activities and Materials (CAM*).* When engaged in talk about CAM, across both cycles, the coach and teachers primarily discussed the materials needed to enact Calendar Math. This included conversations about the calendar, calendar pieces, number line, money, markers, wipes for the dry erase boards, popsicle sticks that would be used to elicit student participation, notebooks, making copies, and laminating materials. Typical exchanges coded as CAM included statements such as “I understand you have notebooks,” “Do you have a sticky chart paper?” and “Do we have a dry erase marker?”

Assessment. Assessment was the second most prevalent theme during both modeling cycles. While engaged in assessment talk, the coach and teachers primarily conversed about assessment logistics, such as selecting which pre-made assessment to give students, as well as when students would take assessments and how long it would take. The following planning meeting excerpt is typical, illustrating how Coach Meg and Teacher Mackenzie decided when to give their pre-assessments:

Meg: ‘Cuz the addition and the multiplication can be done at any time.
Mackenzie: These two can be?
Meg: Well, I mean, yeah. Unless you want to do a beginning baseline and an end baseline. It's completely up to you.
Mackenzie: I mean, we switch for almost, they come in at 11:15 and we don't switch back until 12:35.
Meg: That should be enough time to get ‘em all in. (11/15/16)

Classroom Management. Classroom Management, the third most prevalent theme, most commonly surfaced during coach-teacher talk from the modeled lessons, rather than the planning meetings. The coach and teachers either praised students (“Such hard workers, Meg!”), or discussed classroom incentives (“I can honestly say that once everybody got focused and centered in here, they earned it today.”) and challenging students (“I’m going to have to take her to the office if she won’t do what she needs to do.”).

In summary, during both modeling cycles, the coach and teachers primarily discussed immediate concerns related to planning and implementing the lessons, including materials, assessment logistics, and issues related to classroom management. We now examine the coach-teacher talk during the co-teaching cycles.

Co-Teaching

We were invited to observe 2-4 planning meetings and 3-4 co-taught lessons for each of the three coach-teacher pairs. Overall, the coach and teachers most frequently discussed: (1) Curriculum, Activities and Materials (20%); (2) Assessment (17%); and (3) General Pedagogy (13%). Each topic is explored below.

Curriculum, Activities and Materials. As CAM-related talk during the modeling cycles tended to focus on the materials, a different trend emerged in the co-teaching cycles as most of the CAM talk centered on the curriculum and activities. In particular, the coach and teachers often talked about issues related to: timing as they sequenced activities (“Do we want to try and have them do the first two problems…?”); the difficulty of the curriculum (“This is a hard lesson.”); what students in groups should work on (“This would be good to do in a small group—this chart down here.”); and understanding and/or navigating the curriculum (“Everyday Mathematics I think can be a little confusing...When I go through and look at this, I always look at the game to see if it’s something that I can do whole group.”).

Assessment. Similar to the modeling cycles, coach-teacher talk about assessment frequently surfaced during the co-teaching cycles. However, unlike the modeling cycles where the coach and teachers commonly discussed assessment logistics, during the co-teaching cycles it was more common for the coach and teachers to monitor student learning ("They did really well with expanded form the other day.") or use data to inform their instructional plans ("Why don't we use their independent work and kind of break them up into smaller groups?").

General Pedagogy. Last, unlike the modeling cycles where General Pedagogy rarely surfaced, during the co-teaching cycles, it emerged as one of the most frequently discussed topics. In particular, when the coach and teachers engaged in pedagogical conversations, they typically planned and/or created original materials that went beyond the district-provided curriculum ("We could just have an empty spot where they could write the number sentence or they can actually write a story problem."), discussed differentiation ("Ok, so the on-level group, we decided that it's just going to be higher level factors."), or engaged in more theoretical pedagogical talk ("So…you're doing more like student-led work out here during your centers?").

Hence, in some ways, the coach-teacher talk during co-teaching was quite different than the modeling coach-teacher talk. Specifically, modeling talk more often focused on materials, assessment logistics, and classroom management, while co-teaching talk more often focused on the curriculum and activities, monitoring student learning, utilizing data to inform their teaching, and engaging in pedagogical talk. Despite these differences, however, much of their discussions were rather similar, especially in terms of their limited math focus and depth.

Where's the mathematics?

The lack of math-focused conversation is striking across the modeling and co-teaching cycles. Specifically, only 2-4% of all planning meeting exchanges, and 3% of all modeled and co-taught lesson talk was coded as "mathematics" (see Table 3 above). In the rare instances in which the Mathematics code was used, it primarily captured procedurally-driven conversations about simple computation problems ("1 + 6 is not 5. Right? 1 + 6 would be 7."), definitions ("A multiple are all of the answers to a multiplication problem… The multiples of 4 are 4, 8, 12, 16 because 4 x 1 is 4, 4 x 2 is 8, 4 x 3 is 12."), and mathematical rules or procedures for textbook activities ("The box is not correct 'cuz 2 x 1 is not 3."). Conceptually driven mathematical conversations were, by far, more rare.

Mathematics Indicator. Although math-focused discussions were rare, the coaches and teachers often used math words and phrases while talking about other topics, such as assessment, without attending to the mathematical meaning of those words and phrases. Such instances were tagged with a Mathematics Indicator to reflect that a math term or phrase was listed, however it was not coded as Mathematics because it did not reflect a conversation about the content. For example, the exchange below received a primary code of Curriculum, Activities and Materials.

Claire: So, Wednesday, are we going back to 2.2?
Cathy: <u>Yes, which is exponents.</u>
Claire: <u>I really like that exponents lesson.</u> (3rd planning meeting, 9/19/16)

In addition to the CAM code, the underlined sentences were assigned a Mathematics Indicator, as the coach and teacher used the math word "exponents" while discussing the topic for the textbook chapter.

The Mathematics Indicator most frequently surfaced as the coaches and teachers named math words and phrases while discussing the Curriculum, Activities and Materials ("Lessons 2 and 3 are *exponents.");* Assessment ("This is probably a group that I feel like has a pretty good handle on *place value* compared to last year."); and General Pedagogy ("I don't know how to respond to these whole big *arrays* in your head.").

Depth

As explained above, we used Coburn's (2003) concept of *depth* to explore teachers' opportunities to learn. During both the planning meetings and the modeled/co-taught lessons, the coaches and teachers engaged in primarily low- (63-92%) and medium- (7-33%) depth interactions, while high-depth interactions seldom occurred (1-6%) (see Table 5). This suggests that the coach-teacher talk heavily emphasized surface-level structures and procedures, rather than focusing on topics such as how students learn mathematics, for example. Still, more medium-depth interactions occurred during co-teaching (27%) than modeling (10%), and low-depth interactions were more prevalent during modeling (87%) than co-teaching (70%).

Table 5: Depth for All Modeling and Co-Teaching Cycles

	Low	Medium	High
Modeling Cycles			
Planning Meetings	82%	12%	6%
Modeled Lessons	92%	7%	1%
Overall	87%	10%	4%
Co-Teaching Cycles			
Planning Meetings	63%	33%	5%
Co-Taught Lessons	76%	20%	2%
Overall	70%	27%	4%

Discussion

In this study of two coaches and five elementary teachers, we found that coach-teacher interactions during modeling more often focused on materials, assessment logistics, and classroom management, while interactions during co-teaching more often focused on the curriculum, monitoring student learning, utilizing data to inform teaching, and engaging in pedagogical talk. These differences may be specific to the two particular coaches involved, or may be due to differences in the focus of the cycles (e.g., with modeled lessons centered around Calendar Math, which was materials-intensive and outside the regular curriculum). However, some differences seem likely due to the fact that during modeling, the teachers generally assisted the coach (consistent with the greater focus on materials and classroom management), while during co-teaching, the teacher and coach implemented lessons together. These differences in foci may have prompted the greater depth during the co-teaching discussions.

Still, across the modeling and co-teaching cycles, conceptual discussions about mathematics content were extremely rare. This is disappointing, considering decades of research recommending that effective professional development should have a content focus (Desimone, 2009; Desimone & Pak, 2017). The lack of mathematical depth of discussions may be due, in part, to the fact that both coaches were generalists who lacked specialized mathematics training and were expected to provide professional development in all content areas.

Although our findings require replication before definitive conclusions can be drawn, the results suggest two potential guidelines for school districts. First, professional development for instructional coaches should help coaches gain a deep understanding of math content and pedagogical content knowledge across the developmental spectrum, which will help facilitate deeper conversations about math teaching. Second, more consideration should be given to implementing a content coaching model at elementary schools. In this model, although coaches would likely be shared between schools, they would be content experts who are better able support teachers in their area of expertise.

In this paper, we present findings from an exploratory study of mathematics education stakeholders to understand their professional networks, and acquisition and use of research on mathematics teaching and learning. Evidence suggests that mathematics leaders are key to promoting organizational sensemaking and are more likely to acquire and use research on mathematics teaching and learning which has important implications for improvement efforts at scale.

Keywords: Design Experiments, Policy Matters, Standards, Professional Development

Introduction

Historic approaches to bridging the research-practice divide have often focused on improving the quality of research dissemination efforts to move evidence from research to use in practice. These approaches privileged researchers' perspectives, and though they achieved some success, the field lacks empirical understanding of what forms of research evidence are being drawn upon and used in practice (Finnigan, Daly, & Che, 2012). To improve the use of research in practice, scholars have identified a number of resources and characteristics of schools and districts, such as the influence of mid-level decision makers in organizations because they often "straddle policy and practice and are well poised to put research to work" (Tseng, 2012, p.5). Others challenge the dissemination model and argue for other ways to relate the work of researchers and practitioners, such as research-practice partnerships (RPPs). RPPs have recently gained traction as a promising approach for educational improvement (Coburn & Penuel, 2016). In RPPs, researchers and practitioners identify and commit to addressing a shared problem through long-term, mutualistic collaborations that include research, development, or evaluation (Coburn, Penuel, & Geil, 2013).

As part of an RPP with our state education agency focused on improving the process of implementing new mathematics standards, we conducted an exploratory study of the professional networks and research uses of mathematics teachers, mathematics leaders (e.g. school-based coaches and curriculum facilitators, district-based math leaders), and school-based administrators (e.g. principals, assistant principals). This paper reports results from a questionnaire that was developed to inform the design of professional learning opportunities for mathematics teachers and leaders that centralize research evidence on mathematics teaching and learning. In doing so, we aim and address the following research questions: (1) *From whom and for what purposes do mathematics teachers, mathematics leaders, and administrators have significant conversations about mathematics teaching and learning?; (2) From what sources and to what extent do mathematics teachers, mathematics leaders, and administrators look for and use research on mathematics teaching and learning?;* and (3) *What do mathematics teachers, mathematics leaders, and administrators identify as primary barriers to using research in their role?*

Background

Our partnership began after our state adopted new mathematics standards. State agency leaders were interested in using an improvement science approach in build and refine a process of implementing state academic standards. During the first year of the partnership, we negotiated and specified research evidence and its use in practice among mathematics teachers and leaders as the focus of our work together and co-designed a variety of professional learning opportunities and materials for mathematics teachers and leaders that embody research on student learning, instructional practice, and teacher learning in professional development (Wilson, McCulloch, Webb, Stephan, Mawhinney, & Curtis, 2017).

To inform the design of these efforts, we developed an exploratory questionnaire to understand the ways mathematics education stakeholders acquire and use evidence from mathematics education research in their practice. In what follows, we briefly summarize the literature on professional networks and research use, outline our theoretical perspective, and describe the development and administration of the exploratory questionnaire. We then highlight key findings and conclude with implications for others interested in promoting both organizational learning and the use of research in practice with attention to scale.

Professional Networks and Research Use

Scholars studying the ways research evidence informs practice and policy define research use as the act of drawing on and interacting with research evidence in the course of decision making (Coburn & Turner, 2011; Honig et al., 2017; Tseng, 2012). Investigations of practitioner and policy maker uses of research have identified several broad ways that evidence is used, for example, instrumental use which results in changes in practice (Nutley et al., 2007), conceptual use which results in changes in knowledge (Weiss et al., 1977), or imposed use in which practitioners are pressured to use research by agencies or policy makers (Weiss et al., 2005), among others. In addition, Honig and colleagues (2017) reported that though practitioners claim to use research in their work, it is often interpreted through existing schema to reinforce previous decisions or rejected ideas that conflict with prior understandings.

Much of the scholarship on research use has focused on local or statewide data, such as student achievement scores or local measures. However, little attention has been paid to the ways mathematics education stakeholders use research evidence on mathematics teaching, students' mathematical learning, and/or mathematics teacher learning to inform their decisions. For the purpose of this exploratory study, we wanted to focus on similarities and differences in the ways teachers and leaders acquire and use research evidence on students' mathematical learning, mathematics teaching practices, and mathematics teacher learning given their direct relation to the work of teachers and coaches in the classroom.

Studies on research use in practice often focus on singular roles (e.g. administrators, central office leaders), downplaying the social ecology and complex nature of research use processes within school and district initiatives. Relationships, organizational structures and contexts, and policy all complicate and influence the ways practitioners use research (Tseng, 2012). In addition, acquiring and using research evidence for improvement is a "multilevel phenomena" and occurs both within formal organizational structures and in informal social interactions (Daly et al., 2014). Scholars working in this area have called for more attention to developing an understanding of the ways research is used in practice within district systems between leaders and teachers (Honig & Venkateswaran, 2012) and how research supports implementation and improvement efforts (Daly & Finnigan, 2010). Some have found that small changes at different levels of the system can add up to larger organizational improvements (Coburn & Turner, 2012).

Research-practice partnerships are an increasingly popular approach to improve the use of research in practice (Coburn & Penuel, 2016). Proponents suggest partnerships support both sensemaking and use of research evidence in practice by creating opportunities for mutual engagement with research, translating research into tools that may serve as vehicles for learning and improvements to practice, and serving as models of the use of research (Fishman et al., 2013). However, research has shown that intermediary organizations are insufficient absent leaders who continue to learn about research use while also teaching others (Honig, 2017). Moreover, research has highlighted the importance of "opinion leaders" positions in social networks (Palinkas et al., 2011) as conduits for both the acquisition and use of research in practice (Tseng, 2012). Thus, for this exploratory survey, we were interested not only in the types of mathematics education research used, but also in the reasons mathematics teachers, mathematics leaders, and administrators interact with one another and the ways these interactions may relate to the acquisition and use of research.

Theoretical Perspectives

Our partnership uses design-based implementation research (DBIR) (Fishman et al., 2013) to organize our development, implementation, and research efforts. DBIR focuses not only on developing and refining tools and environments for learning but also on creating structures and supports necessary to scale and sustain them (Fishman et al., 2013). Throughout implementation, partners seek to improve the design of implementation efforts, generate theories of learning and implementation, and create supporting infrastructures to develop capacity and sustainability. Specifically, we use Lave and Wenger's (1991) ideas of participation, practice, and boundaries as a frame for designing for teacher and leader learning. We use organizational sensemaking (Weick, 1995) to broadly frame standards implementation as an organizational learning problem, and draw upon two sets of constructs related to the processes and kinds of resources that individuals or collectives within larger systems use when experiencing ambiguity or violated expectations during periods of systemic change.

Our design process is guided by a set of design and implementation principles derived from our commitments to supporting mathematics teaching and learning, theories of learning and implementation, the research on teacher learning and professional development, and the diverse expertise of our partners (Wilson et al., 2017). In this paper, we attend to our principals of utilizing research on mathematics teaching, connecting teachers and leaders, and designing coordinated tools and resources to better understand mathematics teachers, leaders, and administrators professional networks and the ways they acquire and use research evidence on mathematics teaching and learning.

Methods

Questionnaire Design

In the spring of 2017, we developed a questionnaire to inform ongoing efforts to co-design statewide initiatives related to standards implementation and the promotion of equitable learning opportunities for mathematics education stakeholders. We began by asking a set of demographic questions related to respondents' school district, role, years of experience, and grade-band. We then focused on three constructs identified by the partnership as important to the design of learning opportunities for mathematics teachers and leaders: professional networks, use of research in practice, and instructional vision. In this paper, we focus our efforts on statewide responses from mathematics *teachers*, mathematics *leaders* (e.g. school- and district-based mathematics coaches, curriculum facilitators), and school *administrators* (e.g. principals, assistant principals) related to professional networks and research use to inform our design.

To answer our first research question focused on professional networks, we asked respondents two questions: with whom and how often respondents had "significant exchanges about mathematics teaching and learning in the past year"; and what the primary reason was for the majority of these exchanges. To answer our second research question focused on research use, we asked respondents questions about their acquisition and use of research specific to mathematics education (e.g. research on students' mathematical thinking, mathematics teaching practices, mathematics teacher learning). These questions asked respondents to indicate how often they looked for research on topics related to mathematics teaching, the social sources of the research they encountered, and how likely they were to use research. To answer our third research question focused on barriers in using research, we asked respondents to select two main barriers to using research from eight possible choices.

Several of the questions were adapted from a validated and reliable survey developed by The National Center for Research in Policy and Practice (ncrpp.org). The survey's purpose was to characterize how leaders perceive, acquire, and use research to inform their decision-making. To reduce fatigue effect bias, we selected a subset of the survey questions most directly related to our research questions and implementation efforts and modified portions of these questions to reflect our focus. In addition, there were a set of questions focused on respondent demographics and another set of questions to directly inform future co-design and implementation efforts. Prior to administering the survey, we field tested the items with members of the partnership. We modified and clarified individual items as needed to ensure each measured the constructs of interest.

Data and Analysis

The questionnaire was distributed through listservs at the state agency to mathematics teachers, administrators, and mathematics leaders. The agency estimated the total number of educators on the listservs to be approximately 20,000. The questionnaire was open for 17 days during late May and June, 2016. Potential respondents received one message to invite participation upon its opening and three follow-up reminders throughout the open period.

Responses from those who completed 80% of the items and gave consent for research were considered complete and as data. Our quantitative analysis proceeded in two stages. First, we used descriptive statistics and graphical displays to explore responses to individual questions and then groups of questions. We then used responses to demographic items to organize a search for relationships among professional networks and research use. Because the questionnaire was developed with a primary goal of informing our design efforts, findings are descriptive.

Findings

In total, 1,605 teachers, 197 leaders, and 104 administrators (N=1,906) responses were collected, with a response rate estimated to be approximately 20%. While low, the responses represented 100% of the eight state education regions and 114 of the 115 school districts in the state with a mean and median of 17 and 11 responses per school district respectively. To better understand the representation of respondents across our state, a ratio of students per respondent was calculated by taking the ratio of the total number of students in a district per number of respondents in a district. These scores were then averaged across all districts in each of the eight regions across the state to obtain an average ratio per region. The mean and median of these region averages were 948 and 916 students per respondent respectively (std. dev.=167) – indicating a reasonably acceptable distribution of respondents per region across the state. In what follows, we share findings organized by our research questions.

From whom and for what purposes do mathematics teachers, mathematics leaders, and administrators have significant conversations about mathematics teaching and learning?

Respondents were asked to self-report how often they had significant conversations about mathematics teaching and learning in the last year by choosing *none*, *1-5 times*, *6-10 times*, or *greater than 10 times*. Results were translated to a scale of 0-3 (0 [*none*] – 3 [>*10*]) and means for each role are shown in Table 1. Results indicate that all roles self-report that they regularly engage in conversations about mathematics teaching and learning with teachers in schools. Mathematics leaders self-report that they more regularly engage with teachers and administrators about mathematics teaching and learning than do teachers or administrators, suggesting that leaders span boundaries within and across schools within districts.

Table 1: Mean scores for likelihood of having significant exchanges about mathematics

	Teachers	Math Leaders	Administrators
Teachers within schools	2.45	2.58	2.25
Teachers across district	1.27	1.89	1.05
Math Leaders	1.31	1.97	1.59
Administrators	1.55	2.03	1.77
Higher Ed Faculty	0.81	0.89	0.80

Taken that mathematics leaders self-reported the regularity of their conversations with others, as well as teachers and administrators self-reports of their conversations with math leaders, Table 2 highlights the predominant focus of math leaders' conversations. Results indicate that math leaders have frequent conversations about mathematics teaching and learning across many domains of mathematics education. With teachers, these conversations focus on planning for instruction, instructional practices to support student learning that align with mathematics standards, and resources that can be used in instruction. With one another, these conversations focus on professional development and other activities to support teacher learning that focus on mathematics standards and instructional practices. With administrators, these conversations focus on curriculum, assessments, and instructional practices. Taken together, the frequency and focus of these exchanges may indicate that mathematics leaders are centrally connected to district-wide implementation efforts related to mathematics teaching and learning.

Table 2: Percentage of respondents indicating the predominant focus of their exchanges.

	Math Leaders conversations with...were focused on...
Teachers in schools	Planning (35%), Teaching Practices (17%), Resources (15%)
Teachers across district	Standards (22%), Planning/PD (17%), Teaching Practices (16%)
Math Leaders	Teaching (20%), Standards (17%), PD (15%)
Administrators	Curriculum (21%), Assessment (18%), Teaching Practices (16%),

From what sources and to what extent do mathematics teachers, mathematics leaders, and administrators look for and use research on mathematics teaching and learning?

Drawing from our design and implementation principle focused on utilizing tools based on research on mathematics teaching and learning, we sought to explore stakeholders' frequency and use of research in practice. Respondents were asked questions to indicate how frequently they (1) looked for research in the past year and (2) previously used research in their role on a set of mathematics teaching and learning related topics. Results were translated to a scale of 0-3 (0 [*never*], 1 [*rarely*], 2 [*sometimes*], 3 [*often*]) and means across respondents for teachers (n=677), mathematics leaders (n=81), administrators (n=36) are shown in Table 3. For the survey, each respondent was given the set of questions related to professional networks and then randomly assigned questions related to either research use or instructional vision, thus the number of respondents for research use and instructional vision are roughly half of the total number of respondents.

Table 3: Frequency of prior use of research and looking for research in the past year

How frequently have stakeholders looked for & used research on math teaching and learning?	**Teachers**		**Math Leaders**		**Administrators**	
	Looked For	Prior Use	Looked For	Prior Use	Looked For	Prior Use
Students' mathematical thinking	1.7	2.0	2.0	2.5	1.8	2.3
Mathematics teaching practices	1.8	2.1	2.3	2.5	2.0	2.5
Math professional development	1.4	1.8	2.1	2.2	1.6	2.2
Resources for instruction	2.1	2.2	2.4	2.5	2.0	2.4
Assessment practices	1.8	2.0	2.1	2.3	1.7	2.4

Results indicate that all roles self-report that they look for and using research on mathematics teaching and learning. In addition, mathematics leaders self-report data suggest that they both look for and use research more often than teachers and administrators across each domain of research on mathematics teaching and learning. Moreover, data indicate that respondents are more likely to use research than they are to look for it, which suggests that they may acquire research from a variety of sources. Respondents were then asked to indicate how likely they were to acquire research from a list of social resources. Results were translated to a scale of 0-3 (0 [*never*], 1 [*rarely*], 2 [*sometimes*], 3 [*often*]) and means for each role are shown in Table 4.

Table 4: Mean scores likelihood of acquiring research from the following sources

	Teachers	**Math Leaders**	**Administrators**
Teachers within schools	2.1	1.7	2.3
Teachers across district	1.5	1.7	1.7
Math Leaders	1.4	1.9	2.0
Administrators	1.3	1.2	2.1
Higher Ed Faculty	0.6	1.2	0.4
Professional Associations	1.1	1.9	1.4
Research or Practice Journals	0.8	1.9	1.2

Results indicate that all roles self-report that they rarely to sometimes acquire research from the list of sources. For teachers, they reported that they were most likely to acquire research from other teachers. For administrators, they reported that they were most likely to acquire research from other administrators or mathematics leaders. For mathematics leaders, they reported that they were most likely to acquire research from other math leaders, professional associations, or journals. In addition, if one assumes that higher education faculty have access to or are producing research on mathematics teaching and learning, mathematics leaders reported that they were more likely to acquire research from faculty than teachers or administrators.

What do mathematics teachers, mathematics leaders, and administrators identify as the primary barriers to using research in their role?

Drawing from our design and implementation principles and our commitment to build capacity for sustainability at scale, we sought to explore what stakeholders' identified as the primary barriers to using research in their role. Respondents were asked to choose two main barriers from a list of hypothesized barriers we gathered through our conversations with educators. Results were tabulated across respondents for each role as shown in Table 5.

Table 5: Percentages of primary identified barriers to using research in practice

	Teachers	**Leaders**	**Administrators**
Time constraints	37%	32%	33%
Lack of PD that shares research	21%	22%	20%
Cost/Lack of access to journals	9%	17%	20%
Lack of relevance or ease of use	19%	11%	10%
Timeliness of research (e.g. out of date)	8%	8%	13%
Not valued in my education community	3%	7%	2%
Lack of high-quality evidence	5%	3%	3%

Results indicate that the primary barrier to using research in practice across all roles was time constraints. Secondly, results indicate that teachers, leaders, and administrators all reported a lack of access to professional development focused on sharing research findings as a barrier.

Implications and Discussion

The purpose of this exploratory study was to inform our ongoing efforts to co-design professional learning opportunities for mathematics teachers and leaders. Results of our analysis suggest that mathematics leaders are key aspects of school and district communication infrastructures related to mathematics teaching and learning. An examination of responses about their use of research provides some evidence that this communication shares research findings with others, on occasion. Moreover, leaders are more likely to seek out, promote, and use research on mathematics teaching and learning.

Results from this questionnaire will inform our upcoming efforts to co-design learning opportunities for leaders and teachers focused on mathematics teaching and learning that embody both research and attention to scale. For researchers and practitioners engaged in large scale improvement initiatives, results from our descriptive questionnaire mirror emerging findings about the influences of mid-level decision makers in decisions and the role of professional networks in introducing new ideas to schools and districts. We also note that self-reports of practice that are deemed favorable are regularly overestimated. While it is promising that leaders reported these practices, it is also noteworthy that teachers, leaders, and administrators were unlikely to have significant conversations about research on mathematics teaching and learning with higher education faculty. If we, as mathematics education researchers purport to both engage in and share these forms of research, it is important for us to consider these results.

As we consider the conference theme, "Looking Back, Looking Ahead", we see attention to mathematics leaders as one way to meet enduring challenges of shaping mathematics teaching.

Leveraging their professional networks and supporting them in learning to use research in practice may promote coherence and systemic change as they mitigate shifting policies, changes in curriculum, and expectations of industry. We see this work as supporting research-based mathematics teaching that leads to more equitable learning opportunities for students.

This study examines secondary mathematics and science teacher perceptions of teacher leadership during the first year of a professional development program focused on preparing teacher leaders in rural schools. It also begins to offer details as to what content-focused teacher leadership looks like and how teachers in rural schools enact teacher leadership. Data collection includes interview and survey analysis. Findings indicate four areas of growth for participants and project staff: participants began to expand their thinking and influence beyond the classroom, advocate more for students, develop a richer understanding of what content specific teacher leadership looks like, and gain a deeper understanding that teacher leadership in rural districts may be easier given the context of smaller settings but may also be more challenging in terms of teacher burnout.

Keywords: High School Education, Middle School Education, Teacher Knowledge, Teacher Education – Inservice/ Professional

Introduction

Teacher leadership has been in the literature for over 40 years and more recently, calls have been made to focus on content-focused teacher leadership (Wenner & Campbell, 2016). In 2014, the National Research Council (NRC) held a day and a half convocation to discuss the current and possible ways to better develop and utilize STEM teacher leadership. One result of the convocation was a publication that summarized convocation outcomes such as what STEM teacher leaders can do to effect policy, current models for empowering teacher voices, professional development for STEM teacher leaders, and research in the field of STEM teacher leadership (NRC, 2014). One finding from the report was the impact professional development "can make toward creating a robust corps of STEM teacher leaders" (NRC, 2014, p. 44). Mohan, Galosy, Miller, & Bintz (2017) completed a study to review and synthesize existing research on science and mathematics teacher leadership development programs. In their initial review of 89 research abstracts and 70 programs, their final study included 18 research articles and 15 programs. The review of these articles and programs, in addition to discussions with science and mathematics teacher leadership development leaders, resulted in four "focal areas" or recommendations for science and mathematics teacher leadership programs: programs and the teacher leadership development landscape, purposes of teacher leadership development programs, attributes of teacher leadership development programs, and research on teacher leadership development programs. Two key recommendations within these focal areas were the need to ensure teachers from underserved and underrepresented areas have leadership development opportunities and the importance of sharing findings of science and mathematics leadership development programs (Mohan et al., 2017).

Rural districts represent an underserved and underrepresented area where a focus on teacher leadership development is needed (Anderson, 2008). Rural areas also demonstrate a need for strong teacher professional development to address challenges such as fewer resources for instruction, lower teacher salaries, and less opportunities for professional development for teachers (Bush, 2005; Goodpaster, Adedokun, & Weaver, 2012; Showalter, Klein, Johnson, Hartman, 2017). Specifically, professional development in mathematics and science is needed as already existing teacher shortages in STEM areas are even greater and student performance in and access to higher level mathematics and science coursework is low in rural communities (Irvin, Byun, Smiley, & Hutchins, 2017; Showalter, Klein, Johnson, Hartman, 2017).

In response to this need for content-focused rural teacher leadership development, the Rural Secondary Science and Mathematics Teacher Leader Project (RSSMTL), in collaboration with 10 schools in 15 districts, was developed to prepare secondary mathematics and science teachers in rural districts. This study analyzes data from the first year of the program to determine how science and mathematics teacher perceptions of teacher leadership change through a teacher leader professional development program and what it looks like to become a mathematics or science teacher leader in a rural school.

RSSMTL focuses on Wenner & Campbell's (2016) definition of teacher leadership as "teachers who maintain K-12 classroom-based teaching responsibilities, while also taking on leadership responsibilities outside of the classroom" (p. 7). Given that change takes long time support, we are in the midst of a five-year grant funded program to develop strong secondary mathematics and science teachers in rural areas.

RSSMTL Conceptual Framework

Based on research literature in rural content specific teacher development and leadership as well as the needs articulated by our school partners, the below conceptual framework guided the development of the RSSMTL.

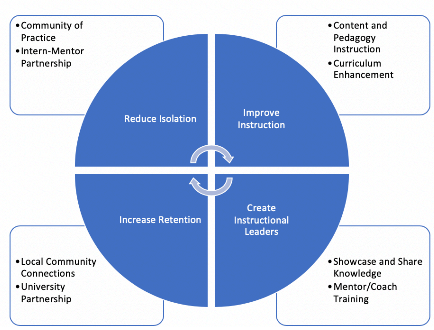

Figure 1. The Conceptual Framework for RSSMTL

Project Components

The RSSMTL conceptual framework four components are explained below and program elements that teachers complete to address each of the four components are described. Table 1 also presents the program components and elements.

Component 1: Reduce Isolation. Teachers in rural schools struggle with isolation given the sometimes smaller size of their schools. A science teacher, for example, may be the only person teaching physics at her school. Component 1 and the affiliated project elements are designed to reduce teacher isolation (Baird, Prather, Finson, & Oliver, 2006). The participating teachers and project team are creating a ***community of practice*** where we are able to learn together as teacher leaders in rural districts. As part of the project, teachers work with our preservice teachers who typically would not be placed in their schools due to the longer commutes but is now more possible with funding to supplement travel costs. Teachers speak to the value of having content partners with whom they can now talk about their teaching – both in terms of their student teachers (***intern-teacher relationships***) as well as fellow teachers in the program. For example, as the only science teacher teaching physics at her school, Brianna can now talk with her RSSMTL colleague who also is the only physics teacher at her rural school. As the RSSMTL participants increase their spheres of influence and connection as teacher leaders, they have been able to share those connections with teachers in their communities.

Component 2: Improve Instruction. Teachers in rural districts often lack access to high quality professional development or to content-specific specialists to aid in continuous improvement of their instruction (Hickey & Harris, 2005; Howley & Howley, 2005). If rural teachers do receive professional development, it is often not well aligned to their specific needs (Jimerson, 2004). Therefore, this component and aligned program elements are designed to improve teacher participant instruction. ***Content and pedagogical instruction*** emphasizing inquiry based teaching practices (Anderson, 2007; Silver, Kilpatrick, & Schlesinger, 1990) coupled with both Project Based Learning (Krajcik, Czerniak, & Berger, 2002) as well as Place Based Learning (Sobel, 2004) are foundational to the program. We meet for a two-week Summer Instructional Leadership Academy (ILA) each summer and spend time learning about these three pedagogical approaches. For example, in terms of ***curriculum enhancement***, each teacher has developed a Project Based Learning unit. Teachers implement and record at least four lessons during the academic year focused on these curricular and instructional changes. They also take three online content specific graduate courses to enhance their content knowledge. These courses are offered online so that teachers do not have to leave their communities to participate in the course yet are able to virtually connect with the instructor and their RSSMTL colleagues throughout the course. Teachers complete projects that are integrated into their daily work of teaching so they can immediately apply their learnings with their students. Teachers have been able to, in turn, as teacher leaders share the content and pedagogical content knowledge they are learning with teachers in their districts. Hence, the initial void of content specific curriculum specialists in some of our smaller, more rural districts that was part of the initial impetus for this work, is beginning to be filled by RSSMTL participants.

Component 3: Increase Retention. Teachers in rural districts tend to have higher rates of retention than in urban or suburban schools (Provasnik et al., 2007) though rural districts do report difficulties in recruiting and retaining high quality mathematics and science teachers (Friedrichsen, Chval, & Tuescher, 2007; Monk, 2007). Strong professional development, community involvement and local school support improves the retention of high quality teachers in rural districts (Goodpaster, Adedokun, & Weaver, 2012). Hence, Component 3 and the accompanying program elements are designed to increase retention among participants. As part of RSSMTL, teachers develop ***local community connections***. As part of the Project Based and Placed Based Learning, teachers connect with resources in their areas to both bring into their classrooms as well as take their students into the community. For example, Tammy connected with a local restaurant to have her geometry students re-design one of their take-out boxes. As part of the project, the restaurant management came to the school to view student presentations on their designs and then selected the best designs to visit their local restaurant. In addition, teachers plan local STEM community nights at their schools to engage parents and the local community in the work of their students. For example, several teachers focused their STEM nights on the eclipse that occurred on August 21, 2017. Furthermore, ***university partnerships*** continue to develop as student teaching interns and their supervisors connect with the teachers as they work in their classrooms. Teachers also co-teach methods courses alongside project team members. For example, as part of the content-focused methods course, teachers come to campus to share with student teachers as well as the methods courses travel to the teachers' schools to view lessons taught to their students.

Component 4. Create Instructional Leaders. Empowering teachers to develop their own instructional practices as well as supporting their ability to support the development of colleague's instructional practices offers teacher ways to become instructional leaders. It also addresses the lack of content-specific specialists in smaller rural districts by equipping classroom teachers with these skills (Hickey & Harris, 2005). Therefore, Component 4 and its accompanying program elements address this need. Teachers in the RSSMTL program ***showcase and share knowledge*** through multiple avenues. First, they complete the National Board Certification process for their specific content area. This process allows them to systematically and deeply reflect on their practice while simultaneously encouraging them to improve and strengthen that practice (Lustick & Sykes, 2006). As National Board Certified teachers, participants are more effective teachers (Cowen & Goldhaber, 2016) and better prepared to take on leadership roles (Sato, Hyler, & Monte-Sano, 2014). In addition, teachers write articles for professional journals as well as present their Project-Based Learning units at state and national conferences. Finally, at the close of the RSSMTL program, teachers will plan and host a professional development conference for their colleagues that focuses on lessons they have learned as part of the RSSMTL program. They also complete ***Mentor Teacher and Coach Training*** to enhance their work with student teachers and induction teachers as well as strengthen their skills to work alongside their colleagues to improve collective practices (Lotter, Yow, & Peters, 2014; Yow & Lotter, 2016).

Table 1. RSSMTL Program Components & Elements

Component	Focus	Aspects	Program Element
1	Reduce Isolation	Community of Practice	Relationships developed among teachers with RSSMTL colleagues and project staff
		Intern-Mentor Relationships	Teachers hosting student teacher interns
2	Improve Instruction	Content and Pedagogy Instruction	Inquiry Based teaching practices coupled with Project Based and Place Based
			Online pedagogical and content graduate coursework
		Curriculum Enhancement	Project Based Unit Development
3	Increase Retention	Local Community Connections	Project Based and Place Based Learning Units that involve local community resources
			STEM Community Nights
		University Partnerships	Teachers hosting student teaching interns
			Co-teach methods courses
4	Create Instructional Leaders	Showcase and Share Knowledge	National Board Certification
			Articles and Professional Presentations
			Professional Development Conference for Colleagues
		Mentor and Coach Training	Complete Mentor Teacher and Coach Training

Methods

Participants

Twenty teachers participate in the RSSMTL program. They were selected from a pool of applicants based on a principal reference, a written essay, transcript and licensure test review, and an interview. All 20 teachers have master's degrees and include ten mathematics teachers (six middle school and four high school) and ten science teachers (four middle school and six high school). Twelve are Caucasian and eight are African-American. Three are male and seventeen are female.

Data Collection

Data collection included a pre-and post-interview and a pre-and post-survey.

Interview. Prior to beginning the program, teachers were interviewed using a semi-structured interview protocol. The interviews lasted between 45 to 60 minutes and were audio recorded. The interview protocol asked about their beliefs about instruction and teacher leadership. In terms of instructional beliefs, teachers were asked questions such as how they thought students learned best, how they structured their lessons, and how they assessed student learning. In terms of teacher leadership beliefs teachers were asked, for example, how they defined teacher leadership and how they saw themselves or others as teacher leaders. A year later, the teachers were asked the same teacher leader questions with a sharper focus on being a mathematics or science teacher leader in a rural context.

Survey. Teachers also completed a teacher leadership survey (Triska, 2007). This survey contained 13 Likert items with a 1 (Never) to 4 (Frequently) scale and 11 items with a 1 (Disagree) to 4 (Agree) scale. Sample questions from the Never to Frequently section included how often they "Tried a strategy in your classroom that you had never tried before?" or "Voiced your personal thoughts about teaching or learning with other teachers?" Sample questions from the Disagree to Agree section included "You modeled reflection leading to improvement of practices in your classroom, which may have impacted other teachers" and "You played an important role in building the professional community here at school." A year later, teachers were administered this same survey though they were asked to do so both a written and verbal format. Teachers completed the survey by hand during the post-interview while also being asked to think aloud as they completed the survey to offer examples or additional context to their Likert scale responses.

Analysis

Data analysis included using SPSS to determine the descriptive statistics on the Triska (2007) teacher leadership survey. The teachers rated themselves highly on the pre-survey so there was no significant statistical change compared to the post-survey. Therefore, the main data analysis for this study was conducted through analysis of the teacher leadership survey think aloud alongside the pre- and post-interview responses. All interviews were audio recorded, transcribed, and inputted into Nvivo 11. Interviews were coded using a constant comparative method (Boglan & Biklen, 1989). The first two authors along with two graduate research assistants initially coded all interviews separately and a list of common consensus codes was determined through group discussion. Then, all researchers recoded the interview transcripts using the revised codes, met again to discuss any variations in the coding, and decided upon themes that represented participant perceptions and enactment of teacher leadership.

Results

Results indicated four findings with regard to the teacher perceptions and growth as teacher leaders. First, teachers are developing as teacher leaders whose focus is expanding to beyond their classrooms. Second, teachers are continuing, and more deliberately, serving as advocates for their students. Third, a more collaborative and comprehensive understanding of what content specific teacher leadership looks like is developing. Fourth, teacher leadership roles in rural districts may be more natural to obtain given the context of a sometimes smaller familiar setting, but may also be more challenging as these roles lead to other tensions including feeling overworked and stressed.

Finding 1: Expanding Focus to Beyond the Classroom

As we began the program, teacher conceptions about teacher leadership were more classroom-focused. Now, they are beginning to think about teacher leadership as also including their influences beyond the classroom. Jenny, for example, initially spoke about a teacher leader as "being receptive to her students – taking their needs and helping them grow." Now, teachers reflect on their current conceptions of teacher leadership as not only helping students grow, but also "being a role model to and sharing with my peers" as well as "presenting at conferences." They are beginning to feel responsibility to serve their students, colleagues, and districts.

Finding 2: Continuing to Advocate for Students

Teachers have always been champions for their students. Through the program, however, their voice as advocates for students has grown stronger. Their understanding that such a voice is part of their role as a teacher leader has also grown – part of being a teacher leader is having a "student-centered mindset" (Hunzicker, 2013). Kyana reflected, "but same is not equal in every school. Our children, being rural, need more outside experiences." She continued to speak specifically to advocating for the best teaching practices: "Math, we have to really make sure that we push for the best way for our kids to learn."

Finding 3: Understanding of Content Teacher Leadership

The teachers and project team are gaining a better understanding of what content-specific teacher leadership means. In mathematics, the teachers speak to the need to remain current in their knowledge of best practices for teaching mathematics. They also speak to the need to be involved with vertical teaming where they collaborate with teachers across grade bands to better understand, for example, what their algebra students learned in their previous pre-algebra course and what content they need to have a strong understanding as they progress into geometry. Science teachers speak to the need to "write grants" as teacher leaders to acquire the materials they need to complete engaging and safe laboratory activities. Mike reflected, "It takes much more to prepare for science." Particular foci and needs are specific to mathematics and science teacher leadership.

Finding 4: Recognizing Rural Teacher Leadership May Be More Natural But Challenging

Teacher leadership roles, both formal and informal, often times come more naturally to teachers in rural settings. For some teachers, they grew up in the community and are well respected so are often asked to take on leadership roles. For other teachers, their rural school is also a small school, so they are asked more often to serve. For example, Jessica noted "wearing lots of hats" as one of two mathematics teachers in her high school. For example, her school needed last-minute prom preparation help so she took her geometry class to the gym. She integrated their polygon lesson while arranging tables: "I turn our prom experience into a math experience." Tawanda noted, "I think it's easier to be [a teacher leader in a rural area] because you don't have to deal with so many. You're on a first name basis. They know me at the district office. They know who we are. They know what we do." However, with added roles come additional responsibility, time commitments and stress. Therefore, further reflection on how best to balance the natural yet challenging dichotomy of these roles needs exploring.

Discussion

In this initial year of the program, RSSMTL participant perceptions of teacher leadership as well as a developing picture of what it looks like to be a mathematics or science teachers leader in a rural school began to emerge. Through the program's focus on four areas (reducing isolation, improving instruction, increasing retention, and creating instructional leaders), four findings surfaced. First, teachers began to expand their focus to beyond the classroom. They began to think more deliberately and felt more empowered to take their expertise outside of their classroom walls to begin to impact and influence their colleagues and larger professional community (Beachum & Dentith, 2004). Second, though many had already served as advocates for their students, they learned of new ways and found an increased sense of agency to advocate for their students. In some cases, they learned of content-based extracurricular activities to offer to their students whose rural locale may have prevented their previous participation in such activities. They also began developing a new knowledge base about strong instructional practices and content expertise that enhanced their teaching and began to advocate for their subjects and these teaching practices (Hunzicker, 2013). Third, the collective knowledge of content-focused teacher leadership continues to evolve. Findings indicated that there are specific content area aspects that pertain to mathematics or science teacher leaders. For example, the concept of vertical teaming and planning within the mathematics community is a fertile ground for continued research in how best to prepare and position mathematics teacher leaders to serve in shepherding such efforts. Likewise, materials and supplies specific to successful lab and field experiences in the sciences lends itself to grant writing among science teacher leaders – and similar manipulative and resource materials in the mathematics classroom may also prove another content-specific area of mathematics teacher leadership. This finding adds to the complex nature of teacher leadership as it pertains to specific content areas (Wenner & Campbell, 2017). Finally, teacher leadership within rural schools can be more natural but at the same time challenging. The familiarity of being "known" in often smaller rural schools often makes it easier for teachers to assume teacher leader roles. With fewer administrators, there are often more opportunities for teachers to become teacher leaders. These same opportunities, however, sometimes lead to overburdening burnout (Little & Bartlett, 2002; Lieberman & Miller, 2004) so additional research into sustainable teacher leadership is warranted.

The complexity of content-based teacher leadership continues to evolve so additional research on how mathematics and science teachers perceive and enact teacher leadership in rural contexts is needed. The RSSMTL program adds to the limited literature around this field and as the program progresses and additional data is collected and analyzed, the authors hope to continue to add to this research literature so all students and teachers have access to high quality learning and leading.

SITUATING DEFICIT DISCOURSE IN THE CONTEXT OF SOCIAL INTERACTION

Sunghwan Byun
Michigan State University
byunsun3@msu.edu

The persistence of deficit discourse has been one of the enduring challenges in mathematics education. This paper aims to contribute to the discussion by situating deficit discourse in the context of social interaction. Drawing on conversation analysis and discursive psychology, I offer an analysis of a conversation that happened in an equity-oriented professional development session. The findings show that deficit discourse was mobilized to do a particular context-specific action, and the action was achieved with multiple rhetorical devices. Thus, successfully countering deficit discourse involves micropolitics and rhetorical resources and skills.

Keywords: Equity and Diversity; Professional Development; Discourse Analysis

As Suh, Theakston-Musselman, Herbel-Eisenmann, and Steele (2013) noted, one of the enduring challenges in mathematics education is the persistent deficit discourse often targeted at marginalized students and families. Its ideological function is to blame the victims of social injustice and sustain the status quo (Valencia, 2010). Following Valencia, I define *deficit discourse* as spoken or written texts that legitimize the unjust social order based on the distorted deficit characteristics of the oppressed.

This paper aims to contribute to the discussion with an effort to situate deficit discourse in talk-in-interaction among mathematics teachers (MT) and mathematics teacher educators (MTE). By doing so, I argue that deficit discourses are mobilized as discursive resources for a participant to pursue a context-specific action; hence, I suggest it is important not only to identify what deficit discourses are but also to examine the practices of performing deficit discourses in a particular context of social interaction.

Linguistic Turn in Examining Deficit Discourse

Deficit discourse is a delicate and complex issue. As Tiezzi and Cross (1997) warned, focusing solely on an individual MT's belief as the root of deficit discourse may lead to MTE's own deficit perspective toward the MT. Deficit discourse is *a social* phenomenon which requires a view from a systemic perspective as well as an examination of the individuals. To do so, Parks (2010) and Suh and colleagues (2013) took a linguistic turn in which they treated language as performance or constructive of the social world. Language, in their views, is the object of study for its own sake to understand the social world rather than a medium to see a person's mind.

Their analyses revealed the discourses that are pervasive in mathematics education such as "the metaphor of a narrow path" (Parks, 2010), "the individual maturation storyline," and "the institutional tracking storyline" (Suh et al., 2013). These types of discursive resources, the authors argued, constrain MTs' ways of conceptualizing students' strength and assets and limit the MTs' own agency to utilize the diverse set of strengths in their classrooms. These discursive patterns often lead to a deficit-oriented statement such as "My students don't have …." In the individual maturation storyline, for instance, brain development is an important part, and the students are positioned as individuals lacking maturation to successfully engage in a particular learning task. Although Parks (2010) and Suh and colleagues (2013) revealed discursive limitations that are often overlooked by researchers, a few questions still remain in the linguistic turn: Why is this deficit discourse deployed here and now? How is it accomplished? To answer these questions, I examine how discursive resources are effectively mobilized in moment-to-moment interactions by the participants. By drawing on conversation analysis and discursive psychology as analytic tools, I examine a non-representative piece of data from a broader research project focused on equity-oriented professional development (PD).

Analytic Framework: Action Sequence and Rhetorical Redescription

Briefly speaking, conversation analysis (CA) concerns how people perform conversations in ordinary settings (e.g., dinner time, phone calls). CA grew out of ethnomethodology and speech act theory and has contributed to multiple fields by revealing the hidden practices in our daily socialization (e.g., turn-taking, sequencing action, repairing). In this paper, I focus on how actions are sequenced in social interactions (Schegloff, 2007), in particular, a storytelling sequence (Jefferson, 1978). Following the ethnomethodology tradition, CA validates claims based on participants' observable actions in talk-in-interaction, what the participants recognize, and how the participants treat those actions.

To examine the rhetorical effectiveness of the talk-in-interaction, I also draw on discursive psychology (DP). Influenced by ethnomethodology, social constructionism, and post-structuralism, DP approaches social psychology from a discursive perspective. I draw on Potter's (1996) work on the rhetorical aspect of discourses situated in social interactions. Thus, I ask how rhetorical resources are mobilized for participants to construct a discourse and how the discourse builds a version of fact.

Examining Deficit Discourse in the Context of Social Interaction

The conversation below happened in the early stage of the second round of an action research cycle, which focuses on incorporating students' active involvement and agency to guide teachers' action research projects. Prior to the excerpt below, one MT, named Renee, addressed her concern about having her first graders explore the suspension practice in the school using mathematics, and a tension emerged between Renee and the MTEs. On one hand, Renee mentioned that her first graders were not mature enough to think beyond themselves at their stage of development. On the other hand, the MTEs tried to persuade her to remain open-minded about her students' capacity and suggested her to pursue the idea of fairness instead of the institutional practice of suspension, and then the following conversation happened:

Excerpt: The Corpus Callosum

MTs: Carol, Danisha, Ramona, Renee, and Kathy; MTE: Susan (in pseudonyms)
Conventions: pause in 1/10 sec, (.*x*); overlapping talk, [ ]; vowel elongation, : ; emphasis, _ ; unrecoverable speech, ( ); rise and fall in intonation, ↑ ↓; low volume, ° °; comment, (( ))

```
01  Sus:   okay so there's suggestion of direction to go.
02         Kathy, you [have] something to add?=
03  Kat:              [Well]

04  Kat:   =I just had a thou:ght. you guys were at (auditorium)?
05                (0.4)
06  Kat:   [you know wel]coming back,
07  Dan:   [YE↑:::S]
08  Ren:   (                ) I wasn't th[ere::.]        Uh Heh Heh Heh heh
09  Kat:                                                   [↑I ↓kno:w.]
10  Kat:   but there was this wonderful speake:r and he talked about
11                the bra:::in.
12                (.)
13  Kat:   [(          )]  [                ]  [and don't   ] ↑QUOTE ME on this
```

```
14  Car:  [he was good.]                          [he was good.]
15  Ram:                 [That's right.]
16  Kat:  but the two parts of the brai::n, there is that thing in the middle?
17               (0.3)
18  Kat:  anyone remembers what is that called?= ((puts two fists together))
19  Car:  =the [(0.2)] corpus=
20  Ram:    [the]
21  Sus:  =the corpus [callosum]
22  Kat:              [corpus] calla- Yeah. (.) ↑that is not even developed
23               about age ten, (sir/so). (0.5) so how do we expect our children to
 24              (0.2) know right and wrong and to
25               [problem solve, do this multiplication,] and division
26  Ram:  [we would have to teach them and have to help them develop it.]
27  Kat:  when they don't even (0.2) truly have the brain [capa]city.
28  Car:
 [right]
29               (0.2)
30  Kat:  so I am just wondering little six year olds.
31               (0.6)
32  Car:  °they are not there.°
33  Kat:  right. I mean they give you what they in↑terpret it is::.
34               (0.3)
35  Ren:  right it [um what I am thinking it is-] is (0.2) that=
36  Kat:                 [right and wrong but]
37  Ram:  =that's true. ((nods slowly))
```

The conversation above contains Kathy's storytelling sequence (line 10-23) about the brain development in relation to children's limited mental capacity, which Suh et al. (2013) named as "the individual maturation storyline." To further the discussion, I ask the following questions: how is the individual maturation storyline situated in this particular action sequence? What are the discursive resources upon which Kathy draws?

Based on where the storytelling is placed in the conversation, the storytelling is formulated as a dispreferred response (i.e., a refusal) to the suggestion of pursuing the concept of fairness. When a response to the suggestion was made relevant (line 1), Kathy opened a storytelling pre-sequence (line 4). In line 23, the refusal was clearly articulated when Kathy stated, "so how do we expect our children to know… ." Kathy's dispreferred response was also recognized by Renee, and after this excerpt, Renee further expands Kathy's refusal by offering her own hypothetical account. Note that the deficit image of young children was invoked not for its own sake but rather as an account to justify Kathy's refusal to the suggestion. In other words, the deficit discourse was mobilized by Kathy to do a context-specific action; that is, in this case, to refuse the MTE's suggestion.

A closer look at the sequence shows how pre-sequences were placed to elicit the solidarity among the teachers against the MTE's suggestion. In line 4, Kathy asked, "you guys were at (auditorium)?" The question was targeted to "you guys", the teachers; thus, it framed the story as 'our shared' story. Moreover, it assigned higher epistemic status on the teachers as co-witnesses since none of the MTEs witnessed the scene. The move toward the solidarity among *all* MTs became more apparent when Renee responded with "I wasn't there::." (line 8). Kathy gave her sympathetic response, "↑I ↓kno:w." (line 9), and it was followed by Renee's loud laughs indicating her affiliation to Kathy.

The sequence contains multiple rhetorical resources such as vivid detailed descriptions that can be used to build up the facticity of an account. For instance, Kathy aided her description of the brain with an embodied gesture when she put her two fists together to model the shape of the brain. Note that she also invoked the image of “little six year olds” (line 30) instead of other possible alternatives (e.g., first graders, children). This depicted the students as ‘underdeveloped’ children. Also, the sharp numerical comparison between the age of 10 (when children reach full development) and age of 6 (first graders) may have enhanced the rhetorical effect.

While mobilizing the rhetorical resources, Kathy also effectively established her neutrality to the description. Kathy indicated that her story was told by “this wonderful speaker”, a third-party male person. When she said, “don’t ↑QUOTE ME on this” (line 13), she reaffirmed her footing as an ‘unbiased messenger.’ To avoid accountability, she also expressed uncertainty when she offered her own idea by saying, “So I am just wondering …” (line 30).

The rhetorical account formulated by Kathy was, indeed, powerful. In contrast to Kathy’s deficit-oriented description, another teacher in the room, Ramona, initially interpreted the same event quite differently. She mentioned, “We would have to teach them and have to help them develop it.” (line 26). That is, the speaker advocated for the need of better support from the teachers to promote brain development. Later in line 37, however, Ramona conceded to Kathy’s argument by stating “That’s true.” and nodding slowly.

The above analysis offers a way to see how a particular deficit discourse is situated in the context of social interaction. I illustrated how a deficit discourse was mobilized to do a refusal, and it involved the delicate handling of social relationships and managing multiple rhetorical devices. To effectively challenge and reframe deficit discourse, then, we need to understand deficit discourse *within the context*. The task will involve disentangling the micropolitics in social interactions, and rhetorical resources and skills will be needed to construct and reinforce the asset-based reality in which diverse strengths of students are valued.

EXPLORING TEACHERS' DECISIONS IN UNIT DESIGN AND IMPLEMENTATION

Ayfer Eker
Indiana Unversity
ayeker@iu.edu

Dionne Cross Francis
Indiana University
dicross@indiana.edu

This study investigates elementary mathematics teachers' decisions in designing and implementing a fraction unit aligned with reform-oriented learning and teaching practices and the factors that influence their decisions. Four 4th grade teachers from different schools designed a fraction unit and implemented it in their classrooms. The data sources include video-recordings of unit design sessions, classroom unit implementations and unit-debriefing sessions; pre and post semi-structured interviews including beliefs questions; and a Likert-scale survey on beliefs in addition to a fraction survey with items to determine teachers' levels of mathematical knowledge for teaching (MKT). The findings suggest that one of the teacher's relatively high level of MKT and her mathematical beliefs compatible with reform-oriented ideas might have affected her decisions and caused low fidelity in implementing the designed unit.

Keywords: Teacher Education-Inservice/Professional, Curriculum, Mathematical Knowledge for Teaching, Teacher Beliefs.

The agenda for reform efforts in K-6 mathematics education have aimed at increasing student math success by focusing on learning with understanding. In efforts to foster critical thinking and reasoning, problem solving and individual knowledge construction in classrooms, reform advocates have attempted to develop reform-oriented mathematics curricula to be used in schools. By acknowledging students as the constructers of math knowledge, their teachers were also expected to take on new roles, such as facilitators of learning as opposed to more traditional teacher roles that positioned them as knowledge holders and transmitters. Although reform advocates have set their goal and agenda clearly, their efforts have encountered pushback from teachers - they have struggled to implement the reform-oriented curricula. Researchers have explored this issue and asserted various reasons including teachers' lack of understanding of the pedagogy proposed within the curricula (Manouchehri & Goodman, 1998), teachers' beliefs and background in mathematics and in general (Remillard, 2005), and teachers' ideas about the appropriateness of the curricula for their students (Stein, Grover & Henningsen, 1996). Additionally, teachers are expected to use a curriculum for which they are not a part of the development process and that causes unfamiliarity with the ideas proposed in the curriculum (e.g. Kirk & MacDonald, 2001). As such, it begs the question, would teachers implement curricula with greater fidelity of they were actively engaged in the development process?

In this regard, I wanted to explore the role of agency in teachers' decisions about designing and implementing curriculum and the factors affecting their decisions through the whole process. Since developing a year-long curriculum would be difficult within the length of the study, the teachers were involved in designing a fraction unit focused on developing fourth grade students' understanding of a fraction concept. The research questions that guided the study are:

What factors influence fourth grade elementary math teachers' decisions in designing and implementing a fractions unit?

a. What are the design decisions made in designing the unit?
b. What are the implementation decisions made in instructing the unit?
c. To what extent does the unit designed by teachers align with the unit implemented?

i. In incidents of alignment, what factors contributed?
ii. In incidents of misalignment, what factors contributed?

Conceptual Framework

This study is designed as part of a larger professional development (PD) program that aimed to improve the quality of elementary teachers' mathematics instruction by developing their mathematical knowledge for teaching (MKT) (Ball, Thames &Phelps, 2008). Ball, Thames, and Phelps (2008) refined Shulman's (1986) earlier categories - content knowledge, curricular knowledge, and pedagogical content knowledge (PCK) - by encapsulating these knowledge under the umbrella of MKT and further subdividing content knowledge and PCK into components (for additional information on different types of knowledge required for teaching, see Ball, Thames & Phelps (2008) and Hill, Ball & Schilling (2008)). They suggest the components of teachers' MKT - specifically common content knowledge (CCK), specialized content knowledge (SCK), knowledge of content and students (KCS) and knowledge of content and teaching (KCT) - affect their instructional practices. Thus, this study considers teachers' MKT as a factor influencing their decisions in designing and implementing a fraction unit.

In addition to MKT, teachers' mathematical beliefs affect their practices (Ernest, 1989; Pajares, 1992). The relationship is sometimes positive; if a teacher holds reform-oriented beliefs about student learning, then she would use reform-oriented teaching methods in her classroom (e.g. Cross, 2009). On the other hand, there are other studies that provide evidence to cases where teachers' mathematical practices do not necessarily reflect their beliefs, or their beliefs do not necessarily match with their practices (e.g. Beswick, 2012). Leatham (2006) provided an explanation to that inconsistency in his *sensible systems framework*. He claims that the conflict between beliefs and practices is not due to lack of a direct relationship, but it is due to the effect of other beliefs that happen to affect practices more than the desired ones. For example, when we realize there is an inconsistency between a teacher's belief, which we believe to affect or bring about a certain type of instruction, and her practice, we should consider there may be other beliefs or factors that are possibly influential on the action. So, teachers' beliefs was another factor possibly affecting teachers' decisions in designing and implementing a fraction unit.

Methods

The study falls under the embedded mixed methods case study (Creswell & Clark, 2011) as the quantitative data were collected before qualitative data and were used to further explain some of the differences in teachers' decisions about designing and implementing the unit. Thus, the data were analyzed using both quantitative and qualitative data analysis approaches. The participants were four 4th grade elementary teachers from four schools across two school districts in the Midwest. All of the participants had at least one year of teaching experience.

The data was drawn from a larger project on teacher PD conducted by researchers from a neighboring university. Data sources included video recordings of unit design sessions where teachers collaboratively designed a fraction unit, classroom sessions where teachers implemented the unit, and unit debriefing sessions where teachers discussed video clip examples from each other's classrooms; audio-recordings of teacher interviews; a belief survey; an itemized MKT survey; and unit reflection forms developed for each teacher by the researcher.

The data analysis incorporated both quantitative and qualitative methods. First, the videos from the unit design sessions were analyzed to determine the details of the designed fraction unit. The final product - the unit to be implemented - included a sequence of tasks selected by teachers along with the corresponding pedagogical considerations (PC) to be employed during the enactment of tasks. Second, the unit implementation videos were analyzed with a focus on teachers' decisions about tasks, the sequence of tasks and the specific PCs used during instruction. In addition to that, the video recordings of the unit debriefing sessions in which teachers discussed their unit implementation by showing short video clips from their classroom were also used to frame the details of implemented unit for each teacher. Third, the level of alignment was determined by comparing i) the number of tasks, ii) the sequence of tasks and iii) the PCs from the designed unit and the implemented unit for each teacher. Finally, the results from beliefs and MKT surveys in addition to findings from the interviews and unit reflection forms were used to explain what factors affected teachers' decisions and how.

Results & Discussion

The designed unit consisted of 12 tasks that focused on identifying the whole, partitioning, equivalence, comparing, and ordering the fractions. In addition to that, a total of 19 PCs were included under the relevant tasks. An example of a PC was "using manipulatives in introducing improper fractions" included under the task about exploring improper fractions. The findings revealed that although teachers had agency in designing the unit, the fidelity of their implementation varied (Table 1).

Table 1. Alignment percentages of fidelity components across cases

Teacher	Number of tasks from designed unit	Sequence of tasks according to designed unit	Employed PCs for the tasks from designed unit
Candy	42%	100%	35%
Britney	58%	100%	56%
Ralph	58%	71%	22%
Tamara	33%	100%	37%

In this paper, I will focus on Candy's case because although she did not have the highest fidelity levels for all components, her case clearly shows the complexity underlying the unit implementation process. Candy used only 5 of the 12 tasks in the exact same sequence with the designed unit. Regarding PCs, she used only 35% of the relevant PCs for the tasks. The findings from the surveys and interviews revealed that she held reform-oriented mathematical beliefs- she believed mathematics is a human endeavor that is continuously changing. Regarding learning and teaching math, she believed "students are the constructers of knowledge" and math instruction should be centered around student thinking. Her score from the MKT survey revealed she had relatively high level of understanding about fractions (CCK, SCK), knew how to interpret student thinking (KCS) and how to respond to student productions meaningfully (KCT).

Regarding the fidelity level for the number of tasks, Candy explained that her students needed help with partitioning, so she decided to spend more time on the relevant tasks. Even though this made her unable to move forward with the additional tasks in a timely manner, the way she implemented the tasks made her instruction more valuable in terms of providing her students opportunities to work on partitioning more extensively by discussing, questioning and actively producing – a feature of classrooms that align with reform-oriented practices. Also, realizing that her students would not be able to move forward in building strong conceptions of more advanced fraction concepts mastering partitioning and deciding to spend more time with relevant tasks indicate that Candy has strong grasp of the knowledge at the intersection of content and students. In other words, Candy's MKT levels appeared to influence her decisions about unit implementation.

There is no evidence to suggest that Candy's students' understanding of fractions increased through the unit, but the interaction captured in her instructional video, her responses to interview questions and survey items and her reflection on her experience during unit debriefing session all indicate that she placed student thinking at the center and built her instruction around it. Even though her fidelity level for PCs appear to be low, among all the teachers, Candy was the one who incorporated the PCs related to questioning, listening student responses and encouraged whole group discussion more frequently. In her reflection she stated, "Having students explain and show is more helpful than paper-pencil." This might indicate that Candy's reform-oriented beliefs about students, learning and teaching mathematics influenced her decisions in implementing the unit. So, although it appears that Candy's participation in designing the unit did not lead to considerably high levels of fidelity in her implementation, our observations would suggest that her teaching of the unit aligned closely with instruction suggested in reform documents.

Teachers' understanding of the content, teaching and students appear to have an impact on their implementation of the curricula. Curriculum developers should consider this while working with teachers and confirm that teachers have a substantial understanding of the overall goals and instructional practices of the curriculum and students' learning trajectory within the curriculum in order to enable their adherence to main goals of the curricula. Further results and implications will be shared during presentation.

Decades of research has shown that most professional development fails to result in changes to teachers' classroom practice. This project explores an innovative professional development focused squarely on mathematics teaching practice and seeks to understand the features of the professional development that effect classroom level change.

Keywords: Teacher Education – In-service/Professional Development, Classroom Discourse, Elementary School Education

Problem Statement

Supporting teachers to improve their practice is a fundamental challenge for professional development. Decades of research have demonstrated that many common approaches to professional development do not adequately support improvements in teachers' capabilities (e.g., Cohen & Hill, 2001). In response, there has been increased work to develop new forms of professional development. Careful studies are needed to understand features of professional development design that support the learning of practice and how key variations in the design impact teacher learning. Further, many studies of professional development do not examine changes in teaching practice and such studies are needed.

This study is grounded in our project's work over the last decade to address the challenge of supporting the learning of practice using an approach to professional development situated in a common "live" case of elementary mathematics instruction occurring as part of a summer program for fifth grade students. The class comprises primarily Black youth, along with a small number of Latinx and white children, mostly from low-income families. The teacher is experienced and comfortable with making her practice visible and open to others. The approach uses this classroom as a "common text" for working on practice, where participants are not only watching and discussing, but are engaged in developing and refining teaching practice. Participants' engagement approximates a form of "legitimate peripheral participation," (Lave & Wenger, 1991) through structured conversations about the lesson plans, close observation, analysis of student tasks, and examination of records of teaching and learning. In addition, participants receive professional development focused on leading mathematics discussions.

The research explores the impact of participation in these structured ways on teachers' practice, as well as on their knowledge and dispositions. Our contribution is to rigorously study the impact of our professional model in situ to determine whether and how the work transfers into classrooms. Specifically, our initial study seeks to answer the following questions: What do teachers learn from structured participation in the class? Does their participation impact their own teaching practice, and if so, in what ways? Does the addition of professional development focused on a particular teaching practice impact teachers' own practice, and if so, in what ways?

Theoretical Framework

Mathematics teaching is something that people do; it is not merely something to know. Teachers must use knowledge flexibly and fluently as they interact in specific contexts with students, with the aim of helping those students become proficient with mathematics. This interactive and dynamic view of instruction can be represented by the "instructional triangle" (Cohen, Raudenbush, & Ball, 2003), a conceptualization of teaching as interactions among teachers, students, and content, in an environment. This conceptualization has important implications for the design of professional development. It means that professional development must attend to the specialized ways that teachers must understand mathematics, how that knowledge of mathematics interacts with teaching practices that support the learning of their students, and how the context of teaching interacts with all of these factors.

Our professional development is designed to support this type of professional learning and draws on recent work supporting teachers' learning of mathematics content and teaching practices. The work of "video clubs" as a means to increase capabilities at noticing student thinking (van Es & Sherin, 2008) in conjunction with research on lesson study as a means for teachers to learn from teaching and to develop and share practitioner knowledge (Perry & Lewis, 2009) informed the design of our peripheral participation model. Our project builds on these efforts and seeks to learn about impact on teacher practice.

We grounded our professional development in a particular decomposition (Grossman et al., 2009) of the teaching practice of leading a mathematics discussion. We define discussion as "a period of relatively sustained dialogue among the teacher and multiple members of the class" in which students respond to and use one another's ideas to develop collective understanding (TeachingWorks, 2015). Our decomposition is informed by research on orchestrating productive discussions (Smith & Stein, 2011), the concept of talk moves (Chapin, O'Connor, & Anderson, 2013), and research on decomposing practices to support learning (Boerst, Sleep, Ball, and Bass, 2011). The table below shows our decomposition of leading discussions with practices organized into three areas of work: (1) framing, (2) orchestrating, and (3) recording/representing content.

Table 1: Areas of Work and Practices for Leading Mathematics Discussions

Areas of Work		
Framing	*Orchestrating*	*Recording/representing content*
Launching Concluding	Eliciting student thinking Probing student thinking Orienting students towards the thinking of others Making contributions	Keeping accurate public records Using representations to convey key ideas

Methods

The study seeks to determine the extent to which peripheral participation in elementary mathematics teaching and focused professional development impact teachers' actual practice and factors that support their enactment of practice, including their ability to notice the specific work of teaching, and children's mathematical strengths. The broader study focuses on elementary teachers (n = 24), all of whom engaged in peripheral participation in elementary mathematics teaching for five consecutive days (~25 hours) and half of whom (n = 12) participated in additional professional development across the five days (10 hours) focused on leading a mathematics discussion. We collected and are analyzing a set of pre- and post-measures including measures of teachers' language in talking about students and teaching, and videos of classroom mathematics discussions which are being analyzed using a tool focused on the work teachers do when leading mathematics discussions (Selling, Shaughnessy, Willis, Garcia, O'Neill, & Ball, 2015).

In order to increase the comparability of teachers' skill with discussion leading practice, our team designed a "common" discussion plan based on work developed in a prior study (Garcia, Selling, & Wilkes, 2015; Selling, Shaughnessy, Willis, Garcia, O'Neill, & Ball, 2015). This enabled us to control for task selection and discussion structure. The accompanying technique checklist tool, which captured techniques related to practices named in our decomposition, was expanded to include advanced techniques that could be expected from experienced teachers.

For this initial study, we focus in particular on the impact of the full professional learning experience (~35 hours) on teachers' skill with leading mathematics discussions. To focus in on this impact, we selected four case study teachers who represented a range of skill with leading mathematics discussions in the pre-intervention data set. We then examined pre- and post-intervention video of their common discussion lessons. Videos were double coded by members of the research team using the technique checklist tool. Discrepancies in coding were resolved by a consensus discussion and reference to code books developed by the research team.

Analysis

Analysis of pre- and post- common discussion lesson videos utilized the technique checklist tool to examine particular techniques used before and after the intervention. Techniques were coded as present, not present, and not applicable. In some cases where we would expect to see a technique used frequently, for example "asks questions that deepen student reasoning," additional codes of once, more than once, and frequently replaced the code of present. We then compared participants at the technique level to determine whether their use of the technique increased, stayed consistent, or decreased from pre- to post-intervention. Table 1 below shows the positive areas of change for each of our case study teachers in each area of work of leading a mathematics discussion. For example, T12 improved in all 3 techniques from pre-post in the area of launching a discussion.

Table 2: Number of Techniques in Each Area of Work Showing Positive Change

	Launching (3)	Concluding (3)	Eliciting (3)	Probing (5)	Orienting (4)	Making Connections (3)	Making Contributions (5)	Recording/ Representing Content (4)
T12	3	0	1	3	3	2	1	2
T14	0	2	0	1	0	2	1	0
T18	0	2	0	0	1	0	0	0
T22	1	0	2	1	1	3	2	1

The initial analysis shows that the three out of four teachers increased their use of techniques in four areas of work: probing, orienting, making connections, and making contributions. Additionally, half of the case study teachers increased their use of techniques in the remaining four areas of work.

In addition to the presence of techniques, the team also coded for problematic areas, including unequally distributed participation, ineffective probes, and incorrect/inaccurate mathematical contributions. All case study teachers had fewer issues in their post-intervention discussion than their pre-intervention discussion. Notably, T12 improved in 7 of 8 issue areas.

Discussion

Initial results of the study show promise for the potential of the current professional development design to impact teaching practice. Peripheral participation paired with a focused discussion leading professional development increased teachers' use of techniques core to the work of leading productive mathematics discussions. Next steps for this work are twofold. First, we will examine impacts of the professional development on other indicators including teachers' mathematical knowledge for teaching and their skill with noticing and naming student strengths. Second, we will examine and compare the impact of peripheral participation with full participation on teachers' discussion leading practice and associated factors.

We investigate teacher noticing of students' prior knowledge in the context of a professional development intervention that integrated lesson study, animation discussions, and video clubs with in-service geometry teachers. We analyzed video club discussions throughout the program in relation to teachers' noticing of students' prior knowledge and found that the discussions in the middle of the two-year intervention had the highest level of noticing, coinciding the lesson revision process. The findings suggest that the lesson revision process spurred connections between teachers' observations of students' prior knowledge and pedagogical decisions.

Keywords: Teacher Education-Inservice/Professional Development, Geometry and Geometrical and Spatial Thinking

This study investigates the effects of professional development on teacher noticing of students' prior knowledge in geometry instruction. We consider how teachers attend to and interpret student thinking while discussing classroom videos. The intervention integrated three strategies, namely, animation discussions (Chazan & Herbst, 2012), video clubs (Sherin & Han, 2004), and lesson study (Fernandez, 2002), with the objective of supporting teachers' attention to student thinking. We consider the ways in which teachers can support students' development of mathematical understandings in secondary schools by noticing their prior knowledge.

Theoretical Underpinnings

Professional Development to Promote Teacher Noticing

Lesson study engages teachers in a cyclical process of conducting instructional material research, planning a research lesson, teaching and observing the implementation of the lesson, and reflecting upon student thinking observed during the implementation of the lesson (Fernandez, 2002). Teachers may engage in the process of revising and re-teaching the lesson to optimize student learning opportunities (Lewis & Hurd, 2011). Traditional live observations may be difficult in the U.S., which prompted us to replace live observations with video clubs. During video clubs, teachers discuss videos from their own classrooms. Sherin and colleagues demonstrated that initially teachers tend to focus on various aspects of instruction, but sustained video club meetings enable teachers to increase their attention to student thinking (Sherin & Han, 2004). Van Es's (2011) analysis of *how* and *what* teachers notice in video clubs demonstrated that the sophistication of teachers' analyses of students' thinking increased over time.

Students' Prior Knowledge

Our conceptualization of students' prior knowledge goes beyond the mathematical prior knowledge and includes students' multiple mathematical knowledge bases (Roth McDuffie, et al., 2014). This understanding of students' prior knowledge acknowledges that students draw upon their prior experiences, including their cultural and community knowledge, when approaching a math problem. Especially in problem-based math instruction, when students learn a target concept through solving a complex mathematical task, students' prior knowledge, both in relation to the mathematical task and the context it is situated within are of great importance.

Research Question

What students' prior knowledge do teachers notice and how do teachers consider students' prior knowledge in video clubs throughout a professional development intervention?

Methods

Five high school geometry teachers from high-needs schools participated in 20 three-hour sessions. All participants taught the lesson while members of the research team videotaped. In subsequent sessions, the teachers participated in video clubs where they discussed students' problem-solving strategies. The research team selected the video clips following criteria established by Sherin, Linsenmeier, and van Es (2009). In year two, the teachers revised and taught the lessons and engaged in video clubs.

We selected four sessions, 3, 4, 12, and 19, as representative video clubs at the start, middle, and end of the intervention. With an entire video club discussion as our unit of analysis, we independently coded the discussions using a rubric that considers teacher noticing of students' prior knowledge based upon van Es' (2011) framework (Table 1). The framework investigates *what* prior knowledge teachers notice and *how* they notice students' prior knowledge.

Table 1:Framework for Teacher Noticing of Students' Prior Knowledge

	Level 1	Level 2	Level 3	Level 4
What students' prior knowledge do teachers notice?	No mention of students' prior knowledge.	Mention students' mathematical prior knowledge in terms of what they have learned in class previously.	Mention students' prior knowledge in relation to the task, including mathematical, contextual, and/or practices.	Attend to relationship between students' prior knowledge and pedagogical issues.
How do teachers notice students' prior knowledge?	No mention of students' prior knowledge.	Describe students' mathematical prior knowledge.	Describe students' mathematical, contextual, and out-of-school prior knowledge.	Make connections between students' prior knowledge and principles of teaching and learning.
		Primarily evaluative comments about students' prior knowledge, with some interpretive comments.	Analyze and interpret noteworthy student actions in relation to their prior knowledge.	On the basis of interpretation, propose alternative pedagogical solutions to use students' prior knowledge.
		Refer to specific events and interactions as evidence.	Refer to specific events and interactions as evidence and elaborate on them in relation to students' prior knowledge and how it shapes their mathematical understanding.	All attributes of Level 3

Findings

The majority (67%) of the selected video club discussions were coded as Level 3 in regard to *what* students' prior knowledge teachers noticed (Table 2). Throughout the professional development intervention, the teachers consistently discussed students' prior knowledge in relation to their work on the task, and frequently considered sources of students' prior knowledge beyond mathematical content taught in school. However, in most discussions the teachers did not connect students' prior knowledge to pedagogical decisions. Thus, in terms of *how* teachers noticed students' prior knowledge during the video club discussions; we coded most of these video club discussions at Level 2 (56%). While it is possible that the teachers offered some interpretation of students' prior knowledge, the focus of the discussion was mostly on evaluation.

Table 2:Teachers' Noticing of Students' Prior Knowledge in Video Club Discussions

	Level 2	Level 3	Level 4
What Prior Knowledge Teachers Notice	11%	67%	22%
How Teachers Notice Students' Prior Knowledge	56%	33%	11%

Figure 1 illustrates the relationship between *what* and *how* teachers noticed students' prior knowledge for each video club over time. The majority of the video club discussions (5 out of 9) were coded at the same level for both what and how teachers notice students' prior knowledge. In the later discussions, the levels differed more frequently, but *what* students' prior knowledge teachers noticed was always rated at the same level or higher than the level of *how* teachers noticed students' prior knowledge. Additionally, teachers' discussions reached the highest levels of noticing during the middle of the professional development. At this point in year two, the teachers were in the process of revising the lesson for the second year.

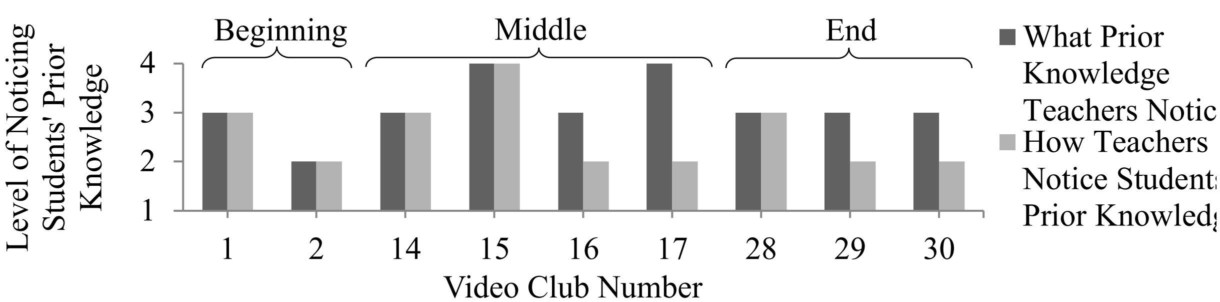

Figure 1. Levels of Noticing Students' Prior Knowledge Per Video Club

Discussion

The findings of our coding for *what* and *how* teachers notice students' prior knowledge show the video club discussions achieved the highest levels in the middle of the intervention. This finding suggests that teachers' motivation to revise the lesson and to re-teach it, as part of their engagement in lesson study, provoked them to examine pedagogical issues in combination with students' prior knowledge. Specifically, the highest levels of the theoretical framework require teachers to go beyond describing, evaluating, and interpreting students' prior knowledge by making connections with their instruction. It seems that the impending need to make changes to the lesson using their observations of students' work in the video club provoked discussion of pedagogical issues. This finding suggests that lesson study can be a motivation for increasing teacher noticing and supports the idea that video clubs can be valuable for lesson reflection.

Although prior research findings suggest that teacher noticing increases over time (van Es & Sherin, 2008), our findings suggest that teacher noticing is not an activity that necessarily increases in sophistication over time. Instead, teacher noticing is purposeful, and highly motivated by activities that promote connections between observations of student learning and teaching. In our case, the need for revising the lesson with the goal of optimizing student learning opportunities provided the conditions for teachers' highest levels of noticing. One implication for teacher education is that activities promoting connections between noticing student thinking and using student thinking in instruction can further teacher noticing.

Conclusion

Combining lesson study and video clubs can provoke teachers to achieve a higher level of noticing because they are motivated to study tasks for optimizing student learning opportunities. In particular, the process of revising the lesson prompts teachers to make connections between observations of student thinking and instructional improvement. Our findings support the importance of implementing the full lesson study cycle. Considering difficulties allocating resources for lesson study, it is important that the lesson revision step continues to be enacted to maximize teachers' learning opportunities.

USING COACHING CYCLES TO TRANFER AND SUSTAIN EFFECTIVE INSTRUCTIONAL PRACTICES

Kristin E. Harbour
University of South Carolina
kharbour@mailbox.sc.edu

Stefanie D. Livers
Missouri State University
stefanielivers@MissouriState.edu

We illustrate a coaching cycle approach situated within a larger professional development design that focused on infusing high quality mathematics tasks and differentiation within inclusive elementary mathematics classrooms. Our design supported teams of general education and special education teachers with integrating tasks and differentiation strategies into co-taught mathematics lessons through reflective coaching sessions. This project yielded positive results in instructional practice and co-teaching collaborations.

Keywords: teacher education-inservice/professional development, instructional activities and practices, elementary school education, equity and diversity

Introduction

Professional development is necessary for teacher growth. In order to be effective, professional development must directly tie to the teachers' practice, focus on specific content, align with school improvement initiatives, strengthen teacher collaboration, and provide consistent follow-up (Wei, Darling-Hammond, Andree, Richardson, & Orphanos, 2009). Often, observations and coaching cycles are strategies used to provide the consistent follow-up and support the transfer of practices learned from professional development to teachers' classrooms. Specific to mathematics teaching and learning, coaching has been linked to increased student achievement, improved teaching practices, changes in teachers' beliefs, and sustained professional development concepts (e.g., Baldinger, 2014; Campbell & Malkus, 2011).

Overview of Professional Development Project

The overarching goals of the professional development project included increasing teachers' content and pedagogical content knowledge, creating communities of learners, particularly between general education and special education teachers, focusing on reducing the achievement discrepancy noted between students with and without disabilities, and shifting instructional practices in inclusive mathematics classrooms. Specifically, three areas were targeted to create the conceptual framework for the overall project: (a) increasing the use of high-quality mathematics tasks (Stein, Smith, Henningsen, & Silver, 2001), (b) incorporating meaningful differentiation strategies to meet the needs of all learners (e.g., Tomlinson et al., 2003), and (c) integrating effective co-teaching models and practices (Friend & Cook, 2010). To meet the goals of the professional development project and provide support to the teams of general education and special education teachers, we designed a longitudinal professional development plan that used multiple formats of professional development delivery (Guskey, 2000). Our design included both synchronous (face-to-face) and asynchronous (independent) opportunities for learning, with on-site coaching sessions to help sustain and transfer the learning from the whole-group sessions to teachers' actual classrooms.

Setting and Participants

The setting was one county district in a southern state located near a large research university. The school district identified a need for professional development in relation to co-teaching in mathematics to increase co-teaching and differentiation. Participants were from eight elementary schools and included 22 general education teachers and 13 special education teachers or paraprofessionals (n= 35 teachers). Co-teaching teams consisted of at least one general education teacher and one special education teacher or paraprofessional with varying numbers of teams per school (ranging from 1-6) for a total of 21 unique co-teaching teams.

Coaching Cycles

Theoretical Framework for Coaching

The theoretical framework for the coaching cycle centers on the cognitive apprenticeship model for learning (Collins, Brown, & Newman, 1987). Cognitive apprenticeship is similar to the traditional or trade apprenticeship ideals of an expert and a novice socially interacting in order to guide the learning of a task in a specific domain (Collins et al., 1987; Dennen, 2004). Unlike traditional apprenticeship models, "cognitive apprenticeship refers to the fact that the focus of the learning-through-guided-experience is on cognitive and metacognitive, rather than on physical, skills, and processes" (Collins et al., 1987, p. 5). The expert-novice relationship translates into a teacher-learner relationship (Atkinson, 1997), where learning occurs through a sequenced use of three teaching methods: modeling, coaching, and fading (Collins et al., 1987).

Coaching Cycle Development and Design

To ensure transfer and support the implementation of the lessons learned from our synchronous professional development sessions (e.g., Guskey, 2000), a coaching cycle was included in our larger professional development model to provide individualized support for each team of general and special education teachers (or paraprofessionals) in their inclusive mathematics classrooms. The participating teams of co-teachers were divided among the three lead facilitators (two elementary mathematics educators and one special education educator). Teams of co-teachers were asked to plan and deliver co- taught, high quality mathematics lessons that included differentiation when needed to meet the needs of all learners.

Similar to the design of coaching sessions used by Baldinger (2014), where there was a pre-session, observation, and post-session, we designed our coaching sessions to use a similar cyclical approach. Prior to implementing the coaching cycle, the facilitators developed a protocol to use during all coaching sessions to increase consistency in the expectations and coaching conversation among facilitators. The protocol established: (a) coaching sessions are to follow each synchronous professional development session, (b) the facilitator is to receive the co-teaching mathematics lesson plan at least 24 hours prior to the scheduled observation, (c) each lesson will be scored using the same instruments (discussed in more detail below), (d) a 30-minute coaching session/conversation will follow each lesson observation with discussions about the planning and delivery of the lesson (focused on co-teaching practices, differentiation strategies, and the quality of the mathematics task), and (e) the coach will record anecdotal notes about the lesson and coaching session.

Coaching Cycle Implementation

The Co-Teaching Checklist (Murawski & Lochner 2011), the Mathematics Classroom Observation Protocol for Practices (MCOP^2; Gleason, Livers, & Zelkowski, 2017), and a debriefing form (adapted from Villa, Thousand, & Nevin, 2013) focused on the three fundamental domains of our professional development model (i.e., high quality mathematics, differentiation, and co-teaching implementation) and were used for the data collection during the lesson observations and as a guide for the coaching conversations.

The Co-Teaching Checklist (Murawski & Lochner 2011) allowed us to measure specific co-teaching aspects, such as both teachers assist student with and without disabilities, the environment showcases a collaborative atmosphere, and the conversations and questions used support inclusive practices. The MCOP^2 (Gleason et al., 2017) allowed us to measure the extent instruction aligns with the Standards for Mathematical Practices and the shared responsibility and authority between teachers and students across 16 indicators. The debriefing form (adapted from Villa et al., 2013) allowed us to use the data collected from the Co-Teaching Checklist and the MCOP^2 coaching conversation and discussions surrounding co-teaching, differentiation, and the mathematics. The teachers first identified things that went well in the lesson, things they would do differently, and their co-teaching approach. Following the teachers' sharing, the facilitator then identified things that went well, as well as wonderings and suggestions. The coaching sessions ended with identifying next-steps and take-aways to focus on in future lessons.

Project Outcomes

A mixed methods design was used to determine the impact of coaching and professional development on teaching practices. Tentative, pre-post results from the MCOP^2 (Gleason et al., 2017) indicate a significant change in teacher facilitation and student engagement. Specifically, teachers increased their facilitation of high quality mathematics practices and meaningful learning experiences with students, and had more students engaged in opportunities to develop positive mathematics practices. These results indicated teachers were moving away from a teacher directed approach to a student-centered approach. Tentative results from the Co-Teaching Checklist (Murawski & Lochner, 2011) indicated more teachers were engaged in co-teaching and exhibiting effective co-teaching behaviors during the observations.

Our qualitative data across the course of the project also revealed positive benefits of the coaching cycles. Data from a sub-sample of culminating teacher reflections (n=9) showed positive results and benefits regarding the coaching sessions. Coding the responses revealed various themes, much of which centered on teacher growth and changes in teaching practices. Additionally, many teachers appreciated the coaching sessions allowed for immediate feedback and reflection time (see Table 1 for all themes and frequency of occurrences).

Table 1: Themes from Teacher Reflections about Coaching Sessions

Themes	Frequency
Growth as a teacher	7
Immediate feedback	4
Change of teaching practice	3
Most beneficial component of professional development	2
Reflection time	2
Energized	2
Accountable for co-teaching	1
Increase school communication	1
Ideas/strategies for extending lesson	1

Summary

Coaching sessions tied to intentional professional development yielded positive and visible results. Classroom observations shifted to a more student-centered practice, and an increase in co-teaching collaborations and behaviors. Teachers found the coaching cycles to be the most beneficial aspect of the professional development. Both our quantitative and qualitative results support the benefit of a coaching component to support and sustain professional development as echoed in prior research (e.g., Baldinger, 2014; Campbell & Malkus, 2011).

CHARACTERIZING REHEARSALS WITH IN-SERVICE TEACHERS

Casey Hawthorne
Furman University
casey.hawthorne@furman.edu

John Gruver
Michigan Technological University
jgruver@mtu.edu

To address the chasm between learning about effective teaching practices and being able to implement those practices competently, teacher preparation programs have begun to adopt rehearsals as a pedagogy. Teaching rehearsals are opportunities to develop an understanding of instructional practices in an authentic, but scaffolded environment. These have been shown to help novice teachers gain competency in complex teaching practices. In this study, we explore this pedagogy with in-service secondary teachers. Results indicate that in these rehearsals the teacher educators were less directive in their suggestions and the participating teachers were more assertive in making suggestions as compared to rehearsals with pre-service teachers.

Keywords: Rehearsals, Pedagogies of enactment, Professional development

Introduction

The divide between theory and practice in teacher preparation has long been recognized (Shulman, 1998). To compound this issue, what teachers see and experience in schools often differs considerably from the current conception of good instruction (Shulman, 1998). This chasm creates a tension between reform methods and current practices. As a result, when teachers are faced with the realities of teaching, they tend to adopt teaching practices they have experienced as students or through classroom observations (Korthagen et al., 2001). Exploring solutions to this historic divide, Grossman and colleagues (2009) examined the pedagogy of professional education across a variety of professions. From their comparative study emerged the notion of an *approximation of practice*, a method of scaffolding preparation in which pre-professionals engage in smaller, more manageable components of practice. This structure embeds training in the actual work of the profession as well as makes the details of professional actions and reasoning more visible.

Building on Grossman's work, several researchers have developed practice-based models of professional preparation in which the instructional focus shifted from primarily developing students' knowledge bases to gaining competencies in enacting particular instructional practices. These models centered around a particular approximation of practice, referred to as rehearsal, in which pre-service teachers (PSTs) engage in authentic, yet controlled instructional activities (IAs). During a rehearsal peers play the role of students, which provides a context where the teacher educators can introduce particular problems of practice and interrupt the flow of the lesson to offer in-the-moment suggestions about the details of instructional moves and decisions. Furthermore, this context allows rehearsals take place within a community organized around a common vision of instruction and shared values.

Rehearsals were conceived as a support for pre-service teacher preparation programs and consequently have been used predominantly in this context. However, the issue of how to implement effective teaching practices in real classrooms continues to challenge even experienced teachers. As such, we felt in-service teachers might also benefit from engaging in rehearsals. In this study, we explore the nature of rehearsals with in-service teachers.

Literature Review

The overwhelming majority of research on rehearsals has been embedded in the context of pre-service elementary programs (see Pfaff, 2017 for an exception). Early studies provided thorough characterizations of rehearsals as well as a theoretical rationale behind their use (e.g. Kazemi, Franke, & Lampert, 2009; Lampert & Grazini, 2009). Later, McDonald, Kazemi, and Kavanagh (2013) built on this structure, outlining an instructional cycle organized around pedagogies of enactment, in which rehearsals are preceded with various practice-based activities in preparation and then followed with the live enactment in front of students. As a more consistent conceptualization of rehearsals has emerged in the field, recent studies have provided detailed descriptions of how PSTs grappled with the nuances of a particular teaching practice (e.g. Ballinger, Selling, & Virmani, 2016; Elliot, Aaron, & Maluangnont, 2015; Pfaff, 2017)

Another area of analysis has been with the rehearsals themselves and in particular the teacher educator's (TE's) leadership and organization. Reviewing a collection of over 90 rehearsals, Lampert et al. (2013) analyzed the various exchanges when a TE interrupted the flow of the lesson to document the substance of the interaction (i.e. what was being talked about) and the structure of the interaction (i.e. how it was being talked about). Similarly, Kazemi, Ghousseini, Cunard, and Turrou (2016) reflected on five years of working with PSTs to give insights into how teacher educators can structure rehearsals to make them productive for PSTs.

We build on this last category of work that gives insight into how TEs can structure the rehearsal experience to make it productive for its participants by extending this work with in-service teachers. In particular, we investigated the nature of the interruptions in the teaching during the rehearsal. Following Lampert et al. (2013), we investigated both the substance and structure of TE interruptions. We did so with the assumption that coding the substance and structure of these interruptions would reveal differences between rehearsals with PSTs and in-service teachers, bringing into greater relief the choices TEs make when leading rehearsals.

Methods

The authors of this paper offered a 20-hour professional development (PD) session for experienced middle school teachers that lasted one week. The PD focused on how to teach figural pattern tasks to help students develop an understanding of variables as measuring quantities. The PD made use of rehearsals and an IA targeting this content area. The overall lesson was decomposed into four similar iterations of the same instructional structure. Each iteration served as the basis of a new rehearsal and differed by the representation and consequently the level of abstraction that students were asked to use to engage in the figural pattern generalization. Over the last two days of the PD (4 hours each day) the teachers participated in six rehearsals. We had fourteen middle school teachers volunteer and participate in the PD. Each of the fourteen was involved in planning at least one of the rehearsals, but only six teachers had the opportunity to serve as the acting teacher (AT) in a rehearsal.

We began our analysis identifying each interruption during the 6 rehearsals. We counted an interruption as beginning when the flow of the lesson stopped. This happened when a TE, participating teacher, or the AT interjected a comment about the lesson. Generally, we counted interruptions lasting until the instruction resumed. However, there were times when several independent topics were discussed without the AT resuming teaching. We counted these discrete discussions as separate interruptions when the substance of the interaction changed notably.

We then coded who initiated each interruption as well as the structure and the substance of the interruption. To develop our coding scheme for structure and substance codes, we starting with the codes used by Lampert et al. (2013), but then added new codes where the Lampert et al.

(2013) codes did not accurately capture the nature of the interaction. We developed new codes by first identifying interruptions where a new code was necessary. We then made descriptive notes about what was discussed during these exchanges as well as the nature of these interactions. Finally, we used grounded theory (Strauss & Corbin, 1998) to create categories that captured the characteristics of these interruptions. This work resulted in the addition of eight new structure codes and one new substance codes. Space restrictions do not allow us to describe each of the codes in our coding scheme, but we describe codes on an as-needed basis. Finally, the percentages of each code were determined relative to the total number of interruptions and then compared to the percentages reported by Lampert et al. (2013).

Results

Below are the percentages of the structure and substance codes that appeared in our study as well as the corresponding codes and values from Lampert et al. (2013) (see Table 1). In all, we had 71 interruptions over the 6 different rehearsals. Several of the interruptions aligned with more than one substance or structure code. In all there were 83 different structure (initiated) codes, 93 different structure (taken up) codes, and 101 different substance codes. 23 of these interruptions (32.4%) were initiated by participating teachers.

Table 1: Coding of interruptions

Structure	Us (Initiated)	Us (Taken Up)	Lampert et al.	Substance	Us	Lampert et al.
Alternate Move	21.13	12.68		Student Thinking	33.80	13.95
Discussion	19.72	28.17	17.29	Elicit and Respond	32.39	35.74
Scaffold Enactment	15.49	15.49	21.09	Representation	23.94	23.64
Share Thinking	16.90	12.68		Select and Sequence	21.13	0
Interpreting the Situation	8.45	12.68		Content Goals	11.27	14.03
Directive	8.45	12.68	60.85	Managing Time	9.86	4.34
Rationale	7.04	12.68		Mathematics	4.23	11.94
Contextualizing Student Thinking	7.04	5.63		Orienting Students	1.41	7.05
Managing Rehearsal	5.63	5.63		Body/Voice	1.41	2.95
Highlighting	4.23	2.82		Process Goals	1.41	6.67
Negotiating Next Move	1.41	8.45		Student Engagement	0	21.55
Evaluative Feedback	1.41	1.41	28.14	Attending to IA	1.41	17.29

Discussion

Overall, our rehearsals with in-service teachers were characterized by a more active involvement by the teachers. Teachers were willing to interrupt the flow of the lesson to initiate discussions about teaching. Most often this was done to give more context to teaching decisions, reflect on various aspects of teaching, or to offer advice.

In comparing the relative frequency of our structure codes with those reported by Lampert et al. (2013) the differences are striking. The majority of Lampert et al.'s (2013) interruption were directive (when a TE tells the teacher what to do), 60.85%, while only 8.45% of our interruptions were initiated as directive. Similarly, there was much less evaluative feedback (when a TE makes a judgement about a move) in our rehearsals. While Lampert et al. reported that 28.14% of exchanges were TEs giving evaluative feedback, only 1.41% of our exchanges were. Reflecting on these results, it appears that when working with teachers who possess significant experience, we wanted to create a less directive and evaluative environment to draw from their expertise and position them as more equal partners. While we as teacher educators brought particular expertise to the rehearsal, we acknowledged that the teachers themselves had much understanding to share. Consequently, we structured the rehearsals in a way that provided teachers opportunities to learn from our expertise, but also to share their understanding as a way to reorganize their previously developed skills towards a new orientation of instruction.

There were also several notable differences in the substance of the interruptions. Two of these include our talk about student thinking and selecting and sequencing student ideas. The most frequently discussed topic in our rehearsals was student thinking (where participants discuss the details of students' ways of reasoning), with 33.80% of exchanges addressing this topic compared to only 13.95% of exchanges in Lampert et al.'s study. Another difference was the frequency of exchanges in which we talked about how to select and sequence student ideas. This code was in our top four, with about 21.13% of exchanges referencing this idea. This is significant because Lampert et al. (2013) did not feel the need to use this code to categorize their exchanges. These differences in substance may be in part attributable to the nature of our IA. In contrast to IAs reported in the literature, which tend to be shorter activities, our IA covered a multi-day unit. Such structure afforded teachers more opportunities to monitor student work and think about how to to leverage student thinking to reach conceptual goals (Smith & Stein, 2011).

Conclusion

This study provides an image of what rehearsals can look like with in-service teachers. As such, it helps to highlight decisions TEs need to make when leading a rehearsal. In particular, TEs will need to decide if the teachers they are working with need more directive feedback on and practice in implementing complex teaching practices or would benefit from reflective discussions about what to do next and why. TEs who wish to create a more reflective than directive environment could consider using some of the types of interruptions discussed here (e.g. suggesting alternative moves, interpreting the situation, or asking teachers to share their thinking). These decisions will likely depend on the experience level of the teachers with whom the TE is working and the goals the TE has in mind for the teachers.

STUDYING LESSON STUDY: CASES OF SECONDARY GEOMETRY TEACHERS

Jenifer Hummer
University of Delaware
jhummer@udel.edu

When teachers anticipate student responses, they are likely to be prepared to respond to student thinking in the moment and facilitate rich mathematical discussions. In this study, three participants in lesson study, secondary geometry teachers, anticipated student responses and planned instructor responses for selected tasks. The researcher, then, observed the teachers enact the tasks and investigated how the anticipation of student responses influenced task enactment. The findings suggest that although participation in lesson study provides opportunities to anticipate student responses, this feature may not be sufficient in supporting teachers with enacting tasks in ways that facilitate open-ended discourse and maintain high levels of cognitive demand.

Keywords: lesson study, geometry, secondary

Some research suggests that when teachers attend to student thinking, they increase their content and pedagogical knowledge and implement student-centered instruction (Fennema, Carpenter, Franke, Levi, Jacobs & Empson, 1996). For instance, when teachers anticipate student responses, they can prepare to improvise instruction and facilitate higher levels of mathematical discourse and problem solving (Stein, Engle, Smith & Hughes, 2008). Participation in the lesson study process provides teachers with natural opportunities to focus on student thinking (Murata, Bofferding, Pothen, Taylor, & Wischnia, 2012). This study explored, in what ways do teachers anticipate student responses before teaching a lesson and respond to student thinking during a lesson?

Theoretical Framework

Lesson study has been found to improve teaching by increasing collaboration, improving content and pedagogical knowledge, and gaining insight to student thinking (Murata et al., 2012; Lewis, Perry & Hurd, 2009). The process of lesson study includes a small group of teachers using curriculum materials to plan a lesson, teach and observe the lesson, and reconvene to debrief and revise the lesson, and lesson study is often supported by knowledgeable others or experts in the field (e.g., school administrators or university professors).

During the planning phase of lesson study, teachers study curriculum to plan or revise a research lesson (Lewis et al., 2009). During this time, teachers focus on student thinking by anticipating possible student responses and instructor responses for tasks in the lesson. This is an important aspect in lesson study because the process of anticipating student responses during lesson study has supported teachers' in using generated student responses to encourage mathematical discussion and reasoning (Suh & Seshaiyer, 2014), and allowed teachers to think in advance about how to organize the sharing of student responses (Inoue, 2011).

Next, during the enactment phase of lesson study, a member of the lesson study team teaches the research lesson, and the rest of the team observes the lesson. During the lesson enactment, observers pay close attention to student thinking and collect data (e.g., student responses). The person teaching the lesson uses the anticipated student responses to influence how they will respond to student thinking during the lesson and strategically choose how to share student responses during a whole-class discussion (Lewis et al., 2009, Murata et al., 2012).

Methods

This study was carried out during the second year of a larger study *Proof in Secondary Classrooms* (PISC) (NSF; Award #1453493, PI: PI Michelle Cirillo) which focuses on developing an intervention for the introduction of proof in secondary classrooms. Three secondary teachers, Logan, Bruce, and Raven had experience teaching geometry for seven, six, and one year respectively. Logan and Bruce taught at the same private high school. Raven taught at a different private high school. For this sub-study, the teachers participated in lesson study as professional development for piloting 16 research-based lessons, focused on proof in geometry. Within the cycle of lesson study, teachers anticipated student and instructor responses for selected tasks in three different lessons. Then teachers enacted the lessons, and the researchers observed enactment.

Data Sources

Two representative tasks per lesson were selected as units of analysis (n = 17; 6 tasks for 3 teachers, excluding one skipped by Logan). The selected tasks addressed critical concepts that students must know to successfully engage with Euclidean geometry proof (i.e., investigating geometric concepts, drawing conclusions, and deductive structure). The teachers' anticipated student responses and planned instructor responses were audio-recorded and transcribed. The lesson enactments were video-recorded, and the selected task enactments were transcribed. The transcripts of the teachers' anticipated student responses and the task enactment transcripts were analyzed using open coding to look for patterns and themes.

Findings

Avoiding Misconceptions Before the Lesson

When the teachers engaged with the tasks and anticipated student responses, they often put forth how students would respond correctly. When teachers were asked how they would respond to correct answers, they said they would facilitate a discussion about correct responses. However, when asked about possible students' misconceptions, the teachers often indicated they would redirect students to a correct response. This report will focus on two tasks which exemplified the enactments of the tasks. For the first example (see Figure 1), students were asked to fold patty paper to explore angles formed by intersecting lines. Each teacher indicated that students would most likely form perpendicular lines and indicated they would facilitate a discussion about other possible responses as well as encourage students to explore other configurations to discover that vertical angles were congruent and adjacent angles were supplementary. In the second example (see Figure 2), the teachers indicated, they would expect the students to name vertical angle pairs or notice vertical angles congruency, and they would lead a discussion about those responses.

Student Task

- Fold the patty paper so that two intersecting lines are formed by the creases.
- Measure each of the angles with your protractor.
- Write a conjecture about what you notice.

Figure 1. Lesson 2, Task 1

Avoiding Misconceptions During the Lesson

When Logan and Bruce enacted the lessons, they increased the possibility that students would achieve anticipated correct responses by modifying tasks or asking closed or fill-in-the blank questions. For example, for *Lesson 2, Task 1*, Bruce first indicated he would want the students to avoid forming perpendicular lines. However, when Logan suggested leading an open-ended discussion about perpendicular lines as a special case, Bruce agreed with him. Yet when it came time to enact the task, Logan skipped the task due to time constraints, and Bruce modified the task by saying "*Fold the paper, so you can make two intersecting lines. Try not to make them perpendicular."* Bruce's modification of *Lesson 2, Task 1* limited the intended opportunities for students to explore the concept of vertical angles formed by intersecting lines and lowered the cognitive demand of the task which influenced limited classroom discussion and opportunities for Bruce to respond to student thinking in the moment.

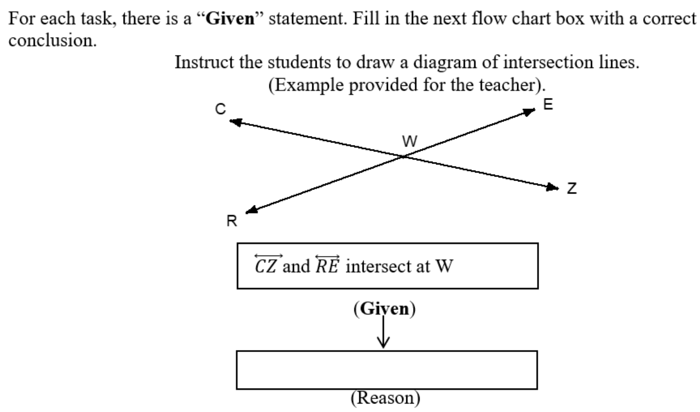

Figure 2. Lesson 7, Task 2

The following transcript from Logan's enactment of Lesson 7, Task 2 is representative of the closed and fill-in-the-blank questions that were observed.

Logan: So, guys, what could we conclude from this? John, what do you think?
John: Angle CWR and angle EWZ are corresponding angles
Logan: Are they called corresponding angles?
John: Uh, congruent.
Logan: They're congruent angles, right? … angle CWR is congruent to angle EWZ.

There were multiple possible responses for this task. However, instead of facilitating an open discussion, after one student responded correctly, Logan quickly moved to the next task.

Considering Multiple Student Responses During the Lesson

In contrast to Logan and Bruce**,** Raven was more likely to respond to student thinking as it occurred by considering multiple student responses and facilitating student discussion. In Raven's enactment of *Lesson 2, Task 1* she did not modify the task. As she predicted, most of the students folded the paper and formed perpendicular lines, so she facilitated an open-ended discussion about other possible ways to fold the lines as she had anticipated in her instructor responses. See the following transcript below for a sample of Raven's enactment of the task.

Raven: Just from observing them, what do you guys notice?
Students: Four right angles from several students. [Quietly]
Raven: Four right angles.
Christine: And they each have vertical angles.
Raven: There's vertical angles there. Ok…How many of you folded it, so you got for right angles, or it looks like four right angles. [About six visible students raise their hands] …Ok. Well, I want to talk about what Christine said for a second. Christine said there's two pairs of vertical angles formed… Do you think that happens every time you have intersecting lines? …
Mark: They don't have to be all congruent.

Jessica: Yeah, they don't have to all four be congruent.
Raven: Measure a pair of vertical angles on your paper and tell me if they're congruent…

Discussion

Previous literature (e.g., Fennema et al., 1996; Stein et al., 2008; Smith, 1996), has suggested that anticipating student responses might contribute to teachers' providing more student-centered instruction by facilitating mathematical discussions because they are prepared to respond to student thinking in the moment. However, previous studies (e.g., Smith, 1996; Wood, Cobb, & Yackel, 1991) have indicated that reform teaching has been difficult to implement because teachers are uncomfortable with releasing control, and mathematics teachers believe they must teach by telling because they believe the teacher's demonstrations are essential for student learning (Smith, 1996). While the teachers in this study indicated they would facilitate open-ended discourse, they often retreated to traditional instruction. It is also possible that anticipating student responses is not sufficient for changing teachers' instructional practices. Other features and conditions for teaching might influence teachers' decisions such as time for implementing a lesson, the cognitive demand required of the task, and teachers content and pedagogical knowledge. The design of this study created opportunities to look closely at cases of task enactment and how anticipating student responses during lesson study might influence teachers' attention to student thinking. Anticipating student responses is a key feature of lesson study, but future research might provide insight as to which features best support teachers.

betsya@iastate.edu

In this study, a researcher collaborated with a middle school mathematics teacher through co-planning, teaching and reflecting upon mathematical modeling lessons to support emergent bilinguals to make sense of mathematics. We investigate how this collaboration impacts the process of co-teaching and co-planning in terms of the interactions between the researcher and the teacher. Our analysis reveals how each role changed and maintained during the collaboration and what factors were discussed to develop and implement modeling-based lessons for emergent bilinguals.

Keywords: Emergent bilinguals, mathematical modeling, modeling based lesson, co-teaching

Purpose of the Study

The purpose of this research was to develop and implement mathematical modeling curriculum that effectively connects to Emergent Bilinguals (EBs; a.k.a. English language learners) through a teacher-researcher collaboration. The project originated from the misconception, yet another myth, that it is not appropriate to provide rigorous mathematics or word problems to EBs due to their English proficiency (Reeves, 2006). If EBs receive only easy tasks by this misconception, they would not have an opportunity to engage in problem-solving that cultivate a deeper understanding in high-level mathematics. Moreover, researchers (e.g., Chval & Chavez, 2011) have recommended making connections between mathematics and EBs' life experience to make sense of mathematics problems. In order to respond to these demands and recommendations, we designed this project between a teacher and a researcher in the co-development and co-teaching of mathematics lessons based on modeling problems that incorporate EBs' real-world contexts. The research question is: "How do teacher and researcher make decisions for developing and implementing a mathematics curriculum in a way of supporting EBs to make sense of mathematical modeling?"

Perspectives

Mathematical Modeling

Principles to Actions (National Council of Teachers of Mathematics, 2014) states an excellent mathematics program requires all students to have access to a high-quality mathematics curriculum and high expectations. Thus, we chose to use mathematical modeling tasks because they require students to do cognitively demanding activities and involve a real-world context that is related to students' cultural and life experiences. Mathematical modeling is also included in the standards of mathematical practice of the Common Core State Standards for Mathematics (NGA Center & CCSSO, 2010). Anhalt (2014) argued a well-designed mathematical modeling problem can engage EBs due to the real-world connection and the insufficiency of given information is necessary because a real-life problem does not provide all necessary information unlike a textbook word problem. This perception is echoed in how Dan Meyer created 3-act tasks that introduce a real-life story contacting conflict that does not include all necessary information and requires students to identify and search for the missing parameters. Meyer (2011) explained each step of the 3-act task: Act 1 is to identify the central conflict of a real-world story; Act 2 is to look for resources and develop new tools; and Act 3 is to resolve the conflict and set up an extension. We claim that it is necessary to add one more step when working with EBs because they may need further information to make sense of the story in Act 1. Therefore, the four actions are: (1) Make sense of the real-life story, (2) Identify the problem in the story, (3) Build a strategy and gather information, and (4) Resolve the problem and look for extension.

Design-based Research

The collaboration of a teacher and a researcher plays a crucial role in this project because their expertise complement each another's needs and build off the other's strengths. Hence, we employ multi-tier design-based research (DBR; Brown, 1992; Cobb, Confrey, Lehrer, & Schauble, 2003) in order to build an effective relationship among a researcher, a teacher, and also students. In this multi-tiered teaching experiment, a teacher acts as a researcher and teacher, and a researcher acts as a teacher, a learner and as an investigator, as they co-develop, co-teach, and analyze the lessons together (Jung & Brady, 2016).

Methods

Context and Participants

This project was conducted in one mathematics classroom in an urban middle school with 76.4% students of free and reduced lunch and 28.4% EBs, including many refugee students. There are more than 100 languages spoken in this district. There were 11 EBs in grades 7 and 8, consisting of 6 female and 5 male students in the EB-specialized mathematics class. The teacher had both mathematics (grades 5-12) and ELL (K-12) endorsement. She had 3 years of teaching experience when this project began and English monolingual. All EBs stayed in the U.S. within two years and their mathematics and English proficiency levels varied, but all scored 0 (lowest level) on the initial English language proficiency assessment conducted by the school district. Among 11 students, there were 3 Spanish speakers, 3 Swahili speakers, 2 Arabic speakers, 2 Burmese speakers, and 1 Karenni speaker.

Data Collection and Analysis

Applying the DBR collaborative research design, the researcher and the teacher met regularly for approximately one semester to co-develop modeling lessons and co-teach the lessons. All meetings were audiotaped, and the classroom teachings were videotaped. In every teaching session, the students were asked to write their work and reflect on their learning experience in a written form. The cycle for one lesson took two weeks: lesson planning in 1st week and teaching in 2nd week. After the 12 weeks, we interviewed five students about their experience and learning as well as an exit survey for the teacher. The data was analyzed qualitatively. Audio recordings and video recordings were transcribed when needed. The research team read all data multiple times and conduct open-coding (Strauss & Corbin, 1990) focusing on the research question. First, each coder identified the decision-making points in co-planning sessions and debriefings and examined who initiated each decision-making process because we believe the one who initiated a conversation with a new topic has a leading role. Based on the results of coding, codebook (Saldaña, 2013) was drafted, constructed by several generalizing and merging codes through several discussions. Then, a map of codes connecting them through phases such as planning, implementation, and debriefing was made to see how each decision-making impacts the following procedures of teaching. In addition, we investigated how the decision-making topics are repeated and addressed differently as time evolves. The multiple sources of data were triangulated.

Results

From the map with the topic of decision-making points during planning and debriefing sessions as well as teaching sessions, we identified the topics that appeared often and repeated in many sessions although the mathematical concepts and the tasks implemented were different. The topics we found in all lessons were how to group students and how to have students share their solutions. The topics we found in four or five weeks were task/context selection, making guiding questions for each Act, including the names students are familiar with in the story problem, assessing students' vocabulary understanding, using objects/manipulatives, timing for each Act, and integrating students' life experiences in the problems.

We found that most topics addressed in planning phases appeared in the following teaching phases but there was some variation. For example, assessing students' understanding of the words embedded in the modeling problems were often discussed and planned how to help students learn those words. These plans were usually executed during teaching phases. In contrast, the plans about writing did not go as planned, especially during the beginning lessons. In the first lesson, the EBs took a long time to write their reflection so we had to postpone the closing of the lesson with completing the writing. Based on reflecting on this factor during debrief, the student's reflection journal form was modified several times to make it more open-ended and provide more guidance. Grouping students was another topic that was discussed in all lessons. Same language speaker groups were used in the first lesson and mixed-level groups were used in the second lesson based on observation of student-student interactions during the first lesson result. After these two weeks, students chose their groups until the last lesson because this group choice seemed to make the EBs work more comfortably. Similar to grouping students, having students share their solution was found in each lesson. However, like writing a reflection journal, implementing this plan was challenging due to time constraints because EBs needed an additional time to solve the problems. After having this challenge a few times, a decision was made to have student's presentation in the beginning part of the lesson to share their process earlier opposed to waiting for EBs to find their solutions. We inferred the high frequency of some topics reveals its importance in terms of teaching mathematics for EBs.

Discussion

Our results demonstrate the teacher-researcher collaboration model allows both the researcher and the teacher to participate in and contribute to lesson planning. The repeated topic analysis showed what the researcher and the teacher consider important factors of developing effective lessons for EBs. We found the majority of repeated topics concentrated on Act 1: Make sense of the real-life story and Act 4: Resolve the problem and look for extension. Act 4 also includes students' sharing of their solutions and Act 1 is one of the reasons why modeling is an effective way to teach EBs mathematics (Anhalt, 2014). This result is well aligned with what the teacher explained in the exit survey.

> ELs [EBs] need digestible bites, especially on new concepts. I think the most important steps were Act 1 and Act 4. Without background knowledge, students do not have a platform to build off of. With ELs [EBs], I believe you can make no assumptions of what they already know. Act 4 ties all of the language and mathematical reasoning together to one final concept. In Act 4, students share out their reasoning and final answers as a group. They are also given an extension problem to go above and beyond the concept we had planned for the day. At the very end, students reflect on what they learned throughout the lesson through pictures or sentences in English or their native language. This ensures students are on the same page as they leave class that day.

We found one crucial factor from the discussion around timing. Timing was the one particularly discussed in the beginning lesson planning. The main topic about timing was how much we should invest for Act 1 because it seemed this step sometimes needed a large portion of the entire lesson period. The goal of Act 1 was to provide contextual clues (Cummins, 2000), connect with students' life experience (Aguirre et al., 2013), and support students' understanding of words embedded in the main problem before the problem is given. The researcher and the teacher discussed how many minutes they should plan for this step and decided to set sufficient time and agreed to extend the time if needed with the belief that it would take a longer time if the EBs do not fully understand the problem (Jackson, Garrison, Wilson, Gibbons, & Shahan, 2013). Once EBs understand the problem, the rest of the procedures can be accelerated. We found the researcher-teacher collaboration model sheds light on the important factors to design a lesson for EBs and this can be an effective form of teacher professional development.

As classrooms become more diverse and include refugee children who bring a wide range of educational and life experiences, one enduring challenge is about how to meet the changing pedagogical and mathematics learning demands for all children. In this study, we draw on a RefugeeCrit framework and particularly focus on teachers' perspectives on the interplay of culture, language, and early mathematics in the teaching and learning of Syrian refugee children in Turkey. In our 2-year exploratory project MIGRA-MATH we focus on mathematical patterns and bring together four implementation components, each of which require the consideration of the needs of teachers working with refugee students. In the initial phase of our project, one preliminary trend we see is the teachers' ideas about what mathematical patterns as a content offer children's algebraic thinking, and teachers' previous multicultural teaching experience, along with their own personal histories as diverse students before, seem to shape the way they support refugee children in mathematics.

Keywords: equity in mathematics education; teacher education; refugee children

Introduction

As classrooms become more diverse and include refugee children who bring a wide range of educational and life experiences, one enduring challenge is about how to meet the changing pedagogical and mathematics learning demands for *all* children. Barton (2017) has highlighted the ethical responsibilities inherent in this challenge for mathematics educators, arguing, "The extent to which we free mathematics and mathematics education from society and culture is the extent to which we are absolving ourselves from responsibility to others and to our world. It frees us from social and cultural responsibility. Ultimately, this makes us amoral (p.3)." There is a need for timely research examining mathematics education practices situated in particular societal and cultural contexts with refugee students around the world to inform our work as mathematics educators and researchers. In this paper, we introduce the *MIGRA-MATH* Teacher Professional Development Project *(MIGRA-MATH: Supporting Teachers of Refugee and Immigrant Students with Respect to their Mathematics Education Professional Practices)* which addresses the current needs of early childhood teachers teaching mathematics in Turkey. Turkey hosts the world's largest community of displaced Syrians and currently has introduced several implementations to accommodate the educational needs of almost one and a half million school-aged Syrian children (United Nations High Commissioner for Refugees [UNHCR], 2018). In this study, we particularly focus on teachers' perspectives on the interplay of culture, language, and early mathematics in teaching and learning of Syrian refugee children in Turkey and the sociocultural role of mathematics education in refugee children's schooling process.

Purposes of the Study

The overall goal of the MIGRA-MATH project is to support the teaching of mathematics, in particular about mathematical patterns as a content area, for early childhood teachers (K-3) working with refugee students. The MIGRA-MATH project emphasizes the idea of multiple representations of mathematical knowledge by highlighting the visual representations of mathematical concepts, relations, and processes to make them more accessible to linguistically diverse children (Ainsworth, 2006; Lesh, Post, & Behr, 1987); the integration of collaborative methods in mathematics learning (Featherstone et al, 2013); and the promotion of school-family-community partnership (Civil, 2002), with a goal eventually to develop a pedagogical model based on the curriculum materials that are developed with teachers. This 2-year exploratory project brings together four implementation components, each of which require the consideration of the needs of teachers working with refugee students: (1) Teacher Knowledge Sharing Rounds; (2) Model Teaching and Classroom Observations; (3) Multivocal Video-Cued Interviews; (4) Family Math Workshops.

Theoretical Perspectives

In this paper we draw on refugee critical race theory (RefugeeCrit) (Strekalova-Hudges & Turner-Nash, 2017). RefugeeCrit is a newly evolving theoretical framework, which builds on critical race theory (Ladson-Billings & Tate, 1995). It offers a perspective to understand the unique lived experiences of children and families with refugee backgrounds, which is missing in current critical theoretical examinations. RefugeeCrit challenges the marginalized images of refugee children and families as suffering, needy and helpless, which ultimately serve as barriers to equitable education, and aims to produce counter-arguments about the problematic positioning of refugee children and families (Strekalova-Hudges, Erdemir & Turner-Nash, 2017). In our study with the teachers of Syrian refugee children in public schools in Turkey, the different tenets of RefugeeCrit supported us to interpret teachers' discourses in terms of how they might recognize the refugee status of children as a mechanism of oppression with a recognition of the intersectionality of children's experiences; how teachers see potential in early mathematics to create educational praxis for refugee children; and how they recognize the possible challenges for multilingual refugee children to learn mathematics through the current educational practices in Turkish schools.

Methods of Inquiry

We work with a total of forty K-3 grade teachers from five different cities which have the highest number of Syrian refugee children in the country. Teachers are randomly assigned to the project on a voluntary basis by the Ministry of National Education. In this paper, we report data from the first year of the project, particularly from the Teacher Knowledge Sharing Rounds where teachers participated in three different interactive sessions about (1) Multiple representations of mathematical knowledge with a particular emphasis on patterns; (2) Raising cultural awareness about refugee children and families; and (3) The interplay between language and mathematics. Throughout the project, we utilize a quasi-experimental mixed-method research design (Tashakkori and Teddlie, 2003) with a teacher action research component (MacIntyre, 2000). The knowledge sharing rounds phase of the research was also designed to incorporate teachers perspectives from the start in planning and designing the professional learning activities. We collected data during three Teacher Knowledge Sharing Rounds through semi-structured focus group interviews with teachers and we videotaped the three interactive sessions in each of these three Teacher Knowledge Sharing Rounds. The questions in the interviews particularly focused on how teachers view mathematics as a bridge to reach refugee children, and what their ideas about refugee children's learning of mathematics in the classrooms.

Results

Our preliminary analysis shows that teachers express struggles in teaching mathematics to refugee children resulting from both the structural barriers and their own professional readiness. However, teachers clearly position refugee children in their classrooms as capable learners of mathematics; and acknowledge the role that language plays in children's mathematical understandings and in the mathematical patterns as a content area. The strategies they developed to support children in mathematics vary. One trend we see is the teachers' ideas about what mathematical patterns as a content offers children's algebraic thinking and teachers' previous multicultural teaching experiences along with their own personal histories as diverse students seem to shape the way they support children in mathematics. Here we share examples of teachers' such notions generated in Teacher Knowledge Sharing Rounds:

Table 1. Teachers' Notions about Teaching Mathematics to Refugee Children

Overall Notions About Working with Refugee Children	One problem is the fear of to be left alone… We avoid differences because of the fear of being alienated from the rest of the society... The way we were taught to teach homogenizes the classrooms. We want all our children to learn mathematics very well, but the structure in the society does not allow for this. We want all students' success, but in real life there are structural barriers to achieve this.
	Because learning is not independent from language, you can't separate language from learning. However, a Kurdish child who does not speak Turkish and a Syrian child who does not speak Turkish are not the same. I am also Kurdish... A Kurdish child and I watch the same TV channels in Turkish language, but Syrian child doesn't have access to such media… Kurdish children (in his classroom) at least have family members who are fluent in Turkish but the Syrian child's family also can't speak Turkish.
	I told the family that not being able to speak Turkish will not prevent your child from learning [math]. I did my best to prevent marginalization in my classroom. The idea of we are all human beings, diverse languages are resources…. I started by assigning responsibilities to the refugee children in my classroom.
Mathematical Patterns: Content	Children learn patterns quickly, I, for example, show them tiles and see that they can get it, or I take them out to play hopscotch, we have shapes on the ground, you know, I make them count and jump… This is how I teach patterns... but when it comes to number patterns, I am not sure if they see the relation in 1,4,7
	I do love math. I do and I also tell my colleagues to engage children in skip counting a lot because it will set the foundation for other mathematical learning. For example, when we play a game, we do this (she produces a pattern by clapping), then I add a sound… It starts with sound, continues with ornamentation [refers to patterns in them] and then it lends itself to numbers, that's the direction it is supposed to go. We need to touch, we need to include real life materials. In this way you get amazing results.
Content Related Language	We do not know their language, for example I do have Syrian children in my classroom, we do not have a smooth communication and we are having difficulty in teaching mathematics.
	Math has a universal language. For example, I realize that when we do addition, Syrian children in my classroom show interest and attend. They do not need to know language.
	This is something I do not only observe with Syrian children but also with other students in my classroom. In a problem about patterns when a word like"in a row" appears, I see that children do not understand the meaning of "in a row". Then, I try to make it concrete for them and I make them to get up and stand like "in a row."

Conclusion

Considering children influenced by the current global refugee crises, there is a growing research literature focused on their access to general educational services (Uyan-Semerci & Erdogan, 2018; Tarim, 2018) and psychological implications for them (Sirin & Aber, 2008). However, we have much to explore in order to understand how content areas like mathematics can offer to support children's transitions to educational contexts in their host countries. Teacher professional development projects similar to one we share here help us to imagine new ways to support teachers and reveal their current exemplary practices in teaching mathematics to refugee students.

ONE DISTRICT'S SYSTEMIC APPROACH TO DETRACK HIGH SCHOOL MATHEMATICS

Brian R. Lawler
Kennesaw State University
blaw@kennesaw.edu

Systemic implementation of research-based instructional practices has persistently been a challenge in high school mathematics. The Escondido Union High School District is pursuing ambitious mathematics instructional reform with an aim to rehumanize the teaching and learning experiences for both students and teachers. I provide an overview of a four-year teacher curriculum that emerged during an ongoing ethnographic study of their work, and the many tensions provoked by the goal to rehumanize mathematics experiences. Specifically, I note the tensions of an effort to rehumanize the work of students and teachers, through a professional develop strategy undergirded by an effort to act teachers into new beliefs.

Keywords: Teacher Education-Inservice/Professional Development, Teacher Beliefs, High School Education, Equity and Diversity

Systemic implementation of research-based instructional practices has persistently been a challenge in high school mathematics (NCSM, 2014). There seem to be many barriers for the systemic and sustained shifts in high school mathematics organization and instruction. Understanding the navigation of these barriers in successful school systems will inform other schools and districts to make meaningful improvements to mathematics instruction.

The Escondido Union High School District (EUHSD) is pursuing ambitious mathematics instructional reform with an aim to rehumanize the teaching and learning experiences for both students and teachers. Realizing experientially and empirically (Cobb & Jackson, 2011) that lasting mathematics instructional improvement at scale is a challenge extending beyond teacher learning, mathematics leadership in EUHSD has doggedly moved forward to attend to both teacher and institutional learning. In this brief presentation, I will describe current state of a five(plus)-year project to shift mathematics instruction by working to redefine teacher's normative identities. From these efforts, I provide an overview of a four-year teacher curriculum that emerged during the work, and the many tensions provoked by the goal to rehumanize mathematics experiences. Specifically, I note the tensions of an effort to rehumanize the work of students and teachers, through a professional develop strategy undergirded by an effort to act teachers into new beliefs.

The findings I propose to share emerged from an ethnographic study of the district's efforts since they were launched in 2013. During that time, I served as an advisor and coach to district leadership, facilitator for leadership team projects, and instructor for some of the professional development workshops organized for mathematics teachers. I visit the schools in the district, teachers, principals, and district administrators five times each year for roughly 15 days. Further, I am in contact weekly with the district mathematics specialist and lead mathematics coach. I document these interactions and visits in a journal; text and email conversations are logged, and I collect and store documents and artifacts of the team's work.

EUHSD is a predominantly Latin@ district (72%) consisting of 5 high schools. The vast majority of the school and district leadership is white, as are the teachers—just over 7% of the district's teachers identify as Latin@. Student outcomes reflect the many challenges associated with urban schools. For example, in 2012 only 33.5% all 12th-grade graduates completed the specific college-preparatory coursework with a grade of "C" or better necessary to qualify to apply to the in-state public universities. Mathematics instruction in EUHSD prior to 2014 reflected unproductive beliefs about teaching, learning, assessment, and children (NCTM, 2014), including a focus on procedures and memorization, expectation for student to mimic teacher thinking, the notion that students possess different innate levels of ability in mathematics, unchangeable, and predicable by race or economic group. Such beliefs were held by many teachers, but even more strongly by many other members of the school community, including counselors, principals, students, and many parents. Similarly, unproductive beliefs could be found in structural elements of mathematics education in the district, including tracking students into more than six possible 9th grade mathematics classes, D-F rates in Algebra hovering around 50%, and student demographics in honors and AP classes not matching those of the district.

A determined effort to rehumanize the mathematics experiences for both students and teachers began in 2013, built on a theory of change to act district educators into new beliefs, to develop new normative identities (Cobb, Gresalfi, & Hodge, 2009). Since then, structural elements of mathematics instruction have shifted, including opening classrooms, detracking, and re-professionalizing teachers. The underlying design for system change was to draw upon a solid student curriculum to focus on developing new pedagogical strategies. Specific elements the design for change included:

1. Structuring schools for adult learning,
2. Curriculum as a lever for change,
3. Teacher beliefs,
4. Changing inequitable structures, and
5. New vision and measures.

Structures were utilized in conjunction with the teacher curriculum with an intention to act teachers into new beliefs. After initial teacher development efforts, an earnest four-year teacher curriculum was developed, grounded in work emerging from previous projects (Robinson et al., 2002), to support teachers to shift classroom structures to center on student-student discourse about student-generated ideas. The principles underlying the four-year teacher curriculum included:

1. Aligned to teacher implementation of new textbooks, sequentially;
2. Built upon (predictable) problems of practice;
3. Paired with expectations designed to act teachers into new beliefs; and
4. Foundation: people learn by thinking & interacting, detracked classrooms.

The foci in each year of the teacher curriculum include the list that follows. Table 1 provides a more complete summary of the four-year teacher curriculum that has emerged in the work at EUHSD.

- Year 1: group work and student discourse as the classroom norm
- Year 2: creating intellectual need through a launch, and Complex Instruction
- Year 3: disrupting deficit orientations, and assessment versus grading

Table 1: Four-Year Teacher Curriculum developed at EUHSD

	Problem of Practice	Opportunities	Structures	What was Learned
Y1	I'm thinking about teaching differently (SMPs), and I need to learn to teach from this new textbook.	Learn a new role for themselves in the classroom	Students in groups, students present, no supplementing	I have a very different role in this classroom; learning to listen to student's mathematics; there is value to kids thinking and interacting; I need to manage student discourse
Y2	I need to figure out how to make my groups work better	C.I. to address deficit orientation to children; explicit conversation about social inequalities replicated in the classroom; routines for supporting groupwork & discussion	C.I. Multiple Ability Treatment, status treatments; skill builders; whiteboards	I need to include all students in conversations; a way to reconcile their deeply held beliefs that all children are smart with why not expressed in the classroom
Y3	I now see learning and understanding differently. How do I grade?	Shift from answer-getting environment to focus on understanding	Invitation to grade differently, reorganize pacing around big ideas, collect and provide feedback on student work	Effort in Years 1 & 2 pay off (faith); some sort of competency-based grading & student ownership is important; and feedback important
Y4	This work is complex and interconnected. I understand equity issues differently.	Divergent equity interests; leadership; re-imagining assessment	Implement revised, district-wide unit exams (toward understanding instead of procedures)	

Alongside these efforts toward both institutional and teacher learning toward a pursuit of ambitious mathematics instruction come many tensions for those involved in the project. These can be classified into categories aligned with institutional and teacher learning, as well as deeply held societal beliefs that serve to maintain White Supremacy. Samples of these tensions include:

- Acting teachers into new beliefs: *Is this a coercive approach to change?*
- Deficit orientations and racism: *Are we doing enough to change hearts and minds? Where is the lever for change?*
- Curriculum as a lever for change: *Limitations of the chosen curriculum. Will we be able to move beyond this curriculum in ways that are more student centered?*
- Sustainability: *How can we ensure the work lives on and continues to develop?*
- Measures: *Will standardized testing corrupt our efforts to rehumanize school mathematics? What measures would reflect our values? And 'whose' values, if we are doing this work in a de-humanizing system*?

Across all categories underlies a challenge about beliefs, and although EUHSD may develop high quality mathematics teaching, deficit-oriented beliefs will continue to generate inequitable outcomes (Jackson, Gibbons, & Sharpe, 2017) and dehumanizing experiences.

MEASURING TEACHER KNOWLEDGE OF TEACHING FOR ALGEBRA READINESS

Hea-Jin Lee	Jaime Kautz	Ivo Herzog

This study is based on a year-long professional development program aimed at improving teachers' knowledge for teaching algebra readiness. Thirty-one 7th and 8th grade teachers participated in the study, and survey data and artifacts were analyzed. Results suggest that (1) teachers' knowledge about algebra readiness indicators mostly aligned with research-based indicators, but they focus too much on pre 7th grade math concepts; (2) teachers have some misunderstanding about the content progression; and (3) teachers view teaching algebra readiness requires understanding students' level, standards, instructional approaches, use of resources, real world connections, and algebra content.

Keywords: Teacher knowledge, Algebra readiness

Objectives of the Study

Algebra has become a core component of school mathematics, and students are required to take algebra courses to meet high school graduation requirements. Consequently, helping middle school students prepare for Algebra has gained critical importance. Questions naturally arise about how best to prepare students for entry into Algebra and how middle school teachers can be prepared to have students ready to learn Algebra. The professional development (PD) program of this study is a year-long program aimed at deepening middle school teachers' content and pedagogical content knowledge for algebra readiness. The purpose of this paper is to explore the impact of the PD on teachers' knowledge for teaching algebra readiness with three guiding questions: 1) What skills and knowledge do teachers perceive as algebra readiness indicators?; 2) To what extent does teachers' understanding of pre-algebra and the algebra curriculum align with curriculum documents at the national/state level standards and frameworks?; and 3) What are teachers' perceptions about the knowledge needed for teaching algebra readiness?

Theoretical Framework

According to research, a conceptualization of learning improves a teacher's mathematical content knowledge and deepens their understanding of student learning, allowing them "to position their students' learning not only in relation to their current classes and the objectives for that cohort, but also in relation to prior and subsequent classes." (Heritage, 2008, p.3) The theoretical framework of the study is based on theories on teachers' knowledge for teaching algebra and frameworks on teachers' knowledge for algebra readiness.

Researchers have defined and categorized teachers' mathematical knowledge and endeavored to measure teachers' knowledge for teaching mathematics. Shulman has categorized teachers' knowledge (1986) into three areas: subject matter knowledge, pedagogical content knowledge, and curricular knowledge. Based on Shulman's categories, researchers have conceptualized and measured "the mathematical knowledge used to carry out the work of teaching mathematics" (Hill et al., 2005, p. 373) and called it Mathematical Knowledge needed for Teaching (MKT). MKT categorizes practicing teachers' knowledge (Blömeke & Delaney, 2012) into three areas: knowledge of content and students, knowledge of content and teaching, and knowledge of content and curriculum.

As school mathematics deals with numerous topics, some researchers differentiate teachers' knowledge for teaching by math topics. Floden and McCrory (2007) focused on school algebra in grades K-12 and proposed three areas of knowledge of algebra for teaching (KAT): school (K-12) mathematics knowledge, advanced mathematics knowledge, and teaching mathematics knowledge (Huang, & Kulm, 2012). Unlike other researchers' broad knowledge categories, Even (1990) described teachers' knowledge of algebra in seven dimensions: essential features, different representations, alternative ways of approaching, the strength of the concept, basic repertoire, knowledge and understanding of a concept, and knowledge about mathematics. Agreeing with existing teachers' knowledge categories, Doerr (2004) added knowledge about student errors and misconceptions in algebra to Shulman's pedagogical content knowledge.

Such concepts, essential for success in an Algebra course, have been outlined by different entities across the nation. The Southern Regional Education Board (Bottoms, 2003) outlines both dispositional skills and mathematics content (readiness indicators) suggested for students to be successful in Algebra. While the state of Ohio, where this study was conducted, does not outline specific algebra readiness indicators, their standards, similar to those of Common Core State Standards for Mathematics (2010), have designated critical areas of focus for both 7th and 8th grade mathematics. These outlined concepts provide the foundation for teachers to determine mathematical content in which students should have strong foundational skills to successfully embark on an Algebra course.

Methods

This study was situated in the context of ongoing work of a year-long PD for 5 high-need school districts. The PD involved an intensive summer institute, follow-up blended PD with structured modules, on-site support from building coaches, site visits by PD providers, and professional learning dissemination at professional meetings. The PD activities covered investigating algebra readiness indicators and vertical progression of algebraic concepts, analyzing students' learning. Thirty-one 7th/8th grade teachers participated in the study. Of the 31 participants, 84 % were female and 97 % identified as white, non-Hispanic. The cohort was comprised mostly of experienced teachers, with 10 years the mean.

The study involved surveys, self-reflections, and PD artifact data. Due to the nature of the qualitative data, the analysis was based on categorizing to investigate emerging themes. The responses were first analyzed for common codes to create patterns, then the codes were finalized by comparison with existing studies. Throughout the data analysis process, common codes and patterns were tallied and percentages of participants' responses were calculated. The initial analysis outcomes of the surveys and PD artifacts were compared with theories and indicators discussed in the Theoretical Framework section.

Results

Teachers' Knowledge about Students

Teachers provided over 90 areas that they use to define student readiness for algebra: knowledge of math content (66%), math skills (16%), disposition (10%), and scores of standardized tests (8%). Math skills needed to be algebra ready were mathematical reasoning, critical thinking, and abstract thinking skills. In addition to skills and knowledge, approximately 10% of indicators were about students' disposition: willingness to learn, struggle, and complete challenging tasks. Some teachers rely on a student's grade and standardized test scores to determine readiness. Most algebra readiness indicators (66%) were specific mathematics concepts; number sense, computations with whole numbers and integers, variables and unknowns, one or two step equations, patters and rules, and (linear) graphs (Figure 2). Approximately 50% of math concepts were number sense and computational skills with whole numbers and integers; the other half was directly related to algebra standards.

Overall, there was no big gap between national/state recommended algebra readiness indicators and indicators discussed by the teachers. However, the indicators favored the younger grade level standards over 7th – 8th grade content. For example, teachers emphasized operations with whole numbers and integers but not so much with rational numbers, dealing with parentheses accurately, distinguishing unknown variables from units, etc. The lack of 7th and 8th grade algebra standards in the list was unexpected, because most teachers in the program were teaching 7th, 8th, and algebra classes. However, teachers' heavy focus on number sense and operations for algebra readiness may have to do with national/state recommendations, "The algebra readiness materials must also break these 16 standards into their component concepts and skills, with a primary focus on developing students' mastery of arithmetic." (Papa & Brown, 2007, p. 17)

Teachers' Knowledge about Algebra Curriculum

The teachers were asked to identify which concepts were indicators of Algebra readiness and to specify the grade level at which the content should be covered (pre-7th, 7th, or 8th grade). Some teachers teaching 8th grade or algebra course eliminated concepts around data and probability. Their perspective was that while all the indicators should be learned before algebra, the data and probability content was not indicative of a successful algebra student. Regarding grade level, teachers were in complete agreement for 11 of the 33 mathematical concepts. With regard to the specific mathematical concepts, the content teachers unanimously assigned were fundamental number and algebraic understanding while the outliers and disagreement upon content focused on non-traditional algebraic content (probability, data, and geometry). The data indicates that the teachers were not able to agree or accurately assign grade-level content to concepts that they are required, by the state, to teach at that level. Another finding suggests that teachers may have a misunderstanding of the number system. Teachers were in agreement about the need for fundamental skills associated with computation with fractions and irrational numbers, however, they assigned rational numbers to all grade levels. These findings may suggest that teachers need additional support with the rational number system. Disagreement over when a concept should be taught spanned over geometry, patterns, and number skills and concepts.

Teachers' Knowledge about Teaching Algebra.

The 67 knowledge areas needed for teaching algebra generated by teachers were categorized into 7 areas: understanding students' current level, their needs, and areas they struggle in (25%); general instructional approaches (21%); standards including content progression (19%), use of resources including manipulatives and technology (7%); and real world connections (6%). Only 10% of teacher comments specifically mentioned instructional approaches related to teaching algebra. Instead of providing specific algebra concepts, teachers simply said "content" knowledge (10%). As Doerr (2004) suggests, our teachers also believed that understanding students is a critical part of pedagogical knowledge. Some of the knowledge areas, such as general teaching approaches and math content, were supported by Even (1990). Unlike other studies, our teachers felt that using resources, making connections to real-world situations, and understanding content progression were important for teaching algebra readiness concepts.

Conclusion and Discussion

The focus of this study was unique in two ways: First, we aimed to deepen the teachers' understanding of teaching algebra readiness in a way that was different from what they experienced in their teacher preparation program or as part of professional development. Secondly, instead of focusing on particular algebraic concepts, we emphasized the nature of shifts in teachers' understanding of the progression of algebraic concepts and perspectives of teaching for algebra readiness.

Trends in data among teacher knowledge of students, algebra curriculum and teaching algebra, suggest that more efforts be made to support teachers in preparing students for algebra. When identifying indicators for student readiness to take Algebra, teachers largely pointed to mathematics content below their respective grade levels (number sense and skills). When this specific content was to be covered was in agreement by groups and aligned to the respective state standards, however, discrepancy existed among groups as the content progressed to higher levels of understanding, with disagreement in fundamental algebraic concepts such as rational numbers and patterns. Despite the lack of agreement on when the progression of content occurs, teachers failed to cite specific content knowledge as an additional teacher requirement in order to prepare students for Algebra. Teachers did identify a need for further understating of standards, but overall, suggested there is a greater need for teachers to be better prepared to assess and instruct on a general level.

Given the findings, focusing on building teacher knowledge of the algebra curriculum is not enough, as teachers identified disposition, mathematical thinking, general assessment strategies, and instructional approaches should also be addressed in a professional development program. This further supports the need for a well-rounded experience that builds teacher knowledge of: students, algebra curriculum, and teaching algebra.

K-8 TEACHERS' STORIES OF MATHEMATICS-RELATED TRANSFORMATION

Rebecca McGraw
University of Arizona
rmcgraw@math.arizona.edu

Aubrey Neihaus
University of Arizona
aneihaus@math.arizona.edu

We describe our use of the frameworks of teacher transformation and narrative inquiry to investigate K-8 teachers' self-reported transformations related to mathematics and teaching, and aspects of the transformations that are associated with participation in Intel Math professional development. This report is part of a larger, ongoing investigation, but we are able, in the space of this report, to highlight the transformative journeys of two participating teachers.

Key words: Teacher Education-Inservice/Professional Development

In this brief report, we share preliminary analyses of elementary mathematics teachers' stories of transformational learning experiences related, in part, to participation in the Intel Math professional development (PD) program. We seek to address the following questions:

1. What narrative structures do teachers employ to describe their professional journeys and professional transformations, especially as they relate to the teaching of mathematics? How do teachers situate professional development within their narratives?
2. To what specific experiences do teachers attribute the transformation? How do they connect experiences to one another and across time?

The PD program includes 80 hours of instruction designed to deepen and expand K-8 teachers' knowledge of mathematics and evidence-based classroom practices. The program includes extended opportunities to learn in a professional community with other teachers, experience as a learner with student-centered instruction, and explicit links to children's thinking/learning – which are key components of effective professional development (e.g., Darling-Hammond, Hyler, & Gardner 2017). Participating teachers solve non-routine problems, connect multiple representations, and communicate and analyze their reasoning. Pedagogical techniques used by program instructors mirror practices that participating teachers can use in their classrooms. In addition to significantly increasing teachers' content knowledge related to elementary mathematics, the program positively impacts classroom practice with respect to richness of mathematics, and student participation in mathematics (Garet, et al., 2016). Although these findings are promising, we know that shifts in practice take time, are often gradual and accompanied by shifts in beliefs, and can be uneven in their implementation (e.g., Loucks-Horsley et al, 2010). At the same time, we have evidence that, for some teachers, the program is part of a transformative learning experience that significantly impacts practice (e.g., Broatch, 2011). Thus, we seek to identify these teachers and examine their professional trajectories, and their views of how the program has played a role in their professional transformations.

Theory and Methods

Our conceptualization of transformative learning is based on the work of Mezirow (1991) who identified states of transformation beginning with a "disorienting dilemma" in which adult learners "discover a need to acquire new perspectives in order to gain a more complete understanding of changing events" (Mezirow, 1991, p.3). Learners engage in critical self-examinations whereby they explore new ideas, roles, and relationships, acquire new knowledge, and experiment and build competence with new ideas (Mezirow, 1991). Building on the work of

Mezirow and others, King (2009) developed and validated a survey instrument to identify whether learners have undergone a perspective transformation linked to educational experiences, and which learning activities contributed to their transformation (King, 2009). We use an adapted version of the instrument to identify teachers who have experienced a perspective transformation linked to the PD program. We then invite teachers to be interviewed to further investigate their transformational experience(s).

We use narrative inquiry methods in this research because it is "through narration, or storytelling, [that] individuals construct and present identities" (Temple, 2008, p. 3). Narrations are partial representations of experience (Riessman, 2008) that are jointly negotiated across speaker(s) and listener(s). "The plot of a narrative can be described as how narrators impose order on their experiences (Riessman, 1993) and . . . how analysts impose structure (Riessman, 2008)" (Ahmed, 2012, p. 235). "A structural narrative approach centering on plot can allow for the complexity of decision making processes, actions, and experiences . . . to be understood and placed in context" (Ahmed, 2012, p. 235). Consistent with a narrative inquiry perspective, we resist the urge to dissect teachers' stories into coded segments that would then be re-assembled to create meaning. Rather, our analysis of the audio-recorded stories involves careful (but not critical) examination of motives, meanings, and actions, and connections among these, as presented by the storyteller (teacher). To achieve this, we listen multiple times to the audio-recorded stories of the teachers, listening for, and making notes about, the ways teachers frame and build their stories, the turning points (explicitly described or implied) in their narrations, and the meanings they assign to transformational experiences. Once these have been identified, we re-present the teacher's experience in a narrative form based in written text. At this stage, we have interviewed eight teachers, with each interview lasting between approximately 30 minutes and one hour. From a narrative inquiry perspective, this is a very short time from which to develop a complete story of a teacher's experience, and we recognize this limitation in our work. We intend to conduct follow-up interviews with teachers, first to hear how teachers contextualize and assign new meanings to their transformational experiences over time, and also to share the stories we create to ensure that these stories resonate with teachers own meanings and experiences.

From the interviews we have conducted thus far, we have selected two to highlight in the space of this brief report. The first teacher, pseudonym Ginny, teaches second grade and has five years of teaching experience at the elementary level. The second teacher, pseudonym Fred, teaches third grade and has fourteen years of teaching experience at the elementary level.

Ginny

(all words are Ginny's unless in brackets or italics)

<table>
<tr><td colspan="2">I've always liked math, I always remember math being following steps, I've always been good at listening, and following directions, . . , but the second it came to reasoning and more critical thinking, I just didn't have a lot of experience, So I don't think I had any confidence with it,
I felt like this isn't math anymore, It's a different kind of thinking that I don't know how to do. That is why I started to shy away from it. . . . I enjoy teaching elementary math but it never made sense, it never had a place in my life anymore.</td></tr>
<tr><td colspan="2">Below, Ginny reflects on her experience in the PD program</td></tr>
<tr><td>I had on the shoes of the learner,
I experienced it.
You have to think,</td><td>I've heard before you need to ask higher order thinking questions and depth of knowledge and things like that,
I've heard about that, I've been taught about it before,</td></tr>
</table>

<table>
<tr><td>You have to think,
You have to figure it out.
Everyone has math to share!</td><td>plenty of times, but its never really like resonated with me before until I experienced it, . . . it was just like, Ok, this is how we think now. . . . I just came out thinking differently and I really don't know how that happened</td></tr>
<tr><td colspan="2">Below are words Ginny used to describe how she feels about math now</td></tr>
<tr><td colspan="2">I have [had] the experience I want my kids to have. . . .[T]his year I looked back at [one] homework [from last year] . . . and I was like I can't even send that home, that makes no sense mathematically . . . that's a cheat, that's a shortcut . . . I'm just realizing that there was a lot of shortcuts I used last year and I was very test oriented . . . last year I'd have anchor charts with steps [for adding/subtracting on a number line] . . . this year its a lot more experimental and I have manipulatives out every day. . . . For the number line, instead of hops and walks, when they move ten on the number line we represent it with a ten rod so the kids are making connections between base ten blocks and counting on the number line because I understand that connection. I have a lot of new teachers on my team, and working with and explaining how I'm going to teach and how they are going to teach I realize I have a way deeper understanding than I did last year.</td></tr>
</table>

Fred

Fred hated math as a child. His memories of learning math include timed competitions in school and jealousy of the student who always won. "And he would walk up and get his two free books for winning that competition. And uh, I was always very frustrated by that." Fred's experiences as a student led him to think that math was a set of steps to be memorized. As a result, he still didn't like math as a beginning teacher, but wanted to teach it as best he could.

A few years later, Sarah Cruz (pseudonym) came to Fred's school as a new teacher. Sarah had been a finalist for a local educational foundation's math accolade. Fred figured that because of this distinction, she was probably pretty good at teaching math. "I actually went to her and I said, 'Listen, math has been a frustration for me for a long time, I'd really like to learn how to do it better.'" Sarah gave him some pointers and he started there, doing exactly what she had told him to do. That year, his students had the best improvement in math that he had ever seen. "I was just really quite delighted by the results. Because I actually enjoyed teaching math that year." That summer, Fred was invited to participate in the Intel Math program.

Fred: I went into it with the same mindset I had as a child. I was really nervous going in because I thought that it would really be a challenge for me. And that the other teachers who were around me were going to see right through me and notice that I'm not very good at this. But it was a real eye-opener for me because the math that they were doing was more logically based than it was memorization based. And, I'm pretty strong with logic. So I found myself, you know, essentially out-performing those who were at the same table from me—with me—and they were looking to me to get a better understanding of what was going on. Because a lot of these teachers were people who were teaching math the same way that I had learned math when I was a kid. I was obviously very very excited about it because a lot of the concepts that were being taught during this time, during the Intel Math training, were exactly what Sarah Cruz had been telling me the year before. And, so I realized that Sarah had, you know, a really good sense of what students needed in order to learn math. And, this Intel Math just really helped me take that to another level in my first year teaching third grade. And naturally, I had nice improvement with my math scores that year.

Fred's experiences learning from Sarah and participating in Intel Math helped him to reimagine math and math instruction as logically-based, instead of as a set of memorized facts.

Fred: I think the biggest thing that I have gotten out Intel Math is that if I really take it to heart and understand that each individual student is at a different place, and continue to work with my small groups … I can really, intimately understand where each of those students is, in their math learning. And I have a greater understanding of why my students are succeeding where others, who are learning how to do tricks with math—is what I call it now, when they learn to do those tricks, they're really not getting the fully number sense.

Fred's professional learning has been so transformative for his instructional practice, he uses the word "devastating" to describe a specific strategy he had previously taught.

Fred: One of the most devastating things that I did as a teacher—and I'm going back about 5 or 6 years now—was how I taught task analysis. Which was where the teacher says, 'These are the exact steps that you follow to solve this kind of math problem.' I took that as 'this is how you teach it.' However, task analysis is meant to be a guide. We need to give students choices in how they solve problems. To teach step-by-step procedures does not allow students to create their own ways of solving problems. And to me, that was just devastating. I think that might work for reading, but it just doesn't work for math because you're asking students to follow steps rather than teaching them to use their minds to figure out their own best way of solving these problems.

Conclusion

By creating a set of stories of teacher transformation, of which Fred and Ginny are two examples, we center teachers' voices, identities, and experiences, and the significance that they assign to different aspects of their professional journeys. At this stage in our research, we are intentionally experimenting with the forms we use to communicate these journeys. However, no matter the form, our goal is convey both the intellectual and affective domains of the stories, and ultimately consider how such stories can inform the work of teacher educators and others.

UNDERSTANDING THE WAYS GRADUATE TEACHING ASSISTANTS LEARN TO TEACH THROUGH DISCOURSE IN PROFESSIONAL DEVELOPMENT

Hayley Milbourne
San Diego State University
hayley.milbourne@gmail.com

Susan D. Nickerson
San Diego State University
snickerson@sdsu.edu

Across the United States, there is increased national interest in improving the way mathematics departments prepare their Graduate Teaching Assistants (GTAs). We focus on GTAs engaged in professional development for active learning. We report preliminary results on the ways in which the understandings of GTAs of various teaching practices changed over a term. With this analysis, we contribute to a better understanding of how to support GTAs with their teaching.

Keywords: Graduate teaching assistants, professional development, teaching practices.

Many mathematics departments in the United States are changing the way they structure the teaching of the Calculus sequence based on the recommendations that emerged as a result of the Mathematical Association of America (MAA) study of successful Calculus programs (Bressoud, Mesa, & Rasmussen, 2015). One of the recommendations was to improve the professional development (PD) offered to the Calculus graduate teaching assistants (GTAs). Much of what we know about these PD programs arises from research focused on the various structures of PD programs, on the outcomes of the programs, or on a small, in-depth case study (e.g., Kung & Speer, 2009). In a review of the research, Speer, Gutmann, and Murphy (2005) stated the need for studies with longitudinal designs so as to "inform the design of exemplary programs that have a lasting influence on instructional practices" (p. 79).

We report on professional development at a large university in the southwestern United States whose mathematics faculty implemented several changes to the Calculus sequence, including to the structure of the PD program for the Calculus I and Calculus II GTAs. A large part of the PD involves formal meetings with mathematics education faculty and mathematics faculty course coordinators with a stated goal of supporting GTAs to teach with a more student-centred approach. In particular, the PD has a focus on supporting effective teaching practices, defined as "…what teachers do and think daily, in class and out, as they perform their teaching work" (Speer, Smith, & Horvath, 2010, p. 99).

The GTAs discussed teaching practices with each other, their course coordinators, and mathematics education faculty. We investigated the ways in which the discourse around various teaching practices evolved over time, so that we can better understand GTAs' learning. We share selected results in answer to: How do the GTAs' publicized understandings of various teaching practices change (through elaboration or transformation) over the course of a term? How do these publications highlight which teaching practices are most salient to their needs?

Background

There are a few studies done on the state of GTA professional development across the United States (e.g. Belnap & Allred, 2009; Bragdon, Ellis, & Gehrtz, 2017; Speer et al., 2010). In addition to these national level studies, there are also several case studies, with a focus on the structure of or the efficacy of the program (e.g., Griffith, O'Loughlin, Kearns, Braun, & Heacock, 2010; Marbach-Ad, Shields, Kent, Higgins, & Thompson, 2010). More recently, researchers are reporting on case studies that focus on changes to professional development and investigating the results, or focusing on what informs changes to the program (Beisiegel, 2017; Pascoe & Stockero, 2017; Wakefield, Miller, & Lai, 2017).

So, work is just beginning on the ways in which graduate teaching assistants develop their teaching practice. By examining their discourse, we better understand how the GTAs are appropriating, elaborating, or transforming various teaching practices in light of their own needs over time. Consequently, this work can inform our professional development work with GTAs.

Theoretical Perspective

The socio-cultural learning theory put forth by Vygotsky posits learning occurs through a reflexive relationship between the individual and the community in which the individual interacts (Vygotsky, 1987). We used a modified version of a framework known as the Vygotsky Space (Harré, 1983) to understand the ways in which the discussion evolved over time. With this framework, the understanding of a teaching practice can be tracked as it is appropriated and transformed by the GTAs throughout the term. See the modified Vygotsky space in Figure 1.

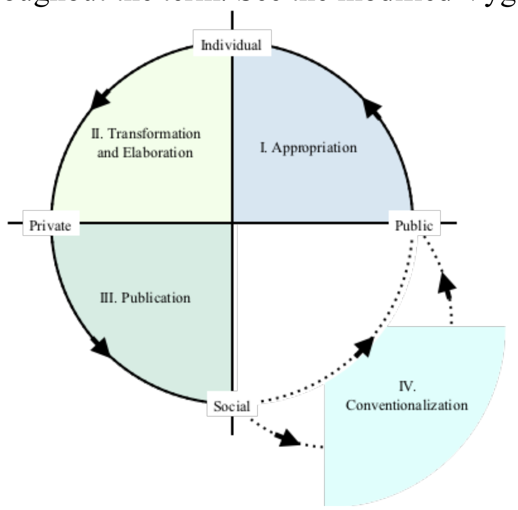

Figure 1. Diagram of the modified Vygotsky Space.

Within this diagram, there are two axes: Public-Private and Individual-Social. These two axes form four quadrants, which contextualize the four aspects of the Vygotsky space. For instance, *appropriation* is within the Public-Individual quadrant because it describes how a teaching practice comes to an individual from the public. *Transformation and Elaboration* is within the Individual-Private quadrant because it describes the way a person has possibly changed the meaning or motivation of a practice through making sense of it within their own context. In the third quadrant is *publication*, which describes how the person makes their own private understanding of a teaching practice known to the social group they are within where it can be then potentially be a resource for others. At this point, the teaching practice may go through several iterations of these three quadrants before it lands within the fourth quadrant, *conventionalization*, which represents that understanding of the teaching practice has become normalized within a community (Gallucci, DeVoogt Van Lare, Yoon, & Boatright, 2010).

Setting

At the university in this study, Calculus is taught in large lectures of approximately 160 students. The Calculus I and Calculus II students meet in break-out sessions twice a week in a class of approximately 35 students. In one of these meetings, GTAs focus on answering homework questions and addressing particular content of the lectures. In the other breakout session, the GTA leads group-based learning activities, typically an application of a topic from lecture. To get support for facilitating these active learning tasks, the GTAs participate in a three-day teaching seminar before classes begin in the Fall. The GTAs continue to meet approximately eight times throughout the term with mathematics education faculty. The GTAs also participate in weekly meetings with their course coordinator in which they talk about the activity for the following week and any administrative issues (e.g., grading of homework and exams).

Furthermore, the structure of the GTA program has been changed to include a Calculus I and II lead TA. The lead TA is a more experienced GTA who provides support in the form of professional development to his or her fellow GTAs, both before and throughout the term (Ellis, 2015). At two or three points in the term, the lead TA visits the break-out activity day sections of his or her fellow GTAs to observe the class and meets with the GTAs afterward to debrief.

Methods

Sixteen GTAs agreed to be part of the study, including both the Calc I and Calc II lead TAs, seven new GTAs, and seven GTAs returning from the previous year. The first author either audio or video-recorded each PD meeting, course coordinator meeting, debrief between the lead TA and a fellow GTA, and break-out sections observed by the lead TAs. We transcribed each of the video and audio recordings and coded each utterance about teaching practices using descriptive coding (Bakhtin, Emerson, & Holquist, 1986; Miles & Huberman, 1994). There were 137 sub-practices related to both traditional and active-learning teaching practices.

These sub-practices were introduced with a particular justification or motivation for their use. In the second phase of analysis, we determined the reasoning expressed for the use of a particular teaching practice. We could then see the ways in which the discourse around that practice transformed throughout the semester. If the meaning was changed, the practice was labeled as transformed. If the meaning had not changed but the practice was discussed in a new context, it was considered elaborated. These publications and transformations of the teaching practices, as well as who stated them and when, were tracked throughout the term to provide an overall portrait of how the discourse and inferred understanding evolved.

Results

There were three main results that were found in answering the research question given earlier: 1) GTAs do appropriate the language of mathematics education but may have different understandings of those practices than the PD leaders; 2) there is evidence that the GTAs found the practices of cognitive demand and lecturing challenging within the new context of active learning; and 3) there is evidence that the GTAs found the practices of asking for justification, checking for understanding, and precision for communication important to discuss but seemed to agree on their meaning and use. In this presentation, we will focus on the first result because of the theoretical and methodological implications it presents.

We took the criteria of conventionalization, the number of transformations, and what the transformations conveyed about the GTAs' understanding of the teaching practice to provide evidence for their appropriation of the language from mathematics education. The GTAs were appropriating some of the language of mathematics education but sometimes their publications revealed different meanings or motivations. This was particularly evident in a sub-practice related to *adding scaffolding* in which what became conventionalized was a transformed version of the practice. For example, math educators might think of scaffolding as in making connections to background knowledge to help the students gain access to the problem, rather than doing more of the problem for the students. Three other sub-practices had a transformed version approaching conventionalization. So, even though the GTAs were using the language of mathematics education, they could be using it in a different way than it was originally introduced or as understood by the mathematics education community.

Conclusion

The results from this study provide additional insight into the ways in which GTAs make sense of active learning teaching practices as they interact with each other and engage with professional development. With this information, the field can begin to understand how GTAs change their interpretations of teaching practice over time and ultimately improve the professional development offered to graduate students who are new to the practice of teaching.

This study examined how participation in online professional development impacted 2,525 participants' perspectives about statistics and teaching statistics. The course design, participant engagement, impacts on perspectives, and influences on changes in perspective are described.

Keywords: Statistics, Teacher Professional Development, Online Learning

Introduction and Background

While statistics has gained prominence in school curricula (Franklin et al., 2007), it is often taught within a mathematics curriculum by mathematics teachers with limited experiences in statistics who are often trained in programs that do not support becoming effective statistics teachers (Zieffler, Garfield, & Fry, 2018). Since statistical thinking is inherently different than mathematical thinking (e.g., delMas, 2004), teachers need opportunities to develop their own statistical thinking and teaching practices. In part, this involves providing learning opportunities that challenge perspectives about the nature of statistics and teaching statistics. In this paper, we discuss how design of online professional development (OPD) that is free, open access, and can impact many educators across geographic boundaries (Kim, 2015).

Beliefs and perspectives about statistics include an educator's ideas about the nature of statistics, about oneself as a learner of statistics, and about the classroom context and goals for students' learning statistics (Pierce & Chick, 2011; Eichler, 2011). Certain beliefs likely result in different approaches to teaching. For instance, if an educator believes that statistics is a way of quantifying data, his or her teaching practices may favor statistical procedures without considering the context of the data, issues related to sampling, and making claims about uncertainty (Pierce & Chick, 2011). Furthermore, the focus of teachers' intended curriculum in statistics can be considered on a continuum from traditionalists (focused on procedures absent of context), to those wanting students to engage in an investigative process that is tightly connected to contexts of real data (Eichler, 2011). Professional development should move educators along this continuum towards a focus on investigative processes, which requires impacting educators' beliefs about the nature of statistics and statistical learning goals for students.

Theoretical Framework

We envision the *Teaching Statistics Through Data Investigations* [TSDI] course as an infinity space (Gee, 2005). In this space, educators with diverse backgrounds and skills come together to learn about strengthening their approaches to teaching statistics. An affinity space begins with content, or a *generator*. In the case of TSDI, the generator is an OPD course that emphasizes how teachers can use an investigation cycle to teach statistics and support students in exploring data to make evidence-based claims. *Portals* are ways individuals interact with content and engage with one another in an affinity space. Portals can also be generators. In our course, portals include the Moodle site that educators use to access the course materials and resources. Within this larger portal of designed resources, every unit includes opportunities for participants to engage in discussions. An affinity space also has an internal and external aspect; *internal grammar* characterizes the way a space is designed and organized, while *external grammar* signifies how people choose to interact with either the content or one another within the space.

According to Gee (2013), an advantage to an affinity space is that educators can access spaces and contribute in various ways with different people for different purposes. Further, educators can access these spaces to acquire resources and also share resources and approaches and strategies for teaching. Once accessed, there is flexibility in these spaces so that educators can interact with others by forming and re-forming groups. Gee suggests that the space is a form of emergent intelligence since various tools, different educators, and diverse skills are networked in ways that increases everyone's knowledge. In this study, we examined the following research questions: *How do educators engage in an OPD course focused on teaching statistics? How do educators' interactions in OPD impact their perspectives about the nature of statistics and the teaching of statistics? What portals influence changes in educators' perspectives?*

Design of the Course

TSDI (http://go.ncsu.edu/tsdi) does not focus on any particular grade band or specific statistical content. Rather, the course was designed to encourage participants to view statistics as an investigative process that incorporates statistical habits of mind, and view learning from a developmental perspective. One of the most important generators of the course, the Students' Approaches to Statistical Investigations [SASI] framework, was built on Franklin et al. (2007), illustrating the investigative cycle, students' statistical reasoning in each phase at three levels of sophistication, and an indication of productive habits of mind. Multiple portals focusing on the SASI framework are integrated throughout the course.

Important aspects of the internal grammar of the affinity space (i.e., the design) are based on design principles of effective OPD (Kleiman, Wolf, & Frye, 2015): (a) self-directed learning, (b) peer-supported learning, (c) job-connected learning, and (d) learning from multiple voices. TSDI was designed so that educators would have multiple opportunities to interact with the content and engage with others through numerous portals. *Learning from multiple voices* was enacted by providing ways to engage with videos of an Expert Panel discussion and classroom videos. *Self-directed* and *job-connected* learning opportunities included Dive Into Data experiences, where participants used free technology tools (e.g., Gapminder, Tuva, CODAP). Extensions in each unit include extra resources (e.g., data sets, lesson plans, applets, etc.). *Peer-supported* learning included two discussion forums where participants interact with others focusing on: 1) specific pedagogical aspects of teaching statistics, and 2) participant initiated discussions about teaching.

Methods

Participants

From Fall 2015 to Fall 2017, participants (n = 2,525) from 84 countries enrolled in six sections of the course. The majority resided in the US (79%), including all 50 states. The majority of participants were female (66%), held an advanced degree (75%), and identified themselves as classroom teachers (61%). Participants' experience as educators varied, with a mean of 14 years (20% had 1-5 years, 19% had 6-10 years, 18% had 11-15 years, 16% had 16-20 years, 21% had more than 20 years).

Data Sources and Analysis

Course activity was tracked through click logs, allowing us to examine trends in participants' engagement in the designed materials in the portal. A Tableau dashboard was used to visualize participants' engagement over time. Other data sources included: 1) discussion forum posts from two Unit 5 forums, 2) open-ended responses to end-of-courses surveys (administered at the end of Unit 5), and 3) a follow-up survey (administered approximately 6 months after course completion). In previous work that examined only Fall 2015 classroom teachers, Lee, Lovett, and Mojica (2017) reported four themes to describe changes in participants' beliefs/perspectives about statistics and teaching statistics. Thus, 721 Unit 5 posts from three sections of TSDI were coded for one of these themes. We also open coded, which led to new themes. Once we were saturated in data and no new themes emerged, we confirmed codes in the remaining sections of Unit 5 posts. End-of-course and follow-up surveys were analyzed using open coding.

Findings

Engagement in TSDI

TSDI was offered six times from Fall 2015 - Fall 2017 in Moodle. Each course remained active for about 10-15 weeks, and participants were able to access and view materials after the course closed. Amongst all who registered, 1,737 (69%) participants accessed any material, which is higher than what Jordan (2015) found across 59 different MOOCs with a typical "show up" rate near 50%. Across all sections, 1,441 (54%) of those who registered engaged in the Orientation Unit. Of those that participated in the Orientation Unit, a majority (71%) engaged in Unit 1. However, only 47% participated in Unit 2. Engagement in Units 3 and 4 were very similar, 38% and 33%, respectively. Only 26% of those who started the course completed Unit 5. Of those who registered, 959 (38%) engaged in a discussion forum. Across all sections, there was a total of 2,164 discussion forum threads, and 6,381 total posts, with an average of 6.65 responses per forum participant, with some participants posting 30-50 times.

Impacts on Perspectives about the Nature of Statistics and Teaching Statistics

Eight major themes emerged in relation to changes in participants' beliefs and perspectives about statistics and teaching statistics based on an analysis of discussion forum data: statistical thinking involves different processes than mathematical thinking; engaging in statistics should involve exploring data; posing good statistical questions and selecting an interesting/relevant context in relation to students is crucial in engaging students in statistical thinking; engaging in statistics is more than computations and procedures and should include investigative cycles and habits of mind; engaging in statistics is enhanced by the use of dynamic technology; engaging in statistics requires real (and messy) data; statistical thinking develops along a continuum; and, teachers do not have to know all answers when engaging students in the investigative cycle.

Findings from the follow-up survey support that engagement in the course impacted learning. Most participants (84%) indicated they acquired new knowledge and skills. Of those that indicated their knowledge/skills increased, 63% signified they had applied this in their practice. Only 45% reported newly acquired skills had an impact on student learning. Participants reported they used specific tasks, websites, technology tools, and other resources in their practice.

Influences on Changes in Perspectives

The SASI framework, expert videos, and videos of students engaged in statistics acted as portals that influenced changes in educators' perspectives to include a more robust vision of statistical thinking and teaching strategies for engaging learners in investigations. Discussion forum and end-of-unit surveys showed how participants often discussed what they learned from different multimedia resources related to the SASI framework. Frequently mentioned portals were the SASI diagram, videos with experts (panel discussion and development of concept of mean), and animated videos of students' work on a weighted die investigation.

Analysis of discussion forum data and end-of-course surveys indicate that the following portals provided learning experiences that impacted educators' perspectives about the nature of statistics and teaching statistics (in decreasing frequency): access to resources, technology tools, websites, and lesson plans; learning from videos of expert panel discussions; learning from videos of students and teachers work in classrooms; introduction to the SASI framework; focus on improving questioning, exploration, engaging students, and active learning; engaging in discussions with colleagues; appreciation for flexibility and learning at own pace; and being grateful for opportunity and inspired to learn more.

Discussion

Preparing and supporting educators to be effective statistics teachers is a challenge in teacher education. We suggest that designing spaces where educators have opportunities to challenge perspectives about the nature of statistics and teaching statistics through OPD is one way to support learning. Designing specific portals for educators can lead to implementation of new ideas in practice. Engagement in OPD can be a powerful experience in supporting many teachers' professional learning across geographic boundaries (Kim, 2015). The themes we identified and the self-reported changes in their practices suggest that the TSDI course, and perhaps other similar OPDs about teaching statistics, can be successful in shifting teachers' perspectives about the nature of statistics and their use of real world investigations in their teaching that align with Pierce and Chick (2011) and Eichler (2011).

Acknowledgments

TSDI was funded by the William and Flora Hewlett Foundation. Findings and recommendations are those of the authors, and do not necessarily reflect foundation views. Thanks to Dung Tran, Theresa Gibson, Alex Dreier and Glenn Kleiman for contributions.

PREPARING ELEMENTARY MATHEMATICS SPECIALISTS (AS-SUBJECTS) AND RECONCEPTUALIZING TEACHER BELIEFS (AS-ENTANGLEMENT)

Kayla D. Myers
Georgia State University
kmyers@gsu.edu

This project was designed to help Prospective Elementary Mathematics Specialists (PEMSs) negotiate their beliefs about mathematics teaching and learning amidst all of the other aspects of teaching, addressing the messiness of teacher beliefs while navigating their role as mathematics teacher and teacher leader. To do this, I take up poststructural theories of subjectivity to consider PEMSs as subjects whose beliefs about teaching and learning mathematics are always already entangled, impossible to think as separate or pre-existing. This reconceptualization gave PEMSs a space to address and navigate the tensions of beliefs and enactment. These tensions have been crafted into conversations, an accessible contribution to the literature.

Keywords: teacher beliefs, teacher education – inservice/professional development

Introduction and Significance

For several decades now, teacher beliefs have been a focus in mathematics education research as well as the broader field of education. The basic rationale for this emphasis has been to understand how teacher beliefs about mathematics teaching and learning impact enacted instructional practices. In my thorough review of the extant literature, I found many studies that assert confirmation of an impact of teacher beliefs on practice; however, there is a growing body of empirical studies that complicates their influence (Fives & Buehl, 2012; Skott, 2015). In this dissertation study, rather than attempting to define teacher beliefs or dispute their impact, I reconceptualize teacher beliefs by writing a different story of beliefs as a *doing*, an entanglement, rather than a thing that can be reflected upon or distinguished. The purpose of this work is to produce new knowledge about teacher beliefs to help mathematics researchers address the documented difficulty in measuring the relationship between teacher beliefs and practice (Charalambous, 2015; Leatham, 2006; Schoenfeld, 2015). This project was designed to better help Prospective Elementary Mathematics Specialists (PEMSs) negotiate their beliefs about mathematics teaching and learning amidst all of the other aspects of teaching, addressing the messiness of beliefs (enacted) while navigating their role as mathematics teacher and teacher leader. To do this, I take up posthuman and poststructural theories of subjectivity and methodology to consider PEMSs as subjects (selves) whose beliefs about teaching and learning mathematics are *always already* entangled, impossible to think as separate or pre-existing (Derrida, 1967/1974). This reconceptualization gave PEMSs a space to address and navigate the *tensions* of teacher beliefs and their practice. These tensions have been crafted into conversations (Bridges-Rhoads, 2011; Davies, 2009; Shor & Freire, 1987), including creative analytical practices/processes (CAP) like narratives and poetry (Richardson, 1997), which is perhaps more accessible, contributing to the current conversation about teacher beliefs as well as extending it to address important issues of perspective and methodology (Koro-Ljungberg, 2015).

Rigorous preparation programs like the one in this study are designed to broaden EMSs' range of teaching practices, develop pedagogical competencies as described in the *Principles to Actions*: *Ensuring Mathematics Success for All* (NCTM, 2014), and prepare them to advocate for pedagogical shifts (AMTE, 2013). The preparation program is full of theory, teaching methods, and content knowledge intended to lead to enactment of such theory and methods in elementary classrooms. Addressing these goals requires a degree of clarity and certainty about the experiences of PEMSs in their enactment, identifying and distinguishing shifts in pedagogy and beliefs. During my own preparation and in my own enactment, naming (and performing) my beliefs led me to deeply question the coherence of my EMS-identity. A poststructural perspective on the subject allows for movement rather than stability during a time of transition and enactment for PEMSs. Therefore, this study is significant because of the impact of EMSs' (re)construction of teacher beliefs on themselves, their students, and others. More specifically, this study produces new knowledge for EMSs that might help them better navigate their role as teacher leaders, thinking about their beliefs about mathematics teaching and learning in a way that no longer limits their subject positions. Rather, EMSs can consider their instruction, pedagogy, and beliefs as intra-actions within the discourses that produce them.

Data Collection, Analysis, and Preliminary Findings

Three PEMSs engaged in this study, and data consisted of three classroom observations (two evaluative, one non-evaluative; nine total), two semi-structured individual interviews (six total), and three focus group interviews during a practicum course in a university K-5 Mathematics Endorsement program, as well as document analyses of observation protocols and professional portfolios both before and after completion by the university supervisor and PEMSs. Analysis consists of "thinking with theory" (Jackson & Mazzei, 2012). Such an analysis, which happens in writing (Richardson & St. Pierre, 2005), makes visible multiple ways of *being* and *becoming* subjects in mathematics education, enabling a story of teacher beliefs as entangled.

For this study, I use writing as a method of analysis, which broadly speaking, uses writing as a way of knowing, thinking, organizing, and creating. It involves thinking and rethinking, reading and rereading of data and theoretical texts side-by-side, writing and rewriting as a cyclical process. Writing in this way is rigorous, and while it looks differently for every researcher, it often involves setting a systematic writing schedule in which we read theories again and again while reading and/or listening to transcripts, documents, and other data. In this process of writing and making meaning, stories and themes come about on the page. These preliminary findings are not fixed or final but rather coming about in the midst of different stories. In this process thus far, I have created poems, conversations between speaking subjects, and narratives, as well as other types of prose, collectively written from transcripts, field notes, hallway conversations, theorizations, journals (mine), reflections (theirs), emails, facial expressions, readings, documents, curriculum, student work—anything that, as MacLure (2013) says, "glows" in the research, sparking my wonder. This is the rigorous process of writing as a method of inquiry, where all of this is welcome to the page in the systematic daily writing that happens alongside readings of data and theory.

I didn't set out with any particular format in mind, but what emerged were conversations, often about *tensions* teachers were feeling in their beliefs and enactment. I started to explore what stories could be told when taking up this format of a conversation. This process of writing a conversation has illuminated, for me, when words are not enough to tell the whole story—when things feel missing, like how their bodies are exhausted, their classrooms are dark and confining, and ways that hands and eyes might say more than spoken words. I am writing in these silences, using my voice to add analysis, commentary, stage directions, environment, citations, and more questions. Below, I present a small excerpt, a preliminary finding, of a conversation about tensions with beliefs and expectations:

Jill: I believe in the research. I believe in what I read and what we've experienced and what I'm seeing, but because our society in general is so test-driven, score-driven, competition-driven, I just want the evidence to be there to support that I'm making the right decision. I just don't want to mess this up and have all kinds of parents say that I ruined their children. They're going to be fine on the test…

Michael: Are they going to be fine on the test?

Jill: Can any of us confidently say 'oh, you just watch, at the end of the year my kids will be stronger, they will be better'? I'm not there yet.

Maggie: We have to tread lightly, making an effort to stick with it. Just reading a book or, you know, seeing an article or something you feel inspired, but not equipped.

Jill: But after going through this course, I do feel better equipped. One of my greatest concerns, though, is- what if I screw this up? What if I screw this up and I miss something and then they go on to fourth grade and they're like, 'whoever was in Jill's class does not know how to add.' I can't do that. So knowing that even though I'm not following the teacher curriculum guide page by page, I'm still getting at the skills, I'm still getting at the concepts, I'm still equipping them to solve problems. That is probably the most rewarding thing I've experienced in years. CGI is *powerful*, you all know that. But painting that picture and showing that to people who haven't seen it is *hard*.

[There is heat behind two of Jill's words– *powerful* and *hard*– that highlights the tensions she's feeling. She describes CGI as powerful, with such enthusiasm, her voice drawn out and deep, that word met with emphatic nods and closed eyes. *Yes, powerful*. You can hear stipulation in her voice. By the time she reaches her last word– *hard*– her body reacts as if it's just received a punch to the gut. The delivery of that word takes too long. Her shoulders slouch, her head hangs, her hands hit the table. Convincing people of that power, people with different expectations, is not just difficult; it's exhausting.]

Michael: Meeting everyone's expectations feels impossible.

These *tensions* are what is driving my reconceptualization of teacher beliefs as an entanglement that we negotiate again and again, impossible to disentangle. By paying attention to ways teacher beliefs are in-tension with these other aspects of teaching, I am not only extending the current conversation about teacher beliefs but also offering a different and responsive way for teachers (and teacher educators) to prepare for those tensions.

A preliminary summary of my findings includes a collection of conversations aimed at these ways I am seeing beliefs-entangled: (a) beliefs as effecting others, like students and colleagues, as well as practice and feelings; (b) beliefs as (not) mattering, feeling defeated by scripted curriculum, like their beliefs don't matter, while at other times it felt like their beliefs were all that mattered; (c) beliefs as exhausting on bodies and on attitudes, impacting things like perseverance and dedication to enactment; and (d) beliefs in tension with differing expectations. These reconceptualizations are not linear or separate but recursive and overlapping in my analysis and writing of conversations. They allow beliefs-entangled to move amidst the many tensions. In writing these results as conversations, I am producing texts that can be read by both researchers and teachers. My hope is that this accessibility can help prepare PEMSs and teachers to be responsive to these tensions, recognizing them in their beliefs-entanglement, and better negotiate and thus navigate their practice and enactment.

Initial Implications

I am finding some important stories that will contribute to the mathematics education research community. First, when preparing PEMSs, complicating the stability of teacher beliefs is allowing them to navigate the tensions they feel and see in their classrooms, schools, students, colleagues, and past experiences. Thus, this also has implications for preparing pre-service elementary teachers, as I myself came upon this problem of teacher beliefs because of my beliefs being questioned that first year I entered the classroom. Perhaps if pre-service teachers are prepared for those tensions and engage in conversations about beliefs as not static or concrete but moving and subject to surrounding discourses, they will be able to better navigate those early years, persevere in those struggles, and become better teachers for it. Further, perhaps by reconceiving of teacher beliefs as move-able and adaptable, teachers can feel more autonomy over their beliefs and practice, and less teachers will be pushed out of the classroom by feelings of inflexibility and inadequacy. These initial implications for the mathematics education research community suggest another implication—a call for different and innovative methodologies in mathematics education research. Perhaps studies like this one, by opening up different conversations, can offer a responsive call to mathematics teacher education.

NOTICING IN SMALL GROUPS: BEYOND MATHEMATICAL THINKING

Byungeun Pak

Brent Jackson
Michigan State University
bjackson@msu.edu

Small groups (SG) is a space where three aspects, such as mathematical thinking, status, and funds of knowledge, come into play. How teachers draw upon these three aspects in facilitating small group work is shaped by what teachers notice. Researchers have used the professional noticing framework (Jacobs, Lamb, & Philipp, 2010) to understand teachers' noticing of students' mathematical thinking. This paper proposes a teacher noticing framework based upon Louie (2017) and Jacobs and her colleagues (2010) to expand teacher noticing for facilitating SG.

Keywords: Equity and Diversity, Teacher Education-Inservice/Professional Development, Teacher Education-Preservice

Introduction

How do equity-oriented teachers make instructional decisions when facilitating small groups (SG) in mathematics classrooms? Our attempt to answer this question was predicated upon our experiences as former teachers when we recognized that we often noticed more than students' mathematical thinking when using SG. Through reviewing the literature on teacher noticing we learned that research-based descriptions of what teachers notice in SG contexts are limited and that current teacher noticing frameworks are not sufficient to understand teachers' instructional decisions when working with SG.

Recent research analyzes individual teachers' cognitive processes that contribute to noticing students' mathematical thinking along conceptual learning trajectories. SG, however, have both mathematical and social goals (Cohen & Lotan, 2014; Davidson, 1990). To achieve these goals, teachers may notice students' mathematical thinking, funds of knowledge, and status simultaneously while working with SG. As such, we argue that more work is necessary to help researchers understand how teachers balance these aspects. This paper proposes a teacher noticing framework that can help researchers more fully understand how teachers make instructional decisions when facilitating SG.

Theoretical Framework

The Noticing in Small Groups framework (NSG framework, Figure 1) is an attempt to conceptualize teacher noticing in the context of SG. Louie's (2017) concern about research on teacher noticing was that this research tended to emphasize individual teachers' cognitive process of students' mathematical thinking and ignore the contextual factors that may influence what teachers notice. Notwithstanding, we felt that focusing on teachers' cognitive process per se is not necessarily problematic in particular relation to SG. We agree with Louie (2017) that "the cognitive focus of existing literature obscures cultural and ideological obstacles to noticing students' mathematical thinking and strengths" (p. 56). When considering SG we concur with Louie (2017) that there is more to negotiate than students' mathematical thinking. The NSG framework highlights three aspects of SG to illustrate what equity-oriented teachers more likely notice when facilitating SG.

In the NSG framework, three aspects of SG are 1) mathematical thinking, 2) status, and 3) children's funds of knowledge. Prior work on professional noticing suggests that teachers' noticing competency of students' mathematical thinking holds promise for advancing students' mathematical understanding (Jacobs et al., 2010) and therefore we have kept this aspect in the NSG framework. In SG, students are expected to work together, while "asking questions, discussing ideas, making mistakes, learning to listen to others' ideas, offering constructive criticism, and summarizing discoveries in writing" (NCTM, 1998, p. 78). This quote brings into the imagination students working smoothly in SG with shared social and intellectual authority. In reality, however, students' status, "hierarchies where some members are more active and influential than others" (Cohen & Lotan, 2014, p. 27) may shape whose ideas are taken or ignored in SG (Cohen & Lotan, 2014). Funds of knowledge are "the historically and culturally based knowledge, skills, and practices found in students' homes and communities" (Turner & Drake, 2016, p. 32). Research has demonstrated that teachers' consideration in planning and use of students' funds of knowledge helps students to make sense of mathematical ideas (Turner & Drake, 2016). For these reasons we have added status and funds of knowledge to be included alongside mathematical thinking in the NSG framework. We think of these aspects to support one another, like in Figure 1, where each aspect of SG takes one side of each triangle. The triangle represents an interrelationship among these aspects because without one side the other two sides cannot stand. Thus, these aspects may be noticed simultaneously in order to support equitable teaching in the context of SG.

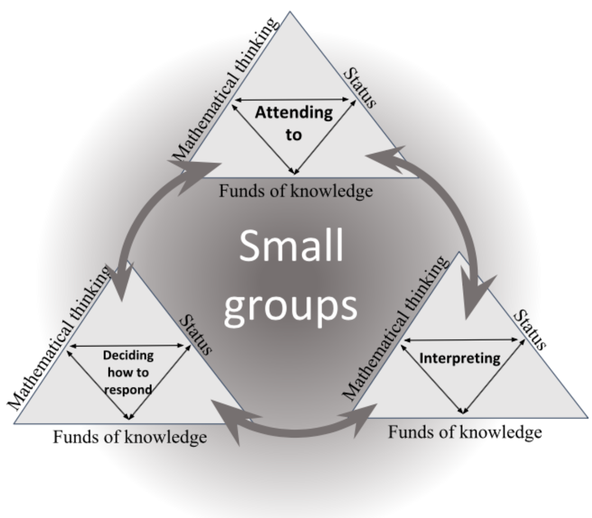

Figure 1: Noticing in Small Groups framework

The NSG framework draws upon professional noticing (Jacobs et al., 2010). Professional noticing of children's mathematical thinking consists of a set of the three components: (1) attending to children's strategies, (2) interpreting children's understandings, and (3) deciding how to respond on the basis of children's understandings. Turner, Drake, McDuffie, Aguirre, Bartell, and Foote (2012) adapted Jacobs and colleagues' professional noticing to address both mathematical thinking and children's funds of knowledge. The NSG framework builds on their adaptation in that it adds a third aspect, status, which influence the dynamics of SG (Cohen & Lotan, 2014).

The circular arrows in Figure 1 represent how the teachers' noticing process pertaining to intervention in small groups works in the NSG framework. These processes do not necessarily happen in any given order, such as, from attention, to interpretation, and to decisions about how to respond, nor begin with any specific component (i.e., attending may not always occur first).

For example, within the context of SG, a teacher may first interpret unequal participation as an issue of status; the teacher may then attend to the both status and funds of knowledge by eliciting from the low-status student an experience he/she has that will be beneficial to the group, which in turn assigns competence. If the unequal participation is first interpreted as related to mathematical thinking a different intervention is likely to occur. Alternatively, a teacher may first attend to a student's use of funds of knowledge and decide to highlight his/her mathematical thinking to position the student as competent among the group members. The inclusion of status and children's funds of knowledge into the NSG framework can invite teachers to be more responsive to students' multiple ways of being mathematically smart.

Illustrative Example

In order to understand the limitations of using professional noticing framework (Jacobs et al., 2010) and further understand the affordances of the NSG framework, we provide an illustrative example from existing research. While reading research regarding SG, we recognized that the in-the-moment decision making process for teachers' facilitation was absent. Although we recognized this absence among several research articles, the transcript from Wood (2013), below, highlights well what we recognized.

Wood (2013) studied the participation of one group of fourth grade mathematics learners to understand how students' mathematical identities can shift within and across lessons. She considered how the in-the-moment identities created or limited opportunities for mathematical learning. In this exchange the teacher asks a student, Jakeel, for his mathematical reasoning on the group's task of finding the area of a right isosceles triangle drawn on grid paper:

Teacher: What's the area of J? [The teacher looks at Jakeel.]
Jakeel: The sum is um [Jakeel points at figure K on his paper.]
Teacher: What is it? Tell me what it is.
Jakeel: Eight [The area of J is 8 squares.]
Teacher: How is that 8? I can't tell that's 8.
Jakeel: Because one, two, three, four five, six, seven, eight, nine, t–. [Jakeel points to the spaces in figure J as he counts. He points once at each space, including the small triangles in figure J, with the pink of his right hand. Because he counts each of the triangles as one, he arrives at a number bigger than 8.] Hold on. [Jakeel points at each space in K with his pinky. This motion suggests that he is silently counting.]
Rebecca: Can I tell him? [Rebecca talks to the teacher. The teacher then leaves.]
(Wood, 2013, p. 798).

Prior to this interaction among the teacher, Jakeel, and Rebecca, Wood described the way in which the students in Jakeel's group had relegated him to the role of a scribe which limited his opportunities for learning. Here, "Jakeel's shift back to mathematical explainer seemed to be tied to the teacher's positioning" (Wood, 2013, p. 798). We are left wondering, what did the teacher notice before posing the question to Jakeel? If the prior interactions between Jakeel and his group were noticed by the teacher, how were those events interpreted? Wood continues to explain that, "Jakeel's reidentification as mathematically capable was not an isolated event. During the remainder of the lesson, the teacher returned to the group three times, each time positioning Jakeel as a mathematical explainer by asking him questions about the area of the figures" (p. 799). Wood's interpretation suggests that the teacher was simultaneously noticing status issues occurring in the group and recognizing the mathematical contributions of the group members.

To be clear, Wood's intent of her analysis was not to better understand the decision-making process involved in the teacher's instructional moves; her purpose was to understand how students' opportunities for learning are mediated by the way they are positioned by peers and teachers. Our brief analysis demonstrates that a framework to understand teachers' facilitation of SG work that is not based solely on students' mathematical thinking can provide new insights.

Conclusion and Implications

To create the NSG framework we have looked across prior research focused on teacher noticing of students' mathematical thinking. Acknowledging that the teacher noticing framework is not enough to understand what teachers notice in the contexts of SG, we proposed the NSG framework as a way to better understand teachers' instructional moves by attending to what researchers document is important in mathematics teaching and learning: 1) mathematical thinking, 2) status, and 3) children's funds of knowledge. We propose this framework as a means to look ahead in order to initiate a discourse on the noticing practices of teachers when working with SG, including how the noticing practices during SG compare with the noticing practices during other modes of instruction.

The NSG framework will allow researchers to better understand how teachers attend to, or not, issues of status and children's funds of knowledge in order to explain the instructional move. Furthermore, the NSG framework may be useful for teacher educators to scaffold prospective and practicing teachers to facilitate SG while developing the dispositions to attend to and respond to small groups in productive ways. In this regard we see that the NSG framework may help develop visions of equitable mathematics teaching that go beyond content knowledge and pedagogical content knowledge, which will begin to address the concern of Louie (2017).

MODELS AND MODELING PERSPECTIVE IN MÉXICO, THE MICHOACÁN FOREST

Verónica Vargas-Alejo Aarón Reyes-Rodríguez César Cristóbal-Escalante
University of Guadalajara, Autonomous University of Hidalgo State, University of Quintana Roo
veronica.vargas@academicos.udg.mx aaronr@uaeh.edu.mx cescrist@uqroo.edu.mx

This study describes the processes of solving a Model-eliciting activity called the Avocado Cultivation. The goal is to examine the potential of the activity in supporting mathematical knowledge and rethinking the mathematical learning in this new age. The theoretical framework was the Models and Modeling perspective. Eight Mexican teachers took part in this qualitative research. They were teaching at high school. The findings indicate that MEA provides opportunities for teachers to modify, extend and refine ways of thinking, validate the estimation to predict situations, and confront traditional ideas.

Keywords: Model eliciting activity, Teachers Knowledge, Linear and Exponential Models

Introduction

Creating a mathematical description or model to understand, explain, communicate, and predict a situation is not an easy task. Without basic knowledge and certain mathematical abilities and skills, people can make wrong decisions such as choosing the wrong credit card or a home loan, or even having difficulties to understand situations. What is the needed mathematical knowledge that education must provide to citizens in this new age?

The concepts of function and variation are useful to understand a variety of situations and phenomena. But many students have difficulty understanding them (Ärlebäck, Doerr, and O'Neil, 2013; National Council of Mathematics Teachers [NCTM], 2011), using algebraic notation, and connecting with representations such as graphs or data tables. A concept may not be learned in isolation from other concepts, phenomena and related processes. How should activities be designed to support the integration of knowledge and abilities? What characteristics should they have? According to Models and Modeling perspective [MMP], Model-eliciting Activities [MEA] allow the construction and integration of mathematical knowledge and abilities (Doerr and Lesh, 2003).

Some years ago, a group of researchers from México, began a project whose goals were modifying, extending and refining ways of thinking about teaching and learning process (Vargas, Cristóbal, Carmona, Reyes, & Alvarado, 2014). The interest was the development of knowledge and abilities about mathematical concepts as function and variation. The theoretical framework was Models and Modeling perspective (Lesh and Doerr, 2003). Researchers adapted and designed models-eliciting activities to Mexican contexts. They created workshops for teachers and students where they problematized the nature of mathematics learning.

In this study we present one of the MEAs designed to develop mathematical knowledge about variation, function and equation. The activity was about the problem of deforestation. We describe the teacher's processes of solving the MEA to know the potential of the activity. The research questions were the following. What happens when the math teachers solve the MEA? How do they engage in mathematical activity? How can we assess the potential of the activity using the six principles to design a MEA?

Theoretical framework

According to Models and Modeling Perspective learning mathematics is a process of developing models that are continuously modified during the interaction between the student and a problematic situation (Lesh & Doerr, 2003; Lesh, Yoon & Zawojewski, 2007; Doerr, 2016). The process of construction of models is a social process. The communication in the classroom between the students and the teacher permits that the conceptual systems or models can be shared, manipulated, modified and reused, to describe, interpret, construct, manipulate, predict or control systems.

The MMP proposes that students solve situations close to everyday life, including the so-called Model-Eliciting Activities, which are designed by following principles as the *Reality Principle*, the *Model Construction Principle*, *Model Documentation Principle*, the *Self-Evaluation Principle*, the *Model Generalization Principle*, the *Simple Prototype Principle* (Doerr, 2016). These activities require that students develop a mathematical interpretation, which require different ways of thinking about the situation.

The process demands posing questions, formulate conjectures, quantify information, organize and analyze data, do calculations, establish relationships, apply procedures, create representations, develop criteria, and evaluate results. The students have to express, test and refine their ways of thinking about the situation. They create sharable, manipulatable, modifiable, and reusable conceptual tools.

The product of learning is not the model but the process of its construction. “Learning mathematical content occurs through the process of developing an adequate and productive model that can be used and re-used in a range of contexts” (Doerr, 2016, p. 198). The models reside in the mind and in the representational media. The “meanings associated with a given conceptual system tend to be distributed across a variety of representational media” used to interpret the situation (Lesh and Doerr, 2003, p. 12).

Methodology

The research was qualitative. The data were collected from eight high school teachers (Teams M, N and P). They solved two MEAs during a workshop. The MEA discussed here is called: The Cultivation of Avocado (MEA1). The second MEA was called: Reforestation Proposal. The goal of MEA1 was to support the modification and extension of the teachers' conceptual system around the concepts of function, variation, equation, rate of change, and unknown; to put them in situations where they had to interpret, explain, justify, and evaluate the “goodness” of the models, as Models and Modeling perspective suggest. And finally, we designed the MEA to raise awareness of the problem of deforestation in Michoacán, México. The six principles of the MEAs construction were used to create the activity because we were interested in provoking that teachers a) created sharable, manipulative, modifiable, and reusable conceptual tools; b) expressed, tested and refined their ways of thinking about what learning mathematics and function, variation and equation concepts mean.

The MEA was about the effect of growth of avocado crop in Michoacán forest. We used information taken from Michoacan state’s official documents (*Comisión Forestal del Estado de Michoacán, 2014*) and national newspapers, such as Greenpeace journal. Data about the historical deforestation since 1976 was also included. Solving the problem required to estimate numbers because the data came from several sources, so there were different quantities.
The implementation of the MEA lasted four hours. The phases, following Lesh and Doerr (2003) recommendations, were: 1) Newspaper individual reading activity; 2) Resolution in small groups (M, N and P); 3) Group discussions of models; 4) Individual problem solving. The qualitative data sources included audio and video clips from the two sessions, letters with procedures to solve the activities, photographs of procedures performed on the blackboard, and teacher's notes.

Results and discussion

In this section, the models created by the small groups/teams of teachers are described. It is explained how students were engaged in the model-eliciting activities and the potential of the activity was assessed to get the meanings using the six principles to design a MEA.

Newspaper individual reading activity

Since the teachers were from Michoacan, and were near the forest, they knew that problem (MEA1) was a real-life situation. So, the eight teachers made sense of it based on their personal knowledge and experiences (*Reality Principle*).

Resolution in small groups

There were two types of models: linear algebraic model, and exponential tabular and graphic model. Teams M and N developed a description, explanation, and prediction of the forest deforestation situation (*Model Construction Principle*). They created models in paper and pencil environment. A variety of representation systems (concrete, graphic, and symbolic) were used to describe and illustrate relationships, operations and patterns. The concepts of function, variation, equation, rate of change, and unknown were used. However, the team P decided that the problem could not be solved because the information was not accurate.

The teachers of the team M created numerical and graphic representations.

> *Teacher M3:* What would I do here? Well… For example I would make a graph, in which it would…. Since when have you done this study?

They predicted that in 40 years there would be 147,000 hectares of avocado, almost equivalent to the existing forest. The exponential model was based on several assumptions.

The teachers of the team N created numerical and algebraic representation. The conclusion of the team N was: "the forest will disappear before the year 2189, but only if the deforestation does not increase year after year". They proposed the function $y = -800x + 145344$.

These responses revealed how they were thinking about the situation and how they used variables, linear and exponential functional relationships, graphical and algebraic representations, and equations (*Model Documentation Principle*).

Group discussions of models

The working group discussion highlighted the value of the models. The teachers modified, extended and refined their ways of thinking about the problem and the model. The eight teachers assessed the usefulness of alternative responses (*Self-Evaluation Principle*). They were able to judge for themselves when their responses were good enough.

The teacher M1 explained that the linear model could be applied to a broader range of situations (*Model Generalization Principle*).

> *Teacher N1: So, I checked the data that we have, and an exponential model cannot be done, can it?* It is a lineal model, and it is not good in a long term, but it gives us a good idea.

He mentioned that the process of estimating was a transferable and reusable way of thinking. The solution provided a useful prototype for interpreting a variety of other structurally similar situations (*Simple Prototype Principle*).

Individual problem solving activity

Six teachers described a linear model as procedure to solve the situation. One teacher wrote that it was not easy to elaborate a model from the data –he referred to build it with precision. The other teacher mentioned that the exponential model was the most adequate. All the teachers commented that undoubtedly, the forest would disappear, but it was difficult to know exactly when, due to the lack of precise data in the problem.

Conclusions

What happened when the math teachers solved the MEA? The teachers were confronted with traditional perceptions of solving routine problems in the classroom that needed a unique solution. The team P was an example, because they did not validate the process of estimation. However, the communication during the teamwork and the group discussion allowed modifying, extending, and refining mathematical knowledge (variation, function and equation), mathematical abilities, such as estimation, because the teachers had to choose and discriminate information. The six principles to design a MEA were fulfilled, we had enough information about the evolution of the teacher's knowledge and the eight teachers learned about the importance of inciting students to create models to learn mathematical knowledge and abilities. Although it is important to note that this was due to group work.

It was found that this MEA was interesting for all the teachers. They exhibited new ways of thinking about learning mathematics, and it emerged a strong interest in applying this kind of activities in the classroom to encourage mathematical learning (function, variation, equation, linear and exponential relations and estimation), to raise awareness of the problem of deforestation, and to develop abilities to interpret, explain, justify, and evaluate models.

TEACHER VIEWS OF USEFUL FEATURES OF MATHEMATICS PROFESSIONAL DEVELOPMENT AND HOW THE VIEWS INFLUENCED INSTRUCTION

William S. Walker, III
Purdue University
wswalker@purdue.edu

This study investigated what two high school teachers viewed as useful from a mathematics professional development (PD) program and how these views influenced their instructional practices. The teachers participated in PD that focused on using standards-based pedagogy and mathematical tasks with higher-level demands. The teachers commonly viewed mathematical tasks for use in the classroom and strategies for small group or whole class participation as useful features of the PD. Each of the PD features that teachers viewed as useful were enacted during instruction. These findings suggest that providers of PD for K-12 teachers of mathematics should learn teachers' views about the usefulness associated with PD programs to improve outcomes.

Keywords: professional development, academic standards, secondary mathematics

Research has documented that standards-based instruction in mathematics can be challenging for teachers to enact (e.g. National Council of Teachers of Mathematics (NCTM), 2014). Changes in teacher practice can be linked to teachers' perceptions about PD (Chapman, 2011; Martin & Gonzalez, 2017). This research investigated the question, what do teachers view as useful from a PD program designed to help teachers implement standards-based mathematics and how do these views influence their instructional practices?

Theoretical Framework

Stein, Remillard, and Smith (2007) describe the temporal phases of curriculum use. The written curriculum represents the design of materials, the intended curriculum represents teacher interpretations, and the enacted curriculum refers to what occurs during instruction. Learning opportunities are transformed among the phases due to teachers, students, and the context of teaching (Stein et al., 2007). The National Governors Association Center for Best Practices and the Council of Chief State School Officers (NGACBP and CCSSO) (2010) identified eight standards for mathematical practice that "describe varieties of expertise that mathematics educators at all levels should seek to develop in their students" (p. 6). The NCTM (2014) outlined eight mathematics teaching practices that "provide a framework for strengthening the teaching and learning of mathematics" (p. 9). The temporal phases of curriculum use and the sixteen mathematical practices were used as frameworks to classify curriculum use.

Methodology

This research is part of a larger study (Walker, 2016) that investigated factors that influenced mathematics instructional practice when participating in PD. A multiple-case study design (Merriam, 2009) was used to collect and analyze data on teachers' views of useful features of PD. The PD program for this research was Teaching Algebra with Practice Standards (TAPS). Fifteen middle and high school mathematics teachers participated in TAPS. Four of the fifteen teachers, all from one high school, volunteered to participate in this research. This summary focuses on two teachers who taught algebra.

Data Collection

Data sources used to describe the PD included field notes from the PD sessions and email interview responses from the PD providers. Data for instructional practices consisted of two observed and videotaped lessons for each teacher. The Wisconsin Longitudinal Study observation tool (Shafer, Wagner, & Davis, 1997), adapted to include the sixteen mathematical practices, was used for the observations.

The teachers were interviewed five times using adapted protocols (Shafer, Davis, & Wagner, 1997, 1998). The first interview took place in the summer after the PD to learn what each teacher found to be useful about the PD. The next two interviews took place during the first half of the school year. These interviews were before and after the first observed lesson to learn the teachers' views about the intended lesson, the enacted lesson, and how the PD related to the lesson. The final two interviews took place during the second half of the school year, before and after the second observed lesson. Influence on instruction was determined by comparing classroom observation notes with the portions of the PD that teachers identified as useful.

Data Analysis

Classroom observation data were used to describe the alignment between each teacher's enacted instruction and the sixteen practice standards. Lessons were classified as no evidence, sometimes, or yes. Reliability was checked with an independently classified lesson by calculating a Krippendorff's (2004) alpha value of 0.8223. Each of the teacher interviews were analyzed using an inductive approach of comparative pattern analysis to create a category coding system (Merriam, 2009). The reliability of the coding system was checked with independent coding by calculating the percent of agreement, which was 90%.

The PD Program

TAPS was a three-year, grant-funded mathematics PD program with two goals: (a) enrich teachers' knowledge and skills for teaching algebra, and (b) improve students' algebraic knowledge, skills, and disposition. Learning about the sixteen mathematics practice standards and finding ways to implement them in classrooms were the main teaching points for the PD. The PD also included the use of mathematical tasks with higher-level cogitative demand (Stein, Smith, Henningsen, & Silver, 2000). TAPS started with a ten-day institute in June 2015. Sample lessons and activities about patterns, relationships, and generalizations were used to help teachers learn about the mathematical practices. Three two-hour after school follow-up sessions took place during the school year. A total of eighty-six hours of PD were provided for the teachers.

Teacher 1: Doug Collins

Doug Collins was a male with thirteen years of teaching experience. This was his second year at the high school and he taught Algebra 1 and Geometry. During the interviews, Mr. Collins made five comments about the usefulness of receiving activities for his class. For example, when asked what was useful about the PD he stated, "For me I think it was really kind of learning, getting some of the different activities and things that you can do." Mr. Collins also made four comments about strategies for students working together as useful. For example, Mr. Collins was asked what features of the PD he would use and he replied, "Partner work, group work, giving [the students] a certain task."

Doug Collins: Enacted Curriculum

The first observed lesson was a task that Mr. Collins developed during the PD. Each student was given an algebraic expression on either a gold or a green piece of paper. Mr. Collins explained that a student with a gold sheet should find a student with a green sheet. They would set their algebraic expressions equal to each other and then find a value for the unknown that would make the equation true. The students worked in pairs on this activity for thirty-five minutes. They checked answers with each other and explained methods used to find an answer.

In the second observed lesson, Mr. Collins used a modified version of “Bridge Strength” (Lappan, 2005), which was presented during the PD. At the beginning of the lesson, he asked the students to find a partner and to gather materials for the lesson. They suspended paper bridges across two books, placed pennies on the bridges, and recorded the number of pennies required to collapse each bridge. When data collection was complete, the students made graphs and answered questions about the activity.

Doug Collins: Summary

The two observed lessons included features consistent with the practice standards like *making sense of problems and persevering in solving them*. These features were evident when the students worked in pairs to find solutions. Mr. Collins identified providing activities for his class and students working together in small groups as useful features of the PD. He used one mathematical task that he developed during the PD and another the PD providers presented. Both of the features that Mr. Collins identified as useful were observed as part of the enacted curriculum in his class.

Teacher 2: Ruth Lawrence

Ruth Lawrence was a female teacher with nine years of teaching experience, eight of them at the high school. At the time of this research, she was teaching Algebra 1 and Geometry. Ms. Lawrence made eleven comments about the PD providing activities for her class. For example, when she was asked what was useful about the PD she responded, “The tasks that you guys showed us were … they were just the best tasks that I have ever been exposed to.” There were four comments by Ms. Lawrence that strategies for students working in small groups was useful. When asked about using practice standards in her class Ms. Lawrence replied, “I feel like there was … one [standard] that referred to students discussing math together, like collaborative. I would definitely say that that would be done.”

Ruth Lawrence: Enacted Curriculum

The first lesson took place over two days. The lesson involved an “S-Pattern” task (Institute for Learning: Learning Research and Development Center, 2015) from the summer PD. Ms. Lawrence asked the students to get into pairs and answer questions about the patterns. The groups answered questions about representing the total number of squares algebraically until the end of the class. The next day, Ms. Lawrence asked different students to share the equations they created with the whole class.

The second lesson also took place over two days. The task was the “Painted Cube” (Lappan, Fitzgerald, & Fey, 2006) from the summer PD. Ms. Lawrence asked the students to get into small groups and complete a worksheet about painted cubes with edge length two, three, four, five, six, and any length “n.” The students used snap-cubes to build models and worked in groups to complete the worksheet. The next day Ms. Lawrence invited students to share algebraic expressions for a cube with an edge length of “n” with the whole class.

Ruth Lawrence: Summary

The two observed lessons included features consistent with the practice standards like *using and connecting mathematical representations*. These practice standards were evident when the students worked in small groups to find algebraic expressions to represent visual patterns. The two useful features of the PD identified by Ms. Lawrence were providing mathematical tasks for the class and students working together in small groups or as a whole class. Each of the observed lessons included a task from the PD and students were observed participating in small group work and whole class discussions.

Discussion and Implications for PD

The two teachers commonly identified mathematical tasks for use in the classroom and strategies for small group or whole class work as useful features from the PD. Each of the useful features were observed when the teachers enacted lessons aligned to the PD. For example, each teacher viewed mathematical tasks for their class as useful and both teachers used tasks from the PD during instruction. This finding is consistent with Martin and Gonzalez (2017) who found that teachers valued focusing on student mathematical thinking and reported increased wait time because of a PD intervention.

Teachers play a critical role in the outcomes of PD. What teachers identify as useful reflects their practical knowledge and situated perspective (c.f. Chapman, 2011). PD that addresses features identified as useful and is consistent with teachers' knowledge of classroom situations can result in instructional changes. PD providers should spend time learning about the practical knowledge of teachers and what teachers view as useful because these views influence how teachers will use the PD in their classrooms.

SUPPORTING AN INQUIRY STANCE WITH DOUBLE DEMONSTRATION LESSONS

Effective professional development (PD) activities positively influence participants' classroom practices. However, ways in which teachers engage in PD activities vary widely. Farmer, Gerretson, and Lassak (2003) identified three levels of teacher appropriation for those involved in PD activities (practitioner, professional, and inquiry stances), with the inquiry stance indicative of teachers engaging in self-sustaining practices. We employed demonstration lessons in various forms as a way to explore classroom practices in an ongoing PD project. In the double demonstration lesson format, teachers took an active role in changing an observed lesson and then viewing impacts of those changes as a second lesson was taught. We offer evidence that this structure provided opportunities for teachers to engage in an inquiry stance on teaching and discuss implications for PD providers in structuring activities to foster an inquiry stance.

Keywords: Teacher Education-Inservice/Professional development

Professional development efforts should have the primary goal of supporting teachers in developing a vision for teaching that includes engaging students with challenging tasks and facilitating rich mathematical discourse (Loucks-Horsley, Stiles, Mundry, Love, & Hewson, 2010; National Council of Teachers of Mathematics [NCTM], 2014). It should further encourage applying knowledge gained to analyze mathematics lessons, and interpreting and using students' mathematical thinking to guide instruction (Sztajn, Borko, & Smith, 2017). Although a variety of PD models exist, demonstration lessons represent one form of PD that is situated within practice and, therefore, holds promise for meeting this goal (Loucks-Horsley et al., 2010).

In this report, we present evidence of teacher stances from a variation on demonstration lessons, *double demonstration lessons (DDLs)*, which we purposefully designed to engage teachers in an inquiry stance toward teaching. By engaging teachers who likely hold a practitioner or professional stance in the processes associated with DDLs, we offered them the opportunity to legitimately participate (Lave & Wenger, 1991) in the act of inquiry on teaching. This work is guided by the question: How might we design PD activities that support a teacher, who likely holds a practitioner or professional stance, in adopting an inquiry stance?

Theoretical Framework

To better understand the ways teachers appropriate knowledge gained from mathematics PD experiences, Farmer and colleagues (2003) offered a reflective three-level model, which included Practitioner, Professional, and Inquiry stances. They argued that although the levels consist of the same elements, how the pieces are viewed by the teachers creates the distinction among the levels. With a *practitioner's stance*, the teacher focuses on specific ideas that can be taken from the PD and used with little modification in his or her classroom. In contrast, the teacher with a *professional stance* approaches the PD as an opportunity for professional learning. Finally, teachers who have adopted an *inquiry stance* see themselves learning from the process of teaching. Farmer and colleagues (2003) noted that teachers who adopt an inquiry stance exhibit "self-sustaining changes in their mathematics instructional practices" (p. 331).

Introduced by Lave and Wenger (1991), situated learning theory espouses learning to be the result of "legitimate peripheral participation in communities of practice" (p. 31). Based on this theory, the community of practice represents a group of experts that possesses the knowledge to be learned by the novice. Legitimate peripheral participation allows the novice learner to engage in the practices of the community, constructing the knowledge of the community over time.

These two theories together form the conceptual framework that guides our work. We view teachers that have adopted an inquiry stance (Farmer et al., 2003) as the experts within a community of practice (Lave & Wenger, 1991), which is represented by our ongoing PD project. By designing PD activities that place novice practitioners (teachers who have adopted a practitioner or professional stance) alongside the experts in the community, the novice practitioners may engage in legitimate peripheral participation with the discussions of the community. The novice practitioners' legitimate engagement aids movement towards developing an inquiry stance. We argue that DDLs provide this opportunity for engagement.

Methodology and Context

This study took place during the fourth and fifth years of a six-year externally funded PD project serving over 150 K-8 mathematics teachers. The overarching goals of the project were to increase the mathematical content knowledge of the teachers and to increase their use of research-based instructional practices. Demonstration lessons were employed in a variety of forms (Strayer et al., 2017) to help teachers better understand how to blend deep learning of content with research-based instructional practices. Double demonstration lessons emerged as a meaningful context for engaging teachers in an inquiry stance. To gain insight into how the structure of the DDL supported teachers in this way, we gathered and analyzed data on a subset of teachers along with other general data sources collected during DDLs.

In a typical demonstration lesson, teachers were briefed on the lesson they were about to watch, watched a project faculty member teach a lesson to a class of students, and then participated in a debriefing of observations. We noticed in the early years of our project that teachers tended to view demonstration lessons with a practitioner's stance. Thus, we developed what we refer to as *DDLs* with a goal of supporting teachers in developing an inquiry stance.

Double demonstration lessons (Strayer et al., 2017) expand the typical demonstration lesson process to include revision of the lesson and an additional teaching and debriefing of the lesson. During the lesson briefing, teachers are made aware of the forthcoming opportunity to revise the demonstration lesson. Their observations of the demonstration lesson are supported through the use of an observation protocol. This combination of the protocol with the explicit goal of revising the lesson provides teachers with the opportunity to participate in processes associated with an inquiry stance, as they reflect on the initial lesson and collaboratively revise the lesson.

In this report, we draw on data from one grades 3-5 DDL. The lesson involved students looking for and making use of structure in a linear systems problem (Riddell, 2016). During the DDLs, we collected multiple writing prompts from all teachers (e.g., entrance/exit tickets, observations guides, debrief documents) and interviewed four purposefully selected teachers before and after the lesson. In addition, we video-recorded the debrief and used this data to document teachers' stances. We coded all data using Farmer and colleagues (2003) framework.

Findings

Written data documents revealed that teachers entered the PD with practitioner and professional stances toward the events of the day. For example, on entrance tickets teachers stated they hoped to learn "how to get students to persevere" (Tonya, Entrance Ticket) or "to gain insight on different teaching strategies" (Courtney, Entrance Ticket). The first evidence of a professional stance and the second a professional stance, both representative responses.

In contrast, we observed evidence of engaging in an inquiry stance in the debriefing discussions at the end of the day. The final group debriefing was prompted by the question, “What are the big ideas that you have in relation to today’s lessons?” Following the second lesson, teachers provided evidence of legitimately engaging in an inquiry stance, particularly as they addressed the role of scaffolding that was introduced as a revision to the lesson.

Tonya: Does the scaffolding always help all students? I think if the number had been higher they would have had to think about it longer, they just doubled. We didn’t think it made that big of a difference.

Peter: What if we had given them this (see Figure 1). Now it leads them to think the pieces are different values. Since we have just two copies of the same thing, I don’t think they had to think about the value of each one.

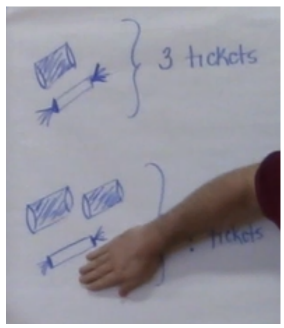

Figure 1. Scaffolding Question Revision

Tina: We wanted students to see the value of the model of all the candies not individual candies. We talked about making it more than 3 tickets, but we didn’t want to take up too much time. The purpose was to see that this group (the two candies that total to 3 tickets in Figure 1), can be pulled into and assigned a value together, instead of separating them apart. So that you don’t have to know the individual prices.

Tina and Peter continued to discuss the students in Lesson 1 and Lesson 2 and the differences in what the students noticed about the task in each fifth-grade class. During this discussion, the lead teacher exclaimed that the scaffolding question provided her exactly what she needed in the second lesson, because the scaffolding question gave her something to direct students’ attention so they were able to continue their thinking. Afterwards, the teachers shared more ideas.

Kim: I do think if the previous class had the scaffolding problem, they would have gotten further. They were struggling to make the 10, by grouping them, they weren’t connecting them because they were still thinking about different values.

Maggie: I really liked that everybody had an entry point. Every kid looked at that (the scaffolding question) and saw the structure, but it gave them something to hold onto that wasn’t beyond the limit.

Mary: Structure, I don’t use that word. I say powers or groupings, but that’s a word I need to make sure I am bringing out in my class. I don’t think the students understood the word structure.

Here, two of the PD instructors paused the discussion to elaborate on mathematical structure. As the PD team, we knew that the idea of structure was a complex concept, and we tried to attend to the difference between mathematical structure and organizational structure. We expressed that creating a structure (e.g., a table) to help notice patterns or numbers is different than the structure underlying the featured problem. A teacher expressed her wondering relating to structure, followed by another teachers' reflection about structure.

Mona: The big idea was wondering if when the students first came I wonder if they understand what structure means, but not just a term, but what structure are they looking for, structure in what?

Lindsay: It has taken a long time of teaching to pick up on structure myself and see how it relates to each component. Structure, as a whole, bridges across all content. It's just making those connections because not being taught that way, it's difficult for us as teachers. At the beginning (before Lesson 1), it's interesting to see when we all personally solved that problem how many of us actually used the structure that we hoped the students would actually pick up on. I bet a majority of us were using algorithms or some equation or something to get us there as opposed to structure, because that's not how most of us learned. Thinking about the use of structure is something I have to push myself to do.

Throughout these exchanges, teachers were exploring student thinking and viewing the demonstration lessons as a place for inquiry about student learning, mathematics teaching, and their own understanding of the mathematics involved.

Discussion

Developing opportunities to engage in levels of practitioner, professional, and inquiry stances is the first step towards encouraging teachers to fully develop an inquiry stance on teaching and become learners of their own practice. By design, DDLs provide teachers with the opportunity to achieve three essential PD outcomes: taking ownership of the teaching through a problem-solving vision; applying knowledge gained to analyze mathematics lessons; and interpreting and using students' mathematical thinking to guide instruction. Furthermore, our results suggested that the DDL model allowed the teachers to take initial steps towards ownership of an inquiry stance, positioning them to make sustained changes in their instructional practices (Farmer et al., 2003). If DDLs can support teachers' development of an inquiry stance during PD activities, then teachers will be better prepared to analyze mathematics lessons and interpret and use students' mathematical thinking to guide their instruction. Teachers will be empowered to implement mathematics instruction that supports the deep learning of mathematics for all students.

SEEING GOALS "COME TO LIFE": TEACHING EXPERIMENTS AND TEACHERS' WORKGROUP CONVERSATIONS

Anna Weltman
University of California, Berkeley
aweltman@berkeley.edu

Shifts in student participation prompted by math teachers' experiments with a new teaching strategy created opportunities for the teachers to learn about student perseverance. The practice, in which teachers asked students stuck on a math problem to share three things they know, achieved one desired goal and got students "unstuck," but the teachers wondered whether the practice supported students to persevere in the sense of learning to draw on one another as resources. Through negotiation of a shared, new, and problematic experience in the classroom, the teachers problematized their prior conceptions of perseverance.

Keywords: Teacher Education-Inservice/Professional Development, High School Education, Instructional Activities and Practices.

Objectives

This study examines four workgroup conversations of a team of high school math teachers studying how to improve student perseverance in math class. The teachers agreed do a teaching experiment in which they tried a teaching strategy that they hoped would help students struggle productively, together. In their workgroup conversations, they reflected on what they noticed while trying the strategy and the implications of their noticings for their joint goal. I analyze their workgroup conversations to better understand: 1) How do the teachers frame their learning goal, "perseverance," across the meetings? and, 2) What do they notice about perseverance and its role in student learning of mathematics when they try their chosen teaching strategy? Preliminary analysis indicates that the shifts in student participation brought about by their use of this teaching strategy allowed problems of practice around perseverance to "come to life" for the teachers. Reflections on those problems of practice in workgroup conversations supported the teachers to negotiate teaching and learning mathematics.

This study indicates that teams of teachers with limited expertise in ambitious mathematics teaching can problematize and discuss their classroom practice by experimenting with teaching strategies that they hypothesize will create richer learning environments for students.

Background

Teachers learn in professional workgroups by negotiating notions of teaching and learning with peers (Little, 2002). Teachers have more opportunities to learn from workgroup conversations when they reflect on problems of practice raised through analysis of records of practice (Horn, Garner, Kane, & Brasel, 2016).

Different teaching experiences surface different problems of practice and, therefore, support different opportunities for teachers to learn. Horn and Kane (2015) found that teachers with more expertise in enacting ambitious mathematics teaching practices had richer workgroup conversations. Ambitious mathematics teaching puts teachers in complex problem-solving situations, in which students' experiences and perspectives are constantly considered (Lampert, 2010). Such situations should be conducive for teacher learning in the moment, as teachers grapple with problems, and in planning and reflection, as teachers consider the influence of their moves on students' experiences of math and math class.

But what about teachers who do not have expertise in ambitious mathematics teaching? Horn and Kane argue that such teachers are caught in a paradox of not being able to learn because they struggle to do the teaching they aim to learn-- teaching that would put them in problematic situations and give them fodder to talk about students' experiences of math and math class. This paper explores a possible way for leaders of professional development to support the workgroup conversations of such teacher: by engaging them in teaching experiments that introduce new, and potentially richer, forms of participation for their students.

Such a use of teaching experiments has precedent in teacher education. Pre-service math teacher educators have suggested introducing novice math teachers to ambitious teaching in part because they hypothesize that novices who use them will find themselves in teaching situations requiring problem-solving (McDonald, Kazemi, & Kavanagh, 2013). Kazemi and Franke (2004) found that when elementary math teachers elicited more thinking from their students, opportunities to learn in their workgroup deepened. These studies suggest that changing opportunities for students to participate can open learning opportunities for teachers even when teachers are not experts in ambitious teaching.

Methods

This paper describes preliminary analysis in an on-going study. A department of four high school math teachers (Cindy, Leo, Soledad, and Jamie) in an urban California district met every two weeks as part of the TRU-Lesson Study (TRU-LS) professional development project. TRU-LS engages departments of math teachers in Lesson Study, in which teachers iteratively research, plan, implement, and reflect on a lesson to learn more about a problem of practice, supported by the Teaching for Robust Understanding of Mathematics framework (Schoenfeld et al., in preparation). As part of TRU-LS, the four teachers engaged in bi-monthly cycles of inquiry leading up to their research lesson. The goal of these cycles was to iteratively build their *research theme*, a problem of practice, and *theory of action*, a hypothesis about what they could do in their research lesson to learn about their research theme. The teachers tried, collected data about, and reflected on an ambitious teaching strategy developed by the TRU-LS research team.

This analysis focuses on their first four meetings of TRU-LS. I co-planned the meetings with the facilitator, Elizabeth, and attended and video recorded the meetings as a participant-observer.

For my analysis, I isolated segments of video in which the teachers discussed what happened when they tried their chosen teaching strategy, up to twenty-five minutes of each hour-long meeting. I made activity logs of these segments, in which I identified episodes in which teachers shared records and problems of practice; negotiated uses of their chosen strategy; and/or revised their research theme and theory of action. I examined my logs for ways that teachers framed records of practice, problems of practice, and goals (Goffman, 1986) and patterns in their participation (Bannister, 2018). This analysis is preliminary.

Analysis

In their first department meeting, the teachers developed the research theme, "Building student perseverance/ capacity to struggle productively, together." In order to gather information about their theme and see it, as Elizabeth said, "come to life," the teachers agreed to try a strategy called Three Things: "If students are stuck on a problem, ask them to state three things they know about the problem and three things they are wondering about."

The teachers hypothesized that Three Things would help students who did not know how to get started on a problem realize how what they knew might be useful. The teachers also thought that Three Things might encourage students to explain their thinking. They hoped that it might become a routine that students could eventually use to get unstuck without teacher intervention. In this discussion, they conceptualized "perseverance" as students' capacity to continue working on a challenging problem after getting stuck. They acknowledged that collaboration and vocalizing thinking for peers are important for perseverance. What role talking with peers might play in supporting students to struggle productively was as of yet unarticulated, however.

In the second and third sessions, the teachers revised Three Things and their goals for its use based on their experiences with students. In the fourth session, three of the four teachers described how Three Things encouraged more students to participate. Cindy reported that when she used Three Things in a whole-class discussion about a challenging problem, students who did not typically turn in written work were encouraged to talk. Jamie and Soledad described how Three Things helped students get unstuck on math problems. From this discussion, it seemed that Three Things helped the teachers support students to persevere in both the sense of getting students unstuck and encouraging them to share their thinking.

Leo then challenged whether use of Three Things actually promoted collaborative productive struggle. He agreed that Three Things increased student participation, which was a positive step. But he argued that it shifted the burden to struggle away from students:

> "Um so I think that it *(Three Things)* increases student engagement. And that, sort of, decreases our opportunity to see persistence because they don't run into that wall? You know what I mean? So in my mind persistence is you get stuck, and then you try something else, or you—there's some strategy that you use. But we're providing a way to—to avoid that resistance, to avoid the wall. So we don't necessarily see the persistence."

Shifting the burden of coming up with a strategy to persevere from student to teacher, Leo argued, was contrary to their goal of supporting students to struggle productively, together.

This comment led the teachers to revise their definition of "persistence," which they used interchangeably with perseverance. They reflected on how persistence looks for students who experience math problems differently. Jamie summed up the distinctions they made:

> "Cause like, for some students, persistence means, I come to a grinding halt, I reassess, and I continue. For others it means, like, tinkering and continuing along? And for—and for others, they haven't, because of where the cognitive demand is currently, they haven't even come to that level of needing to persist."

Guided by the TRU framework, the teachers brainstormed experiences that might lead students to shut down. Elizabeth captured their thinking in this way:

> Cognitive Demand: "Why are we doing this? This is so hard. When do we get to the real math?"
>
> Equitable Access: Kids don't feel like they have a toolbox
>
> Agency/Ownership/Identity: Fixed mindset—"I'm not good at math."

Building on this thinking, Soledad suggested that Three Things gave students "more access to content, less access to perseverance" by taking away the opportunity for students to build and draw on a toolbox. The other three teachers gave a thumbs-up as Elizabeth recorded this. Her comment and the discussion that followed teased apart two goals that they had for student perseverance. They wanted students to persevere so that more students had access to challenging mathematical content and practices. But they also wanted students to develop the tools to move through struggle together, without relying on a teacher. Three Things was not helping them achieve this second goal for student perseverance. If perseverance means the capacity for students to struggle productively, together, having a teacher ask for three things did not help students develop that capacity.

As a result, the teachers chose a new strategy, “Ask what your partner said.” When the teachers approached a group stuck on a challenging problem, they would ask one student to share what another member of a group thought or said about the problem. The teachers hypothesized that this strategy would encourage students to turn to one another as resources when they got stuck. This new strategy launched them into another cycle of inquiry, armed with deeper understanding of the goals for student perseverance in math class.

Discussion

Noticing shifts in participation as a result of teaching experiments can open opportunities for teachers to learn during workgroup conversations. The teachers’ lack of experience with teaching practices that put students’ experiences at the forefront was mitigated by a teaching strategy that supported the teachers to notice new forms of participation from their students. Further research into the interplay between teachers’ learning in workgroups and experience in the classroom is needed to better understand the learning opportunities in this kind of teaching experiment.

INVESTIGATION INTO THE ROLE OF MATHEMATICS COACHES

Brian Bowen
West Chester University
bbowen@wcupa.edu

Keywords: Teacher Education-Inservice/Professional Development

Hill, Rowan, and Ball (2005) explored the effects of a specific type of teacher knowledge, mathematics knowledge for teaching. They found that "teachers' mathematics knowledge for teaching positively predicted student gains in mathematics achievement during the first and third grade" (p. 399). From the results of their work, the authors called for identifying teachers who have a diminished knowledge in this area and provide them focused professional development.

To be effective, opportunities for teachers to grow in their understanding of mathematics knowledge for teaching must be persistent and long term (Garet et. al., 2001). One strategy for establishing long-term professional growth is the development of a specialized group of educators that situated in the school environment (Ansty & Clarke, 2010). Hull, Balka, and Miles (2009) describe an iteration of this specialized group as mathematics coaches, "an individual who is well versed in mathematics content and pedagogy and who works directly with classroom teachers to improve student learning of mathematics" (p. 3). Research suggests that mathematics coaches can have a positive impact on student achievement when there is "school-based professional interaction between coaches and teacher is of sufficient duration to permit emergence of coherent collective efforts marked by active learning and focused on content and pedagogy, as well as on student understanding." (Campbell & Malkus, 2011, p.451).

While mathematics coaches provide an opportunity to support effective mathematics instruction, it is less clear how mathematics coaches are currently being prepared and what their interactions are with practicing teachers (Campbell & Malkus, 2011). This study looked to gain a better understanding of the role of mathematics coaches by surveying superintendents and practicing mathematics coaches. Data gathered from superintendents focused on why school districts do or do not employ mathematics coaches, as well as the attributes they value in the position. Data from mathematics coaches focused on the ways in which they were prepared and utilized in their schools. Results suggest a positive perception of mathematics coaches form superintendents, but concerns related to financial limitations. Results from mathematics coaches suggest significant variation in both their preparation and utilization.

FIVE COMPONENTS TO CONSIDER WHEN CHARACTERIZING MATHEMATICS TEACHERS' ACCESS TO PROFESSIONAL DEVELOPMENT

Emily Bryant	P. Holt Wilson	Beverly Vance
UNC-Greensboro	UNC-Greensboro	NC Department of Instruction
elbryant@uncg.edu	phwilson@uncg.edu	beverly.vance@dpi.nc.gov

Implementing changes in policy, such as new mathematics content standards, is a persistent challenge of large scale educational improvements. To support implementation efforts, professional development (PD) has been shown to be a determining factor for educators to make sense of new standards (Hill & Cohen, 2001). While a consensus exists about features of effective PD (Darling-Hammond et al., 2009), in practice, opportunities that teachers have to learn and improve their practice varies, is shaped by local education leaders, and is often not aligned with these research-based recommendations.

Following newly adopted state mathematics content standards, a research-practice partnership (Peneul et al., 2015) was formed between our state education agency and four universities in our state to co-design PD resources for standards implementation and research these efforts. To organize this work, we draw upon design-based implementation research (Fishman et al., 2013) to structure the development of materials and study the implementation. As part of our ongoing work, we developed a framework that identifies and describes key components of effective mathematics PD. The framework was created using a synthesis of literature identifying five key components of high quality mathematics PD: content, pedagogical model, teacher learning environment, attention to context, and structure. The framework includes both a description of each component and examples of activities and tools research-based mathematics PD programs draw upon with each component. Organizing the components in this way is not meant to be prescriptive, but rather to provide a link from observable characteristics of high quality mathematics PD to research evidence, offer examples, and serve as a boundary object (Wenger, 1998) for the partnership and the math leaders within. In doing so, we aim for the framework to serve as an implementation measure (Bryk et al., 2015) to gauge progress in improving implementation and opportunities teachers have to learn at scale and for district- and school-based mathematics leaders to use when adapting co-designed PD resources to their local contexts.

In this poster session, we will share the development of the framework, the ways it can be used as an implementation measure, and the ways in which districts and schools can use the framework when adapting co-designed PD resources for use in local contexts. Our hope is that this framework will support efforts to provide more equitable access to high quality mathematics professional development to teachers across the state.

THE EFFECTS OF A STATE-IMPLEMENTED CO-TEACHING TRAINING ON STUDENTS' MATHEMATICS ACHIEVEMENT SCORES

Kaitlin Bundock
Utah State University
Kaitlin.bundock@usu.edu

Kristen R. Rolf
Utah State University
Kristen.rolf@usu.edu

Co-teaching is an instructional model in which special and general education teachers collaboratively educate a class made up of students with and without disabilities. Co-teaching has become an increasingly popular special education service delivery model over the past fifteen years, yet few studies have evaluated the effects of co-teaching on student achievement (McDuffie, Mastropieri, & Scruggs, 2009; Murawski, 2006; Murawski & Swanson, 2001).

The purpose of this study is to describe a state-sponsored co-teaching professional development project (the Co-Teaching Project), and analyze student mathematics achievement data from classrooms participating in the Co-Teaching Project. The Co-Teaching Project, in its sixth year of implementation, aims to create inclusive middle and high-school math classrooms by providing effective training and on-going coaching in co-teaching and other inclusive educational strategies. Co-teaching pairs, consisting of general and special education teachers who will be teaching together in the upcoming school year, receive training in the summer as well as on-going coaching throughout the school year. T-tests conducted on pilot pre- and post-test data from nine classes indicate that students without disabilities made significant ($p <.01$) improvements in eight classes, with an average Cohen's d effect size of 4.31 (range 0.67-11.45). Students with disabilities made significant ($p < .01$) improvements in seven classes, with an average Cohen's d effect size of 2.62 (range 0.8-6.23). While these results are promising, more sophisticated analysis methods are needed to thoroughly analyze and disaggregate student achievement results in relationship to the Co-Teaching Project.

In this follow-up study, we use Generalized Equation Estimating (GEE) to analyze and compare the mathematics achievement of approximately 1200 sixth- through ninth-grade students with and without disabilities in both co-taught (15 classes) and non-co-taught comparison classrooms (15 special education resource classes, 15 non-co-taught general education classes) to answer the following research questions: (1) Do students with (and without) disabilities achieve at higher rates in co-taught settings versus non-co-taught settings?; (2) Do students with disabilities achieve at comparable rates as students without disabilities in co-taught (and non-co-taught) settings?; (3) To what degree do student factors (other than disability/no-disability) affect the growth rates of students in co-taught and non-co-taught settings? These factors include: (a) Gender, Ethnicity, SES, language status, (b) Grade level, (c) Type of disability, (d) Prior Achievement level.

The research in this poster was supported with funding from the Utah State Board of Education (Award # 201017). The findings, conclusions, and recommendations presented are those of the authors, and do not necessarily reflect the views of the funding agency.

COACHING THE 5 PRACTICES THROUGH LESSON IMAGING

Amanda Casto
UNC Charlotte

Keywords: Lesson imaging, coach press, 5 practices

Stein and Smith's seminal book, *5 Practices for Orchestrating Productive Mathematics Discussions* (2011)*,* outlines practices that can support teachers attempting a student-centered approach to instruction. Although teachers may understand these practices, it is another thing to implement them, especially if there is little mentoring support. We present data from a study in which a coach led a team of teachers to implement the five practices for the first time.

Participants and Data Collection/Analysis

Four 7th-grade teachers, one ELA school coach, two university faculty, and two doctoral students met once per week for a 1.5- hour planning meeting during which one faculty member coached. Our main research questions were, *how do teachers take up the five practices differently as they implement a reform textbook for the first time and what mentoring techniques support the change in their practices?* Transcriptions of the meetings were analyzed using the Constant Comparison Method (Glaser & Strauss, 1967) to identify themes as well as code for the types of supports the coach was giving.

Findings

The university coach used *lesson imaging* (Stephan et al., 2016) during planning meetings. Lesson *imaging* is the process of imagining the flow of the lesson, what the teacher might say during a launch, what questions she might ask, and how students might engage in the activities. Data indicate that the coach pressed teachers to a) image how students might solve the tasks in ways that result in both correct and incorrect answers, b) unpack the mathematical goal of the lesson, c) consider what parts of the launch students should understand in order to participate effectively in the lesson, and d) use learning progressions to determine whether the activity could be eliminated. As the project progressed, teachers started asking these questions and the coach became more of a participant. Our poster elaborates the imaging process and the university coach's role in pressing teachers to take the students' perspective as they imagine the flow of lessons. This can contribute to the knowledge base on coaching that tends to focus on model or co-teaching, video watching, and providing feedback.

RURAL INSERVICE MATH TEACHERS' PERSPECTIVES FROM A THREE-YEAR SUMMER MATH INSTITUTE PROFESSIONAL DEVELOPMENT PROJECT

Keywords: mathematical knowledge for teaching; teacher beliefs; teacher education - inservice/professional development; teacher knowledge

Professional development opportunities can greatly impact teachers' pedagogical perspectives and content knowledge (Ball, 1990; Hill, 2007). Through a situated lens, teachers' learning depends on the social and cultural contexts in which that learning occurs (Lave & Wenger, 1991). This study examines the effects of a Summer Math Institute that is part of a three-year professional development project known as *Math Counts*. *Math Counts* focuses on supporting elementary teachers' learning in math pedagogy and content in the context of a rural Appalachian school district. In this analysis, we focus on the development of the participating teachers' pedagogical perspectives and content knowledge, drawing from surveys, content assessments, and interview data. The study informs the ongoing project and contributes to efforts that seek to support the mathematics learning of elementary students and their teachers in historically underserved communities. We examine the teachers' learning, key resources, and opportunities for learning during a Summer Institute in which we engaged teachers with math-focused tasks and utilized a *decentering* approach. This approach shifted attention to the elementary students taught by the participating teachers and the modification of tasks and supports based on the teacher's knowledge of students' math learning challenges and assets. We investigated the following research questions in this study:

1. What are teachers' perspectives on content knowledge, pedagogy, and student/teacher relationships?
2. How is the teachers' content knowledge affected by the Summer Institute?
3. What resources from the Summer Institute contributed to the teachers' learning from their perspective?

Findings indicate that teachers' content knowledge increased in most cases and that many teachers viewed the discussions about their students and task adaptation as resources for their learning. The findings of the study have implications for designing professional development that is effective in supporting teacher voice, content understanding, and task implementation.

This poster presents the development of teacher observation instruments focused on mathematics instruction for students with disabilities (SWDs). Looking back, there is an evidence base to support several instructional practices that develop the math abilities of SWD, but there remains the enduring challenge of translating the evidence base to practice. Looking forward, there is a need to integrate research conducted in different fields, specifically mathematics education and special education, to support special education teachers (SETs) in their content instruction for diverse learners. The aim of these observation instruments is to reliably evaluate SETs mathematics instruction and provide content-specific, actionable feedback that results in improved outcomes for SWDs (Hill & Grossman, 2013).

The poster will describe the use of Evidence-Centered Design to create a coherent assessment system (Johnson, Crawford, Moylan & Zheng, 2018; Mislevy, Steinberg, & Almond, 2003). It outlines the development process for several mathematics instruction rubrics: Developing Conceptual Understanding, Developing Understanding of Procedures, Practicing Procedures, and Word Problem Solving. Attention is placed on two phases of development intended to translate research-to-practice: a) creation of items that reflect the research base from special education and mathematics education, and b) development of performance-level descriptors derived from observation of actual practice. The poster will also present psychometric properties of one particular rubric, the Developing Understanding of Procedures rubric, studied through many-facet Rasch measurement (Eckes, 2011). We present findings from analysis in which 45 videos of mathematics instruction (15 teachers, 3 videos each) were scored with a partially-crossed, connected design by 12 raters. The poster will summarize reliability and fit statistics for four facets: teachers, lessons, raters and items. Finally, the poster will describe next steps in developing a validity argument for these observation instruments.

SUPPORTING SHIFTS IN CLASSROOM PRACTICE: LESSONS FROM A COLLABORATIVE PROFESSIONAL DEVELOPMENT

Enrique Galindo
Indiana University
egalindo@indiana.edu

Jinqing Liu
Indiana University
jinqliu@iu.edu

Pavneet Kaur Bharaj

pkbharaj@iu.edu

Keywords: Teacher Education-Inservice/Professional Development, Mathematical Knowledge for Teaching

We share a model of professional development and lessons learned from a two-year professional development project involving 60 teachers in grades K – 6 and 8 schools, addressing five goals: (1) increase students' understanding of and achievement in mathematics; (2) improve teachers' knowledge of mathematics; (3) strengthen teachers pedagogical skills; (4) improve teachers knowledge of uses of technology to support learning; and (5) strengthen teachers' dispositions to both reflect on their practice and collaborate to improve their teaching.

Our work was guided by the Leading for Mathematical Proficiency Framework (Bay-Williams & McGatha, 2014) to support teachers' shifts in classroom practice to implement the Standards for Mathematical Practice (CCSSO, 2010). We followed a "responsive and emergent" professional development curriculum (Confrey & Lachance, 2000, p. 244), centered around teachers' needs and research-based approaches to improve teaching skills. We formed a professional development team (PDT) including 2 mathematics educators, one mathematician, a math coach, and 2 mathematics education graduate students. A subgroup of seven lead teachers worked closely with the PDT to plan workshops, provide support to other teachers, and serve as a resource to other teachers so that project ideas are integrated into practice at their schools.

In order to contribute to the research on the changing mathematical and pedagogical demands on the preparation of teachers, we examined the shifts in classroom practice after two years of professional development, as well as the teachers' development of their mathematical knowledge needed for teaching. Data sources included an initial teacher inventory of classroom practices, lesson plans created by the teachers, and pre- and post-measures using the scales developed by the Learning Mathematics for Teaching (LMT) project (Hill, Ball & Schilling, 2004).

We are beginning to see the benefits of this approach. As we will share in our analysis, many teachers are incorporating number talks, formative assessment, and a Math Workshop model (Fosnot, 2007) into their lessons and experiencing shifts in classroom practice that display teaching skills that provide opportunities for students to demonstrate the Mathematical Practices (CCSSO, 2010).

TEACHER PERSPECTIVES ON FEEDBACK: A COMPARISON BETWEEN IMPLICIT THEORIES

Kristin Hartland
Middle Tennessee State University
Kristin.hartland@mtsu.edu

Keywords: Implicit Theories, Feedback, Mathematics Teacher Education

Many studies have shown feedback to be one of the most influential factors on student achievement; however, there are conflicting results and inconsistent patterns (Hattie & Timperley, 2007). This may be attributed to the variations of how feedback is given as well as the reasoning for why a teacher may provide feedback in a particular way (Shute, 2008). For example, teachers may provide feedback according to their initial judgement of their students' ability levels or based on whether the students demonstrate grit or perseverance (Dweck, 2006).

Personal experiences, cultural contexts, attitudes, or implicit beliefs held by teachers about learning mathematics may also contribute to a teacher's judgment when providing feedback (Brown, Lake, & Matters, 2011). In fact, Boaler (2016) claimed that out of all contributing factors, teachers' implicit beliefs may have the most influence on the information conveyed in the classroom. Often teachers believe they have little influence on their students' mathematical ability (Dweck, 2006; Dweck, Chiu, & Hong, 1995). As a result, teachers may only provide feedback that leads students to one method of solving a problem or only the correct solution. Teachers' underlying assumptions of students influence their decisions to provide feedback, even though it is unclear how or why (Dweck et al., 1995).

In order to be successful, students must be given opportunities to engage with meaningful mathematics and be given feedback to help them move forward in their learning and understanding (Boaler, 2015). Although implicit theories have been shown to be a mediator of students' actions in the classroom (Good, Aronson, & Inzlicht, 2003), teachers' implicit theories are often overlooked as a mediator of the feedback they provide.

My study focuses on why elementary mathematics teachers provide feedback during mathematics instruction. With very little existing research on why teachers provide different types of feedback (Rattan et al., 2012), this study will give insight into factors that may attribute to teachers' initial judgements when providing feedback. The results will serve to inform mathematics teacher educators who design professional development aimed at supporting teachers' feedback practices.

COMPONENTS OF WHOLE-CLASS DISCUSSIONS IN ELEMENTARY MATHEMATICS CLASSROOMS

Amy Hewitt
The University of North Carolina at Greensboro
alhewitt@uncg.edu

Keywords: Whole-class discussion, elementary mathematics

Whole-class discussion has been identified as a core practice of mathematics teaching. These discussions are often embedded in a lesson structure that includes a launch phase in which teachers introduce a mathematical task, an exploration phase in which students work on the task and the teacher circulates, and a discussion phase. The discussion can take many forms, but often includes the teacher displaying one or more pieces of student work from the students' engagement with the task and facilitating a conversation around the mathematical ideas in the strategies depicted in the student work (Stein, Engle, Smith, & Hughes, 2008). Despite the importance of discussions, implementing them remains a challenge. Much of the research on whole-class discussions has focused on the facilitation of discussions, while less attention has been given to other components of discussions.

To address this gap, I characterized components of whole-class discussions in the context of fraction instruction. Specifically, I used grounded theory to analyze 29 videos of classroom lessons documenting all potential components of the discussions. I looked for a variety of components identified in the literature, but also noted components that were not frequently mentioned. The lessons were taught by grades 3–5 teachers who were at various points in their participation in three years of professional development focused on children's fraction thinking and how teachers can build on that thinking during instruction. My study occurred within the context of a larger study, *Responsive Teaching in Elementary Mathematics*, and focused on the 29 teachers who posed an equal sharing problem with a fractional answer and chose to include a whole-class discussion during the lesson in which they were observed.

Analyses revealed an extensive list of whole-class discussion components, which were narrowed to identify four components that could be used to characterize the formats of discussions in elementary mathematics classrooms: (a) the start of the discussion; (b) how the strategy was displayed to the class, including the possible recreation of the strategy by the teacher; (c) the characteristics of student work shared; and (d) the end of the discussion. These components can enhance our understanding of the *discuss* phase of mathematics lessons and help support teachers in envisioning and implementing this challenging phase.

EXPLORING CONVERSATION THEMES IN PROFESSIONAL LEARNING GROUPS

Jennifer Holm
Wilfrid Laurier University
jholm@wlu.ca

Ann Kajander
Lakehead University
ann.kajander@lakeheadu.ca

Previous research into professional learning groups (PLGs) in mathematics has mainly focused on the benefits of the professional development on the teachers (e.g., Brahier & Schäffner, 2004). Since previous research on PLGs has pointed to a need for the professional development to be participant-driven (e.g., Gojmerac & Cherubini, 2012), what types of discussions are used within these groups in mathematics is important for discussions in creating effective and sustainable PLGs. The research project this poster is a part of focused on the discussions of the professional learning group in order to explore where teachers focused their own professional development by examining their conversations during the 17 individual (mainly half day) PLG meetings.

This research is a portion of a three-year narrative case study with grades 6-10 teachers who were board mandated to create a PLG to discuss the transitions from grade 8 to grade 9. The research data within the study included meeting tapes and transcripts, artefacts, and teacher interviews. The data was analyzed as part of the larger study; however, the focus of this portion was to determine themes related to the discussions of the teachers. In order to determine themes, the entire data set was explored to identify characteristics of the conversations. Conversations were only considered *if* there was an interaction between two or more participants using the framework of symbolic interaction (Blumer, 2004) as a basis to determine the portions that were important to the research. Next, these conversation characteristics were compiled in order to determine overarching themes. The themes were then combined as needed, and then the data set was again revisited to ensure that all of the themes were included in the final description.

In the end, eight themes were determined to be representative of the entire group conversations: factors outside of teacher control, topics related to group structure, classroom strategies, student-related conversations, mathematics-specific conversations, learning trajectories, and program differences. Although a smaller topic of conversation, it was noteable that the teachers did spend time discussing things like scheduling problems and whether or not there would be funding to continue the group meetings (factors outside of teacher control). The entire, larger research study concluded that this PLG was successful in supporting the development of the teachers within the group (to varying degrees). With this being a successful form of professional development, exploring the teacher conversations was important in exploring what teachers felt was important for improving their mathematics teaching in order to expand the conversation of how to operationalize the strengths of this group to other groups. Since PLGs are entirely teacher-driven (e.g., Gojmerac & Cherubini, 2012), a focus on the conversations within a group are essential to expand the research in mathematics education around how to support teacher growth through this type of professional development.

EXPLORING ASIAN AMERICAN MATHEMATICS TEACHERS' PERCEPTION AND IMPLEMENTATION OF CULTURALLY RELEVANT PEDAGOGY

Min Jung Kim
Boston College
kimbzw@bc.edu

Keywords: Teacher Identity, Culturally Relevant Pedagogy, Asian American Teachers

This study explores Asian American mathematics teachers' perception and implementation of culturally relevant pedagogy through a multiple case study approach. Rubel (2017) described the concept of meritocracy, color-blindness, and inability to relate to students as "tools of whiteness" (p. 68) in mathematics education. The model minority myth (MMM) is an example of how those tools are manifested in society. Specifically, in education, the MMM ignores the structural obstacles that stem from race and socioeconomic class inequalities and emphasizes that hard work and a good work ethic are sufficient to be successful (Chen & Buell, 2017). The ideas embedded in the MMM directly oppose the principles of culturally relevant pedagogy (CRP). Contrary to the values of the MMM, culturally relevant pedagogy considers students' cultural and racial backgrounds as assets and as significant components of a curriculum (Ladson-Billings, 1994). Asian American mathematics educators, especially those who teach in urban and diverse contexts, are in the middle of this tension between the MMM and CRP.

Previous studies have argued that teachers' narratives as learners and reflections help to construct their teaching practices and professional identity (Drake, Spillane, & Hufferd-Ackles, 2001; Richardwon, 2003). Given this significance of personal histories and reflections, it is worthwhile to investigate Asian American teachers' narratives and how they perceive and implement culturally relevant pedagogy.

Interview data with three Asian American secondary mathematics teachers, along with an analysis of their lesson plans and sketches of themselves, led to a preliminary conclusion that teachers who have struggled with their personal identity construction as Asian Americans were more likely to foster students' personal identity construction through mathematics lessons. For example, one participant, Sunny, who defined herself as someone who "became Asian American" and that her identity "is still changing," planned a lesson that incorporated students' identity construction. Her students graphed an avatar of themselves using a computer program and then had to describe why and how that avatar represented them. Whereas another participant, Ann, who simply described herself as a "Korean American" and did not have much opportunity to discover her racial identity, did not perceive CRP as an effective pedagogy and turned to direct instruction. Findings suggest that reflections by pre-service and in-service are critical to the mathematics teacher's professional identity construction process, positive perceptions of CRP, and effective implementation of CRP strategies.

WOMEN IN MATHEMATICS EDUCATION: AN ANALYSIS OF GENDER IN PROFESSIONAL ORGANIZATIONS GLOBALLY

Brianna Kurtz
University of Central Florida
Brianna.Kurtz@ucf.edu

Farshid Safi
University of Central Florida
Farshid.Safi@ucf.edu

Keywords: Gender, Equity and Diversity

The underrepresentation of females in mathematics has been widely studied and analyzed. However, once women are retained in STEM fields including mathematics, further disparities are seen in their representation in leadership roles, especially in professional organizations (Welch, Parker, & Welch, 2013). Although efforts have been made to encourage the qualities necessary to hold leadership roles, this has been a more recent development (Dugan, J.P., Faith, K. Q., Howes, S. D., Lavelle, K. R., & Polanin, J.R., 2013). This begged the question as to if the disparities experienced by women in mathematical organizations in leadership roles was also experienced by women in mathematics education organizations. Historically, women have been more present in mathematics education when compared to mathematics (Safi, 2012). However, if this was reflected in leadership representation was unknown. Additionally, through these organizations, the representation of women's research in proceedings was questioned.

A theoretical framework of cultural feminism was used for the analysis in order to challenge not only the presence of women in leadership role but also to consider the general cultural attitudes toward women professionally as tied in to country or region of organization (Vasavada, 2012). Historical rosters were gathered from professional organizations for mathematics educators from six continents. The specific countries in these were chosen not only for their organizational presence but also for availability doctoral programs in mathematics education (Safi, 2014). Recent conference proceedings for select organizations were analyzed to determine relative proportions of accepted female presenters. It was found that, although research by females does tend to be featured at organizational conferences, representation at leadership levels is disproportionate in favor of males nearly uniformly across the globe. Further implications include funding initiatives to promote women's leadership is such organizations.

REHEARSALS WITH IN-SERVICE TEACHERS: RECOGNIZING AND RESPONDING TO TEACHERS' CONFIDENCE

Gemma Oliver
Michigan Technological University
gloliver@mtu.edu

John Gruver
Michigan Technological University
jgruver@mtu.edu

Keywords: Teacher Education-Inservice/Professional, Middle School Education

Mathematics teacher education can be challenging to deliver in a way that it makes an impact on teachers' practice. Over a century ago, John Dewey emphasized teachers' need for laboratory experience (Dewey, 1904/1965). Similarly, Lampert et al. (2013) argue that situating the knowledge teachers gain in teacher education courses in actual teaching practice can help ensure that the knowledge translates to practice. They have argued for the use of teaching rehearsals, where teachers practice teaching a lesson to peers in a low stakes environment where a mathematics teacher educator (MTE) provides in the moment feedback. Rehearsals can be an answer to Dewey's century old call for laboratory experience. While this is a promising instructional technique, little is known about how in-service teachers engage in these rehearsals. This research focuses on conceptualizing in-service teachers' engagement in rehearsals so MTEs can better support teachers in productively engaging in these rehearsals.

In the summer of 2017 two MTEs engaged 14 middle school teachers in a week long professional development session using rehearsals. The professional development centered on how to teach a unit on algebraic generalization using figural patterns. During the week, there were six different rehearsals taught by six of the 14 participants. I chose three of the participating teachers who seemed to engage in different ways to focus my analysis on.

During the rehearsals, the MTEs or the other participants would pause the teaching to give in the moment feedback or discuss particular teaching moves. I analyzed these pauses, attending to the acting teacher's gaze and gestures as well as noting the purpose and topic of the pause. The following questions became salient in terms of characterizing the differences in the teachers' participation: Where does the teacher look for suggestions? And How does she engage with the suggestions? Teacher A tended to look to peers for feedback and generally accepted that feedback. Teacher B tended to look to the MTEs for feedback. Teacher C looked to both sources for feedback, but also seemed to see herself as a competent contributor.

This is significant because MTEs can use these results to better notice and support teachers' engagement. In particular, MTEs could specifically attend to where the teacher is looking for suggestions and how she is engaging with those suggestions. If an MTE was working with a teacher like Teacher A, they could create opportunities for that teacher to engage more critically with suggestions from others. If someone like Teacher B is looking to the MTEs for a suggestion, the MTEs could turn the question to the rest of the group. Thinking about who the teacher is asking for suggestions and how she is engaging with those suggestions can be helpful as MTEs decides how to facilitate productive engagement.

ANALYZING ADJUNCT INSTRUCTOR'S ENGAGEMENT WITH A RESEARCH-BASED PRECALCULUS CURRICULUM

Zareen Gul Rahman
James Madison University
rahmanzx@jmu.edu

Keywords: Teacher Education-Inservice/Professional Development, Teacher Knowledge, Post-Secondary Education

Teachers play an important role in sustaining educational reform efforts by shaping how curriculum unfolds inside the classroom (Cohen & Ball, 1999). They need support to develop instructional capacity and influence their students' learning (Cohen & Ball, 1999). Support is important for teachers despite their appointment type, for example, full-time versus part-time faculty (Gappa, Austin, & Trice, 2007). Research points to a growing trend in higher education towards hiring part-time adjunct faculty (Mason, 2009; Curtis, 2014; Snyder & Dillow, 2015). This trend warrants research on adjunct instructors' experiences (Kezar & Sam, 2013). I provide an in-depth look at three adjunct instructors' experiences as they implemented a research-based Precalculus curriculum. Findings from this study have implications for designing professional developing programs for adjunct instructors.

To analyze adjunct instructors' experiences as they implemented a research based mathematics curriculum, I employed a sociocultural framework focusing on "mediated action" (Wertsch, 1998). I analyzed 3 adjunct instructors' engagement with the curriculum as they planned their instruction, enacted their lessons inside their classrooms, collaborated with their colleagues or reflected on their teaching experiences. Using the case study methodology (Yin, 2009) I describe adjunct instructors' engagement with the curriculum. Data was collected in the Fall 2016 and Spring 2017 semesters using semi-structured interviews, classroom observations and collaboration data from online meetings.

As the instructors engaged with the curriculum while planning, enacting, collaborating and reflecting, each mode of engagement influenced instructors' engagement through other forms. For example, planning was influenced by challenges faced while enacting the curriculum, by ideas discussed with other instructors and instructors' own reflection. Challenges arose while instructors planned their instruction and enacted their lesson. Collaboration and reflection took the form of supports for the instructors. Findings from this study adds to the limited body of research that focuses on mathematics adjunct instructors' experiences and can guide the development of professional development that is aligned with their needs.

HEAD START PRESCHOOL EDUCATORS' CONCEPTIONS OF MATHEMATICS LEARNING AND TEACHING

Paul N. Reimer
AIMS Center for Math and Science Education
preimer@aimsedu.org

Ralph T. Putnam
Michigan State University
ralphp@msu.edu

Keywords: Early Childhood Education, Pre-School Education, Teacher Education–Inservice/Professional Development, Teacher Beliefs

Mathematics education leaders and national organizations have called for improved training and professional development for early childhood educators (Ginsburg, Lee, & Boyd, 2008; NAEYC & NCTM, 2010). To address these calls, our research group is designing and implementing a collaborative professional development (PD) model to support preschool mathematics teaching that builds on children's mathematical thinking and play. The PD involves 25 Head Start educators in whole-group learning sessions, video-club discussion, collaborative activity design, and classroom coaching.

Throughout the PD we are attending to teachers' development of new ways of thinking, being, and acting in classroom interactions. In this poster, we focus on two research questions: (a) how do these Head Start teachers conceptualize children's mathematics learning and development? And (b) how do these teachers conceptualize their role in supporting children's mathematical development?

We interviewed teachers at the beginning of the school year to explore their perspectives. The teachers discussed and provided examples of their mathematics teaching practice and their views of their roles and children's learning. We analyzed 11 transcribed interviews using an inductive coding approach. Teachers most often identified their roles in classroom activity as *Instructor* (64%) and *Nurturer* (55%). Four of the 11 teachers (36%) described their role as *Facilitator*; three (27%) made comments coded as *Observer*. Teachers made fewer comments overall related to children's learning, with 45% describing learning as *Engagement*, 36% learning as *Active*.

Teachers' emphasis of instructor and nurturer roles over facilitator and observer roles suggests assumptions about the locus of the generation of mathematical knowledge (Platas, 2015). Whether teachers assume a facilitative role or are active participants with children, teachers' self-positioning influences the structure of mathematical interactions in their classrooms (Graue et al., 2015) and can inform professional development efforts toward play-based pedagogy.

ONLINE COMMUNITIES OF PRACTICE TO SUPPORT INQUIRY-ORIENTED INSTRUCTION

Rachel Rupnow
Virginia Tech
rachr15@vt.edu

Keywords: Teacher Education-Inservice/Professional Development; Mathematical Knowledge for Teaching; Technology

At small colleges, only one professor may be equipped to teach certain courses, making content-based discussion with colleagues very difficult. Online support systems have emerged to fill this void. The online communities of interest here were created to support Inquiry-Oriented (IO) instruction, which requires different Mathematical Knowledge for Teaching (Ball, Thames, & Phelps, 2008) than other curriculum materials typically require (Johnson & Larsen, 2012). In addition, instructors are encouraged to use different instructional techniques than they may be used to. This shift in instruction can be taxing on instructors, with several challenges documented in the literature (e.g. Johnson & Larsen, 2012). This poster examines online groups of math faculty created to support one another while putting IO instructional materials into practice.

The members in the two Online Working Groups (OWGs) studied were mostly college faculty members. Data collection consisted of observations of two meetings from each OWG and 20-50 minute interviews of six OWG members. The field notes from OWG meetings and interviews were transcribed and coded using thematic analysis (Braun & Clarke, 2006). In order to analyze the OWGs, a community of practice (CoP) lens was used (Wenger, 1998). Wenger posited three dimensions of communities of practice: mutual engagement, a joint enterprise, and a shared repertoire. In order to concretize these dimensions, Wenger also provided fourteen indicators of a CoP; these indicators became the codes used for thematic analysis. Code prevalence was used to determine the extent to which each indicator of CoPs was present. This analysis addresses the research question: to what extent did these OWGs form a CoP?

Based on this analysis, eight of the fourteen indicators of a CoP given by Wenger to characterize CoPs were clearly present in the OWGs: shared ways of engaging in doing things together; substantial overlap in participants' descriptions of who belongs; knowing what others know, can do, and can contribute; mutually defining identities; specific tools, representations, and artifacts; jargon and shortcuts to communication; certain styles recognized as displaying membership; and shared discourse reflecting a certain perspective. The other indicators were present to a lesser extent. Thus, each OWG formed a CoP by the end of the semester.

RESULTS OF A COMMON CORE MATHEMATICS TRAINING PROGRAM: VETERAN TEACHERS' PERSPECTIVES

Evelyn Seeve
Daemen College
eschachn@daemen.edu

Keywords: Elementary School Education, Teacher Education/Professional Development, Standards

Research shows implementation of the Common Core Mathematics Standards can be challenging (Bostic & Matney, 2013), especially for veteran teachers (Burks, et al, 2015). The NCTM underscores the importance of professional development in assisting mathematics teachers in this area (NCTM, 2013). Design of this teacher training program considered features of form, duration, active learning, and coherence (Birman, Desimone, Porter, & Garet, 2000) to address needs of experienced teachers struggling with implementing the CCSS-M. Research questions included: (1) In which ways, if any, will a one-year Common Core professional development training influence experienced elementary teachers' mathematics instruction? (2) What are the teachers' perspectives regarding influences of the training on their students' math performance and communication? (3) Which features of the training do the teachers report most useful in improving their mathematics instruction? Which additional features are recommended?

Training for teachers of grades 1-6 in one private girls' school included one session exploring mathematics practice standards using video demonstration and simulated collaborative problem solving as well as Common Core grade specific content applications. One model lesson targeting content and practice standards was conducted for each grade level, and follow-up consultations and classroom observations were conducted throughout the year. Seven veteran teachers participated in video recorded interviews for this study. Results were analyzed qualitatively.

Results and Implications

Initial results indicate all teachers reported influences of the training on their mathematics instruction, such as implementing more collaborative tasks, using deeper questioning, emphasizing strategy instruction and justification of solutions, and using more precise math language. Reported changes for students included more willingness to take risks, use of varied strategies, and improvement in mathematics communication skills. Teachers highlighted features of the training that helped shape their instruction, and recommended more consistent coaching for planning instruction in particular content areas. Findings of this project indicate ways in which mathematics professional development may influence teaching practices and students' learning. Features of this training project have import for researchers and practitioners designing mathematics teacher professional development.

NEW TEACHERS' VISIONS OF HOW GROUPWORTHY TASKS CAN HELP TO CREATE EQUITABLE MATHEMATICS CLASSROOMS

Kathleen Jablon Stoehr
Santa Clara University
Kstoehr@scu.edu

Amy Olson
Duquesne University
olsona@duq.edu

Keywords**:** equity & diversity, teacher education-inservice/professional development

Theoretical Framework

All students need "access to high quality mathematics curriculum, effective teaching and learning, high expectations, and the support and resources needed to maximize their learning potential" (NCTM, 2014). Yet many of today's mathematics classrooms continue to place students in specific learning groups based on perceived ability (Alpert & Bechar, 2008). This practice, known as ability grouping, is of great concern, as it is often girls and diverse students that are most likely to be placed in lower-ability groups (Cohen & Lotan, 2014).

Featherstone et al. 2011 examined specific ways to eliminate ability grouping in the elementary mathematics classroom by creating student learning through "*groupworthy tasks.*" These are tasks that are complex in nature and offer multiple ways of thinking in order to be solved. Groupworthy mathematical tasks leverage the *mathematics smartness* of all students in mixed-ability groups, thereby providing opportunities for all students to gain deeper mathematical understandings.

Methods and Analysis

The participants in this study were sixteen newly credentialed elementary teachers who attended a weeklong professional development workshop focused on utilizing equitable mathematics teaching through groupworthy tasks. Data collected for this qualitative study included mathematics tasks, mathematics lesson plans, and individual reflections that centered on groupworthy tasks. An iterative analysis (Bogdan & Biklen, 2006) was used to demarcate the data sources that pertained to the teachers' views of groupworthy mathematics tasks.

Findings

All sixteen of the teachers expressed a commitment to provide their students with equitable mathematics learning experiences. Themes included 1) a classroom community built by students working together, 2) students supporting each other's ideas and strategies, 3) students trusting each other while struggling together to create mathematical understanding, 4) students taking risks while trying something different, 5) students being provided with multiple learning spaces and movement in the classroom, 6) teachers redefining what mathematics "smartness" looks like, and 7) teachers deconstructing the stereotypes of who can be a successful mathematics student.

UNPACKING A GEOMETRIC LEARNING TRAJECTORY THROUGH THE ANALYSIS OF A MATHEMATICAL TASK AND STUDENTS' STRATEGIES

Jennifer M. Suh
George Mason University
jsuh4@gmu.edu

Sara Birkhead
George Mason University
sbirkhea@gmu.edu

Keywords: Teacher Education-Inservice/Professional Development, Geometry, Learning Trajectories; Instructional Activities and Practices

This study examines teachers use of a learning trajectory to plan, implement, and debrief on student strategies to better understanding the developmental progression of geometric thinking during a Lesson Study. To guide the planning, we provided a lesson planning template called the Vertical Articulation to Unpack the Learning Trajectory (VAULT) that adapted from Confrey's (2012) five elements to unpack a learning trajectory. The VAULT planning guide asked the team to reflect on the cognitive demand of the task to be sure there was worthwhile mathematics and to develop conjectures on students' solution paths and barriers (See Figure 1). The Lesson Study team used the *Shapes and Properties* LT from TurnonCCMath.net to anticipate the student strategies, representations and misconceptions; develop questions to help probe student thinking, and look for sophistication of ideas to extend learning.

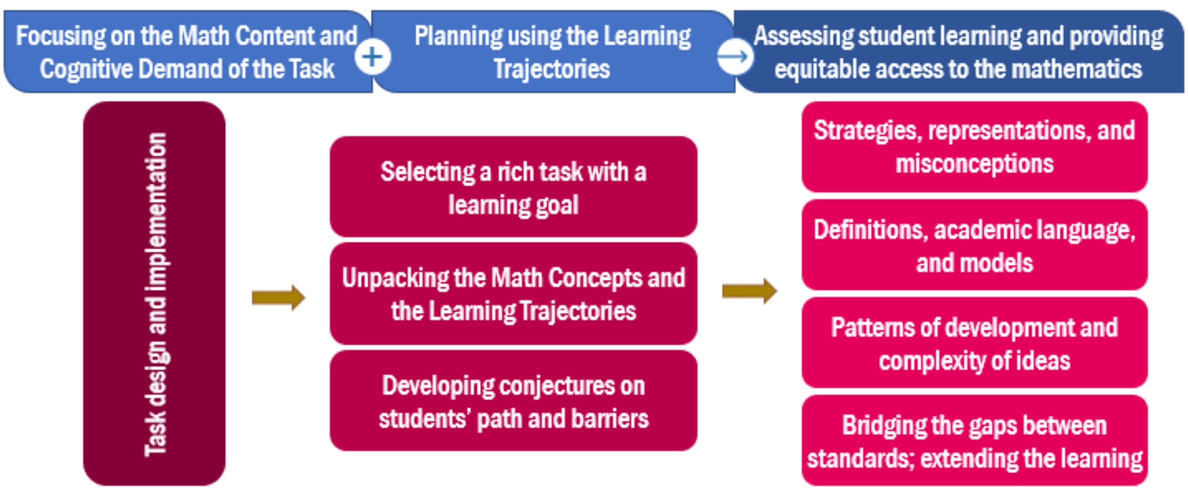

Figure 1. Vertical Articulation to Unpack the Learning Trajectory (VAULT) Planning Guide

When reflecting on student learning, the lesson study team analyzed student work and developed their own LT for comparing area, based on evidence from student strategies, which progressed from using shape relationships to order areas, to using fraction knowledge to be more precise in comparing areas, to using grid paper to assign area, and ending with using area formulas. Using an LT supports teachers in understanding student work as a progression of strategies that reflect conceptual development and intermediate understandings of mathematics.

Implementing changes in policy aimed at large scale educational improvements, such as new academic content standards, is a perennial challenge in education for both individual teachers and school districts. Most implementation efforts involve top-down approaches that expect implementing agents (i.e., teachers, mathematics teacher leaders at the school and district level) to change their practice to meet the goals of reform. However, researchers have consistently demonstrated this approach is problematic, highlighting that implementing agents typically notice superficial similarities to previous standards, attend to the familiar, have varied interpretations, and receive mixed messages about implementation vertically and horizontally throughout the system (Spillane, Reiser, & Reimer, 2002). Recognizing the challenges associated with standards implementation at scale, our research team partnered with our state education agency to develop online professional development (PD) modules to provide implementing agents with equitable access to opportunities to learn about standards and promote clear and coherent messages across the system.

In this poster session, we provide an overview of organizational sensemaking (Weick, 1995) as our theoretical perspective and use Sandoval's (2014) approach to conjecture mapping as a tool to guide our design of PD modules which were developed to be implemented across an organizational system (i.e., the state). We share the ways in which we drew on this perspective to develop module features that cued sensemaking processes, prompted intersubjective meaning making, and promoted action (Maitlis & Christianson, 2014; Weick, 1995). In presenting our poster, we will discuss our design process, including our conjecture maps, and provide examples of the online PD modules that embody the organizational sensemaking processes.

In this case study, we examine the usage of language — how teachers used and regulated their language when teaching English language learners (ELLs) with learning disabilities (LD) how to solve mathematics multiplication problems. We focus on types of scaffolds used by teachers to identify how scaffolding helps ELLs with LD build better multiplicative reasoning. Using an exploratory case study, we find that more linguistic scaffolding and small group interactions are beneficial for ELLs with LD. In combination with kinesthetic scaffolding, they form an effective instructional method for improving multiplicative reasoning among ELLs with LD.

Keywords: Classroom Discourse, Number Concepts and Operations, Mathematical Knowledge for Teaching, Elementary School Education

Introduction

According to the section on English language acquisition in Title III of the Elementary and Secondary Education Act (ESEA) reauthorized by the Every Student Succeeds Act (ESSA) in 2015, schools are required to be accountable for the improvement of all children, including those with “disability, recently arrived ELLs, and long-term ELLs” (Non-Regulatory Guidance, 2016, p. 4). Students with limited English proficiency or what ESSA now refers to as English Learners (ELs) must also meet benchmark goals as a subgroup for passing achievement goals (pass/do not pass) and making adequate growth annually in mathematics. In order to meet district and school accountabilities requirements for dually classified ELLs (ELL and special education), it is necessary to provide appropriate support and interventions in a timely manner to promote their academic performance and address persistent achievement gaps in math (Zhou, 1997).

Math Problem-Solving Skills and Literacy Skills

Good literacy skills, which include reading, reading comprehension, and technical reading skills, play a significant role in students’ ability to solve math word problems efficiently, especially for students who have good calculation ability (Kyttälä & Björn, 2014). According to findings from previous studies, reading fluency predicts student performance in solving mathematical word problems (Vilenius-Tuohimaa et al., 2008; Kyttälä & Björn, 2014). In addition, Cummins et al. (1988) showed that children sometimes make mistakes on math word problems due to ambiguous language in the problem statements or miscomprehension of the verbal instructions, shaped by their level of English proficiency.

Content in an Academic Setting

ELL students experience a complex process with challenging academic content along with academic proficiency in language (Gerena & Keiler, 2012). Although ELLs may appear to be verbally fluent in English, they are still struggling with complex academic material that requires the production of specific academic discourse (Gerena & Keiler, 2012; Olsen, 2010) that differs from social language use.

Scholars in the field have researched and recommended the use of instructional scaffolds to convey meaning to students at varying levels of English proficiency, which include visual/graphic scaffolding, linguistic scaffolding, interactive scaffolding and kinesthetic scaffolding (Gibbons, 2014; Gottlieb, 2016). These scaffolds are important considerations in the planning of math instruction for dually classified ELLs (DC ELLs) (McGhee, 2011).

Scaffolding

In the teaching-learning framework, scaffolding is a central notion adapted from Gibbons (2002, 2014) which is supported by a constructivist theory of learning. Scaffolding is a support to "enable children to perform tasks independently that previously they could perform only with the assistance or guidance of the teacher" (Gibbons, 2002, p. vii). Scaffolding uses the theoretical framework that Halliday (1993) highlighted about registers of language through the classroom interaction of teachers and students working together to develop "new skills, concepts, and levels of understanding" (Gibbons, 2002, p. vii). Gibbons (2002, 2014) also suggested that scaffolding can be used for English language teaching to ELL students in mainstream classrooms, where they spend the majority of their school day.

Scaffolds are strategies that support the delivery of target content with an explicit inclusion of a given scaffold appropriate for each ELLs' level of English proficiency and, in this case, the added dimension of a learning disability. Gottlieb (2016) describes four types of instructional scaffolds that teachers can use and students can appropriate to create understanding around target content. These scaffolds include visual, linguistic, interactive and kinesthetic scaffolds (Gottlieb, 2016).

Visual scaffolding. Visual scaffolding helps ELL students by using drawings or photographs to connect English words to visual images and assists ELL students in learning the subject. This approach makes complex ideas feel more accessible to students and makes language more memorable, all while providing comprehensible input of the target content (McCloskey, 2005, p. 1). There are a variety of instructional supports that can build students' visual experience in the classroom, including manipulatives, real objects, and multimedia material (Carrasquillo & Rodrigues, 2002; Gottlieb, 2012).

Linguistic scaffolding. Linguistic scaffolding can be conceptualized according to the zone of proximal development (Vygotsky, 1978). Teachers must provide effective and responsive support for students' language output performance, which requires teachers to use language that is comprehensible to students when providing them with new and more sophisticated knowledge, including using a slower rate of speech or simplified vocabulary with consistent reinforcement of a target set of words (Gibbons, 2003; Bradley and Reinking, 2011).

Interactive scaffolding. As mentioned above, Heath (1982) described a "literacy event" as "any occasion in which a piece of writing is integral to the nature of participants' interactions and their interpretive processes" (p. 438). Moreover, Goffman (1993) put forward the idea of "interactionism," which relates "only to those aspects of 'context' that are directly observable and to such immediate links between individuals as their 'roles,' 'obligations,' 'face-to-face encounters,' and so on" (p. 439). An example of instructional support for both students and teachers is using active roles in pair work and small group work (Gibbons, 2008).

Kinesthetic scaffolding. Asher (1969) first introduced a strategy called *Total Physical Response Technique*, which directly relates to kinesthetic scaffolding. This approach requires the students to listen to a foreign language command and obey it using a physical action immediately with no expectation of speech production (Asher, 1969). Brand et al. (2012) suggested that students who use kinesthetic scaffolding can benefit from “sign language, translation into another language, gestures” during sessions (p. 139), while not being restricted from participating due to their lower levels of English proficiency.

In this paper, we apply four different kinds of scaffolding to analyze the mathematics instructional discourse exchanges between a teacher and an ELL student with LD within the context of a small group constructivist-oriented learning environment. We intended to answer following research questions:

1. What types of scaffolds do teachers and dually classified ELLs make in multiplicative reasoning during instruction and assessment activities?
2. How do teachers regulate language usage and scaffolding to facilitate the multiplicative reasoning of ELLs with LD?

Research Methodology

This exploratory case study investigates the interplay between teacher and student in mathematics instruction from a constructivist perspective of learning (Vygotsky, 1962). Constructivism is a philosophy of learning that focuses on individuals actively participating in learning rather than passively receiving knowledge (Gunning, 2010). In this perspective, the learning process can only occur when the learners are actively engaged in integrating new knowledge with existing knowledge (Morrow & Tracey, 2012). Therefore, constructivist theory will be the research framework for our analysis of teacher-student discourse.

Mode of Inquiry

We use an exploratory case study to examine the scaffolds used by teachers and appropriated by dually classified ELs. In light of the research process, Yin (2014) defined a case study as “an empirical inquiry that investigates a contemporary phenomenon (the ‘case’) within its real-life context, especially when the boundaries between phenomenon and context may not be clearly evident” (p. 16). The researcher-teacher (a math educator/ university professor) worked with an ELL student with LD and another native English speaker with LD in each session. The teacher used the constructivist teaching experiment method (Cobb & Steffe, 1983; Steffe, Thompson & von Glasersfelf, 2000) with the team of students.

Setting and Context of the Study

This study was conducted within the larger context of a National Science Foundation (NSF) funded project (Xin et al., 2008). This study took place at a local elementary public school resource room in the Midwestern United States. The participant attended 26 weekly teaching sessions of 25-35 minutes in pairs with another non-ELL student with LD. Each day, the math teacher worked with the pair of students together. Each lesson was designed based on an assessment of the student’s level of understanding of the given math content from the previous session. The study was conducted over a period of eight months. Each session, the instructor provided a pedagogical approach to promote the ELL’s progress toward multiplicative reasoning (Tzur et al., 2010) and problem solving (Xin, 2012).

Participants

The participants were selected from a local elementary school in the Midwestern United States. This study worked with students during an after-school program. The participants for this study were a fifth-grade ELL student with learning disabilities (Eliza) and a fifth-grade native English speaker with learning disabilities (Leslie). According to Eliza’s IEP, she was included in a general education class setting for 50% of the time, and received 45 minutes of math instruction in the resource room each day from different math instructors. Eliza was placed in a learning support classroom for reading, English language arts, and math. Eliza's intellectual functioning was in a very low range (IQ (OTIS) full scale is 69 with a verbal score of 69). Eliza has been placed in the special education program each of the past four years. The fifth-grade native English student (Leslie) worked as a group partner with Eliza during each session.

Data Sources

The sources of data were teaching videos and field notes taken during instructional observations. The teaching videos recorded the teacher and focal students, and the field notes were taken by graduate students. We included the transcripts and corresponding field notes for five out of the seven recorded teaching sessions. The rationale for including only those sessions was due to availability of the data.

Data Analysis

We coded both the instructor's discourse and the ELL student's problem solving and reasoning. The approach was coding the discourse moves of the discourse between the teacher and the student. The coding method we used was coding in terms of four different scaffoldings: visual/graphic scaffolding, linguistic scaffolding, interactive scaffolding and kinesthetic scaffolding. The purpose of this coding method was to answer the first research question and try to find the most successful scaffold that the math teacher used for ELL students with LD, which is the main purpose of this study.

Coding Scheme of Discourse Moves

We used NVivo 11 to transcribe and code the verbal and nonverbal mathematical communication for both the teacher and the pair of students (one of them, Eliza, is our participant) (Xin et al., 2016), as well as their behavior (e.g., using finger counting, creating the mathematical model on scratch paper). We did not transcribe unrelated mathematical verbal or nonverbal communication or behavior as it was not central to our inquiry.

Using the coding scheme, we coded each transcript by the type of scaffolding, including visual /graphic scaffold, interactive scaffold, linguistic scaffold or kinesthetic scaffold for both students and the teacher discourse (Table 1).

Moreover, in order to analyze the linguistic scaffold, we adopted the concordance software AntConc 3.4.3w (Windows) 2014. AntConc is a useful tool for analyzing a detailed corpus in linguistic research (Lei, 2016). After obtaining the organized discourse coding transcripts from Nvivo, we imported them into AntConc to analyze the frequency of the teacher's language in session transcripts by counting the four categories, such as "How many towers?" "How many cubes?" "How many more?" and "PGBM" (Please Go and Bring Me), which were the major activities involved in the constructivist-oriented learning of multiplicative reasoning (Xin, Tzur, and Si, 2008).

Table 1: Scaffolding Coding Scheme

Scaffolds	Teacher	Students
Visual/Graphic Scaffold	"Please generate a model of 5 towers of 9 on the grid ½ sheet."	"Can I use paper to double-check?"
Interactive Scaffold	The teacher helps E with the arithmetic and shows her the error she made—now E has 45.	The teacher asks S to help E and he does. S counts towers for E until S shows 5 with his hand.
Linguistic Scaffold	T: How many cubes do you already know are in a tower? L: 6 T: How many towers in all? E: 5	L: How many cubes in each tower? E: 5 L: How many towers? E: 6
Kinesthetic Scaffold	"Use my finger to keep track of it. And we can use our fingers if it is helpful. Here it is very helpful because you can keep track how many groups you have."	"I counted with my fingers."

In addition, we defined the interactive scaffolds by three characteristics: teacher-student interaction, student-student interaction and small group interaction (Table 2).

Table 2: Interactive Scaffolds

Teacher-student interaction	Student-student interaction	Small group interaction
The teacher helps E with the arithmetic and shows her the error she made—now E has 45.	The teacher asks S to help E and he does. S counts towers for E until S shows 5 with his hand.	T: How many cubes in all? E: 28 T: OK. What did you get on the calculator? (to L) L: 44 (with calculator)

Findings

In the first stage of analysis, we report the frequency results for the scaffolds used by the teacher and appropriated by the student (Eliza). The highest frequency of scaffolds used by the student and the teacher were kinesthetic scaffolds, while the second highest amount was interactive scaffolds (Figure 1). The teacher often used finger counting to help students do multiplication to solve the different types of problems, such as unit rate (UR) (e.g. "how many cubes in each tower"), composite units (CU) (e.g. "how many towers") and 1's (e.g. "how many cubes in all") (Tzur et al., 2010). Students in these sessions often used finger counting to show a finger trick for multiplication with numbers. Below is an example exchange between Eliza (E) and teacher (T).

Excerpt 1 (December 11, 2008)

E: 7 plus 7 equals 14 for 2 towers. She counted 15, 16, 17… (Finger counting) (Counted up to 34. She tries to keep track with her fingers and wanted to be at seven fingers when she had her answer.)

T: (prompt) Write down the number of cubes you got.

E: I lost count.

T: Try again. Do you want to use my fingers?

E: Yes. (counts the towers, 1, 2, 3, 4, 5, 6, 7, 8, 9, 1 finger/tower… 10, 11, 12 …

T: (Explains the trick to E use fingers)

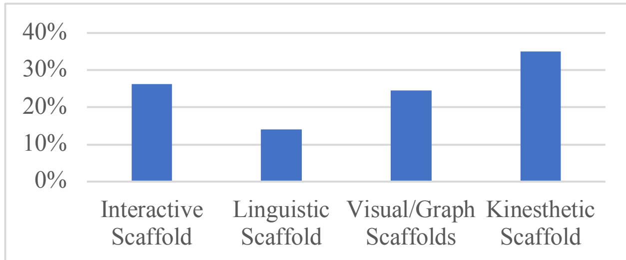

Figure 1. Frequency of Scaffolds across students and the teacher

As shown in this example, the teacher prompted to get Eliza's method and Eliza tried to use both her fingers and the teacher's fingers to solve the problem. We can find that in this situation, the teacher and the student had an effective interaction, and then the teacher could express the method that should be used for these types of problems. Therefore, Figure 2 shows the different types of interaction that the teacher and student used in sessions. It indicates that the teacher preferred to use small group interaction during the sessions, and students had more interaction during group work with both classmate and teacher. For example, the following excerpt is from a transcript between the teacher (T) and students Eliza (E) and Leslie (L).

Excerpt 2 (February 17, 2009)

T: Question number one
L: How many cubes in each tower?
E: 5
L: How many towers?
E: Six
T: Six what?
E: Six cubes.
L: How many cubes... in each
E: 5
L: How many in all?
T: How many what?
L: How many towers in all?
E: Six.
T: I think the question you're looking for is how many cubes in all. Can you ask it?
L: How many cubes in all?
E: 30

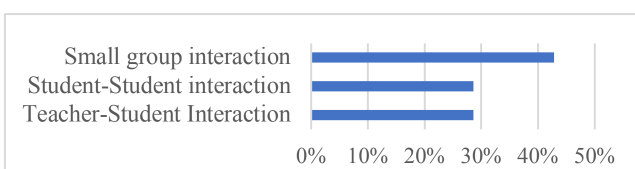

Figure 2. Frequency of scaffolding used by interaction types

The example above shows that the ELL student Eliza answered the native English speaker using different types of questions (Unit Rate [UR, Xin, 2012] and Composite Unit [CU]) in an interactive way to help each other understand the three basic elements (i.e., UR, # of Units, and Product) in elementary multiplicative problem solving. Also, the teacher was involved in the student-student interaction to ensure the accuracy of their linguistic usage and to check their understanding (such as "how many what?").

Using AntConc, we found that in the session transcripts the teacher used the phrase "how many" 111 times, while "how many towers" was used 18 times, and "how many cubes" was used 37 times. Another key word that the teacher frequently used was "PGBM" or "Please Go and Bring Me," which is the main task of a turn-taking 'platform' game PGBM (Xin et al., 2008). The authors created this game and used a simple language to name it and make it easier for ELLs with LD. The frequency of the language used by the teacher indicates that "PGBM" was used more and more often to engage the ELL in learning multiplicative reasoning and problem solving (e.g. "PGBM a tower of eleven," "PGBM six cubes").

Conclusions and Implications

In response to our research questions and in terms of the findings from our analysis, we draw the following conclusions:

1. The types of scaffolds that the teacher made in multiplicative reasoning to scaffold instruction for an ELL with LD are interactive, linguistic, visual/graphic and kinesthetic scaffolds. Among these, the kinesthetic scaffold was the most frequently used by the teacher. The teacher used finger counting as a method to show the student how to solve composite units (CU) and unit rates (UR). The second highest scaffold frequency was interactive scaffolding. We redefined and divided interactive scaffolding into three characteristics: student-student interaction, teacher-student interaction and small group interaction. The results show that small group interaction is the most effective and useful interaction that was used among the students and the teacher. Students, particularly Eliza, in the small group demonstrated a greater willingness and capacity to think and answer multiplication problems.
2. When the teacher taught multiplicative reasoning to the ELL with LD, he frequently used simple phrases such as "how many" and "PGBM." The rationale of using the linguistic scaffolding is that the teacher repeatedly used and also let students repeatedly use the simple phrase "how many" to illustrate the process of thinking and solving multiplication problems. In addition, "PGBM" characterizes the "platform" game used, which also benefits English language learners to get directions promptly and attend to multiplicative reasoning.

In general, we found that the four scaffolds in classroom discourse that the teacher frequently used with students can influence the multiplicative reasoning of the English language learner with learning disabilities and improve mathematical problem-solving achievement. We also found that kinesthetic scaffolding is the most direct method tied with helping the ELL with LD solving multiplicative problems. However, in order to better serve English language learners with LD, especially in the classroom environment, teachers should focus on better linguistic scaffolding usage within small group interactions. In our future research, we will analyze the level of intellectual work (Xin et al., 2016) done by the teacher and the students through determining how the four scaffolds promote students comprehend multiplicative reasoning at the abstract level, in particular, to meet the challenging math curriculum standards.

IDENTIFYING LATENT CLASSES OF MIDDLE GRADES TEACHERS BASED ON REASONING ABOUT FRACTION ARITHMETIC

İbrahim Burak Ölmez
University of Georgia
i.burakolmez@hotmail.com

Andrew Izsák
Tufts University
Andrew.Izsak@tufts.edu

The purpose of this study was to examine distinct latent classes of middle grades mathematics teachers with respect to reasoning about fractions. Survey response data came from a nationwide sample of 990 in-service middle grades mathematics teachers. The survey focused on four components of reasoning about fractions in terms of quantities: referent unit, partitioning and iterating, appropriateness, and reversibility. The mixture Rasch model analysis detected three latent classes, each with strengths and weaknesses. Chi-square tests indicated significant relationships between latent class membership and various teacher characteristics such as gender, mathematics credential, grade-level experience, and highest grade-level certification. The results extend recent advances in measuring mathematical knowledge of teachers.

Keywords: Data Analysis and Statistics, Rational Numbers, Teacher Knowledge

Fractions are core content in the upper elementary and middle grades mathematics curriculum and are highly interconnected to whole-number multiplication and division, and ratios and proportional relationships (e.g., Vergnaud, 1988). Additionally, fractions are necessary for algebraic reasoning and further study in mathematics (Hackenberg & Lee, 2015). Although most teachers can multiply or divide two fractions by computing correctly, many studies acknowledged the difficulties that teachers experience in reasoning about products or quotients of fractions when they are embedded in problem situations (e.g., Ball, Lubienski, & Mewborn, 2001; Lee, 2017). Despite strong emphasis by recent curriculum standards such as the Common Core State Standards for Mathematics (CCSS-M; e.g., National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010) on the necessity of developing reasoning about fraction arithmetic when solving problems embedded in situations, two main challenges exist in mathematics education. One main challenge is to foster teachers' reasoning about fractions in terms of quantities. A second main challenge is to understand how to use psychometric models for measuring teachers' fine-grained mathematical knowledge. Many recent applications of psychometric models to measure teachers' mathematical knowledge have relied on traditional item response theory (IRT) models. These efforts include the Learning Mathematics for Teaching (LMT) project (e.g., Hill, 2007), the Diagnostic Mathematics Assessments for Middle School Teachers (DTAMS) project (Saderholm, Ronau, Brown, & Collins, 2010), and the Knowledge of Algebra for Teaching (KAT) project (Senk, 2010). Traditional IRT models rely on the assumption that all examinees in a given sample belong to a single population. Some recent studies (e.g., Izsák, Orrill, Cohen, & Brown, 2010; Izsák, Jacobson, de Araujo, & Orrill, 2012), however, have demonstrated the existence of distinct latent classes of middle grades teachers. The presence of distinct latent classes violates local independence, a key assumption of traditional IRT models. To address this issue, the present study employs the mixture Rasch model (Rost, 1990), a combination of a latent class model and a traditional IRT model. When applying the mixture Rasch model, one can examine model fit for different numbers of latent classes. Each class is characterized by a distinct pattern of item responses, and differences in response patterns are thought to indicate different underlying cognitive strategies (Bolt, Cohen, & Wollack, 2001). For each examinee, the mixture Rasch model provides an estimate of ability (as does a unidimensional traditional IRT model) and a probability of class membership.

The present study used responses from a sample of 990 in-service middle grades teachers across the U.S. to the Diagnosing Teachers' Multiplicative Reasoning (DTMR) Fractions survey (Bradshaw, Izsák, Templin, & Jacobson, 2014). The survey measures teachers' capacities to reason about multiplication and division of fractions in terms of quantities. The purpose of this study was to identify distinct latent classes of middle grades teachers on reasoning about fractions and investigate the relationships between class membership and teacher characteristics such as gender, mathematics credential, grade-level experience, highest grade-level certification, and years of teaching experience. The following research questions were addressed:

1. Do distinct latent classes exist in the national sample of middle grades teachers?
2. If so, what areas of strength and weakness on reasoning about fractions distinguish the distinct latent classes?
3. Are there significant relationships between latent class membership and teacher characteristics including gender, mathematics credential, grade-level experience, highest grade-level certification, and years of teaching experience?

Theoretical Framework

The theoretical framework for this study considers middle grades teachers' reasoning about quantities and focuses on using drawings (e.g., area models and number lines) to learn and teach fraction arithmetic. We consider fine-grained components of reasoning as the property of an individual by following the constructivist perspective, in which the individual dynamically stores each component in his/her mind. We think that reasoning, which goes beyond computational fluency, requires a teacher to make sense of quantities in fraction arithmetic problems using drawings. From this standpoint, a teacher's capacity to reason about quantities with drawings can be increased by paying more consistent attention to distinct fine-grained components such as *referent units*, *partitioning and iterating*, *appropriateness*, and *reversibility* — the importance of which have been established in past research (e.g., Bradshaw et al., 2014; Izsák, Jacobson, & Bradshaw, in press) and explained later. Moreover, we take the stance that reasoning depends on context. That is, a teacher's performance about the use of one component in one situation might be appropriate, but his/her performance in another situation might be problematic, depending on the wording of the situation, the arithmetic operations required, or the representations provided. Hence, it is important to examine teachers' capacities to employ particular components across a range of problem situations.

Methods

Participants

The data consisted of survey responses from a sample of 990 in-service middle grades teachers across the U.S. (Table 1).

Table 1: Demographic information

Variables	%
Gender (*N = 976*)	
Female	75.0
Mathematics credential (*N = 974*)	
Yes	67.0
Grade-level experience (*N = 972*)	
K-5	46.0
Grades 6-8	29.0
Grades 9-12	25.0
Highest grade-level certification (*N = 971*)	
K-6	8.0
Grades 7-9	57.0
Grades 10-12	35.0
Years of teaching experience (*N = 966*)	
0-4 years	17.1
5-14 years	52.9
> 14 years	30.0

Instruments

The DTMR Fractions survey consists of two parts. The first part has 27 items (19 multiple choice and 8 constructed response) that measure four distinct components of reasoning about fractions including *referent unit*, *partitioning and iterating*, *appropriateness*, and *reversibility*. *Referent unit* deals with reasoning about units when numbers are embedded in problem situations and consists of three sub-components. *Norming* refers to the formation of standard units for measurement and occurs either in case of selecting a standard unit from alternate choices or in case of making at least two choices for a measurement unit in a given situation (i.e., renorming). *Referent unit for multiplication* and *referent unit for division* concern the problem situations that can be modeled by the equation $M \bullet N = P$ where M and N refer to different units. The second component, *partitioning and iterating*, refers to dividing a quantity into equal-sized pieces and concatenating unit fractions. It consists of three sub-components. *Partitioning in stages* refers to making a repartition to obtain a desired partition. *Partitioning using common denominators* and *partitioning using common numerators* refer to using common denominators or numerators to obtain common partitions. The third component, *appropriateness*, concerns identifying situations that can be modeled by multiplication and division and includes three sub-components: *identifying multiplication*, *identifying partitive division*, and *identifying quotitive division*. The fourth component, *reversibility*, deals with returning to a starting point after making some process. We conjecture that proficiency in use of these four components of reasoning across different problem situations enables teachers to solve fraction arithmetic problems in terms of reasoning with quantities.

Because the DTMR Fractions survey items are secure, we present one example item similar to an actual survey item (Figure 1). This item measures *referent unit* and *partitioning and iterating*. The correct choice is (b). A teacher who chose (a) or (c) would indicate confusion about the referent unit for 1/8. A teacher who chose (e) would indicate an incorrect partition (5 groups of 6 pieces that create 30ths). A teacher who chose (b) would demonstrate both the correct referent unit (the 1 meter) and the correct partition (5 groups of 8 pieces that create 40ths). The rest of the multiple-choice items were also constructed so that the different choices provided information about the four components of reasoning. A correct choice provided evidence for the components of reasoning intended for that item; incorrect choices simply indicated lack of evidence for the components of reasoning intended for that item. Constructed response items were also scored using rubrics for evidence of intended components of reasoning.

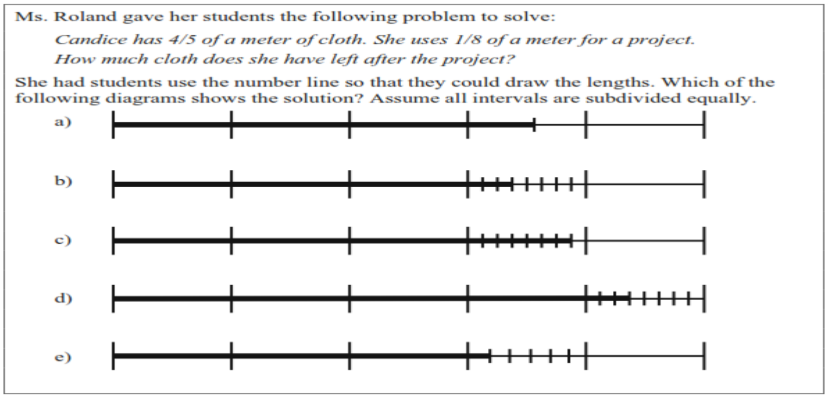

Figure 1: An item that measures referent unit and partitioning using common multiples of denominators. From Izsák et al. (2010).

The second part of the survey consists of a questionnaire to obtain information about various teacher characteristics including gender, mathematics credential, grade-level experience, highest grade-level certification, and years of teaching experience (see Table 1).

Data Analysis

We analyzed the data using the mixture Rasch model implemented in the computer program WINMIRA (von Davier, 2001). First, we estimated the mixture Rasch model with one, two, three, four, five, and six latent classes. Second, we compared three information indices to select the best fitting model: Akaike's information criterion (AIC), Bayesian information criterion (BIC), and consistent AIC (CAIC). With each of these criterion, smaller values indicate better fit. We selected the model with the smallest BIC values as the best fitting model (Li, Cohen, Kim, & Cho, 2009). Next, we analyzed the reasoning characteristics of each latent class by examining raw response data. In addition, we evaluated the relationships between latent class membership and teacher characteristics using analysis of variance (ANOVA) and chi-square tests across the latent classes.

Results

Checking Dimensionality

An exploratory factor analysis using maximum likelihood estimation as implemented in the SPSS 16.0 software (SPSS Inc., 2007) indicated eigenvalues of the first three factors as 5.1, 1.5, and 1.3, and the total variance explained by the first factor was 19%. Because the first eigenvalue was relatively large (Lord, 1980), a unidimensional model could be fit to the data.

Model Selection

Values for the three information indices are given in Table 2. Minimum values for BIC (30226.79) and CAIC (30312.79) indicated a three-class solution in the data.

Table 2: Model fit indices of the mixture Rasch model

Model	AIC	BIC	CAIC
One class	30526.03	30663.16	30691.16
Two classes	30011.27	30290.43	30347.43
Three classes	29805.59	**30226.79**	**30312.79**
Four classes	29706.11	30269.35	30384.35
Five classes	29672.67	30377.94	30521.94
Six classes	**29579.19**	30426.49	30599.49

Note. AIC = Akaike information criterion; BIC = Bayesian information criterion; CAIC = Consistent Akaike information criterion; the smallest information criterion index is bold.

Table 3 presents the descriptive statistics about raw scores for each of the three latent classes. Based on Table 3, Class-C is the least proficient latent class with the average score of 7.948 over the total score of 27, and 39% of the teachers (385 over 990 teachers) are members of this class. Moreover, Class-B is the middle proficient latent class with 19% of the teachers (184 over 990 teachers) in this class. And, Class-A is the most proficient latent class with 42% of the teachers (421 teachers over 990 teachers) in this class.

Table 3: Descriptive statistics for the latent classes.

	Class-A	Class-B	Class-C
Raw scores			
M	15.399	10.750	7.948
SD	4.165	4.265	3.529
N (%)	421 (42.5)	184 (18.7)	385 (38.8)

Analysis of Raw Response Data

To get the clearest view of the reasoning characteristics associated with each latent class, we narrowed analysis to the raw response data of the 649 teachers who were assigned to a latent class with a probability of .9 or higher. Table 4 lists the characteristics of the latent classes based on the percentage of teachers in each class who answered the survey items correctly.

Table 4: Characteristics of the latent classes (N = 649)

Component	Sub-component	Characteristic	Class-A	Class-B	Class-C
RU	Norming	Choosing a standard unit from alternate choices	Strong	Partial	Weak
RU	Norming	Renorming in the presence of proper fractions	Strong	Strong	Weak
RU	Norming	Renorming in the presence of improper fractions	Weak	Weak	Weak
RU	RU for Multiplication	Distinguishing part-of-a-part from part-of-a-whole	Partial	Partial	Weak

RU	RU for Multiplication	Reasoning when the whole is not present visually	Partial	Partial	Weak
RU	RU for Division	When quotient as a whole number	Partial	Partial	Partial
RU	RU for Division	When quotient as a fraction	Partial	Partial	Weak
PI	Partitioning in Stages	Partitioning in stages	Strong	Weak	Weak
PI	Common Denominator	Using common denominators	Strong	Weak	Weak
PI	Common Numerator	Using common numerators	Strong	Weak	Weak
APP	Identifying Multiplication	Identifying multiplication	Strong	Partial	Weak
APP	Identifying Partitive Division	Identifying partitive division	Strong	Strong	Strong
APP	Identifying Quotitive Division	Identifying quotitive division	Strong	Strong	Weak
REV	Reversibility	Reversibility	Strong	Strong	Weak

Note. RU=Referent Units; PI=Partitioning & Iterating; APP=Appropriateness; REV=Reversibility.

Finally, an exploratory examination of the latent classes obtained from the mixture Rasch analysis and an examination of the raw response data of the 649 teachers revealed the reasoning characteristics of each latent class (Figure 2). Based on this analysis, Class-C teachers perform well only in *identifying partitive division* (*Appropriateness*) problems, but have trouble in the remaining three components of fraction arithmetic (i.e., *referent units*, *partitioning and iterating*, and *reversibility*). On the other hand, Class-B teachers are found to perform well in *identifying multiplication* and *identifying quotitive division* (*Appropriateness*) problems, in addition to problems that involve *identifying partitive division* (*Appropriateness*), and in using *reversibility*. However, similar to Class-C teachers, Class-B teachers struggle with items that measure *referent units*, and *partitioning and iterating* such as *partitioning using common denominators* and *partitioning using common numerators*. In addition to having the strengths of Class-B teachers, Class-A teachers perform well in *partitioning using common denominators*, *partitioning using common numerators* and *partitioning in stages* (*Partitioning and iterating*). On the other hand, Class-A teachers have partial difficulty in *renorming* and *distinguishing part-of-a-part from part-of-a-whole* (*Referent units*). In this component, Class-C and Class-B teachers experience much more difficulty than Class-A teachers.

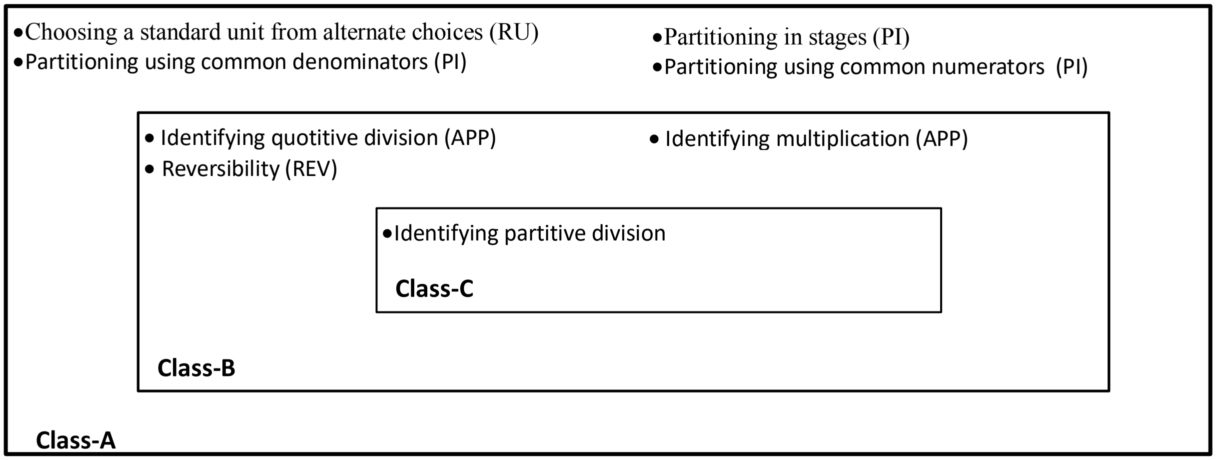

Figure 2: Identifying latent classes based on mixture Rasch analysis (N = 649).

The Relationships between Latent Class Membership and Teacher Characteristics

We also examined the relationships between latent class membership and various teacher demographic and professional history characteristics. First, we found significant differences for total mean raw scores based on ANOVA (F (2, 987) = 363.557, p = .00). The effect size (η^2) of the main effect was .42, indicating that the latent classes explained 42% of the variance in the total mean raw scores. Post hoc analyses using Scheffé's test showed significant differences of the three latent classes from each other (p = .00 for each comparison). This indicated teachers in Class-A scored significantly higher than those in Class-B, and teachers in Class-B scored significantly higher than those in Class-C. Second, a chi-square test for gender was significant ($\chi^2(2)$ = 25.40, p < .001), but Crámer's V statistic was .16, indicating a weak association between latent class membership and gender. Third, a chi-square test for mathematics credential was significant ($\chi^2(2)$ = 15.27, p < .001), indicating a relationship between having a mathematics credential and latent class membership. Fourth, the relationship between latent class membership and grade-level experience was significant ($\chi^2(4)$ = 25.07, p < .001). Fifth, the author(s) found a significant relationship between latent class membership and highest grade-level certification ($\chi^2(4)$ = 29.20, p < .001). Finally, we found a significant relationship between latent class membership and years of teaching experience ($\chi^2(4)$ = 11.92, p = .018). These results indicate that teachers who achieved higher scores, those who had a mathematics credential, those who had a high-school credential, and those who had more teaching experience tended to be in Class-A as opposed to other latent classes.

Discussion

Results of the present study demonstrate how combining research in mathematics education with psychometric models can reveal patterns in middle grades teachers' fine-grained reasoning about fractions. We used the mixture Rasch model to characterize differences in reasoning about fractions of middle grades teachers. Results for the first research question revealed three distinct latent classes. Results for the second research question indicated that teachers in the three latent classes were distinguished by their attention to norming and referent units for multiplication (i.e., *referent unit*), using common numerators (i.e., *partitioning and iterating*), identifying multiplication and division (i.e., *appropriateness*), and *reversibility*. These results extend those reported by Izsák et al. (2010, 2012). For instance, Izsák et al. (2010) found two latent classes in a convenience sample of 201 in-service middle grades teachers where teachers in one class were more proficient in *referent unit* than those in the second class. The present study used a more refined instrument and a much larger sample to refine the earlier results, found three latent classes instead of two, and identified differences across the latent classes based not only on *referent unit* but also on other components of reasoning including *partitioning and iterating*, *appropriateness*, and *reversibility*. For the third research question, we found significant relationships between latent class membership and the teacher characteristics such as mathematics credential, grade-level experience, highest grade-level certification, and years of teaching experience, as similar to the results of Hill (2007) and Izsák et al. (in press). Future studies should continue examining teachers' mathematical knowledge using innovative measures and applications of diverse psychometric models, including the mixture Rasch model.

REFLECTED ABSTRACTION AS A MECHANISM FOR DEVELOPING PEDAGOGICAL CONTENT KNOWLEDGE

Michael Tallman
Oklahoma State University
michael.tallman@okstate.edu

John Weaver
Oklahoma State University
john.weaver@okstate.edu

Tallman (2015) argued that pedagogical content knowledge is a form of content knowledge with particular characteristics that endow it with pedagogical utility, and he conjectured that an essential characteristic of a teacher's content knowledge is her conscious awareness of the mental actions and conceptual operations that comprise her mathematical schemes. We report the results of a study that explored this conjecture by examining the pedagogical implications of engaging a pre-service secondary teacher in a mathematical intervention to support her construction of a powerful scheme for constant rate of change and to engender her conscious awareness of the mental processes that constitute this scheme.

Keywords: Pedagogical content knowledge; Reflecting abstraction; Mathematical knowledge for teaching; Pre-service teacher education

Researchers have long been concerned with conceptualizing the knowledge base that enables teachers to effectively support students' conceptual mathematical learning. Shulman's (1986, 1987) notion of *pedagogical content knowledge* (PCK), which he defined as a "special amalgam of content and pedagogy," represents a significant advance to this end (1987, p. 8). While researchers since Shulman have strived in various ways to elaborate the PCK construct, there is an aspect of Shulman's initial conceptualization that is almost never abandoned: the notion that PCK is a combination of content knowledge and pedagogical knowledge (Depaepe, Verschaffel, & Kelchtermans, 2013). Although many researchers follow Shulman in defining PCK as an amalgam of knowledge of content and knowledge of pedagogy (e.g., Ball, Thames, & Phelps, 2008; Fennema & Franke, 1992), the relationship between these distinct types of professional knowledge, as well as the specifics of their synthesis, remains elusive.

To investigate the relationship between teachers' content knowledge and their instructional actions, Tallman (2015, in submission) compared an experienced secondary mathematics teacher's knowledge of sine and cosine functions with the knowledge he enacted in the context of teaching. Through this comparison, Tallman identified the influences that affected the nature and quality of the subject matter knowledge the teacher leveraged in his lesson planning and instruction. Tallman's analysis revealed that the inconsistencies between the teacher's personal and enacted mathematical knowledge resulted from him possessing weak connections and multiple schemes for particular concepts related to trigonometric functions, as well as from his unawareness of the mental actions and conceptual operations that comprised these often powerful but uncoordinated cognitive schemes. Tallman concluded from these results that PCK is a form of content knowledge with particular characteristics that endow it with pedagogical utility; he argued that the pedagogical character of PCK derives from the specific ways in which a teacher's content knowledge informs her enactment of effective pedagogies. Additionally, Tallman conjectured that an essential characteristic of a teacher's content knowledge is the extent to which she is consciously aware of the mental actions and conceptual operations that comprise her own mathematical schemes.

In this paper, we report the results of a study that explored this conjecture by examining the pedagogical implications of engaging a pre-service secondary teacher in a mathematical intervention to support her construction of a powerful scheme for constant rate of change and to engender her conscious awareness of the mental processes that characterize this scheme. We leveraged Piaget's (2001) notion of reflected abstraction to stimulate such conscious awareness.

Theoretical Background

Piaget proposed abstraction as the mechanism of scheme construction and refinement and distinguished five varieties: *empirical*, *pseudo-empirical*, *reflecting*, *reflected*, and *meta-reflection* (Piaget, 2001). We discuss only *reflecting* and *reflected* abstraction because of their unique role in the construction and refinement of mathematical schemes and because these two types of abstraction served as design principles and analytical constructs in the present study. Reflecting abstraction involves the subject's reconstruction on a higher cognitive level of the coordination of actions from a lower level, and results in the development of *logico-mathematical knowledge*, or schemes at the level of *operative thought*. Reflecting abstraction is thus an abstraction of actions and occurs in three phases: (1) the *differentiation* of a sequence of actions from the effect of employing them, (2) the *projection* of the differentiated action sequence from the level of activity to the level of representation, or the reflected level, and (3) the *reorganization* that occurs on the level of representation of the projected actions (Piaget, 2001). A subject must differentiate (dissociate) actions from their effects before she can construct an internalized representation of them, what Piaget called projecting actions to the level of mental representation (i.e., the "reflected level"). Additionally, the subject must coordinate the actions that produced the effect before she can project and represent them on this higher cognitive level. Once a subject differentiates actions from their effect and coordinates them, she is prepared to project these coordinated actions to the reflected level where they are organized into cognitive structures, or schemes.

Reflected abstraction involves operating on the internalized actions that result from prior reflecting abstractions, which results in a coherence of actions and operations accompanied by conscious awareness. It is the act of deliberately operating on the actions and operations that result from prior reflecting abstractions that engenders such awareness. To consciously operate on actions at the level of representation suggests that one has symbolized coordinated actions at this higher level. Reflected abstraction thus relies on what Piaget called the *semiotic function*, or the subject's capacity to construct mental symbols to represent aspects of her experience. As a result of the conscious awareness of internalized actions that occurs as a byproduct of reflected abstraction, the subject's ability to purposefully assimilate new experiences to the reflected level provides evidence that she has engaged in reflected abstraction. Additionally, performing operations on the symbols the subject constructs to represent coordinated actions at the level of representation results in increasingly organized cognitive structures. Reflected abstraction is therefore the means by which systems of organized actions at the level of representation become progressively coherent and refined.

Conceptual Analysis of Rate of Change

As we mentioned above, we engaged a pre-service secondary teacher in a mathematical intervention to support her construction of a particular scheme for rate of change. In this section, we briefly describe the meanings we designed the intervention to support.

A mature rate of change scheme relies upon productive conceptualizations of ratio, rate, and continuous variation. A *ratio* is a multiplicative comparison of the measures of two constant (non-varying) quantities while a *rate* defines a proportional relationship between varying quantities' measures (Thompson & Thompson, 1992). Constructing a rate therefore involves images of smooth continuous variation (Thompson & Carlson, 2017), as well as the expectation that as two quantities covary, multiplicative comparisons of their measures remain invariant.

A rate is a reflectively abstracted constant ratio (Thompson & Thompson, 1992, p. 7), which means that constructing a rate involves internalizing the coordinated actions involved in multiplicatively comparing particular values of covarying quantities. An individual has done so if on the basis of her conceptualization of a particular quantitative situation she anticipates that subsequent multiplicative comparisons of the covarying quantities' measures will yield the same numerical value.

Rate of change is a quantification of two covarying quantities and results from a multiplicative comparison of changes in covarying quantities' measures. The rate of change is constant if changes in the quantities' measures are proportional. Conceptualizing changes in quantities' measures as quantities themselves involves a quantitative operation with attention to a point of reference (Joshua et al., 2015). Conceptualizing rate of change requires students to construct changes in quantities' values as quantities themselves and then to abstract an invariant multiplicative relationship between changes in the quantities' values.

Methods

This study's experimental methods proceeded in four phases. First, we video recorded all nine lessons from a pre-service secondary teacher's instruction of rate of change and slope in a 7th grade class during her student teaching semester. We then asked the participant, Samantha, to use the data analysis software Studiocode (Studiocode Version 5.8.4, Sportstec, Ltd., 2015) to identify segments of her first two lessons that exemplify high quality instruction as well as segments that indicate room for improvement. She wrote brief justifications for each selection. Samantha performed this analysis of her teaching videos independently and met with the research team after she had finished to answer clarifying questions and to provide additional rationale for her written responses. We then conducted a teaching experiment (Steffe & Thompson, 2000) during the third phase of the study to construct a model of Samantha's scheme for constant rate of change and to characterize the evolution of this scheme as she engaged in particular instructional experiences designed to promote reflecting and reflected abstractions. The teaching experiment consisted of eight teaching episodes that each lasted between 60 and 90 minutes. During the fourth phase of the study, we asked Samantha to analyze five teaching videos (including the two she analyzed prior to participating in the teaching experiment) using the codes "High Quality Instruction" and "Room for Improvement" and to provide written rationale for her selections. We again interviewed Samantha to probe her justifications for her selections and to ask focused questions about the segments of her instruction she identified as exemplars of high- or low-quality teaching. Our focus in the fourth phase of the study was to determine whether the criteria by which Samantha evaluated the quality of her instruction had changed, and to identify the role played by her content knowledge in making such evaluations.

Results

Due to space limitations, we discuss only our analysis of the data relevant to Samantha's first lesson on rate of change.

Samantha's Instruction of Rate of Change

Samantha began her teaching of rate of change by asking students to describe what they think of when they hear the word "rate" and to provide examples of rates. She then defined a rate as "a ratio of two quantities with different units" and described a unit rate as "a rate with a denominator of one." After defining these terms, Samantha asked students to interpret the meaning of a car traveling at a constant speed of 65 miles per hour. She validated a student's response, "You're traveling 65 miles in an hour" and then restated for the rest of the class the student's interpretation: "Every 65 miles that I travel, that's an hour of time; or if I travel for an hour, I've gone 65 miles." Samantha then asked students to "find the unit rate in miles per hour" if a car travels 155 miles in two hours. After students divided 155 by two, Samantha explained that the resulting 77.5 represents the number of miles the car travels each hour.

Samantha's definition of rate as a "ratio of two quantities with different units" supported students' understanding of constant rate as the change in some quantity's measure that corresponds to a one-unit increase in another quantity's measure. Her discussion of the meaning of a vehicle traveling at a constant rate of 65 miles per hour is a case in point. She encouraged a meaning based on a coordination of additive changes, instead of a proportional correspondence between continuously varying changes in accumulated distance and accumulated time.
Toward the end of the lesson, Samantha asked her students to compute the unit rate provided the values in Table 1. Her discussion of computing this unit rate supported a conception of rate as an additive comparison grounded in images of discrete variation. In response to the task, a student proposed dividing the weight of two books (6 lbs.) by the number of books—a reasonable strategy considering that just prior to this task the class had computed the unit rate of a car traveling 155 miles in two hours by dividing the car's distance traveled (155 miles) by two hours. Another student recognized that the number of pounds per book was evident in the third column of the table (3 pounds corresponds to one book). Samantha noticed that the two students were focusing on comparing the *values* in the table, rather than determining the *change* in the number of pounds that corresponds to adding one additional book. She subsequently directed students' attention to these changes.

Table 1: Find the unit rate.

Books	0	1	2	3
Pounds	0	3	6	9

Samantha's Pre-Intervention Video Analysis

After Samantha concluded her instruction of rate of change, but prior to the teaching experiment, we asked her to watch the videos of her first two lessons and to identify moments that exemplify high quality instruction as well as moments that suggest room for improvement. She categorized her opening discussion—in which she asked students to describe what they think of when they hear the word "rate"—as indicating room for improvement. In her written justification Samantha explained,

> I like that I ask students what they think of when they hear the word 'rate.' However, I think there is room for improvement because I tend to talk to one student (whoever answers the question) instead of addressing the whole class with the student's answer.

Samantha identified her explanation of the meaning of 65 miles per hour as representing high quality instruction and rationalized her selection as follows:

> I think this portion went really well because we really isolated what a unit rate is. I used speed limits because I knew it was something the students could understand. I liked that I asked the students what '65 miles per hour' means. When a student explained it using the same words found in the question, I asked if another student would repeat what he said but say it in their own words. I thought this was an effective way to get more than just one

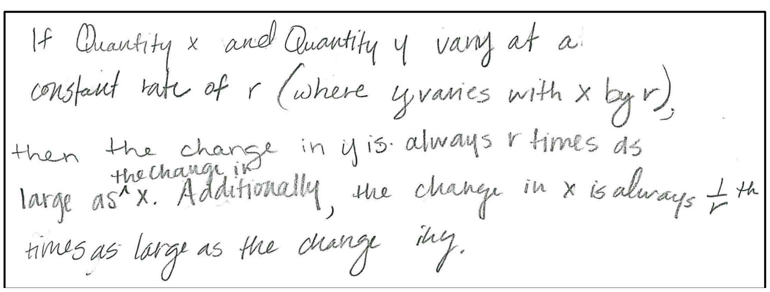
> student involved and to check that others understood the concept. Additionally, I liked that I had students give several examples. This helped me to see that they knew what a unit rate was and it kept them engaged.

We notice that Samantha prioritized students' engagement and participation as important criteria for evaluating the quality of her teaching. This focus on students and their activity was reflected in five of the six written justifications she provided for her selections. Samantha's appraisal of her teaching was based primarily on the extent to which she sustained students' interest and elicited their contributions. None of her written responses reflected a critical evaluation of the meaning of rate of change her instruction supported.

Teaching Experiment

We leveraged Piaget's notion of reflecting and reflected abstraction to design an instructional sequence that would enable Samantha to construct a scheme for rate of change that reflects the meaning we articulate in our conceptual analysis above. This instructional sequence unfolded over nine teaching episodes. On many occasions throughout the teaching experiment, Samantha repeatedly and convincingly demonstrated her understanding of constant rate of change as an invariant multiplicative relationship between changes in the measures of covarying quantities.

To engender reflected abstractions—that is, to support Samantha's awareness of the mental actions and conceptual operations that comprised her rate of change scheme—we provided Samantha with her written work to particular tasks in the instructional sequence and prompted her to compare the thinking required to correctly solve select pairs of tasks. We asked her to articulate her comparison in writing and then to respond to our clarifying questions about what she had written. Although the tasks in the instructional sequence varied substantially in terms of the information provided and the quantity Samantha was asked to compute or represent, all tasks in the sequence could be solved by leveraging a meaning for constant rate of change as a proportional correspondence between changes in covarying quantities' measures. After having recognized that similar or identical thinking is required to solve all 12 pairs of tasks from the instructional sequence we asked her to consider, we prompted Samantha to summarize in writing the meaning for rate of change that might enable a student to reason productively about all tasks in the instructional sequence. We include her response in Figure 1.



If Quantity x and Quantity y vary at a constant rate of r (where y varies with x by r), then the change in y is always r times as large as the change in x. Additionally, the change in x is always $\frac{1}{r}$ th times as large as the change in y.

Figure 1. Samantha's meaning for constant rate of change.

At the conclusion of the teaching experiment, Samantha was able to demonstrate her conception of constant rate of change as a proportional relationship between changes in covarying quantities' measures and to articulate the mental imagery, actions, and operations that comprised her meaning for constant rate of change. We were interested in assessing the implications of Samantha's sophisticated rate of change scheme and her awareness of its contents for the criteria she leveraged to evaluate her teaching and to propose alternative instructional actions.

Samantha's Post-Intervention Video Analysis

Just as she had done in her pre-teaching experiment video analysis, Samantha identified the opening discussion of the first lesson as indicating room for improvement. In this discussion, Samantha invited students to describe what they think of when they hear the word "rate" and to suggest some examples of rates. Prior to the teaching experiment, Samantha critiqued this episode of her first lesson based on her lack of success in getting more students involved in the discussion. The following is Samantha's justification for identifying this opening discussion as "room for improvement" after having participated in the teaching experiment:

> I think there is room for improvement here because I think there is a better way to introduce rates. I feel like asking students what they think of when they hear a word is a fine way to get them talking and engaged but it doesn't direct the conversation to the mathematical meaning of a rate. Instead, this question sort of just starts a guessing game between myself and the students rather than engaging in mathematical discourse. … I could've started the conversation off by posing a question like, 'Clara runs 7 miles per hour. How far will she run in 2 hours?'

We were interested in why Samantha suggested posing the question, "Clara runs 7 miles per hour. How far will she run in 2 hours?" so we asked her write a transcript of a hypothetical alternative to the opening discussion from the first lesson and to explain why she prefers this alternative. After having asked students to determine how far Clara will run in two hours, Samantha's transcript indicated her asking them to determine how far Clara will run in three hours, half an hour, and 4.3 hours. She then prompted students to generalize a (multiplicative) relationship between Clara's distance traveled (in miles) and the number of hours Clara had spent running. The following is Samantha's explanation for why she expected this alternate introduction to be more effective than how she actually began her first lesson:

> I think this interaction reflects an ideal unfolding of the conversation because we start with a basic example that is easy to understand (i.e. Suppose Clara runs 7 miles per hour. How far will she run in 2 hours?) This part gives students an easy starting point to use. Then I ask some follow up questions, like how far would she go in half an hour, another good benchmark. I move on to give an example that needs a little more explanation so that we can start thinking about how to break up the time (4.3 hours) and figure out what the respective number of miles is. It's not as obvious as 4 hours and I could have even chose something like 0.59 hours instead. … I think that opening with these examples fosters a conversation of how to find rate of change and what it means for those quantities to vary directly. The end of the conversation opens up many routes; we could talk about finding time and then add some initial values and dig into changes in quantities.

Samantha's alternate introduction to the first lesson reflects both her image of what it means to understand constant rate of change as well as her expected trajectory through which students must progress to construct this understanding. Rather than proposing instructional actions that simply elicit students' participation, Samantha's transcript and accompanying rationale demonstrate that her criteria for effective teaching had shifted to incorporate attention to the mathematical meanings her instruction supported.

The transformation in the criteria by which Samantha evaluated the quality of her teaching was evident in her analysis of other episodes from the first lesson. Regarding her definition of rate as a "ratio of two quantities with different units," Samantha commented:

> I'm not really a huge fan of doing a ton of definitions so I don't know why I did this. I don't think I would use this definition (the book definition) for rate again. Although it connects rates to ratios, it doesn't really give any meaning to rates. One could recite this definition without actually knowing how to do any problem that involves rates.

Samantha's appraisal of her discussion of what it means to say that a car travels at a constant speed of 65 miles per hour similarly reflected her attention to the understanding of rate she promoted:

> I think we are getting closer to what I would really like conversations about rate to look like. This is what I would call the first stage of understanding rates of change. The students seem to have an understanding that 65 miles per hour means that for every hour traveled, one goes 65 miles. I think this a great place to start conversations about rates of change. Maybe some other contexts could get the conversation moving further so we could generalize the idea by talking about changes in quantities.

Additionally, Samantha expressed contrition for asking students to determine the unit rate provided the values in Table 1. Specifically, she acknowledged that the context did not support students' conception of rate of change as conveying a relationship between *changes* in quantities' measures:

> I see what I am getting at here. I am trying to get at the idea of changes in pounds for changes in books and how that is a rate. Honestly, the examples I chose aren't the best for trying to make students think hard about changes in quantities. The problems are almost trivial, clearly every book is three pounds. Once students see that, it's hard to get them to talk about changes in quantities because the answer to the question has already been found and can be explained simply.

Samantha critically evaluated the mathematical meanings her instruction supported in 14 of the17 justifications she provided for the segments of her lessons that exemplify high quality instruction or indicate room for improvement. In Samantha's initial analysis of her teaching videos, none of her written responses suggested that she was attending to the understanding of rate of change her instruction promoted. This shift in the criteria by which Samantha evaluated her teaching quality did not escape her attention. When asked what she initially considered when evaluating her instruction, Samantha explained, "I think it was student engagement, using something the students care about or would be interested in, asking good questions, getting them to repeat back." Samantha acknowledged the importance of attending to issues of classroom management and students' participation, but then suggested that instruction viewed only through this lens does not enable one determine whether students are being provided with opportunities to construct productive ways of understanding. Having come to this conclusion, Samantha described the additional criterion that she considered after having engaged in the teaching experiment to assess the quality of her teaching:

> As we went over rate and what it means to be a rate together, I started thinking more about what am I doing to promote understanding. … Going back I think cared a lot more about classroom management versus when I went back and looked at these I acutely cared about, ok wait, is this promoting understanding. … I cared more about what they knew.

Discussion

Our findings expose a common assumption that underlies much of the literature on mathematical knowledge for teaching as well as mathematics teacher preparation and professional development programs: Mathematical knowledge for teaching is comprised of a variety of distinct but related knowledge "types" that coalesce in the practice of teaching. Mathematics teacher education programs based on this assumption focus on supporting teachers in developing these categories of knowledge without seriously attending to how knowledge in one domain informs or derives from knowledge in another. The central findings of our study suggest that teachers' image of effective teaching—and the pedagogies they enact to ensure that their practice conforms to this image—are influenced by having constructed powerful mathematical schemes and by having achieved an awareness of the mental actions and conceptual operations that comprise these schemes. The results of our study therefore support Tallman's (2015, in submission) hypothesis that engaging pre-service teachers in mathematical experiences designed to engender reflecting and reflected abstractions has positive implications for their image of effective teaching and the pedagogical actions they enact (or envision enacting) to achieve their instructional goals.

INVESTIGATING HOW A MEASUREMENT PERSPECTIVE CHANGES PRE-SERVICE TEACHERS' INTERPRETATIONS OF FRACTIONS

Muteb M. Alqahtani
State University of New York at Cortland
muteb.alqahtani@cortland.edu

Arthur B. Powell
Rutgers University-Newark
powellab@newark.rutgers.edu

Learning fractions has been one of the challenges that mathematics educators face for few decades. Theoretical and empirical revisions of our common practices of teaching fractions are needed. This study investigates how re-examining fractions from a measurement perspective influences pre-service teachers' (PSTs) interpretations of fractions. Sixty-seven PSTs engaged in re-examining fractions from a measurement perspective during a 15-week semester. They also completed pre- and post-tests that assess their interpretations of fractions represented in discrete and continuous models. Findings show statistically significant increase in PSTs' scores on the post-test, specifically on questions that used continuous models. This study shifts investigating fractions learning from an exclusive focus on the partitioning perspective to the measurement approach and highlights its affordances.

Keywords: Teacher Knowledge, Number Concepts and Operations, Rational Numbers, Instructional activities and practices

Introduction

Supporting students' meaningful learning of fractions has been a prominent challenge of mathematics educators. Teachers struggle to help students from early ages to conceptualize fractions and know how to operate on them. Research on teachers' and students' learning of fractions and operations on fractions has been based on two ontological perspectives: partitioning and measurement. The partitioning perspective views a fraction as a relation established between parts of a whole partitioned into equal parts. This ontological perspective is rooted in a belief that counting is the basis for arithmetic and has led to the commonly accepted part/whole conception of fractions. For instance, it is how the Common Core State Standards (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010) suggests introducing factions in the elementary school grades. Nevertheless, research indicates that this perspective seriously limits the robustness of students' understanding of fractions (Kerslake, 1986). It tends to support the erroneous idea that a fraction is composed of two different quantities and impedes understanding of improper fractions. Little research has investigated the known alternative source for fraction knowledge, the measurement perspective.

In response to this conceptual gap in the literature, we investigate how a measurement approach influences elementary pre-service teachers' (PST) interpretations of fractions. In contrast to a part/whole conception a measurement conception views fractions as numbers or ordered pairs that represent relations between two measurable, continuous quantities (Davydov & Tsvetkovich, 1991; Gattegno, 2009/1960). The relation is a multiplicative comparison of the two quantities measured by the same unit. The comparison is based on one quantity being a particular multiplier of the other. In our work with PSTs, we aim to investigate how their knowledge of multiple of representational models of fractions is influenced by their re-examination of fractions from a measurement perspective.

Theoretical Framework and Relevant Literature

Research on fraction learning indicates that both American students and teachers lack conceptual knowledge of fractions and operations on fractions. This deficiency coexists with current curriculum standards and textbooks grounded in known ineffective ontological and epistemological perspectives about fractions (Ni & Zhou, 2005). These perspectives and their corresponding curricular practices are based on partitioning approaches such as the part/whole method (Lamon, 2012). However, though the part/whole subconstruct and its partitioning approach are conceptually deficient, what is not known is how other definitional perspectives facilitate robust conceptual understanding of fractions. Measurement as an ontological source for fraction knowledge has been the object of limited research efforts. Informed by theoretical work of Davydov and Tsvetkovich (1991), we conceptualize the ontology of fractions and epistemology of fraction knowledge based on the objective source of fractions in measurement.

We view a *fraction* as a relation, a/b, a multiplicative comparison between two quantities measured by the same unit: Suppose A and B are two objects that have a common extensive attribute such as length expressed as quantities with a common unit, u, where A equals a units of u and B equals b units of u. Then, in the expression, a/b, b is understood to measure a and a/b is the relation of a measured by b. The quantities a and b have the same unit of measure.

Measurement as a material source of both whole numbers and fractions has been theoretically and pedagogically investigated by Davydov and others who have adapted Davydov's curriculum (Davydov & Tsvetkovich, 1991; Morris, 2000; Schmittau & Morris, 2004). The contributions of Morris (2000), Schmittau and Morris (2004), Brousseau (Brousseau et al., 2008), Davydov (Davydov & Tsvetkovich, 1991) and others to understanding affordances of a measurement perspective for whole number and fraction knowledge raises questions about what are possible approaches from a measurement perspective that can support students, younger than fourth graders, to develop number sense about fractions.

Methods

Our empirical study engages pre-service elementary teachers in an intervention about re-examining fractions from a measurement perspective to investigate changes in their knowledge of representational models of fractions. The intervention took place in an elementary mathematics methods course during a 15-week semester, fall 2017, and involved 67 PSTs. During the first week of the semester, the teachers completed a pre-test about fractions that involves expressing different fractions in discrete and continuous representations. In the last week of the semester, teachers completed the same assessment as a post-test. For approximately one hour every two weeks, the teachers used Cuisenaire rods to solve collaboratively fractions tasks. From a measurement perspective, the tasks intend to engage the PSTs in re-examining their number sense about magnitude, order, equivalence of fractions, and operations on fractions viewed as relations that express multiplicative comparisons between two measurable quantities measured by common unit.

Data for this study come from pre- and post-tests that PSTs completed during the first and last weeks of the semester. We adopted a fraction test created by Norton and Wilkins (2010) that involves representing fractions less than one and greater than in discrete and continuous models. The discrete problems ask PSTs to represent fractions of collections of dots. The continuous problems ask PSTs to represent fractions using rectangular and circular models. Each test includes 10 questions that involve only two of the representational models of fractions. We followed Boyce and Moss's (2017) method in grading PSTs' responses on the tests. They would receive either a one, 0.5, or a zero depending on the accuracy of their response. We used *t*-test to examine differences in responses between pre- and post-tests and among the different interpretations of fractions.

Results

Analyses of pre- and post-tests scores show an increase from before and after the intervention (see Table 1). On the pre-test, the PSTs scored an average of 2.96 out of 5 points on the five questions for each representational model. This indicates that PSTs have limited interpretations of fractions when expressed in different forms. The PSTs' scores on the post-test show statistically significant increase compared to their scores on the pre-tests. The scored an average of 3.53 points out of five total points. Even though this increase is significant, the scores indicate that some PSTs still need additional support to develop robust understanding of fractions.

Table 1: Pre- and Post-Test Scores

	Pre-test	Post-test
Mean	2.96	3.53
Median	3	4
Standard deviation	1.24	1.22
The t-value is 3.78762. The p-value is .000094. The result is significant at $p < 0.001$.		

When investigating PSTs' responses for each representational model (see Table 1), we can see that PSTs scored higher in the pre-test on questions that used circular models than questions that used discrete models or bars. This performance was also noticeable in the post-test. However, the most gain in scores between the pre- and post-tests was on questions that used bars to represent fractions. Using a *t*-test, we found that PSTs scores on questions that used bars increased significantly ($p < 0.001$) between pre- and post-test. Similarly, PSTs' scores on questions that used circular representations increased significantly ($p < 0.05$) between pre- and post-test. There was no statistically significant change in scores regarding questions that used discrete model to represent fractions.

Table 2: PSTs' Pre- and Post-Test Scores by Fractions Representational Models

	Bars		Circles		Dots	
	Pre	Post	Pre	Post	Pre	Post
Mean	2.59	3.56	3.47	3.71	2.79	3.34
Median	3	3.5	3	4	3	3.75
Standard deviation	1.30	1.27	1.02	1.12	1.25	1.28
Significance level (t-test)	$p < .001$		$p < .05$		not significant	

These results show that re-examining fractions using a measurement perspective can influence how PSTs interpret fractions represented in a rectangular or circular form. The rectangular model be a two-dimensional version of the three-dimensional manipulatives used during the intervention and this could explain the strong change in PSTs' scores on questions that used bars to represent fractions. The circular model, however, is mathematically different than the rectangular model. Circular models concern areas of circles and circular sectors where rectangular models concern the length of the bar or rectangle (only one dimension of the rectangle while holding the other dimension constant). Even though the intervention did not engage the circular models when re-examining fractions, PSTs were able to better interpret fractions when expressed using circles and circular sectors. This shows the potential that a measurement perspective can offer when introducing fractions.

Discussion

In this study, we examined the influence of re-examining fractions from a measurement perspective on PSTs' knowledge of fractions expressed through different representational models. Using Cuisenaire rods, we engaged 67 PSTs in mathematical tasks that allowed them to view fractions as multiplicative comparisons between two measurable, continuous quantities (length of different Cuisenaire rods). The PSTs completed a pre-test before the intervention and a post-test afterward. The pre- and post-tests included questions about interpreting fractions using rectangular, circular, and discrete forms. Findings show that, in general, PSTs scored significantly higher on the post-test. When examining the different representational models of fractions, PSTs scored significantly higher on the post-test for the questions that involve rectangular and circular representations of fractions. There was not significant change on PSTs' scores on post-test for questions that involve the discrete model. These findings show that re-examining fractions using a measurement perspective offers opportunities for PSTs to engage their multiplicative reasoning (Vergnaud, 1988) when conceptualizing fractions.

Our findings for the analysis of PSTs' scores on the pre-test, which are similar to the findings of Boyce and Moss (2017), highlight how PSTs' knowledge of fractions is limited, especially for fractions represented in continuous models. The significant changes in PSTs' scores on the post-test indicate that the affordances of measurement perspective can help learners overcome some of the challenges of conceptualizing fractions in different forms.

Our study is significant for practice. It supports teachers building deep understanding and flexible representational models of fractions, which, in turn, lead to improving students' fractions learning. In addition, this study contributes to the literature of teaching and learning of fractions by shifting from an exclusive focus on the partitioning perspective to an attention to the measurement approach to highlight its affordances.

KNOWLEDGE RESOURCES FOR PROPORTIONAL REASONING IN DYNAMIC AND STATIC TASKS

In this study, we consider the knowledge resources invoked by middle school teachers as they solve two related proportional reasoning tasks. For one task, teachers were asked to think aloud about a situation in which an artist is asked to create a larger image. The other task was administered in a clinical interview setting and asked questions about the relationship in size between bears in a dynamic sketch in which one bear dilated. Analysis focused teachers' reasoning. Findings focus on the knowledge resources that were invoked. Implications focus on why the knowledge resources matter and opportunities for additional research.

Keywords: Teacher Knowledge, Technology, Number Concepts and Operations

Purpose and Background

In this study, we consider how teachers solved two mathematical tasks with similar underlying mathematics. One of the tasks relied on a dynamic sketch created in Geometers' SketchPad, while the other was a traditional paper and pencil task. Our interest in conducting this research came from noticing that teachers engaged with the mathematics differently in the dynamic environment than in the paper-based environment. Our research questions for this study were: (a) What knowledge resources do teachers invoke when they solve the dynamic task correctly?; (b) What knowledge resources do teachers invoke when they solve the dynamic task incorrectly?; and (c) How are the knowledge resources used in the dynamic environment similar to or different from those used in a paper and pencil task with similar content?

The tasks of interest in this study both required teachers to differentiate between situations that are and are not proportional. We built from a growing body of work (e.g., De Bock, Van Dooren, Janssens, & Verschaffel, 2002) investigating high school students' inappropriate use of proportionality. Across a number of studies, the researchers found that students overuse proportional approaches in situations that appear proportional but are not.

We rely on knowledge in pieces (KiP; diSessa, 1988, 2006) as our conceptual framework, which posits that knowledge is organized as fine-grained knowledge resources and that these resources are interconnected in ways that make them available in a wide range of settings. From this perspective, learning is achieved through the development of new knowledge resources, the refinement of existing resources, and/or the development of connections between resources.

Methods

We used a convenience sample of 32 in-service middle grades mathematics teachers from four states in the U.S. Their teaching experiences ranged from one to 26 years. Of the participants, 24 identified as female and eight as male. Five participants identified as Black, one as Biracial, and the rest as White. Participants taught at a variety of schools including urban, suburban, and rural schools that were public, private, or charter.

Participants completed two different types of interviews. The first was a think-aloud protocol that was mailed to them. The second interview was a one-hour clinical interview recorded using two video cameras to capture the participant's voice as well as any writing, pointing or use of Sketchpad during the interview.

Table 1: Most frequently occurring knowledge resources found in this study

Resource Type	Code	Description
Proportional Reasoning Resources	Constant ratio	Recognizes the invariant multiplicative relationship between two quantities.
	Scaling up/down	Uses multiplication to scale both quantities to get from one ratio in an equivalence class to another.
	Horizon knowledge	Demonstrates knowledge that extends into mathematics beyond proportions.
	Rule	Shares a verbal or written rule (e.g., Red = Blue - 2) stated in a way that conveys a generalizable relationship.
Pedagogical Resources	Anticipates or builds from others' thinking	Talks about what others would or might do in solving a problem or builds from the mathematical thinking of others.
Representation Resources (not unique to proportional reasoning)	Problem solving	Uses static or dynamic representations to support reasoning about and solving the problem. This includes sense-making. This is also exploratory and happens during problem solving.
	Justifying or communicating	Uses the representation to explicitly justify or explain a position already developed, rather than to solve a task.
	Conjecture testing	Makes a conjecture and then tries it out with the representation.

We developed a coding scheme (e.g. Charmaz, 2014) to identify the proportional knowledge resources being invoked by the participants. Two or more members of the team individually coded each utterance. Then the codes were discussed until 100% agreement was reached. Codes were applied based on mathematical reasoning used rather than correctness. The knowledge resources relied upon by the most teachers in the two tasks for this study are shown in Table 1. The resources fall into three categories: proportional reasoning, pedagogy, and representations.

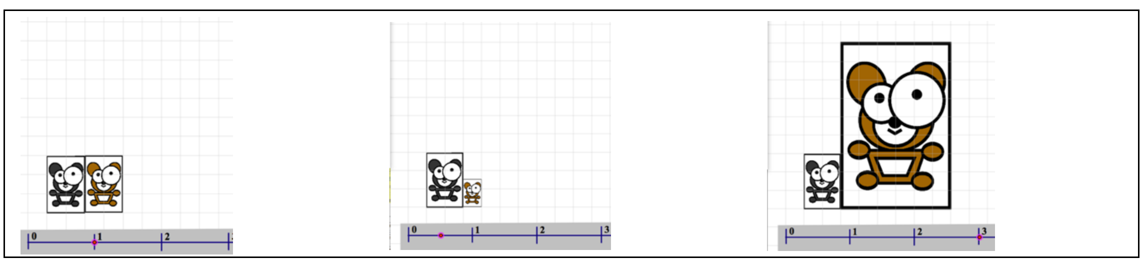

Figure 1. Screenshots of the bears task.

The Bear task presented the participants with a pair of bears (Figure 1). The bear on the left remained static, while the one on the right dilated as the point on the number line was dragged. During the clinical interview, participants were asked to interact with Bears in SketchPad Explorer to answer a series of questions.

The Santa Task was modified from De Bock et al.'s (2002) task to be more appropriate for teachers. The task asked teachers to consider that 56 cm high Santa was painted on a bakery door using 6 ml of paint. The painter was asked to create an enlarged version of the painting on another window. The new painting would be 168 cm high. The task asked how much paint was needed for the larger image. Three scaffolds were included to support appropriate reasoning.

Results

By the end of the series of questions around the Santa task, 13 of the 32 (41%) teachers correctly recognized that the area situation was not proportional and reasoned accurately. For the Bear task, 26 of the 32 teachers (81%) correctly identified proportional relationships.

Table 2. Number of participants using and frequency of use for each knowledge resource.

	Santa Task		Bear Task	
	# of teachers	# of occurrences	# of teachers	# of occurrences
Constant Ratio	1	1	17	25
Scaling Up/Down	21	33	22	55
Horizon Knowledge	5	7	20	34
Rule	2	2	21	58
Anticipates/Builds on others' thinking	16	26	2	2
Problem solving with representation	3	3	24	113
Justify/communicate with representation	6	8	29	97
Conjecture test with representation	2	3	15	30

The most common proportional reasoning knowledge resource used by participants in both tasks was Scaling Up/Down (see Table 2). Nearly two-thirds of the participants demonstrated evidence of this knowledge resource in both tasks. A typical Scaling comment in the Santa task was, "… if our figures are in fact proportional, this would have to be multiplied by three" (Ella, all names are pseudonyms). Here, Scaling was used to support an incorrect answer.

The only non-representation focused knowledge resource commonly used in the Santa task was Anticipates or Builds on the Thinking of Others (hereafter referred to as Anticipates). We conjecture that this pedagogically-focused code was commonly used in this task because all of the scaffolds asked the teacher to interpret students' thinking in some way. As shown in Table 2, this knowledge resource was used by 16 participants when solving the Santa task.

In the Bears task, participants used more knowledge resources. This was likely tied to the difference in interview format as there was an interviewer to ask follow-up questions here, but not for Santa. Perhaps because of the nature of the task, the role representations played in teachers' reasoning was more pronounced in the Bears Task with those three representation resource codes (in the gray rows of Table 2) being used commonly. The three representation resource codes in Table 2 were used by participants regardless of their reasoning (linear or area). For an utterance to be coded as one of these three codes, the participant had to use the sketch to explore a mathematical idea or explain their thinking to the interviewer by demonstrating the idea on the sketch. In addition, 21 participants were able to correctly generate a rule for the given dynamic situation. Constant Ratio was demonstrated by 17 of the participants while solving the Bear task. Horizon knowledge was evident for 20 participants while solving the Bear task.

Discussion and Implications

Scaling up and down was the only knowledge resource used consistently between the two tasks. This is notable because scaling can be accomplished through additive or repeated reasoning (e.g., Kaput & West, 1994) and suggests these teachers may have relied on additive reasoning rather than multiplicative reasoning in these tasks. In the Bears task, the same participants relied on two proportional reasoning knowledge resources: describing a rule for the relationship and reasoning with a constant ratio. In contrast to the common Scaling resource, reasoning with a constant ratio requires attention to the multiplicative relationships inherent in the proportion. While the format of the interview was different, we suspect the difference in presentation drove some of the differences in approach. This was corroborated by the high number of teachers who relied on the dynamic sketch to make sense of and solve the Bear task.

The use of particular knowledge resources matters because it highlighted the degree to which teachers reasoned about the situation rather than solving tasks. There is ample evidence that proportional reasoning is too often focused on solving a proportion (e.g., Lamon, 2007) rather than reasoning about the relationships between quantities. From the limited data presented here, we suggest that moving toward dynamic environments may support more reasoning about proportional situations. In our findings, we particularly note that over half the participants reasoned about one of the key structural aspects of a proportion, the constant ratio, in the dynamic environment. Similarly, the dynamic representation seemed to have opened avenues for teachers to draw on a broader body of knowledge as well as create meaningful generalizations about relationships in the Bear task. If our goal in engaging teachers in mathematical situations is to help them build connections between their knowledge resources, it appears that Bears was more effective in supporting that goal. We hypothesize the ability to generalize may be tied to the infinite instances inherent in the dynamic situation. This is an area for additional research.

HIGH SCHOOL TEACHERS' CONTENT KNOWLEDGE AND KNOWLEDGE OF STUDENTS' ERRORS ABOUT QUADRATIC FUNCTIONS

Qintong Hu	Ji-Won Son	Lynn Hodge
Columbia College, SC	University at Buffalo, SUNY	The University of Tennessee
qhu@columbiasc.edu	jiwonson@buffalo.edu	lhodge4@utk.edu

This study examined forty high school algebra teachers' content knowledge as well as their knowledge of students' errors about quadratic functions through a teaching-scenario task. The teachers' responses were analyzed quantitatively and qualitatively. Analysis results show that the teachers have sufficient content knowledge and they performed better on translating among different representations of quadratic functions than on solving a real-world problem by using quadratic functions. Most of the teachers identified students' obstacles in translating from algebraic to graphic representations of quadratic functions and they tended to respond in a teacher-centered procedural way. The implications of this study for teacher education programs as well as professional developments are presented in accordance with the findings.

Keywords: Algebra and Algebraic Thinking, Mathematical Knowledge for Teaching

Algebra has long been regarded as a critical bridge to high school mathematics. National Council of Teachers of Mathematics [NCTM] (2000) highlighted the importance of algebra to all students. Among all the high school algebraic topics, quadratic functions are fundamental and essential (Even, 1990), given that it is a critical transition from straight lines to curves. To help students achieve both conceptual understanding and computational proficiency of the topic, teachers were suggested to have solid content knowledge (Harris & Sass, 2011; Hill, Rowan & Ball, 2005) as well as a variety of pedagogical content knowledge, which has been recognized directly relates to students' mathematics achievement and this relationship starts from upper-elementary grades (Campbell, et al., 2014). Among all the categories of teachers' pedagogical content knowledge, we explored teachers' knowledge of student errors because NCTM (2000) suggested that recognizing and responding to student errors appropriately is one of the main tasks of teachers in teaching mathematics. Additionally, researchers indicated that student errors provide teachers windows into student understanding that should be endeavored to help students develop conceptual basis of their errors (Ball, 1990; Borasi, 1994).

As for content knowledge, we examined how high school teachers apply quadratic functions to solve a real world problem and how they transform among different representations of quadratic functions. The reasons why these two aspects were investigated are that generating equations to represent the relationships in typical word problems has long been recognized as one of the major areas of difficulty for high school algebra students (Clement, 1982; Kieran, 1992) and that teachers should emphasize cultivating students' algebraic thinking in a way that enables "the use of any of a variety of representations that handle quantitative situations in a relational way" (Kieran, 1996, p. 4, 5). In terms of teachers' knowledge of students' errors, we studied how they interpret and respond to students' learning obstacles in translating from graphic to algebraic representations of quadratic functions. The specific research questions are:

1. How do high school teachers use quadratic functions to solve real world problems?
2. How do high school teachers transform among different representations of quadratic functions?

3. How do high school teachers interpret and respond to students' errors about translating from graphic to algebraic representations of quadratic functions?

Theoretical Framework

Zaslavsky (1997) summarized a few common obstacles related to students' understanding of quadratic functions. First, it is hard for students to imagine the parabola as extending forever. Second, students confused about the relation between quadratic functions and quadratic equations. They missed the fact that though $x^2 + 2x - 3 = 0$ is equivalent to $2x^2 + 4x - 6 = 0$, the function $F(x) = x^2 + 2x - 3$ is not equivalent to $F(x) = 2x^2 + 4x - 6$. Third, they prefer going from equations to graphs rather than from graphs to equations. Also, they prefer the standard form to the vertex or the factored form of quadratic functions. Later on, Eraslan (2005) systematically explored two honors Algebra II students' obstacles in learning quadratic functions. He found that the students struggled to translate quadratic functions from graphic to algebraic representation, tended to use the standard form over the vertex form, and failed to use quadratic model to solve problems given in real-world situations. In addition to high school students, preservice teachers also struggled to integrate algebraic and graphic representations of functions (Huang & Kulm, 2012). This relates to the current study, in that, we asked participants to respond to a students' error in a teaching scenario where the student is challenged to represent a parabola by algebraic equations.

Employing student errors as springboards to develop worthwhile mathematics inquiries, Borasi (1994) suggested that a consistent use of error analysis enables students to better understand the nature of mathematics, facilitates the learning of significant mathematical content, make students more proficient in doing mathematics and make them more confident in their ability to learn and use mathematics. In order to use students' errors constructively, Seifried and Wuttke (2010) suggested that teachers need to be competent in three aspects, including knowledge of possible error types, available strategies of reaction, and a constructive view on errors. Nevertheless, few research examined students' errors in learning mathematics, much less known is information about students' errors on specific and fundamental mathematics concepts, especially variable, equation, and function (Li, 2006).

Analyzing participants' responses and explanations to students' errors, we examined mathematical focus, pedagogical actions, form of address, degree of student error use and communication barriers (see Table 1).

Table 1: Analytical Framework for Teachers' Responses to Students' Errors

	Aspect	Categories
Global	1 Mathematical/ instructional focus	Conceptual vs. procedural
	2 Pedagogical action(s)	Re-explains, suggests cognitive conflict, probes student thinking, etc.
Local	3 Form of address	Show-tell vs. give-ask
	4 Degree of student error use	Active, intermediate, or rare
	5 With/without communication barrier	Over-generalization, a Plato-and-the-slave-boy approach, or a return to the basics, specific

Methods

Twenty Chinese and twenty U.S. high school teachers, who are currently teaching or have taught Algebra I topics before, joined the study and finished a questionnaire including two math problems and a teaching-scenario task. The first math problem was adopted from Chinese text *ShuXue*, the most frequently used text in China, to examine how the teachers abstract an algebraic expression of quadratic functions to solve a real world problem. The second math problem aiming to explore the participants' knowledge of transformation among different representations of quadratic functions was adopted from Vaiyavutjamai's study (2009). The teaching-scenario task, where a student was required to write an algebraic equation for a given parabola but she didn't know where to start, was from Eraslan's work (2005).

To answer the research questions, this study applied grounded theory inquiry (Strauss & Corbin, 1994). As for teachers' content knowledge, we checked the correctness and explanations of the teachers' responses. In terms of responses to students' errors, the authors individually analyzed and coded the participants' responses according to the analytical framework while looking for new categories. We reached a satisfying agreement rate between 75% and 90%.

Results

Teachers' Content Knowledge of Quadratic Functions

We found that the teachers performed well on using quadratic functions to model real-life situations and further to solve problems. More than half of the teachers have chosen to apply the vertex form of quadratic functions, which is a wise choice because the vertex of the quadratic function is given and in this way the calculation process becomes easier. While most of the teachers used the vertex form, twenty-five percent of the teachers employed the standard form. Although both the standard and vertex forms of quadratic functions can be used to solve the problem, the teachers who applied vertex form showed deeper procedural knowledge than the teachers who employed the standard form because they were flexible in terms of choosing an appropriate form to represent functions and they did this based on the real-world situation. Six percent of the teachers showed conceptual knowledge of the problem in the way that they attempted the problem by using different methods as well as explained the solution by using different representations of the quadratic functions and analyzed the effects of parameters on the graphs of the functions (we plan to show examples in the presentation).

Transforming from graphic to algebraic representations of quadratic functions, all the teachers solved the problem correctly. Similar to their performance on modeling a real-life situation, more than half of the teachers applied the vertex form that showed deep procedural knowledge. Three teachers demonstrated their conceptual knowledge by identifying the operations and transformations played on the parent function $y = x^2$ to get the formula for the transformed parabola.

Teachers' Knowledge of Students' Errors

The teachers identified the student's (Amy) learning obstacles in reading graphs, choosing appropriate form of quadratics, and applying the method of undetermined coefficients. Among the teachers who identified Amy's knowledge deficiency, half of them recognized more than one piece of her learning obstacles. When the participants responded to Amy, they chose either to focus on conceptual knowledge that help Amy to solve this type of problems or to emphasize showing her the problem solving procedures. However, procedural explanation is a dominated method, which is not a surprise since most of the teachers solve problems procedurally themselves. With respect to procedural knowledge, most of the teachers demonstrated how to find three points from the given graph and plug the coordinates of the points into the standard form of the quadratic function to get three equations. Among the teachers who tried to build conceptual knowledge for Amy, some suggested to use the relationship between graphs and algebraic expressions, function transformation knowledge while the others explained how it would be more helpful to use the vertex or the factored form over the standard form.

Providing guidance to help Amy finish the problem, most of the teachers responded in a teacher-centered way. Since Amy did not make any mistake, the teachers barely used her errors but directly taught her how to solve the problem. More than sixty percent of the teachers guided Amy to finish the problem in a specific way, which means there is no communication barrier between the teacher and Amy and she is expected to finish the problem independently later on. Also, around thirty percent of the participants gave general instructions that provide a direction to solve this type of problems, for example, some of the teachers explained the rationale of the method of undetermined coefficients. However, this type of explanation will not help Amy solve the problem directly and probably causes more confusions for her.

Discussion and Conclusions

We found that the high school teachers have sufficient content knowledge about quadratic functions and they did better on translating among different representations of functions than on using quadratic functions to solve real world problems. Most of the teachers showed deep procedural and procedural knowledge and they responded to students' errors in a procedural way. A few teachers demonstrated conceptual understanding of quadratic functions but not all of them explained to Amy conceptually. Except knowledge focus, teachers who showed conceptual knowledge and those who presented procedural knowledge are consistent in terms of the pedagogical strategies used to respond to Amy. This study provides implications to teacher educators and professional developers. The teachers' emphasis on providing teacher-centered instruction points to the need for teacher educators to give preservice teachers opportunities to practice pedagogical strategies about responding to students' errors. Professional developers should consider content intensive sessions to develop teachers' content knowledge on problem solving, especially on abstracting a mathematical model from real world situations and using the mathematical model to solve problems.

To improve teaching and learning in content courses for secondary mathematics teachers, we take the approach of supporting faculty who teach these courses – often mathematics faculty – in developing their own mathematical knowledge for teaching (MKT) at the secondary level. We describe a framework that has informed the design of educative curricula for a set of these courses. This framework integrates theory for knowledge development, empirical work on dimensions of knowledge used in teaching, and findings on observable behaviors in teaching that reveal prospective secondary teachers' knowledge development.

Keywords: Mathematical Knowledge for Teaching, Teacher Education – Preservice

Mathematics teacher preparation programs for all levels aim to provide opportunities for prospective mathematics teachers (prospective secondary teachers) to develop mathematical knowledge for teaching (MKT) (e.g., CBMS, 2012). Yet, mathematicians, who often teach content courses for secondary preparation programs (Murray & Star, 2013), who may have much to offer in the way of mathematical knowledge, often do not have experience teaching in K-12 settings. They may not be positioned to notice nuances in the development of prospective secondary teachers' MKT at the secondary level (Lai, 2016), especially on tasks that situate mathematics in pedagogical contexts. This problem exacerbates existing tensions between intended outcomes of secondary preparation programs and teachers' perceptions that their mathematical preparation is irrelevant to their teaching (e.g., Goulding, Hatch, & Rodd, 2003).

One approach to this problem is developing educative curricula (Davis & Krajcik, 2005). We take this approach, focusing on curriculum supports for mathematics faculty to learn MKT at the secondary level and ways to observe and analyze the development of prospective secondary teachers' MKT, particularly in enactments of approximations of practice (Grossman et al., 2009). In this paper, we discuss a framework that has informed the design of educative curricula for mathematics faculty teaching content courses for secondary level prospective secondary teachers. This framework integrates theory for knowledge development, empirical work on dimensions of knowledge used in teaching, and findings on observable behaviors in teaching that reveal prospective secondary teachers' knowledge development. Such a framework is potentially a critical resource for supporting mathematics faculty in teaching MKT. Our purposes in this paper are to describe this novel framework, and how it can support mathematics faculty in learning MKT and providing substantive feedback to prospective secondary teachers about their MKT, and serve as a resource to refine research on learning and teaching MKT.

Conceptual Foundations

To construct the framework, we integrated Rowland and colleagues' Knowledge Quartet framework for observing MKT and Ader and Carlson's (2018) framework for analyzing and observing teaching with Silverman and Thompson's (2008) developmental framework for MKT. We take MKT to be "practice-based theory of knowledge for teaching" (Ball & Bass, 2003, p. 5) and follow Thompson, Carlson, and Silverman (2007) in taking MKT to include coherent and generative understandings of key ideas that make up the curriculum.

The empirical analysis of mathematics teaching at the elementary and secondary level underlying the Knowledge Quartet suggests four dimensions of observable MKT: Foundation (knowledge of mathematics and its nature), Transformation (presentation of ideas to learners), Connection (sequencing of material for instruction), and Contingency (the ability to respond to unanticipated events) (Rowland, Thwaites, & Jared, 2016).

Ader and Carlson's (2018) framework for analyzing instructional interactions identifies levels of understanding and acting on student thinking in terms of teachers' mental actions and observable behaviors. They characterized teachers' executions of responses to student thinking in terms of Piaget's (1977/2001) notions of decentering and reflective abstraction.

The Knowledge Quartet and Ader and Carlson's framework can be used to articulate Silverman and Thompson's (2008) framework for use in educative curricula for teacher education, as we detail in the next section. Silverman and Thompson used Simon's (2006) idea of key developmental understandings (KDUs) in combination with decentering and reflective abstraction to construct stages of MKT development. Although they described components of development, but they did not elaborate where these components might be observed in actual teaching practice or in approximations of practice, or how one instance of decentering or reflective abstraction may be more sophisticated than another.

Framework for Observing and Analyzing the Development of MKT

The framework we use is based on the work described above and then refined based on the analyses of 15 secondary prospective secondary teachers' responses to an approximation of practice used in a mathematics content course, which has been used at three different institutions in different states in multiple years. The responses analyzed are representative.

Table 1: Framework for Observing and Analyzing the Development of MKT

Developmental component[a]	Knowledge dimension[b]	Mental actions[c]	Level (L), in terms of observable behaviors[d]
Personal KDU	Foundation	Reflective abstraction on personal math. knowledge	L1: Performs procedures within topic L2: Describes procedures accurately L3: Connects isolated features to underlying concepts L4: Connects structure of procedure to underlying concepts
Decentering applied to Activities and Analyzing Potential for Student KDU	Transformation	Reflective abstraction on student thinking	Gives explanations, representations, and examples that: L1: Describe only procedures L2: Describe own way of thinking L3: Attempt to change students' current thinking L4: Enhance students' understanding
	Connection		Poses questions that: L1: Focusing on procedures or echoing key phrases L2: May reveal student thinking, but then gives explanations while not asking students to provide reasoning L3: Attempts to move students' reasoning L4: Supports advancing students' reasoning
	Contingency		Responses to student thinking: L1: Do not act in any visible way upon the thinking L2: Evaluate but do not use the thinking in teaching L3: Directly use the thinking L4: Frames questions or explanations in terms of students' thinking, to make connections and deepen understanding

Note: Levels here depend on the KDU. This is just one possible example of how levels may appear. Constructs for each column were refined through our analysis and based on: (a) Silverman and Thompson, 2008; (b) Rowland, Thwaites, & Jared, 2016; (c) Piaget, 1977/2001; and, (d) Ader and Carlson, 2018

Discussion: Uses of Framework in Teacher Education

The framework presented in this paper is a resource for implementing and writing educative curricula in teacher preparation, as well as for future research in the learning and teaching of MKT. In terms of implementing curricula, we used the framework to inform guides for faculty to use when interpreting and responding to prospective secondary teachers' work. Differentiating between the dimensions of MKT used can support faculty in noticing different kinds of knowledge in teachers and providing more explicit feedback. Foundation, Connection, and Transformation emphasize potential differences among a prospective secondary teacher's display of personal knowledge, providing explanations to students, and posing questions that elicit student reasoning. Although faculty may not traditionally make these distinctions in providing feedback in a mathematics course, these distinctions are also ones that may be familiar to faculty and may well be informative educative for their own teaching practice (e.g., Pascoe & Stockero, 2017).

It is worth noting that our analysis indicated that the dimensions of knowledge were independent in the context of prospective secondary teachers' enactments of approximations of practice, a context for which the dimensions had not been previously analyzed. This suggests that development of MKT may well proceed along these dimensions in different ways. One prospective secondary teacher in our dataset explained the connection between a definition and procedure as a rationale for a task they would assign to their students (Foundation, L4), but only posed questions that focused on echoing key phrases (Connection, L1), proposed only explanations of procedures to the students (Transformation, L1), and did not acknowledge any of the sample student thinking provided by approximation of practice (Contingency, L1). Another prospective secondary teacher began with using the provided sample student work to make a specific mathematical point about a definition (Contingency, L4) then did not provide any subsequent examples or explanations to connection of procedure and definition (Transformation, L1).

In our own work writing approximations of practice for use in content courses and hearing initial feedback from mathematics faculty, articulating how observables may correspond to knowledge dimensions has prompted us to think more clearly about the opportunities presented by approximations of practice. For instance, in an early draft of an approximation of practice, we asked prospective secondary teachers to respond to student thinking, but we did not give a clear mathematical goal for the teaching situation. This left unspecified the Foundation knowledge we were aiming to elicit, which impacted the Transformation and Connection knowledge visible in prospective secondary teachers' responses.

Finally, the framework supports validating and refining the articulation of the development of MKT. We view this framework as a set of testable hypotheses grounded in known results. At the same time, we have drawn from work in emergent stages. We see great opportunity in using this framework, which unifies work from different groups, to push researchers' understanding of the development of MKT. Future work made visible by this framework includes investigating how well these codes hold up to responses to approximations of practice across content courses; whether the interpretation of levels for the purpose of providing feedback to teachers improved teaching and learning outcomes; and the independence or dependence of levels and dimensions. As Morris and Hiebert (2009) argued, a professional knowledge base – such as that for teaching mathematics courses for prospective secondary teachers – can only advance with shared goals and artifacts that articulate those goals for the professional community in ways that can be observed. We propose a framework that articulates the goal of developing teachers' MKT in terms of actions observable in approximations of practice used in content courses. Our framework simultaneously leverages theory for the development of MKT, empirical analyses of teaching, and empirical analyses of approximations of practice used in content courses.

We aim to develop a theoretical foundation for the knowledge needed by mathematics teacher educators to support prospective teachers in developing the knowledge needed for teaching. We have approached this goal by exploring existing frameworks that not only generalize conceptualizations of teacher knowledge, but also position teacher knowledge as a subdomain of the knowledge needed for teaching teachers. We envision this generalization to teacher educator knowledge as a "fractalization" of teacher knowledge. Applying this concept, we propose our own fractalization model for the knowledge of mathematics teacher educators and discuss some resulting consequences.

Keywords: Mathematical Knowledge for Teaching, Teacher Knowledge, Post-Secondary Education, Teacher Education-Preservice

Mathematics teacher educators (MTEs) have long considered the knowledge needed for teaching mathematics to be distinct from the knowledge needed for doing mathematics. Much work has been done in explicating the domains of Mathematical Knowledge for Teaching (MKT, e.g. Ball, Thames, & Phelps, 2008), but researchers are only beginning to explore the knowledge needed by MTEs to help prospective teachers (PTs) develop the knowledge needed for teaching. We aim to develop a theoretical foundation for the mathematical knowledge for teaching teachers (MKTT) by analyzing, synthesizing, and extending existing literature on MTE knowledge. In this paper, we will discuss several proposed frameworks that conceptualize teacher educator knowledge as a generalization of teacher knowledge. That is, these frameworks not only position teacher knowledge as a subdomain of teacher educator knowledge but also echo the structure of teacher knowledge. Our analysis of these frameworks led us to use "fractalization" as a metaphor for this generalization, as the visualizations of many of these frameworks resemble part of a fractal. We propose a model of MTE knowledge that applies this fractal metaphor to the MKT framework (Ball et al., 2008), begin to conceptualize the subsequent domains of MKTT knowledge, and discuss some consequences of framing MKTT as fractalization of MKT.

Frameworks of MTE Knowledge that Use Fractalization

In synthesizing the extant frameworks for understanding teacher educator knowledge, we noticed that several frameworks generalized teacher knowledge in a way that we envisioned as following a "fractalization" model (Welder, Prasad, Superfine, & Olanoff, 2017). Below we will explore four examples of such frameworks and discuss how they follow this model of fractal generalization.

In his 1985 presidential address at the meeting of the American Educational Research Association, Lee Shulman identified three aspects of teacher knowledge: *content knowledge*, *curricular knowledge*, and *pedagogical content knowledge*, which he called the "missing paradigm" in the study of teaching (Shulman, 1986). Chauvot (2009) has expanded Shulman's (1986) framework to develop a knowledge map for MTEs. In this model, she identifies the knowledge base for "Math Teacher Educator-Researchers" as being comprised of *subject matter content knowledge*, *pedagogical content knowledge*, and *curricular knowledge*. Her model fractalizes Shulman's work by placing all three of his domains of knowledge for teaching within the *subject matter content knowledge* of MTEs. Her map also integrates Grossman's (1990) *knowledge of context* to consider how the context in which MTEs work (i.e., university-based teacher preparation, school-based professional development, etc.) affects what they need to know.

Similarly, Zaslavsky and Leikin (2004) have fractalized Jaworski's (1992) model for the practice of teaching mathematics to better understand the practice of teaching teachers of mathematics. Jaworski's model, known as the "teaching triad of mathematics teachers," highlights the interactions among three important components of teaching: *challenging content for students* (mathematics), *the management of students' learning*, and *sensitivity to students*. Zaslavsky and Leikin created analogous terms for aspects important to the teaching of teachers: *challenging content for mathematics teachers*, *the management of mathematics teachers' learning* and *sensitivity to mathematics teachers*. In developing their "teaching triad of MTEs," Zaslavsky and Leikin consider Jaworski's "teaching triad for math teachers" to be contained within the component of *challenging content for mathematics teachers*.

Perks and Prestage (2008) propose a "teacher-educator knowledge tetrahedron," as an expansion of their "teacher knowledge tetrahedron." Both frameworks highlight the interactions among four aspects of classroom practice: *teacher knowledge*, *learner knowledge*, *professional traditions*, and *practical wisdom*. However, in the teacher-educator knowledge tetrahedron, the learners in question are prospective or practicing teachers; thus, in this meta-framework, the teacher knowledge tetrahedron is entirely contained within the learner knowledge portion of the teacher-educator knowledge tetrahedron.

Another example of fractalization can be noted in Ball's (2012) proposal to expand a model she and her colleagues offered for the instructional dynamics that affect student learning (Cohen, Raudenbush, & Ball, 2003). This expanded framework models the instructional dynamics that affect the learning of teachers. Both models highlight the ways in which *teachers* and *students* interact with each other and how they interact with the *content* of interest. In the case of teacher education, the *teachers* are teacher educators, the *students* are teachers, and the *content* of interest now encompasses the entirety of the original model.

Fractalization of the MKT Framework

Applying the idea of fractalization, we propose a model of MKTT that extends the MKT framework developed by Ball and her colleagues (Ball et al., 2008) to a set of analogous domains of teacher educator knowledge (see Figure 1). We are considering all aspects of MKT as being comprised within the overall *subject matter knowledge* needed by MTEs. On the other hand, MTEs' *pedagogical content knowledge* encompasses the mathematical knowledge needed for working with prospective and practicing teachers (i.e., adult learners, rather than K-12 students). We envision this knowledge to encompass the ways in which PTs interact with the mathematical content they will be teaching and effective methods for facilitating their relearning of mathematics in a way that will support their development of MKT (Castro Superfine, Welder, Prasad, Olanoff, & Eubanks-Turner, in press). While we have a general idea of what this conception of MKTT requires of MTEs, characterizing the specific aspects of the subdomains of MKTT requires further exploration.

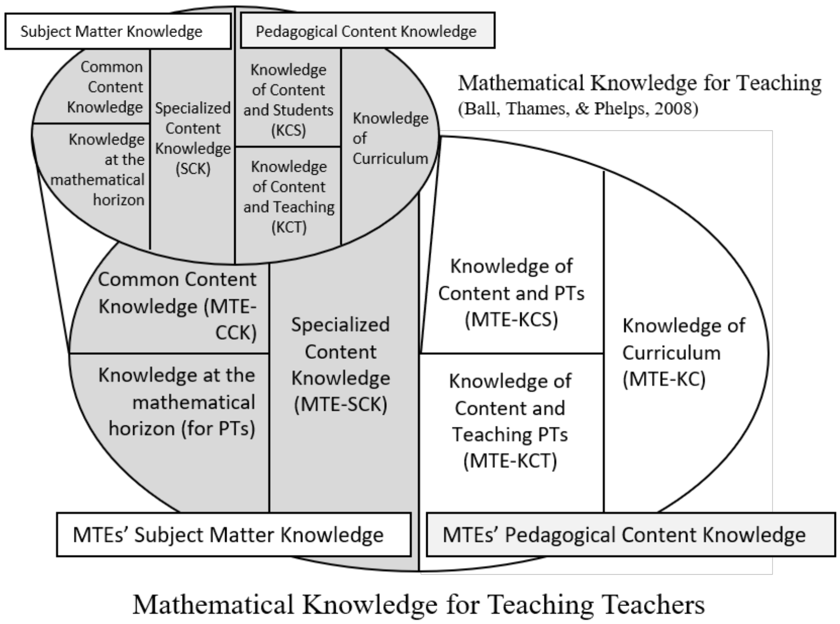

Figure 1. Our "Fractalized" Model for Mathematical Knowledge for Teaching Teachers

Discussion

Conceptualizing MKTT as a fractalization of MKT provides a basis for a framework for the knowledge needed for teaching teachers. We believe further exploring fractalization models will allow researchers an entry point into theorizing about the unique aspects of MKTT that exist separately from MKT. It is important to note that one consequence of this conception is that MKT becomes a subset of MKTT. This implies that MTEs' knowledge must include all aspects of MKT at the level of mathematics teaching for which they are preparing PTs. Given the varied academic and experiential backgrounds of MTEs (including research mathematicians and mathematics educators who have not had experience teaching in K-12 contexts), this requirement may be logistically impossible. On the other hand, if facilitating PTs' development of MKT is considered a goal of teacher preparation, it could be argued that the MTEs teaching courses for PTs would need to possess such knowledge.

Another aspect of MKTT that needs to be further explored within this fractalization model is the role that MTEs' knowledge of research plays in their practice of teaching teachers. There is no clear analogue between a domain of MKT and MTEs' knowledge of research, as most frameworks for teacher knowledge do not explicate knowledge of research. Yet, research is an important component of the work of many MTEs and is thus part of their knowledge base. Of the frameworks we have discussed, Chavot's (2009) is the only one that makes explicit reference to knowledge of research, situating it uncomfortably in the middle of her framework for MKTT.

In this report we have explored a subset of frameworks for MTE knowledge that utilize a fractalization model of teacher knowledge. However, different frameworks of teacher knowledge exist, and may also lend themselves to conceptualizations of MKTT, perhaps through a form of fractalization. Additionally, there are frameworks for teacher-educator knowledge that are not conceptualized as fractalizations of teacher knowledge. Such frameworks may have different consequences for the development of a knowledge base for teacher educators, and there is further work to be done in exploring them.

EXAMINING TEACHER KNOWLEDGE RESOURCES FOR PROPORTIONAL REASONING VISUALLY

Chandra Hawley Orrill

In this paper, we rely on Epistemic Network Analysis to examine the connections between knowledge resources to understand the coherence of teachers' knowledge resources used in solving proportional reasoning tasks. Our findings show that teachers who scored lower on the LMT tended to use more knowledge resources and to coordinate knowledge resources in less systematic ways than those teachers who scored higher on the LMT. We also noted a shift from strategies suggest additive reasoning to strategies that focus on the multiplicative nature of proportions. Implications for teacher development and for further research are included.

Keywords: Cognition, Teacher Knowledge, Mathematical Knowledge for Teaching

Introduction

Research suggests that, like students, teachers struggle with proportional reasoning (e.g., Harel & Behr, 1995). However, the research on teachers' knowledge is still somewhat limited. We have ample evidence that teachers have trouble solving some kinds of tasks (e.g., Harel & Behr, 1995; Pitta-Pantazi & Christou, 2011) and some studies that provide in-depth descriptions of how one teacher or a small number of teachers approached particular tasks (e.g., Riley, 2010). We sought to better understand how teachers use their existing knowledge resources across a set of tasks so we could determine which tasks may need to be further developed. To better understand how teachers reason about a variety of proportional situations we asked:

1. What proportional reasoning knowledge resources do these middle school teachers use to solve a diverse set of proportional tasks?
2. Are there differences in the resources used by teachers who exhibit higher or lower levels of knowledge on a multiple-choice assessment?

Theoretical Framework

This research is grounded in the Knowledge in Pieces perspective (KiP; diSessa, 2006). KiP asserts that people develop understandings as fine-grained knowledge resources that can be refined and connected to other resources to create a more coherent set of understandings. Having well-connected knowledge resources allows access to more ideas *in situ*. Thus, expertise could be seen as developing more knowledge resources and more connections between and among those knowledge resources. This is consistent with research on expertise (Bédard & Chi, 1992).

Methods

Data were collected from 32 in-service middle school teachers (grades 6-8) from four states. The teachers reported having between one and 26 years of teaching experience. Twenty-four were female and eight were male. Five participants identified as Black, one as Biracial, and 26 as White. The participants taught in a variety of schools including urban, suburban, and rural schools as well as public, private, and charter schools.

We collected three kinds of data from each participant. The first was the *Learning for Mathematics Teaching* (LMT, 2007) assessment for Proportional Reasoning. For each teacher, a single score was calculated that reports the logit score for the teacher in standard deviations from the mean. Teachers' scores ranged from -0.563 to 2.657 on the LMT. The second data source was a one-hour think aloud interview protocol that was mailed to each teacher along with a LiveScribe pen that captured their utterances and any inscriptions at the same time. The third data source was a video-recorded one-hour clinical interview with each teacher. The tasks for both interviews asked the teachers either to solve a proportional situation or to make sense of hypothetical students' or colleagues' mathematical thinking.

Both the clinical interview and think-aloud protocol were transcribed verbatim. We coded each using a code set that was developed using grounded theory techniques that allowed us to build from the literature as well as from the trends emerging in the data (Charmaz, 2014). Each utterance was coded using a binary approach to determine whether each code was present in the data. In all, there were 18 codes specifically focused on proportional reasoning concepts for which each utterance was coded (Weiland, Orrill, Brown, Nagar, & Burke, 2016). Every interview was coded by at least two members of the research team.

To understand the knowledge resources used, we relied on Epistemic Network Analysis (ENA; Shaffer, Collier, & Ruis, 2016) to understand in what ways the knowledge resources were connected. ENA is a computational modeling technique that focuses on the connections between elements. ENA was developed to model connections between elements (knowledge resources) and to show the strength and association among elements in a network (Shaffer et al, 2016). Using ENA, an equiload graph was generated to examine teachers' responses based on the group means, where groups were defined by LMT performance. The equiload graph shows each knowledge resource as a node. The lines connecting the nodes indicate that two resources were used in the same task multiple times (a proxy for connectedness of resources, e.g., Chesler, et al., 2013). These equiload graphs were developed using ENA Webkit software (http://www.epistemicnetwork.org/).

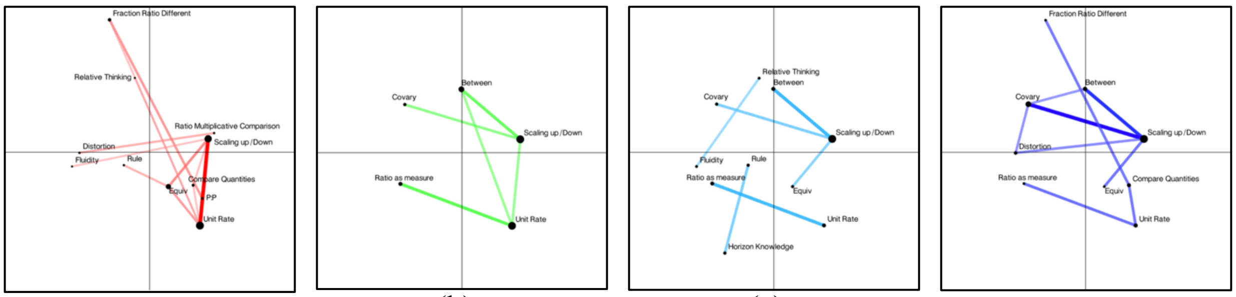
Findings

To understand the knowledge resources used by the teachers in this study, we organized teachers into groups based on LMT scores: (a) teachers scoring -1 to 0 (*n*=3; referred to as Group A), (b) teachers scoring between 0 and 1 (*n*=11; referred to as Group B), (c) teachers scoring from 1 to 2 (*n*= 9; referred to as Group C), and (d) teachers scoring between 1 and 2 (*n*=9; referred to as Group D). Figure 1 presents the mean equiload graphs for each of these groups. In the equiload graphs, it is clear that some co-occurrences of knowledge resources were much more frequent than others. For example, in Figure 1a, the co-occurrence of Scaling Up/Down and Unit Rate is much bolder than the other co-occurrences, indicating that it was a more common pairing than some of the others. For Figure 1a, the co-occurrence of Unit Rate and Scaling Up/Down occurred in a total of 14 tasks across the three participants in this group. Given that there are 35 tasks in all, this means that the co-occurrence of Scaling Up/Down and Unit Rate occurred in 12% of the tasks for this subgroup. Similarly, in Figure 4d, the heavier line between Scaling Up/Down and Covary indicates relatively more co-occurrences between these resources. In fact, across the 9 participants in Group D, there were 33 co-occurrences of this pairing (10%), with many of those pairings occurring not just within the same task, but also within the same utterance.

Expertise as Knowing More and Having More Connections

Consistent with the KiP perspective, the participants in this study exhibited a number of different connections between knowledge resources. Further, within each group we see several resources and different kinds of connections between those knowledge resources. If we use the

LMT scores as a measure of teachers' knowledge, then the weakest teachers in this study would be those scoring between -1 and 0 on the LMT (Group A). Group A participants relied on the connection between Scaling Up/Down and Unit Rate, which are additive approaches. The reliance on this pairing was lessened in Group B (see Figure 1b), where Ratio as Measure was paired with Unit Rate and Scaling Up/Down was paired with Between Measure Space reasoning. We also note that Group B has fewer connected resources showing in the mean equiload graph, indicating that their knowledge resources are potentially better organized.



(a) (b) (c) (d)

Figure 1. Mean equiloads for four teacher groups (A, B, C, and D) based on LMT scores.

Overall, the members of Groups B, C, and D relied on Covary, a structural aspect of proportions, co-occurring with other resources. Similarly, these groups paired Ratio as Measure with Unit Rate, suggesting participants were not only invoking 'how much per x' reasoning, but also have solidified that reasoning within the context of the situation by identifying the abstractable quantity that results from the proportion.

Teachers who performed the strongest on the LMT (Group D) and those who performed the weakest on the LMT (Group A) both had connections between Fractions and Ratios are Different and Comparing Quantities. Similarly, only Groups A and D had connections between Distortion and another code. This is important because it shows a connection between geometric ideas of similarity and dilation to numeric scaling (Group D) and to an understanding there is a fixed multiplicative relationship between the two quantities in a ratio (Group A).

The knowledge resources exhibited by participants in this study changed between the groups of teachers based on their performance on the assessment. In the mean equiload graph for Group A, we see many more knowledge resources used together, but fewer clear patterns in the thick lines. In Group B, we see fewer resources than in Group A and more consistent connections – suggesting more consistency within the group in their patterns of use of knowledge resources. In Group C, additional knowledge resources emerge, but there are still several connections that are consistently prevalent. Then, in Group D, the participants performing the highest on the LMT, we see a clear growth from Group C to continue using several of the connections, but also bringing in additional connections. The relative sophistication between groups is also notable with Group A relying on unit rate and scaling, which are two ideas that can be used with additive or multiplicative reasoning. In Group B, we see more explicitly multiplicative ideas (e.g., Covariation and Between Measure Space Reasoning). In Group C, the participants brought in fluidity in symbolic manipulation as well as continuing to attend to clearly proportional ideas including Ratio as Measure and Covariance. Then, in Group D, geometric ideas were included in the participants' discussions of Covariance and Scaling, suggesting that their knowledge is organized in such a way that they have easy access to similar ideas from multiple strands of mathematics across a variety of proportional reasoning tasks.

Implications and Conclusions

In this paper, we set out to understand what knowledge resources teachers used to solve a set of proportional reasoning tasks and whether there were differences in the patterns of knowledge resources used between teachers exhibiting different levels of performance on an assessment of proportional reasoning. As shown in Figure 1, each group of teachers relied upon a number of reasonable knowledge resources to solve the tasks in both interviews. Figure 1 shows there are clear differences between the groups of teachers.

This work is still in an exploratory phase. However, it can already contribute in meaningful ways to the discourse about supporting teacher understanding of proportional reasoning in mathematics education. From a professional development or teacher education perspective, it is clear that there are some knowledge resources that teachers have and can use in pairings with other knowledge resources. This provides guidance on ways to shape PD to be most effective.

IN-SERVICE TEACHERS' ABILITIES TO MAKE SENSE OF FIXED NUMBER OF VARIABLE SIZED PARTS TASKS

Chandra Hawley Orrill
UMass Dartmouth
corrill@umassd.edu

John Millett
UMass Dartmouth
jmillett@umassd.edu

In this study, we interviewed 32 practicing middle grades teachers to determine whether they were able to invoke reasoning about a fixed number of variable-sized parts in a proportional situation. To this end, we presented them with a sample student response to an item that relied on such reasoning to determine whether teachers understood the approach and whether they thought it was appropriate. Findings suggest that teachers who did not invoke this reasoning were unable to make sense of the student's reasoning, thus limiting their ability to make sense of students' work.

Keywords: Teacher Knowledge, Middle Grades Mathematics, Mathematical Knowledge for Teaching

Introduction

Ratios and proportional relationships are important topics in school mathematics (e.g., Lamon 2007). Reasoning with ratios and proportions serves as a foundation for more advanced topics (e.g., Lobato & Ellis, 2010). Additionally, it has been well document that these topics can be difficult for both teachers and students (e.g., Lamon, 2007).

While there is a considerable body of research focused on students' understandings of ratios and proportions, research on teachers is more limited. The literature on teachers highlights both how future teachers and in-service teachers solve proportional situations (e.g., Beckmann & Kulow, 2018; Harel & Behr, 1995; Riley, 2010) and the ways in which they make sense of students' thinking in proportional situations (e.g., Jacobson, Lobato, & Orrill, 2017).

This study contributes to both of these categories of research on teachers' understanding of proportions. We consider one aspect of proportional reasoning (described below) to determine whether teachers can make sense of it and whether they believe a student's work is useful.

Theoretical Framework

Variable Parts Perspective

Beckmann and Izsák (2014; 2015) identified two distinct but complementary perspectives on how quantities vary together in proportional relationships. One perspective on proportional relationships is the *multiple batches* perspective. This approach relies on coordinating the two quantities in a ratio and iterating them. It relies on composed unit reasoning, which has been written about elsewhere (e.g., Lobato & Ellis, 2010).

The second perspective on proportional relationships is the *fixed number of variable parts* perspective ("Variable Parts"). In this perspective a proportion is conceived of as a ratio made of a fixed number of equal sized parts in which the size of the part can vary. This is different than the multiple batches perspective where the number of groups vary and the size of the parts are fixed. For example, in a relationship of 2 parts of oil to 5 parts of vinegar in a salad dressing recipe, those parts can be conceived of as teaspoons, cups, half-gallons, or any other unit. The flavor of the batch of salad dressing will remain unchanged as those as the ratio of the units is held constant.

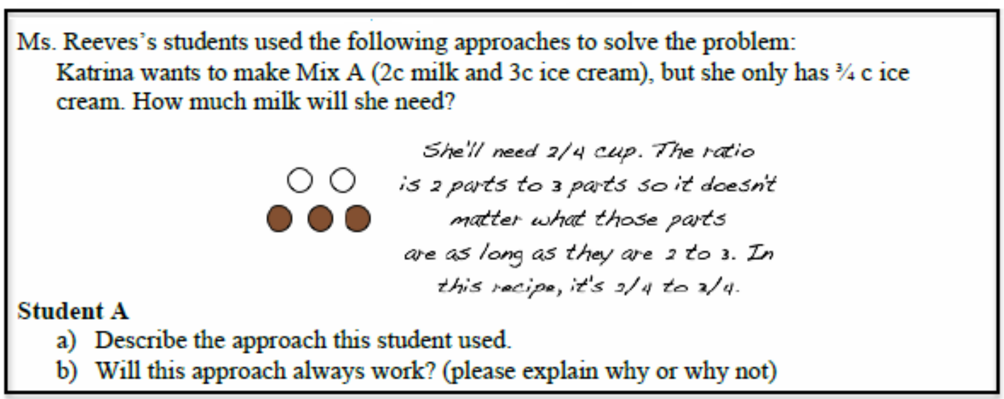
The existing body of variable parts research has mainly been conducted with preservice teachers enrolled in a course in which they are explicitly taught to reason using both perspectives (Beckmann & Izsák, 2014; Beckmann, Izsák, & Ölmez, 2015; Beckmann & Kulow, 2018; Ölmez, 2016). Most of the research has focused on mixture tasks. In this paper, we extend the existing research by considering the knowledge resources used by in-service teachers who have not received instruction in Variable Parts reasoning. Specifically, we considered what knowledge resources teachers used to make sense of a student's variable parts solution to a mixture task.

Knowledge in Pieces

Our study relies on knowledge in pieces (KiP; diSessa, 1988). KiP posits that understandings are developed as fine-grained knowledge resources. Through perturbations, those knowledge resources can be refined or added to. They can also be connected in myriad ways. As a person develops deeper understandings of a domain, they would be expected to develop a more robust set of knowledge resources, but even more, they would be expected to have more connections between and among those resources. We argue that because teaching requires considerable engagement with novel ideas, teachers need a robustly connected set of knowledge resources to support the widest variety of students.

Methods

For this study, we asked 32 in-service teachers to complete a think-aloud protocol by mail. Each teacher was provided with a LiveScribe pen to use so their utterances and inscriptions were recorded and coordinated. The think-aloud protocol included a number of questions about seven contexts, one was the milkshakes context, which included the task used in this study (Figure 1).



Ms. Reeves's students used the following approaches to solve the problem:
Katrina wants to make Mix A (2c milk and 3c ice cream), but she only has ¾ c ice cream. How much milk will she need?

She'll need 2/4 cup. The ratio is 2 parts to 3 parts so it doesn't matter what those parts are as long as they are 2 to 3. In this recipe, it's 2/4 to 3/4.

Student A
a) Describe the approach this student used.
b) Will this approach always work? (please explain why or why not)

Figure 1. Milkshake Task used for this study

Data were coded from transcripts. Each interview was analyzed by at least two team members who coded independently, then met to identify and solve any coding discrepancies. In cases where agreement was not readily possible, the utterance was brought to the full research team, a decision was made and documented in the definition for the code to ensure consistency across all coding. The codes were developed from both the literature and from emergent coding of the data (Charmaz, 2014). Each code identified a knowledge resource used to solve the task. The coding set included 18 knowledge resource codes related to proportional reasoning, including one identifying whether Variable Parts reasoning was present.

We separated participants into a Variable Parts group and a group that did not use Variable Parts. We then returned to the original transcripts and, when necessary, recordings from the interviews. While analyzing the transcripts, we used memoing (Corbin & Strauss, 2014) as well as the original coding to identify knowledge resources used to solve a task that suggested variable parts reasoning.

Results

In this section, we briefly describe findings from the Milkshake task shown in Figure 1. Our goal was to understand whether teachers made sense of a student's solution that relied on Variable Parts reasoning and whether they believe that reasoning was useful.

Variable Parts Group Approaches

For this task, we found that 13 teachers (41%) used Variable Parts reasoning while 19 teachers (59%) did not. Teachers who relied on Variable Parts reasoning made sense of the students' reasoning by saying things like:

> This was very clever. The student recognized that the ratio of milk to ice cream is 2 to 3, so, yeah. It doesn't matter. As the student said, it does not matter what those parts are, as long as they are 2 to 3. So that's a wonderful… a wonderful approach. Doesn't… doesn't have to be concerned that it's three quarters of a cup. It's just 3/4ths… 2/4ths. Excellent. (Charlotte, all names are pseudonyms)

Similarly, these teachers were able to make sense of the student's drawing saying things like, "So, they said each, instead of each part being a full cup they considered each part to be ¼ of a cup. So instead of having 2 full cups to 3 full cups they have 2, ¼ cups to 3, ¼ cups. I like it." (Heather) Interestingly, though, some of the teachers who understood the Variable Parts perspective and valued it as an approach, were unsure how they might teach it. For example, Georgia noted, "I think this approach would always work, I really like this approach. I'm not sure how to teach this type of understanding. But if they had that type of abstract understanding this would be a very good approach or way to show the work."

Non-Variable Parts Group Approaches

The 19 participants who did not rely on Variable Parts reasoning struggled to make sense of the student's reasoning. For example, Tonya explained:

> I'm not sure of the approach the student used. I see that the ratio is 2 parts milk to 3 parts ice cream. I'm not understanding why they think they will need a 2/4th cup if I need 3/4ths of milk…I'm not sure of what the approach is.

And, 12 of the 19 teachers who did not rely on Variable Parts were either confused by the drawing or created an alternate drawing to make sense of the task. Christine said:

> But I don't understand how…I don't understand her writing, how her written description correlates to her drawing…this is kind of baffling to me because I…I just don't understand…I don't understand her writing.

Not making sense of the work resulted in nine participants determining that the student's approach was not useful. They stated that this approach was for a particular type of student, predicted that the student would struggle with this this type of reasoning in the future, or in some cases the teachers doubted the students' understanding of proportional relationships. For example, Bridgette uttered:

> If they were to do this in the test for me I would ask for a little more explanation as to how they got the denominator four. Because from that picture I don't know if I would easily conclude how they got the number four.

In short, teachers who did not invoke Variable Parts reasoning did not understand this approach and dismissed it as being limited or not useful for students.

Scholarly Significance of the Study

The most notable implications for this work surround the teachers' abilities to make sense of student reasoning. As a community, teacher educators know that there is tremendous value in teachers listening to students (e.g., Darling-Hammond, 2006). However, these participants appeared unable to make sense of the student work unless they invoked the Variable Parts knowledge resource. We do not have adequate data to determine whether the teachers understood variable parts reasoning or whether this task simply did not invoke that reasoning for them. But, we do see compelling evidence that not accessing Variable Parts reasoning correlated to struggling to make sense of student thinking and working the task a way other than the student's way. This suggests to us that having access to and being able to invoke variable parts reasoning may be an important aspect of a teacher's robust understanding of proportional reasoning and, thus, should be given explicit attention in teacher preparation and professional development.

HIGH SCHOOL TEACHERS' MATHEMATICAL KNOWLEDGE FOR TEACHING EXPONENTIAL FUNCTIONS: MKT AS DECISION-MAKING

We propose expanding traditional conceptions of teachers' MKT to include decision making. We explore this idea using the decisions two teachers make while implementing an exponential task to create an equation from context using a table. This framing better allows us to understand the mathematical reasoning teachers know to be relevant for students to complete a mathematical process and the actual actions they choose to engender this reasoning.

Keywords: Mathematical Knowledge for Teaching, Research Methods

The field widely accepts that teachers' mathematical knowledge for teaching (MKT) is strongly related to their effectiveness and has long-endeavored to describe and investigate this specialized way of knowing. However, more research is needed to advance understanding of how to conceptualize, develop, and assess MKT (National Resource Council, 2012). Current descriptions treat MKT as declarative knowledge and have not emphasized the thinking processes that contribute to teachers integrating and enacting the knowledge (Borko, Roberts, & Shavelson, 2008). Focusing on describing MKT in action may contribute to understanding how teachers develop and utilize this special way of knowing. Taking the view of decision making as the core work of teaching (Borko et al.), this brief report describes the affordances of using decision making to examine the nature of teachers' action-based MKT for exponential functions.

Theoretical Framing

Because we view MKT as intertwined with the process of teaching (Rhoads & Weber, 2016), we seek to describe MKT in action. That is, we want to describe the body of mathematics knowledge teachers draw upon to make decisions when teaching and the active process of making decisions within a particular social context for a specific purpose targeted to influence the mathematics learning opportunities afforded to their students.

We borrow from enactivism (Maturana & Varela, 1998) which indicates knowing is doing and doing is knowing. That is, knowing is enacting behaviors the individual deems effective for a particular purpose in a particular context. Knowledge is the body of effective behaviors and the underlying cognition that engender one to perceive the situation and categorize which behaviors are effective. Concerning teaching mathematics, we view knowing as making decisions the teacher deems effective in affording students' opportunities to reason about mathematics. We term this knowing *enacted MKT*.

Decisions have two components: a decision outcome (i.e., what was decided, the observable behavior) and a decision rationale (i.e., why the decision outcome was chosen). The work of teaching involves such an enormous quantity of decisions it is impossible to identify them individually. During instruction, though, a teacher's actions are the overall results of their decision outcomes and the overall impact of those decisions is observable. Characterizing the teacher's actions, then, is a way of capturing the gestalt of the teacher's decision outcomes. A teacher cannot explain the rationale for each decision given the sheer volume of decisions made during instruction and the time distance between instruction and providing explanations. Over time, an experienced teacher will have built up a body of coordinated behaviors he or she deems effective for particular contexts and purposes (Brown & Coles, 2011). An expert teacher will be able to engage in a deliberate analysis of their behavior to construct a plausible rationale (Brown & Coles, Herbst & Chazan, 2011) for the actions taken. These rationale can point to an underlying propensity for making certain decisions (Herbst & Chazan). We seek to describe our teachers' decisions and their propensity for making decisions related to teaching exponential functions.

Part of a larger study, this work targeted the following research question: What is the nature of a teacher's exponential functions enacted MKT when viewed through the lens of decision-making? Answering this question involves describing decisions the teacher makes and the underlying rationale for those decisions.

Methods

For the larger study, we collected data from seventeen high school teachers engaged in teaching units related to exponential functions. We report findings from two teachers. Ms. M taught an honors section of Algebra II that tracks into an IB program; Ms. L taught College Algebra. Both teachers had taught for over ten years, had obtained their master's degrees, and had participated in teacher leadership programs. For each teacher, we video recorded three to five lessons. We conducted interviews prior to and following the teaching of each lesson as well as an overall introductory interview and a final reflecting interview over the set of lessons observed.

We transcribed the observations and partitioned each lesson into smaller segments called *episodes* and *sequences* (Wells, 1996) based on transitions between classroom tasks. For each segment, we described the overarching mathematical purpose. We formed hypotheses about the decision outcomes that contributed to the development of the intended mathematical purpose. Using the identified decision outcomes and mathematical purposes, we coded relevant sections of the interview transcripts to provide insight into the teacher's rationale for their decisions.

Preliminary Findings

To illustrate how we use a teacher's decisions to formulate a description of her KMT, we present examples of decisions made by Ms. M and Ms. L around the purpose of generating an exponential expression from a context. These cases exemplify how our framing allows for making explicit what teachers know for teaching exponential functions by identifying decisions around a mathematical learning purpose. Both teachers enacted tasks where students generated table of values to develop an exponential expression. We note the decision outcomes (actions) of the teacher to enact the purpose and their described rationale as taken from the interviews.

The Case of Ms. M

Modifying *The Domino Skyscraper Task* (http://threeacts.mrmeyer.com/dominoskyscraper/), Ms. M presented a situation where dominos were placed next to each other so that each successive domino is 1.5 times the height of the previous domino. Students worked in small groups to determine the number of dominos needed to equal the height of a given skyscraper. Ms. M intended students to create a table and then develop a formula for the n^{th} domino.
Ms. M encouraged students to generate and use tables of values to develop the explicit formula for the situation. Ms. M guided the students to explore how the output values of their tables

changed as they *moved up* (i.e., starting with the height of the skyscraper and decreasing in size) or *moved down* (i.e., starting with the initial height of the domino and increasing in size) so students would notice *repeated multiplication by a constant ratio* was relevant to the explicit formula. She further pushed students to consider *skipping ahead* (i.e., consider the change in height from one domino to another domino several stages away) to encourage moving away from generating the table values recursively and to facilitate the use of an exponent. "I was trying to get them to realize that … if I needed to skip steps, then I had to multiply by 1.5 multiple times, how do I write that? So I was trying to get them to realize that it was an exponential rather than a multiplication problem." Ms. M asked students to check their generated equation by comparing the values in the table against outputs of their equation and to modify the equation if the outputs did not match. Through this checking, some, not all, students found that they needed to modify the exponents of their equations based on how they numbered their dominos.

The Case of Ms. L

Ms. L chose to engage her students in the Social Media Task which asked students to find the number of users in 2006, 2007, and 2008 given that the number of social media users in 2005 is 3.2 million and the number of users is tripling every year. Students worked alone or in groups on this task. Then Ms. L facilitated a discussion of the student solutions and how to use those solutions to generate an expression to represent the context.

During the whole-class discussion of the task, Ms. L solicited and organized student answers (Table 1). Although students consistently described their procedure for generating the number of users in a specific year in terms of multiplying the previous number of users by three (e.g., to get the number of users in 2007, take 9.6 million and multiply by 3), Ms. L pressed students to consider the number of times one must multiply 3.2 million by 3 and to represent that relationship in the form of an exponential expression (see the middle column in Table 1). The decision to focus on the middle column suggested that Ms. L wanted students to attend to the exponential expressions that highlight the multiplicative pattern inherent in the context.

Table 1: Developing an Exponential Expression from a Context

2005	3.2 million	3.2×3^0	4	Numbers in the fourth column represent the order in which the expressions were created
2006	9.6 million	3.2×3	1	
2007	28.8 million	$3.2 \times 3 \times 3 = 3.2 \times 3^2$	2	
2008	86.4 million	3.2×3^3	3	
2052		3.2×3^{47}	5	

Ms. L then asked students towards formulating an equation to represent the situation, but quickly changed to have students find an expression for the number of users in year 2052. After recording the expression for year 2052, Ms. L asked students to (re-)consider writing an expression for the number of users in year x. Ms. L documented a student's solution of $3.2 \times 3^{x-2005}$ on the board.

Discussion and Conclusions

The second and third columns of Table 2 describe the choices teachers made to facilitate student learning to create an exponential expression that represents a context. The sequences of actions and the teachers' described rationale suggest Ms. M and Ms. L know a trajectory of mathematical reasoning for this process (first column of Table 2). Note the shared trajectory of thinking for T1-T4 with slightly varied enactment. Consider the points of diversion in rows T5 and T6. Ms. L provided a separate, explicit opportunity for students to reason about the necessary exponent value utilizing a specific input prior to writing the expression. Ms. M did not explicitly provide that opportunity except in cases where the students made an error in their initial attempts to generalize the expression.

Table 2: Implied Reasoning Trajectory with Associated Decision Outcomes

Trajectory of reasoning		Ms. M decision outcomes	Ms. L decision outcomes
T1	See how the value at a point can be determined from recursive multiplication	Have students generate tables of data values by multiplying the previous domino's height by 1.5	Have students generate data values by multiplying the previous year's data by 3
T2	Notice the explicit expression will account for the multiplicative relationship	Have students explore moving up and down the tables	Write values as a repeated multiplication by 3 using the initial value
T3	See how the values at any point can be generated from the initial value	Have students explore skipping ahead	
T4	See how the data can be re-represented to highlight the repeated multiplication as exponentiation	Have students re-represent thinking from T3	Rewrite the repeated multiplication expressions with exponents
T5*	Connect the exponent value in the expression to the input value	---------	Formulate the expression for some value in the future
T6*	Generalize the expression for any input value	Have students utilize T4 reasoning, attempt an expression, then modify expression by checking table values	Have students utilize T1-T5 reasoning to find an expression for year x

The combination of the decision outcomes and the implied trajectory allow us to describe the mathematical reasoning the teachers know to be relevant for students to complete a mathematical process and the steps and moves chosen to facilitate this reasoning. Comparing the decisions between the two teachers enabled further explication of the relevant decisions. Such descriptions of teacher enacted MKT can push the field to understand how teachers develop and utilize this knowing in specific contexts for specified purposes.

Keywords: Modeling, Mathematical Knowledge for Teaching, Teacher Education-Preservice

Through the years, mathematical modeling has been shown to help develop mathematical competencies that support students' skills in solving problems arising in everyday life, society, and the workplace. With the implementation of the Common Core State Standards of Mathematics (CCSSM) in the majority of the states in the U.S., mathematical modeling has come into the forefront of the learning and teaching of mathematics. As a result, teachers are expected to support their students' classroom modeling experiences. Nonetheless, teachers have not experienced modeling thoroughly themselves in their training, because mathematics teacher education programs seldom integrate mathematical modeling in their curricula. Research studies begin to reveal how learners engage in mathematical modeling and how mathematics is supported through the exploration of modeling tasks, however, there is a gap in looking at how mathematical modeling can help support PSTs' MKT. It is important to explore modeling in relation to MKT because many studies have linked teachers' MKT to the effectiveness of mathematics instruction, and achievement gains in students. Therefore, this study aims to address a gap in the field by exploring the relationship between mathematical modeling and PSTs' MKT algebra topics and answer the following research question—what is the nature of the relationship between MEAs and PSTs' MKT algebra?

To explore this question, the researchers used a multiple case study design in order to provide a detailed understanding of three cases and a comparison of these cases to illustrate the topic being examined. Out of the 30 participants in the study, three PSTs were selected using a maximum variation purposeful sampling method. Specifically, the PSTs were given a pre-assessment to measure their MKT using a Learning Mathematics for Teaching (LMT) algebra scale. Those selected had scores belonging to one of the following three categories: (a) less than 25th percentile range, (b) between 25th and 50th percentile range, and (c) greater than 50th percentile. The participants were video and audio recorded as they explored three MEAs, artifacts pertaining to their explorations were collected, and interviews were conducted to gather extensive information about the PSTs' mathematical modeling experiences and MKT algebra topics. We developed a conceptual framework using a thorough review of the literature. Seminal work in the MKT and the Models and Modeling Perspective fields were used to guide the research, and the data analysis of the study. The results of the study demonstrate that MEAs can be used to elicit PSTs' MKT algebra through the implicit characteristics of planning, analyzing, writing, forming connections, and reflecting on the mathematical content and processes.

TRACING THE EVOLUTION OF MATHEMATICAL KNOWLEDGE FOR TEACHING FROM A LONGITUDINAL PERSPECTIVE

Keywords: Mathematical Knowledge for Teaching, Teacher Knowledge, Number Concepts and Operations

Across various disciplines in mathematics and other sciences, numerous efforts have documented the manner in which each field has developed throughout time, and the institutions that have led the way in this process (Kilpatrick, 1992). Beginning with the first doctorate granted in mathematics education in 1906, academic institutions have produced thousands of mathematics teacher educators who have played a vital role in shaping policy decisions which have impacted classroom instruction, research and the preparation of future mathematics educators. Previous efforts have looked at key doctoral institutions and their influences on producing doctorates in the field of mathematics education (Reys, Teuscher & Nevels, 2008). Efforts have also been made to look at the preparation of doctorates as future educators and researchers (Shih, Reys & Engledowl, 2016).

This poster will illustrate a historical perspective of the evolution of mathematics education to demonstrate certain connections between research areas, academic institutions, and influential figures in the mathematics education community. An extensive data-driven approach has been used to compile information spanning over a century for this ongoing study. A longitudinal analysis of the data indicates influential figures, and institutions that have played a role in the development of various research trends. More specifically, study of the influential figures in the generations following specific mathematics educators shed a light on the development of research relating to conceptual knowledge, and content knowledge for teaching, which has been influential in curriculum development for K-12 mathematics, as well as in the preparation of pre-service teachers. In order for mathematics education to continue developing in a robust fashion, it is important for both current and future mathematics teacher educators to be aware of the development of research areas throughout time and the role that institutions have played/ are currently playing in this process. In this manner, mathematics teacher educators and doctoral programs can not only maintain a historical perspective, but also utilize these research findings to impact the development of future mathematics teacher educators and the research areas that have yet to be fully explored for generations to come.

ELEMENTARY TEACHERS' RECOGNITION OF ARITHMETIC PROPERTIES

Gayle M. Millsaps
Eastern Washington University
gmillsaps@ewu.edu

Carlos W. Castillo-Garsow
Eastern Washington University
ccastillogarsow@ewu.edu

Teachers require more than an implicit understanding of the properties of arithmetic in order to take advantage of instructional opportunities and to engage students in productive discourse (Ball et al, 2001). Elementary teachers need to have the ability to recognize and use structure in order to recognize and promote this mathematical practice in their students. Ball et al observe that practicing teachers' inability to recognize the contributions of arithmetic properties to related content interferes with their ability to support their students' sense-making activities. In this study, we ask: what aspects of mathematical structure in arithmetic equations do EPTs attend to when asked to sort equations that have been designed to represent the different arithmetic properties and arithmetic operation definitions into categories? What can EPTs' explanations for how they categorize such equations tell us about the learning progression for recognizing mathematical structure?

Data were collected in two class sessions of two sections of a first content course for EPTs at a Western rural regional university. 39 to 47 EPTs participated. Students were asked to sort 20 equations on individual strips of paper into categories based on what change they observed between one side of the equation to the other. The following are representative examples:

- (2 x 3 groups) x 4 items/group = 2 x (3 groups x 4 items/group) [Associative]
- 8 groups x 4 items/group = (4 groups x 4 items/group) + (4 groups x 4 items/group) [Distributive]
- 3 x (10 groups x 4 items/group) = (10 groups x 4 items/group) x 3 [Commutative]

The categories and rationales for categories were collected and analyzed on (1) the explanations that the EPTs gave for the categories that they formed and (2) the clustering of the sentences. The open-coding of the individual EPTs' explanations yielded five types of explanation that correspond to three types of abstraction.

The resultant codes for the EPTs' explanations mapped closely to Piaget's types of abstraction (Campbell, 2001) At the level of empirical abstraction were explanations representing the use of the same numbers or same operation in the members of the equations. Two levels of pseudo-empirical abstraction were observed: (1) explanations representing recognizing equations whose members evaluated to the same numerical amount, and (2) observation that different sets of numbers were in parentheses on one side of the equal sign than on the other. At the level of reflective abstraction was EPTs' recognition that there were patterns of changes in number relationships from one member of an equation to the other--closest to corresponding to recognizing one or more structural properties. The findings of the study suggest a learning progression: (1) recognizing superficial features of equations such as the numbers and symbols used, (2) evaluation of equations, (3) recognizing the organization of arithmetic processes, (4) observing patterns of number relationships.

FUTURE TEACHERS' PEDAGOGICAL CONTENT KNOWLEDGE IN MATHEMATICAL MODELING INSTRUCTION

Ayse Ozturk
The Ohio State University
ozturk.25@osu.edu

It is agreed that teaching mathematical modeling is challenging, especially for teachers new to the process (Anhalt & Cortez, 2015). In addition to relevant mathematics to solve a problem, teachers have to possess an instructional system to facilitate students' mathematical thinking process (Blum, 2011). While ample studies have documented future teachers' knowledge for teaching various mathematics concepts, little is known about knowledge for teaching mathematical modeling. This poster details findings of our research on secondary preservice teachers' pedagogical content knowledge for teaching mathematical modeling.

Ferrini-Mundy and colleagues (2005) conceptualized three types of pedagogies that draw explicitly on mathematical knowledge domain of teachers: *Decompressing*, *Trimming*, and *Bridging*. Teachers' *decompressing* is the process of selecting or modifying tasks based on teachers' own analysis of students' mathematical understanding. *Trimming* involves transforming mathematical ideas from a more advanced form to one that preserves the essence, but that will be accessible to students based on their knowledge. *Bridging* encompasses the various kinds of connections that teachers do such as linking one area of school mathematics to another. Relying on this framework we examined preservice teachers' knowledge of teaching mathematical modeling using case based interviews.

Three secondary preservice teachers participated in the study. Selection of participants was deliberate, targeting variability among mathematical backgrounds and self-efficacy towards doing and teaching mathematical modeling. The participants were given three mathematical modeling tasks and each one was interviewed three times. In each interview, the participants worked on a modeling task and then commented on how they would implement the same task, challenges they anticipated regarding learners' difficulties and their plans for addressing them.

Analysis revealed that while the participants managed the demands of solving the modeling tasks, they experienced difficulty in the *decompressing* process to anticipate how school learners might perform on the same tasks. They viewed mathematical modeling as a tool for *bridging* mathematics to other subject areas. However, despite the fact that they were able to anticipate challenges that learners might encounter relative to defining variables or identifying parameters when working on tasks, the participants were unable to define ways to address challenges. For example, *trimming* was only meant to simplify the modeling problem into an application problem by adding some numerical variables. The study suggests that exposing preservice teachers to mathematical modeling scenarios might not be sufficient in helping them develop pedagogical approaches to facilitate classroom implementation.

Keywords: Mathematical Knowledge for Teaching, Teacher Education – Preservice

In what ways are the tasks of teaching prospective teachers (PTs) different from the tasks of teaching K-12 students? In this poster, we present a portrait of a few aspects of *mathematical knowledge for teaching teachers* (MKTT) that highlight some of the distinctions between it and mathematical knowledge for teaching children (MKT; Ball, Thames, & Phelps, 2009). We conceptualize the process of designing and revising tasks for PTs as a distinct form of mathematical knowledge for teaching, one that is specific to mathematics teacher educators. In this poster we share insights and reflections on how our MKTT guided and was enriched by the design and revision of lessons on five mathematical concepts.

Using a form of lesson study outlined by Berk and Hiebert (2009) and attending explicitly to the iterative process of task design outlined by Liljedahl et al. (2007), we developed five mathematical tasks for a mathematics content course for elementary PTs. The process of task design and revision highlighted the ways in which teaching PTs differs from teaching K-12 students, as PTs need to *relearn* mathematics (Zazkis, 2011); that is, PTs must reflect on previously-held conceptions and unpack their knowledge of procedures and problem-solving strategies to reveal the underlying conceptual foundations.

In the portraits of task design presented on this poster, the idea of uncovering and addressing PTs' preconceptions was essential to the MTEs' design and revision of each task. We contend that the centrality of this goal in the MTEs' thinking during this process makes these portraits examples of MKTT in action. For example, a task that presents growing visual patterns to children may focus on developing students' abilities to continue a visual pattern or on introducing functional thinking (Warren & Cooper, 2008); a task that presents growing visual patterns to PTs must do those things, as well as address any previous conceptions surrounding linear growth, algebraic generalization, or sequences that PTs may have. Thus, the purpose of designing tasks for PTs differs fundamentally from the purpose of designing tasks for students.

HOW DO UNDERGRADUATE STUDENTS MAKE SENSE OF POINTS ON GRAPHS IN CALCULUS CONTEXTS?

Erika David
Arizona State University
ejdavid@asu.edu

Kyeong Hah Roh
Arizona State University
khroh@asu.edu

Morgan Sellers
Arizona State University
mearly1@asu.edu

The purpose of this study is to examine the characteristics of students' thinking about graphs while evaluating statements from Calculus. We conducted clinical interviews in which undergraduate students evaluated mathematical statements using graphs to explain their reasoning. We report our classification of students' thinking about aspects of graphs in terms of value-thinking and location-thinking, which emerged from our data. These two ways of thinking were rooted in students' attention to different attributes of points on graphs we provided: either the input and output values represented by the points or the location of the points in space. Our findings indicate that students' thinking about aspects of graphs accounts for key differences in their understandings of mathematical statements.

Keywords: Geometry and Geometrical and Spatial Thinking, Post-Secondary Education, Cognition, Reasoning and Proof

The purpose of this study is to characterize students' thinking about aspects of graphs of real-valued functions and to investigate its role in understanding and evaluating statements from Calculus, such as the Intermediate Value Theorem (IVT). Through analyzing students' evaluations and interpretations of these statements using graphs, we seek to address the following research questions: *What are characteristics of undergraduate students' thinking about aspects of graphs related to statements from Calculus contexts?* Specifically,

(1) How do students interpret outputs of a function on a graph, points on a graph, and a graph as a whole?
(2) How do various types of student thinking about graphs of real-valued functions affect students' understanding and evaluation of the Intermediate Value Theorem and similar statements?

Literature Review

Undergraduate Calculus courses, from elementary through advanced Calculus, are comprised of many definitions and theorems about real-valued functions. Often, these statements are accompanied by visual representations in the form of graphs of relevant functions. For example, the Intermediate Value Theorem (IVT) is one such statement commonly associated with a visual representation (e.g., Briggs, Cochran, & Gillett, 2011; Finney, Thomas, Demana, & Waits, 1994; Larson, Hostetler, & Edwards, 1994; Stewart, 2012). Although research has called for the inclusion of such visual representations in mathematics instruction (e.g., Arcavi, 2003; Davis, 1993; Dreyfus, 1991; Hanna & Sidoli, 2007), few empirical studies have been conducted to look at undergraduate students' thinking about graphs of real-valued functions.

While it is hoped that students focus on the details of a provided graph that highlight the intended concept, some students may construe other properties of the given graph rather than the intended ones. For example, Moore and Thompson (2015) found that some students treat graphs as an object itself, and infer details of a situation from the shape of a graph, rather than coordinating the numerical values represented by the points of the graph. If students' interpretations of graphs differ from what is intended, students' interpretations of provided graphs might hinder their subsequent mathematical activities, such as rigorous proofs (Alcock & Simpson, 2004). Although several studies have looked at students' understanding of graphs as a whole (Monk, 1992; Moore & Thompson, 2015; Moore, 2016), it is not widely known what meaning students have for various aspects of graphs, such as the input, output, and points on graphs.

Theoretical Perspective

This study, including the data collection, data analysis, and development of the theoretical framework, is grounded in a constructivist perspective. We adopt von Glasersfeld's (1995) view that students' knowledge consists of a set of action schemes that are increasingly viable given their experience. This perspective also implies that we, as researchers, do not have direct access to students' knowledge and can only model their thinking about graphs based upon their observable behaviors.

We adopt components of Arcavi's (2003) definition of visualization for this study, which he states as "The ability, the process, and the product of creation, interpretation, use of and reflection upon pictures, images, diagrams, in our minds, on paper, or with technological tools" (p. 217). While Arcavi's description of visualization is broad, in this paper, we focus on investigating how *students* interpret, use, and think about aspects of graphs of real-valued functions and relations.

Methodology

As part of a larger study, we conducted two-hour clinical interviews (Clement, 2000) with nine undergraduate students from a public southwestern university in the United States. We selected three undergraduates who had just completed one of the following three mathematical courses that may cover the IVT: Calculus I, Introduction to Proof, and Advanced Calculus. During the interview, the interviewer asked students to evaluate each of the four mathematical statements in Table 1 and to provide justification for their evaluations. The second statement, the Intermediate Value Theorem (IVT), was the only true statement we presented. The remaining three statements (1, 3, and 4), all of which are false, were created from the IVT by reordering the quantifiers (for all, there exists) and/or the variables (N, c).

Table 1: Statements Presented to Students

Statement 1	Suppose that f is a continuous function on $[a, b]$ such that $f(a)\neq f(b)$. Then, for all real numbers c in (a, b), there exists a real number N between $f(a)$ and $f(b)$ such that $f(c)=N$.
Statement 2 (IVT)	Suppose that f is a continuous function on $[a, b]$ such that $f(a)\neq f(b)$. Then, for all real numbers N between $f(a)$ and $f(b)$, there exists a real number c in (a, b) such that $f(c)=N$.
Statement 3	Suppose that f is a continuous function on $[a, b]$ such that $f(a)\neq f(b)$. Then, there exists a real number N between $f(a)$ and $f(b)$ such that for all real numbers c in (a, b), $f(c)=N$.
Statement 4	Suppose that f is a continuous function on $[a, b]$ such that $f(a)\neq f(b)$. Then, there exists a real number c in (a, b) such that for all real numbers N between $f(a)$ and $f(b)$, $f(c)=N$.

After students evaluated the four statements, the interviewer presented six graphs. The graphs were chosen to represent a spectrum of possible functions, relations, and relevant counterexamples and included: a polynomial with extrema beyond the endpoints of the displayed function, a vertical line segment, a continuous sinusoidal function, a monotone increasing function, a constant function, and a function that is discontinuous on $[a, b]$. The interviewer asked if the students could use any of these graphs to explain their evaluation of each statement, which they could change at any time. Students were also asked to explain how they interpreted various aspects of each graph and to label relevant points and values on the graphs where appropriate.

Our data analysis was consistent with Corbin and Strauss' (2014) description of grounded theory, in which our categories of students' thinking about the graphs emerged from the data analysis. We began preliminary analysis during and immediately following each interview to note relevant findings. After all the interviews were conducted, we employed open coding (Corbin & Strauss, 2014) to document students' interpretations of aspects of the graphs they worked with. We refined these categories and re-coded the video interview data using axial coding (Corbin & Strauss, 2014). Through this process, we finalized two codes, *value-thinking* and *location-thinking*, to broadly characterize student thinking about the graphs.

Results

In our data, we found two distinct ways that students thought about graphs, specifically outputs, points, and the graph as a whole. We observed that some students primarily focused on the *values* represented by the coordinates of points on graphs while others primarily attended to the spatial *location* of these points. To describe these findings, we use the term *value-thinking* to refer to student thinking which focused on the *values* represented by the coordinates of a point. We use the term *location-thinking* to refer to thinking that primarily attends to the spatial *location* of the point. We detail characteristics of both categories of thinking in Table 2 by listing the meanings for aspects of the graph for each category and observable behaviors indicative of these meanings.

Table 2: Comparison of Value-Thinking and Location-Thinking

Value-Thinking

By *value-thinking*, we mean thinking about graphs that focuses on the input and output values represented by the coordinates of points on the graph of a function. Figure 2 contains two labeled graphs from one of the students, Jay, whom we considered to be engaged in value-thinking. One of the key characteristics of value-thinking is distinguishing between the outputs of a function and the points on a graph. Students who engaged in value-thinking labeled points as ordered pairs (see Figure 2, left), and spoke about points as representing both input and output values simultaneously. When considering the output of a function, students who thought in this way tended to label relevant output values on the output axis of the graph of a function (see Figure 2, right), and specifically spoke about the *values* of the output only. Students engaged in value-thinking thus treated graphs as a collection of ordered pairs that relate corresponding input and output values. In terms of the four statements, these students interpreted N in the phrase "N between $f(a)$ and $f(b)$" as referring to *values* between two values $f(a)$ and $f(b)$. They typically indicated the N values on the y-axis, as shown in Figure 1, right.

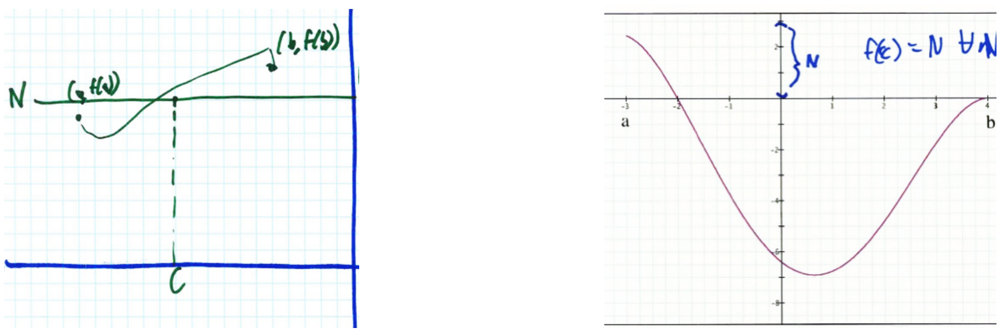

Figure 1. Jay's graph labels, characteristic of value-thinking

Location-Thinking

By *location-thinking,* we mean thinking about graphs that relies on the spatial locations of points in a Cartesian plane. Students who engaged in location-thinking focused on the location of points, while the values of the coordinates for the points were either in the background of their reasoning or absent from it. In contrast with value-thinking, one of the key characteristics of location-thinking we observed was treating the output of the function as indistinguishable from the location of the point. Accordingly, students who engaged in location-thinking often labeled points on the graph as outputs, rather than ordered pairs, and spoke about points in terms of their location in the coordinate plane. While students who engaged in value-thinking labeled outputs on the output axis, students who engaged in location-thinking frequently placed the output label at the location of the point on the graph. Instead of speaking about output *values*, these students speak about *points on the graph* as the result of an input value. Students engaged in location-thinking treated graphs as a collection of locations in space associated with inputs.

Outputs as locations. Zack was one such student who labeled $f(a)$, N, and $f(b)$ not on the y-axis, but on the graphs that he drew, as shown in Figure 3. As a result, Zack did not label points as ordered pairs.

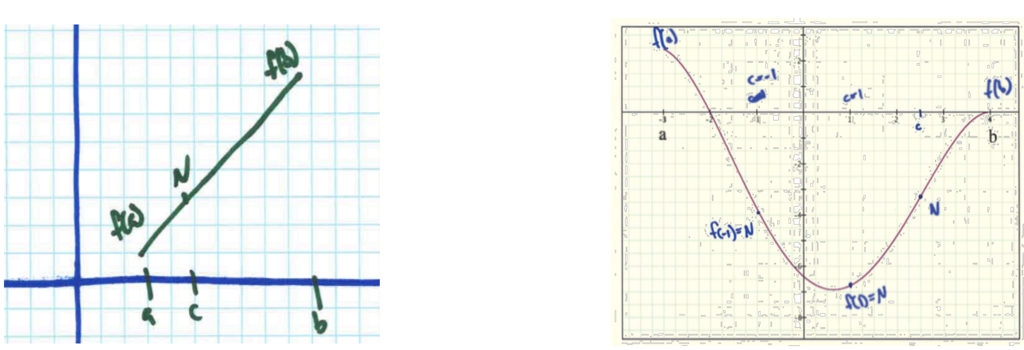

Figure 3. Zack's labels of points as outputs, a common characteristic of location-thinking

Zack's placement of an output label at a location on the graph, rather than on the y-axis, indicates that he considered these outputs to be locations on the graph, rather than values on the y-axis. Additionally, Zack called the endpoints of the graph in Figure 3, right "f(a)" and "f(b)," again indicating that he conceived of outputs as locations on the graph. Furthermore, when Zack referenced possible N's between f(a) and f(b), he swept along the entire graph of the function, rather than along the y-axis. His gesture along the graph when describing N's between f(a) and f(b) is also consistent with his conception of outputs as locations along the graph. We thus take Zack's label on the graph, words, and gestures as evidence of his consideration of outputs of the function as locations, indicative of location-thinking.

Points as locations. In addition to his graph labels of outputs at points in Figure 3, more striking evidence of Zack's location-thinking was observed when he was working with a constant function and claimed that f(a) is not equal to f(b). When the interviewer presented Zack with the graph of a constant function, Zack confirmed that the function is continuous on the interval [a, b], pointed to the endpoints of the graph, and stated that f(a) is not equal to f(b). Zack read off the remainder of Statement 3, and again pointed to the endpoints of the graph when reading the phrase "N between f(a) and f(b)." Next, he pointed to a spot on the graph, which he explained was an example of N between f(a) and f(b), plotted a dot there, and labeled the dot on the graph as "N." He also labeled the endpoints of the graph as f(a) and f(b), respectively, as shown in Figure 4.

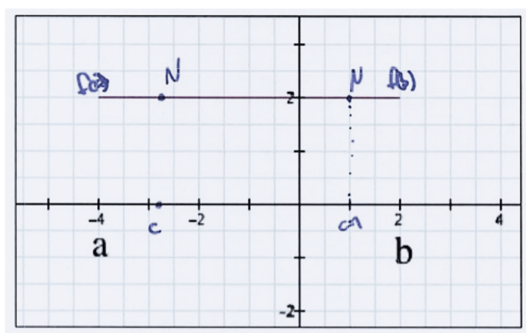

Figure 4. Zack's labeling of *f*(*a*), *f*(*b*), and possible *N*'s when he claimed *f*(*a*)≠*f*(*b*).

We take Zack's claim that *f*(*a*) and *f*(*b*) are not equal for the constant function *f* as evidence that he attended to the different spatial *locations* of the endpoints, rather than the pairs of input and output *values* represented at each point. For Zack, the point *N* that he labeled on the graph was in between the *locations* of the endpoints, which he referred to as *f*(*a*) and *f*(*b*). We also note that Zack labeled points as *f*(*a*), *f*(*b*), and *N*, rather than as ordered pairs. In essence, for Zack, there was no difference between outputs of the function and points on the graph, as both referred to spatial locations on the graph. We thus conclude that Zack conceived of *points as locations*, an indication of location-thinking.

***N* as a location between *f*(*a*) and *f*(*b*).** Like Zack and other students who engaged in location-thinking, Nate also considered outputs as locations, rather than values, and points as locations, rather than ordered pairs. We highlight Nate's meaning for the phrase "*N* between *f*(*a*) and *f*(*b*)," which was indicative of location-thinking. When working with one of the provided graphs, Nate first labeled the endpoints of the graph as *f*(*a*) and *f*(*b*), respectively. Then, Nate explained that for every *c* on this axis, he could find an *N* on the curve that *c* maps to. He also motioned from the *x*-axis vertically to the graph when describing that *c*'s mapped to *N*'s *on the* *graph*. Similarly, when describing *N*'s, he swept along the entire graph of the function from what he marked as *f*(*a*) to *f*(*b*). Nate's graph labels are shown in Figure 5 below.

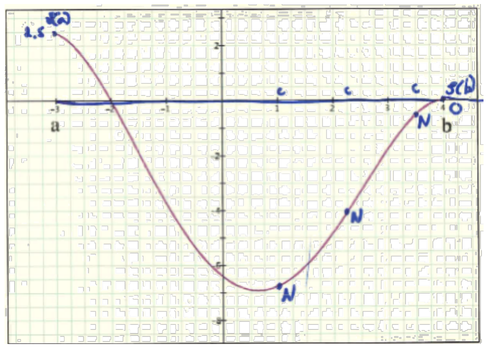

Figure 5. Examples of N's Nate claimed were between f(a) and f(b)

Nate labeled possible *N*'s on the graph that are, from our perspective, not between *f*(*a*) and *f*(*b*). Noticing Nate's placement of *N* labels and his sweeping motion along the graph, we infer that Nate interpreted "*N* between *f*(*a*) and *f*(*b*)" to mean *all* the points on the graph between the points that he labeled *f*(*a*) and *f*(*b*).

To further examine Nate's meaning for this phrase, the interviewer extended the graph to the right and marked a point on this extension of the graph, at approximately (5, 1), whose output value, 1, is between the values of *f*(*a*) and *f*(*b*) (see Figure 6). The interviewer then asked Nate if this output was between *f*(*a*) and *f*(*b*). After thinking about the question briefly, Nate stated that the output was *not* between *f*(*a*) and *f*(*b*).

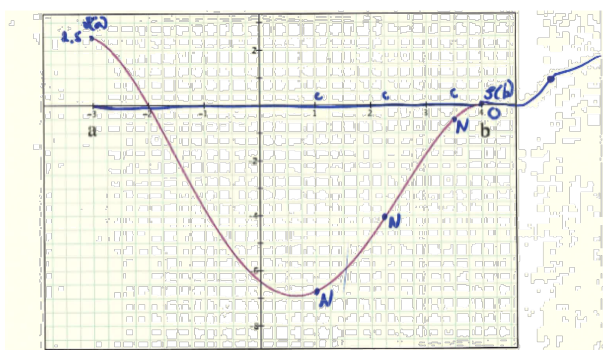

Figure 6. A point at which Nate claimed the output was not between f(a) and f(b)

The interviewer's prompt allowed Nate to more carefully consider his meaning for "*N* between *f*(*a*) and *f*(*b*)." Nate explained that there are two possible interpretations of this phrase, which he described as a "number interval" and a "function interval." By "number interval," Nate referred to the set of all output values between 0 and 2.5. In contrast, Nate used "function interval" to refer to the set of all points on the graph between the endpoints which Nate labeled *f*(*a*) and *f*(*b*). While Nate said the point that the interviewer marked was not between *f*(*a*) and *f*(*b*), he acknowledged that this point was "in the number interval" between 2.5 and 0 (the values of *f*(*a*) and *f*(*b*)). Nate clarified that although the output value of this point was between 0 and 2.5, the point was not between *f*(*a*) and *f*(*b*) because it was not "in the function interval." As he described the "function interval," Nate motioned along the entire graph between the points which he had labeled *f*(*a*) and *f*(*b*). Although Nate acknowledged the numerical interval of output values, [0, 2.5], he considered his notion of the "function interval" as more relevant for interpreting the phrase "N between $f(a)$ and $f(b)$." We thus take Nate's interpretation of "N between $f(a)$ and $f(b)$" in terms of the *spatial location* of the points, rather than the values of the outputs, as indicative of *location-thinking*.

Value-Thinking, Location-Thinking, & Students' Evaluations of Statements

We found that students' interpretations of aspects of graphs, whether in terms of value-thinking or location-thinking, were related to their evaluations of the four statements we presented. Among the five engaged in value-thinking, three students evaluated all four statements correctly. In contrast, no student engaged in location-thinking evaluated all four statements correctly. Table 3 reports our classification of each student's thinking (Value-Thinking or Location-Thinking), along with each student's mathematical level (Calculus, Introduction to Proof, and Advanced Calculus), and final evaluations of the four statements (True, False, or Sometimes True).

Table 3: Students' Final Evaluations of Statements

Students Observed Engaging in…	Student Name	Math Level	Final Student Evaluations S1(F)	S2(T)	S3(F)	S4(F)
Value-Thinking	Jay	Advanced Calculus	F	T	F	F
	James	Advanced Calculus	F	T	F	F
	Nikki	Introduction to Proof	F	T	F	F
	Ron	Introduction to Proof	T	T	F	F
	Mike	Introduction to Proof	F	F	F	F
Location-Thinking	Zack	Calculus	ST	ST	ST	ST
	Nate	Advanced Calculus	T	T	F	F
	Hannah	Calculus	T	T	T	T
	Marie	Calculus	T	T	T	T

Shaded cells indicate mathematically incorrect evaluations.

Although all students who correctly evaluated the statements engaged in value-thinking, not all the students who engaged in value-thinking evaluated the statements correctly. Ron, a student who engaged in value-thinking, failed to attend to the restriction on the values of N, which led him to evaluate statement 1 as true. Mike, another student who engaged in value-thinking, evaluated all four statements as false due to unconventional meanings for the logical quantifiers (for all, there exists) involved in the statements. Thus, we view value-thinking as necessary, but not sufficient, for correctly evaluating the IVT and similar statements. In contrast, no student who engaged in location-thinking evaluated all four statements correctly. We take this as an indication that location-thinking does not support students in correctly evaluating the statements we presented. Even Nate, a student with a more advanced mathematical background, incorrectly evaluated Statement 1. His location-thinking was the main factor in his incorrect evaluation.

Conclusion & Discussion

Our findings in this study reveal critical distinctions in students' interpretations of aspects of graphs, namely in terms of value-thinking and location-thinking. In our study, some students interpreted and labeled points as pairs of input and output values, while others interpreted points as locations in space and labeled them with output notation. Our results highlight and explain significant aspects of students' interpretations of graphs not previously accounted for by current theories and studies on students' thinking about graphs. Thus, the use of our constructs of value-thinking and location-thinking may progress the depth of analysis in the field of students' understanding of graphs.

These two distinct ways in which students interpreted points, and thus graphs, have significant implications for how students understand important mathematical ideas, such as the Intermediate Value Theorem (IVT), as we observed with our students. We acknowledge that, in this study, value-thinking supported students in correctly evaluating the IVT and similar statements. However, in other contexts, such as diagrams in geometric settings, location-thinking may be preferable. Additionally, other contexts, like graphs of parametric curves, may require both location and value-thinking for interpreting various aspects of the same image. Ideally, students should possess the ability to think in both ways, focusing on the values represented at a point and the point's spatial location, along with the ability to discern when it is appropriate to use each way of thinking. To support students in recognizing these two ways of thinking, instructors and curriculum developers may consider providing students with opportunities to think both ways and bring to light this distinction. We hope that our findings increase practitioners' awareness of the subtle yet significant details of students' interpretations of aspects of graphs and may thus inform decisions in curriculum design and instruction.

COMPUTATIONAL AND INFERENTIAL ORIENTATIONS: LESSONS FROM OBSERVING UNDERGRADUATES READ MATHEMATICAL PROOFS

Paul Christian Dawkins
Northern Illinois University
pdawkins@niu.edu

Dov Zazkis
Arizona State University
dzazkis@asu.edu

This paper presents selected findings from an assessment of university students' moment-by-moment reading of mathematical proof. This method, adapted from an assessment of narrative reading validated by psychologists, yields novel insights into the strategies students use to construct meaning for the equations in a proof text. In particular, we present evidence that novice readers constructed meanings for the equations using mathematical practices familiar from non-proof oriented courses – substituting and solving for variables – while more experienced readers drew upon practices native to proof-oriented mathematics – inferring properties of quantities. We refer to these as computational and inferential orientations, respectively. We interpret this mismatch of practices in terms of Systemic Functional Linguistic's notion of textual metafunction and briefly discuss its implications for proof-oriented instruction.

Keywords: Reasoning and Proof, Post-Secondary Education, Cognition

Researchers of language in mathematics education have long noted that there exists a *mathematical register* (e.g. Halliday, 1975; Pimm, 1987) constituting a subdomain of spoken English (in the English-speaking world). Halliday (1975) explains that the mathematical register constitutes much more than technical terms and the extensive use of symbols. He explains, "It is the meanings, including the styles of meaning and modes of argument, that constitute a register, rather than the words and structures as such" (Halliday, 1975, p. 65). Many have noted that students' ability to participate in mathematics depends on developing competencies within the mathematical register (e.g. Schleppegrell, 2007; Morgan, 1998), but relatively few studies have investigated the nature of those competencies. This paper helps address this gap in the literature.

This report presents findings stemming from a study of undergraduate students' reading of mathematical proofs. We adapted a moment-by-moment think aloud protocol that has proven valuable for assessing narrative text reading competencies (Magliano & Millis, 2003; Magliano, Millis, Team, Levinstein, & Boonthum, 2011). Adapting this methodology to mathematical proof has yielded many insights into novice and experienced student reading behaviors. Hereafter, we highlight one difference between some novice and experienced readers' sense-making about equations in proofs. We refer to their strategies as *computational* and *inferential orientations*.

Studies of reading behavior

Two mathematics education studies particularly investigated undergraduate students' reading of mathematical text by comparing it to expert reading behaviors. Shepherd and van de Sande (2014) observed that mathematics faculty and graduate students read (i.e. articulated written text) equations in terms of their conceptual structure while undergraduates read them symbol-by-symbol. Inglis and Alcock (2012) used eye-tracking technology to compare undergraduate and mathematician reading of mathematical proofs. They found that experts focused much more on the text surrounding equations, which encoded the logical links in the proof, while undergraduates focused much more on equations themselves. However, eye-tracking methodology did not provide any explanation for why this difference emerged.

As mentioned above, we adapted our methodology from an assessment for narrative reading comprehension developed by Magliano, Millis, and colleagues (Magliano & Millis, 2003; Magliano et al., 2011). That assessment (called RSAT) presents students with narrative text one line at a time and asks students to think aloud or to respond to particular content-related prompts. The validated assessment distinguishes novice and expert readers based on the types of connections they make (not the quality). Students who connect the text to prior information in the text or outside knowledge tend to be more competent readers than those who simply paraphrase or restate the given line. One group of psychologists (Fletcher, Lucas, & Baron, 1999) adapted this method to reading high school proofs. They found that reading such text was more effortful than reading narrative and allowed new types of connections such as anticipating later lines of the text. The findings from moment-by-moment assessment techniques correlate with end-reading comprehension tests, but they reveal a different set of behaviors and insights into the reading process itself. We accordingly adapted the methodology to gain new insights that might not be yielded from existing assessments of proof end-reading comprehension (Mejia-Ramos, Lew, de la Torre, & Weber, 2011) or proof validation (e.g., Alcock & Weber, 2005).

Conceptualizing the linguistic functions of proof

Most studies of language learning in mathematics education draw upon Halliday's (1975; 1984) theory of Systemic Functional Linguistics (SFL). This theory is particularly useful because it is rooted in language use, it focuses on speakers' and hearers' choices by which they make meaning in language, and it emphasizes the role of linguistic function to explain language use. As Schleppegrell (2004, p. 137) explains, "It is important for students to develop academic register options in different disciplines because particular grammatical choices are functional for construing the kinds of knowledge typical of a discipline." SFL posits that three metafunctions are always operative in the construction or interpretation of a text: the *ideational* metafunction concerns what is being talked about, the *interpersonal* metafunction concerns who is involved in the discourse and how they are positioned, and the *textual* metafunction concerns what type of text is being constructed and what features are necessary or appropriate for such text.

Consider the following excerpt from one of our proof tasks:

For every primitive Pythagorean triple (a, b, c) there exist some numbers s and t with no common factors such that $s > t \geq 1$ where $a = st$, $b = \frac{s^2 - t^2}{2}$, and $c = \frac{s^2+t^2}{2}$.

1. Let (a, b, c) be a primitive Pythagorean triple.
2. Then $a^2 = c^2 - b^2 = (c + b)(c - b)$.
3. We want to show that $(c + b)$ and $(c - b)$ are both squares and share no common factors.
4. Suppose that d is a common factor of both $(c + b)$ and $(c - b)$.
5. Then d is also a factor of $(c + b) + (c - b) = 2c$ and a factor of $(c + b) - (c - b) = 2b$.

Figure 1. Excerpt from the primitive Pythagorean triples proof (Rotman, 2013).

Ideationally, the proof is about characterizing primitive Pythagorean triples. Many portions of the proof are dedicated to deducing numeric properties such as sharing common factors or being perfect squares. *Interpersonally*, mathematics text tends to hide any direct reference to human participants by expressing relations about mathematical objects. In this text, the subjects of most clauses are quantities to which properties are attributed. *Textually*, the symbols and equations mark the text as clearly mathematical. They conform to the genre of mathematical proof by drawing (and justifying) inferences. The conflict between the claims in lines 3 and 4 further suggest to an expert reader the beginning of a proof by contradiction (or proof that $d = 1$).

A key function that distinguishes mathematical proof from other texts is the emphasis on both making and justifying claims. There is an implicit expectation for the reader to identify the implied warrant in line 5: "the sum and difference of multiples of d are also multiples of d." Students must parse the equation in multiple ways to construct the intended meaning. They must recognize that both sides of the equation represent the same quantity, which is the object of the clause "d is a factor of." They must parse the left sides as the sum and difference of the two compound quantities discussed in line 4, which is supported by parenthetical grouping. Finally, a reader should determine that the property of being a multiple of d is being transferred from two quantities known to share the property to a pair of new quantities $2b$ and $2c$. Though equations are symmetric, this inference is directed (from left-hand quantities to right-hand quantities).

While the various claims about the normative or intended construal of this text are cued in subtle ways in these three lines, an expert reader in many ways constructs its meaning using textual expectations and devices. Ultimately, the text is far from explicit regarding all that it intends to convey. This is not a particular defect of mathematical proof, but rather,

> Inferencing on the basis of background assumptions plays a central role in the interpretation of all texts. Highly complex and abstract background assumptions which are not spelled out are often necessary for the interpretation of written language, especially in school contexts. (Schelppegrelle, 2004, p. 11)

With this background we may now better articulate the key question investigated in this report: what textual assumptions and functions do novice readers use to construct meaning for equations in mathematical proofs and how do these differ from those used by more experienced readers?

Methodology

One contribution of this study is the adaptation of the moment-by-moment think-aloud reading assessment protocol to advanced mathematical proof. Our study involved interviewing mathematics students ranging in experience from no proof-oriented courses to beginning graduate study. To accommodate such diverse experience, we sought out proofs that (a) had at least 10 lines of text, (b) required no knowledge of mathematical concepts with which novices were not familiar, and (c) were relatively outside the curriculum such that experts were less likely to have seen the exact proof being presented. We used four such proofs in our interviews, though due to space limitations we only report on the proof quoted from in Figure 1.

Adapting moment-by-moment read aloud protocol to proof

Similar to RSAT (Magliano & Millis, 2003), each proof was presented one line at a time. Unlike RSAT, the previous lines of our proofs remained visible. For three of the four proofs students first read relevant definitions and theorems. These remained available for their reference on sheets of paper that doubled as scratch paper. Students were instructed to read each line aloud and think aloud before the interviewer might provide more specific response prompts. We developed the response prompts by listing all the connections that we expect expert readers could make for each line. These included (a) relations to previous lines, (b) implicit warrants, (c) use of definitions, (d) elements of proof frames such as universal generalization, case structure, proof by contradiction, or induction, (e) opportunities to anticipate future lines, and (f) goal statement or achievement. We then decided for which lines we would provide targeted prompts such as "why is this line justified," "what do you expect in the following lines," or "why did the author introduce d." The interviewers explained the meaning of terms or statements upon request, though we tried to withhold judgment about the students' interpretations. We note that this methodology does not elicit a naturalistic reading because inviting students to think aloud and respond to targeted prompts in many ways mimics the self-explanation training that Hodds, Alcock, and Inglis (2014) found to improve proof comprehension. Rather, we interpret our data as representing an optimal reading for each student at that time. Such readings still elicit the students' capabilities as readers of mathematical proof.

Participants and analysis

Participants were recruited from a large public university in the Southwestern United States and a mid-sized public university in the Midwestern United States. Volunteers were solicited from courses ranging from differential equations, introduction to proof, real analysis, and topology (the latter two were dual-listed as undergraduate and graduate courses). To date, 17 students completed interviews for which they were given minor monetary incentives. Three students recruited from differential equations had no collegiate proof coursework and three other participants were recruited from real analysis, which was their first completely proof-oriented course. We classify all six as *novice readers*. The nine other undergraduate students had completed at least one proof-oriented course and were classified as *experienced readers*. Finally, two mathematics graduate students participated who were considered *expert readers*.

Coding began by forming narrative note files for each interview that described students' reading behavior for each line of text. From these line-by-line notes, we formed categories of noteworthy behaviors and patterns in student reading behavior. The two authors independently coded two novice reader interviews in this way and met to discuss and compare the findings. By comparing the various categories of reading behaviors across the four proof tasks, we identified five meta-categories that organized the primary range of categories. We then independently coded the rest of the interviews, meeting regularly to discuss our interpretations and coding. These five meta-categories remained relatively stable, though nuanced to accommodate further cases. The meta-categories are computational versus inferential orientation, depth of encoding for proof claims, logic structure and language, meanings for relevant mathematical concepts, and sense-making activities. Due to space concerns this paper only presents findings about the first category, computational versus inferential orientation.

Results

The meta-category computational versus inferential orientation most directly addresses students' reading behaviors relevant to the textual metafunction characterized by SFL. In particular, it concerns the mathematical practices that students called upon to make sense of the proof's use of equations. We briefly introduce the two constructs with reference to line 2 in Figure 1. Every study participant could identify and justify the algebraic manipulations the line expressed. This type of reorganization of equations is very common in computational mathematics courses and thus familiar to all of these students. The proof goes on to use this equation in two other ways. First, because d is defined as a factor of $(c + b)$ and $(c - b)$, this equation supports the inference that d is a factor of a. The property "d is a factor" (more precisely d^2 is a factor) is transferred from the right side of the equation to the left. Then, once it is established that $(c + b)$ and $(c - b)$ share no common factors, the equation is used to infer that both of those quantities are perfect squares. In this case, the property "is a perfect square" is transferred from the left side of the equation to the two components on the right. This latter use of the equation as a vehicle for inferring properties about the quantities within is not native to early collegiate non-proof-oriented courses. As a result, we noticed much greater discrepancies in students' abilities to construct these meanings for the equations.

We thus define two orientations as follows:

- *Computational orientation*: Mathematics is about computing and solving for numbers, so proofs use equations for counting, evaluating, computing, and solving for quantities.
- *Inferential orientation*: Mathematics is about relating mathematical properties, so proofs use equations for stipulating, inferring, and denying properties of quantities.

We posit a few points about these constructs before presenting some instances of student data that exemplify how these orientations operated in our data. First, the two are not mutually exclusive since both are accurate reflections of mathematical practices. Both of these claims express resources that students may use to interpret linguistic choices in a proof, specifically ideational and textual choices. The main concern is when a proof was constructed according to one orientation and is interpreted according to another. All students recognized that line 2 could be justified in terms of computational practices. However, not all students recognized the uses of line 2 in terms of inferential practices. Also, such orientations are implicit and are merely enacted by students in reading. We now present two cases of novice reading behavior that exemplify reading inferential proof texts using a computational orientation.

Nov5 – Explaining operations rather than inferring properties

Nov5 was a chemistry major taking differential equations when he participated in the study. He had no collegiate proof-oriented coursework. He spent about 45 minutes reading the Pythagorean triples proof (17 lines). He expressed low confidence in his interpretations and confusion about what the interviewer meant by questions about "justifying" lines of the proof. His responses to such questions most often focused on explaining the author's reasoning or on trying to explain why each step in the proof was chosen. He explained line 3 (that introduced subgoals for the proof) saying "I guess they are saying that the focus is going to be on this part of their equation." When he read line 4 that introduced the quantity d, he explained:

N5: Ok. I guess they are gonna put in a variable d that I guess is a factor of both, so it's both divisible by d [rising tone as if a question].

I: What is the purpose of introducing d here?

N5: Uhh. Probably to somehow come out with the quotient for b and c being 2.

I: When you say quotient, what were you pointing at?

N5: Just the denominator here [reads b and c equations in theorem] just showing where that 2 is coming from. [reads line 5]

I: So why is this true?

N5: Well I am pretty sure what they did was set the parentheses equation up to the $c^2 - b^2$ and then attempted to solve and then since you would have a square root to solve, you have to have the positive and the negative version of it. I feel like I am wrong, but. […] Yeah. Multiply it out here. [He multiplies $(c + b)(c - b)$ on paper.] Well I guess that proves number two for sure. Let's see what they. I think my idea is off. Ok, now I am not 100% sure where that came from. d is a common factor.

I: So tell me something about what you are thinking here.

N5: I am thinking maybe possibly that, that these here the $2b$ and $2c$ are derivatives. Because the derivative of c^2 would be $2c$ and the derivative of b^2 would be $2b$. I am just trying to think where they got the addition from.

N5: [Later, he reads line 7, which says] "If d is a factor of both b and c, then d is also a factor of a." Ok yeah cause that would match their equation.

I: Which equation are you looking at?

N5: Pythagorean theorem because if you mess with one side of the equation you also have to do it with the other side of the equation or else it's not equal, so I guess, yeah.

We notice that Nov5 drew on multiple resources to make meaning from the text. He did not explain the introduction of d in terms of the goals in line 3, which he only interpreted as focusing the reader's attention. Rather, he hoped to explain why the equations for b and c in the theorem both had a denominator of 2. He next cited the algebraic procedure of introducing positive and negative possibilities when taking the root of an equation to explain why the two equations in line 5 differed by addition and subtraction. When he could not recreate the inferred algebraic manipulations, he connected the right sides of the line 5 equations to the derivatives of terms in the line 2 equation. In each case, we notice that Nov5 drew upon computational practices (substituting, solving, and taking derivatives) to make meaning of the text.

Finally, we note that Nov5 was able to make sense of the property inference in line 7, but he explained it in terms of operations performed on each side of the equation rather than in terms of the equality between the quantities. On one hand, we may celebrate his linguistic improvisation for conveying a meaning that he did not seem to have ready tools to express. On the other, his explanations give the sense that he understood "d is a factor of" as an operation to be performed rather than a static property of a number. We expect that an inferential orientation and the language to express its meanings are interdependent and co-emerge (Schleppegrell, 2004).

Nov2 – "What is the goal of this equation?"

Nov2 was an electrical engineering major recruited from differential equations who had not taken any proof-oriented courses. She also spent about 45 minutes reading the Pythagorean triples proof. The following represents her reading of the fourth and fifth lines:

I: So what is the purpose of introducing d?

N2: Umm, d would, d would show the correlation between the number b and c, to see how they, to figure out what c and b is possibly.

I: Ok. Anything else that comes to mind about this line?

N2: I mean if you multiply everything out and add d to the equation, you could solve for one of them, if you knew one of the numbers.

I: Ok let's see what comes up [shows line 5].

N2: [Reads line 5]. Umm. [Long pause.] I'm just seeing how d fits into everything, I guess?

I: My question about this is why is this line justified? Why does this have to be true?

N2: Well if you, obviously if you do the math you would figure out that. Sorry I am not good at putting this into words.

I: So when you say "do the math" can you tell me more specifically what you are thinking about?

N2: Well if. So are we trying to figure out what b and c is? What is the goal of this equation? What are we trying to figure out? Just figuring out what the missing variables are?

N2 showed direct awareness that she was confused about the purpose of introducing d and the equations in line 5. She inferred that the purposes were to substitute and solve for variables, consistent with the practices in non-proof-oriented courses. She used the parlance "do the math" to refer to algebraic operations, suggesting an identification between the two. When asked to explain, she posed four questions about the purpose and goal of the equations in line 5. These convey a clear sense that her current understanding did not help her construe the text coherently, but she did not know what other goals or practices to infer beyond solving for variables.

By claiming that N2 interpreted using a computational orientation rather than an inferential orientation, we do not claim she did not draw inferences and try to justify them. For instance, after the proof establishes that d cannot be a factor of b and c, line 10 asserts that "d is 1 or 2." N2 responded saying:

N2: I am guessing it's 2 because, being a factor of 1 is being a factor of everything, right?

I: Yeah, 1 is a factor of every number.

N2: So since d is not a factor of b and c, it can't be 1. So it would have to be 2.

It is important to note that the proof's references to the property "share no common factors" up to this point left the caveat "factors greater than 1" unstated. Some other study participants made the same observation that N2 did, but concluded that if 1 is a factor of every number then "share no common factors" must implicitly exclude 1. However, from N2's current construal of the text that d is not a factor of b and c, her inference that $d = 2$ is justified. As a result, we argue that N2 was clearly capable of drawing (deductive) inferences from the proof, but her inferences did not always match the intended inferences. This further nuances what we mean by students reading with a computational orientation. It describes the resources that students use to make meaning from the text, not their capabilities for engaging in particular mathematical reasoning.

N2 was perturbed enough by the end of reading this proof that she sought to explain herself:

> I am really awful at proofs. […] I am more of a plug and chug person, so I am good at integrating and all that stuff. Word problems like this where I have to think about it and why it equals something, it is not my forte. […] For me I want to solve, I don't really care about like why is it this, why is it that. I just wanna solve for it. I am just so used to solving, I have never even thought about why is this this and this. It is a little new to me.

Our view of N2's learning capabilities is higher than what she expressed here. We maintain that reading capabilities such as an inferential orientation can be learned through experience with proofs and her difficulty with reading can be overcome. However, her explanation corroborates our claim that her extensive experience with computational practices in mathematics led her to use them to make sense of the proof, even when different practices were intended.

Inferential orientation readings of line 5

The majority of study participants, specifically all of those with more proof experience, constructed meaning for line 5 in terms of attributing the property "d is a factor of" to two quantities. Furthermore, they interpreted the interviewers' request for justification in a more normative manner rather than simply trying to explain why the author chose to add and subtract the quantities they did. We still observed a range of reading behaviors for justifying the inference. Some students imagined substituting some expression including d in place of $(c + b)$ and $(c - b)$ and noted that d could be factored out, verifying that the sum and difference should also have d as a factor. We consider this as essentially *constructing a mini-proof* of the implicit warrant. This type of proof still drew upon algebraic meanings for factor, namely to substitute and "factor out." Other students – primarily more experienced readers – searched for a general form of the particular inference to evaluate its validity. For instance, they might paraphrase the inference as "if d is a factor of two numbers, then it is a factor of the sum or difference of those numbers." This pattern may be called *generalizing the inference*. Finally, one of the graduate student readers justified line 5 by citing that any linear combination of multiples of d would also be multiples of d. In this case, she *recalled a warrant* to justify the inference. Thus we recognize that within an inferential orientation students may exhibit a range of meaning-making behaviors.

Discussion

Using observations of students' moment-by-moment reading behavior, we characterize two textual orientations that students drew upon to make meaning for the equations in a proof text: *computational orientations* and *inferential orientations*. We claim this contributes to the existing literature in two ways. First, our findings could explain Inglis and Alcock's (2012) eye-tracking finding that novice readers focused much more on the equations in a proof rather than the surrounding text. Their calculus student participants may have read the provided proofs using a computational orientation that led them to draw upon the wrong kinds of practices, while the expert readers focused on the inferences expressed by the surrounding text. Second, it begins the process of characterizing some of the reading capabilities that students need to develop to interact productively with advanced mathematical proof texts. Our findings highlight the ways in which students draw upon their knowledge of mathematical practices to read a text. We expect that their ability to understand new practices (such as proving properties of quantities in number theory), to read texts intending to express those practices, and to use language to convey those practices are interdependent and co-emergent in student learning. As noted above, interpreting inferential text in terms of computational mathematical practices was observed only among our least experienced study participants. This could be interpreted in one of two ways. Either basic proof-oriented instruction was successful in fostering an inferential orientation or those who did not construct an inferential orientation did not succeed in proof-oriented courses before we recruited participants. Further data gathering would be required to understand the interaction between these orientations and instruction. We expect that further study should reveal significant variation among the reading behaviors within the inferential orientation. These could be used to understand advanced mathematical reading competencies and how they develop.

A FINE-GRAINED ANALYSIS OF PROOF SUMMARIES: A CASE STUDY OF ABSTRACT ALGEBRA STUDENTS

Eyob Demeke
California State University, Los Angeles
edemeke@calstatela.edu

In this paper I explore eleven undergraduate students' comprehension of a proof taken from an undergraduate abstract algebra course. My interpretation of what it means to understand a proof is based on a proof comprehension model developed by Mejia-Ramos, et al. (2012). This study in particular examines the extent to which undergraduate students are able to summarize a proof using the proof's higher-level ideas. Additionally, eleven doctoral students in mathematics were asked to provide a summary of the same proof that the undergraduate students received. Undergraduates' holistic comprehension of the proof was then analyzed in light of summaries that the doctoral students provided. The main finding of the study is that undergraduates' comprehension of the proof was overall inadequate—notably, they demonstrated limited skills in summarizing a proof via the proof's key ideas. Moreover, undergraduates failed to recognize the scope of the method used in the proof.

Key words: Proof, Proof Comprehension, Abstract Algebra.

In advanced undergraduate mathematics courses, students are expected to spend a significant portion of their time reading proofs. Although proof comprehension is a fundamental aspect of undergraduate mathematics education, studies by Conradie and Frith (2000), Rowland (2002) and Weber (2012) suggest that mathematicians rarely measure their students' comprehension of proofs. For example, Weber (2012) reports that mathematicians assess their students' comprehension of proofs by asking students either to reproduce the proof or prove a similar or a trivial consequence of proofs they presented in class. However, Conradie and Frith (2000) suggests that asking students to reproduce a proof may not be a pedagogically useful way of assessing students' understanding of a proof because students can and do correctly reproduce a proof by simply memorizing it word for word, with virtually no understanding at all.

Despite its importance in undergraduate mathematics education, research on undergraduates' comprehension of proofs is limited. In fact, much of the proof literature focuses on students' aptitude to construct or validate proofs and less on their ability to comprehend proofs (Mejia-Ramos et al., 2012; Mejia-Ramos & Inglis, 2009). Mejia-Ramos and his colleagues (2009) systematically investigated a sample of 131 studies on proofs and they found that only three studies focused on proof comprehension. They hypothesize that the scarcity of the literature on proof comprehension is perhaps due to the lack of a model on what it means for an undergraduate student to understand a proof. In this study, I adopt an assessment model for proof comprehension that was developed by Mejia-Ramos, et al. (2012) to explore undergraduates' comprehension of proofs. In particular, this study seeks to address the following research questions.

To what extent do undergraduates comprehend a proof? More specifically, to what extent do undergraduates:

- summarize a proof using its high-level ideas,
- recognize and appreciate the scope of a method used in a proof?

Theory: Assessment Model for Proof Comprehension

Mejia-Ramos, et al. (2012) proposed that one can assess undergraduates' comprehension of a proof along seven facets. These seven facets are organized into two overarching categories: local and holistic. A local understanding of a proof is an understanding that a student can gain "either by studying a specific statement in the proof or how that statement relates to a small number of other statements within the proof" (p.5). Alternatively, undergraduates can develop a *holistic* comprehension of a proof by attending to the main ideas of the proof. Below, I will elaborate on what it means to understand a proof holistically.

Assessing the Holistic Comprehension of a Proof

According to the proof comprehension model, the holistic understanding of a proof consists of being able to: (1) summarize the proof using the proof's main ideas, (2) identify the modular structure of the proof, (3) recognize and extend the method used in the proof, and (4) illustrate the method of the proof using a specific example or diagram. They developed these four facets of holistic comprehension of proofs based on: (a) mathematicians' perspectives on how and why they read and present proofs and what it means for them to understand a proof; (b) the proof literature on the role of proof; and (c) the recommendations by mathematicians and mathematics educators on proof presentations that would presumably improve students' proof comprehension. Below, I elaborate on (1) and (3).

Summarizing a proof via its high-level ideas. Mejia-Ramos, et al. (2012) state that "one way that a proof can be understood is in terms of the overarching approach that is used within a proof" (p.11)." Being able to summarize a proof via its high-level ideas entails understanding the proof's "top-level overview" or "big idea". A good summary of a proof may include what Raman (2003) describes as a proof's *key ideas.* Raman (2003) defines *key ideas* as "heuristic ideas which one can map to a formal proof with appropriate sense of rigor" (p. 323). *Key ideas* provide "a sense of understanding and conviction why a particular claim is true" (Raman, 2003, 323). Mathematicians can evaluate their students' understanding of this aspect of a proof in at least two ways. They can, for instance, directly ask students to provide a brief summary of the proof that includes the proof's higher-level ideas. Alternatively, they can provide students with a few summaries of the proof and ask them to choose which summary best captures the main ideas of the proof (Mejia-Ramos et al., 2012). In this study, I asked undergraduates to provide a proof summary using the proof's main ideas.

Transferring the general ideas or methods to another context. Mejia-Ramos, et al. (2012) suggested that identifying the scope of a method or technique used in a proof is an important aspect of proof comprehension. Mathematicians can assess this aspect of proof comprehension by asking students to (a) identify methods or techniques without which the proof would have collapsed, or (b) prove new claims by applying methods similar to those used in the original proof. In this study, undergraduates were asked questions to elicit their understanding of the scope of a method used in a proof.

Review of the Literature

As noted earlier, educational research on proof comprehension in undergraduate mathematics has received little emphasis. Osterholm (2006) was among the first to look into student's comprehension of mathematical texts. He conducted a quantitative study of reading comprehension of abstract algebra students (he compared texts with one including symbols and another one not). He concludes that "mathematics itself is not the most dominant aspect affecting the reading comprehension process, but the use of symbols in the text is a more relevant factor" (p.325). His contention is based on the fact that the group of students who had almost no symbols and notations in their reading assignment outperformed, in a reading comprehension test, those whose reading assignments involved mathematical symbols and notations. Although Osterholm (2006) does point to difficulties student encounter while reading mathematical texts, it should be noted that his study only asked students to read mathematical texts and not proofs specifically.

Research also suggests that undergraduates are not successful in gleaning understanding from the proof they see during lecture (Selden & Selden, 2012; Lew et al, 2015). For example, students interviewed in Lew et al.'s (2015) study fail to comprehend much of the content the instructor desired to convey, including the method used in the proof. Students interviewed in Selden and Selden's (2012) study also failed to understand a proof holistically since they were fixated on verifying each line and put little emphasis in attending to the overarching methods used in the proof. One purpose of this study is to build on the growing body of research on proof comprehension.

Methods

Research Settings

This study took place in a large public university in the northeastern United States. The content of the proof used in this study come from an introductory abstract algebra course. In the chosen research setting the standard textbook used is *Abstract Algebra: An introduction* by Hungerford (2012). The goal of the course (as stated in the syllabus) is to introduce students to the theory of algebraic structures such as rings, fields, and groups in that order.

Participants

Undergraduate student participants. Since the main purpose of this study is to explore undergraduates' comprehension of proofs—in particular, proofs that appear in an introductory abstract algebra course—I personally approached undergraduates who had taken or were enrolled in an introductory abstract algebra course. Eleven undergraduates agreed to participate in this study and were assigned pseudonyms S1-S11. At the time of the study, six of the eleven undergraduate participants (S3, S5, S6, S7, S8, and S9) were enrolled in an introductory abstract algebra course. Seven participants—S1, S2, S3, S5, S6, S7, S8, and S9—were pursuing a major in secondary mathematics education and said they intended to be high school mathematics teacher. The remaining four students were mathematics majors. Furthermore, each participant had taken a minimum of three proof-based courses and all but three (S1, S3, and S6) said they received an A or B in their introduction to proof course. Participants' responses on a background survey suggest that each participant spent at least two hours per week reading proofs outside of class.

Doctoral students. Eleven doctoral students at the aforementioned research site agreed to participate in this study. I used doctoral students to analyze undergraduates' summaries of a proof. At various times, I asked the doctoral students to provide, in writing, a summary of a proof using the proof's key or main ideas. To avoid confusion, in the remainder of this paper I will refer to these doctoral student participants as experts.

Materials and Research Procedures

In this study undergraduates were asked to read a proof that shows that any finite integral domain is a field. This proof is given in appendix 1. I chose this proof because (a) it nicely draws connection between two important topics covered in abstract algebra: integral domains and fields, and (b) it uses a proof technique that I speculated most participants probably have not seen.

The principles I employed to write this pedagogical proof—a proof that is geared toward undergraduates for the purpose of pedagogy—is based on the Lai, Weber, & Mejia-Ramos (2012) study. Lai et al. (2012) report that mathematicians valued pedagogical proofs that (1) made assumptions and conclusions of the proof explicit, (2) centered on important equations to emphasize the main ideas, and (3) did not contain "true but irrelevant statements." (p.94). Also, when writing the proof, I consulted mathematics professors and made appropriate modifications.

Participants were asked to read the proof until they felt they understood it and were encouraged to write and/or highlight on the proof paper as well as to think out loud while reading. Once a participant finished reading the proof, she/he was asked to:

- to provide a good summary of the proof including the proof's main or higher-level ideas
- to indicate assertion(s) in the proof that would fail if $\boldsymbol{R}$ was infinite.

Analysis

Recall that eleven doctoral students in mathematics were asked to write a summary of the proof using what they think are the main ideas of the proof. Doctoral students were also asked to describe the key ideas of each proof. First, I carefully studied doctoral students' summaries of the proof. I then developed a synthesized summary for the proof. This synthesized summary, which will hereafter be referred to as the expert's summary, also incorporated all the key ideas that doctoral students described for each proof. That process resulted in the following summary of the proof.

> The proof shows that a finite integral domain R is a field by showing that any non-zero element of R has a multiplicative inverse. Let a be any non-zero element of R. The absence of zero divisor in R taken together with the fact that R is finite gives us that left multiplication by a defines a bijective map from the integral domain to itself ($f_a: R \to R$ given by $f_a(x) = ax$ is a bijective). Surjectivity of this map guarantees that a has a multiplicative inverse.

The key ideas identified in the expert's summary of the proof are:

- Overarching method: given an arbitrary non-zero element $a \in R$, show that there exists $b \in R$ such that $ab = 1_R$
- Approach: define a left multiplication by a non-zero element $a \in R, f_a: R \to R, x \mapsto ax$. Using kernel of f_a one can show that it is injective.
- The finiteness of R and the injectivity of f_a to show that f_a is a surjective map from R to R.

The above expert's summary of the proof was eventually verified by two experienced researchers in mathematics education as to whether or not it indeed incorporated all the *key ideas* of the proof that doctoral students discussed; modifications were then made to the expert's summary, as needed.

Finally, using a rubric, two researchers, both with a master's degree in mathematics, independently conducted a comparative analysis of undergraduates' summaries of the proof against expert's summaries. When disagreement emerged, w engaged in discussion until a consensus was reached.

Results and Discussion Results on Undergraduates' Summaries of the proof

Recall that undergraduates' summaries of the proof were analyzed in comparison to the expert's using a rubric that is omitted here for a shortage of space. Nearly all participants, nine out of eleven, provided a summary of the proof that suggested a limited proof comprehension. In particular, their responses indicated that they either *poorly* or *very poorly* understood the proof. The results of students' summaries of the proof is given in Table 1. Note, in table 1, that a majority, six undergraduates, provided a *very poor* summary of the proof, which implies that their summary failed to highlight the main ideas of the proof that was described in the expert's summary.

Table 1: Undergraduate students' summaries of the proof

Evaluation	Undergraduate students
Very poor	S3, S5, S6, S8, S9, S11
Poor	S1, S2
Satisfactory	S4, S7, S10
Good	None

In order to give you a sense of a *very poor summary*, I will provide a detailed description of summaries given by S5, S8, and S9. When asked to provide a good summary of the proof including the proof's main ideas, S5 offered the following summary:

> *R* is an integral domain and field. It is both surjective and injective to the kernel of the function that defines it. There is also $1_R \in R$ that allows it to have multiplicative inverse, thus units. I know a field's non-zero elements all make units, a field.

S5's summary consists of incomplete sentences and phrases that are either mathematically incorrect or appear to have been copied from the proof word for word. For instance, S5 begins by supposing the thing that needs to be shown—that *R* is a field. Also, there is evidence of a misunderstanding about injectivity and surjectivity of a map. This is evident when he asserts that *R*, as opposed to f_0, is both surjective and injective. Finally, S5's summary doesn't mention how crucial assumptions in the proof such as the finiteness of *R* are used in the proof. Thus, S5's summary is deemed to be *very poor*, which means it was considered to be very different from the expert's as it did not highlight main ideas of the proof. S8, likewise, provides a *very poor summary*:

> The proof basically gave a less textbook traditional explanation of a way to prove that all finite integral domains are fields. It used the understandings of kernals [sic], bijections, injection, surjections in order to prove facts about rings, where usually you learn the facts about rings before being introduced to functions

Her summary above makes no mention of the proof's high-level or *key ideas* and thus does not suggest a satisfactory comprehension of the proof. While she enumerates topics that are used in the proof, her summary does not illustrate how they were employed in the proof. S8's summary, for example, indicates that the concept of bijectivity is employed in the proof, but she does not explain how it is used. Along the same lines as S5, and S8, S9 also supplied a summary of the proof that did not suggest a satisfactory comprehension of the proof. For example, S9 provided the following summary:

> Given a finite integral domain, you can prove that it is a field by showing it has a multiplicative inverse, no zero divisors, injective and surjective, kernels, and if there is a multiplicative inverse such that $ax = 1_R$ and $a \neq 1_R$ then R is a field.

S9's summary above says very little beyond restating the claim. S9 essentially repeats phrases that appeared in the proof verbatim. He does not draw any connection between *key ideas* described in the expert's summary of the proof. Also, S9's summary states that *R* is first shown not to have zero divisors, but this is neither necessary nor true; *R* is assumed to be an integral domain and therefore it does not have zero divisors. Overall, S9's summary fails to mention the proof's key ideas and consequently shows limited comprehension of the proof.

While the majority, six out of eleven students, provided what is considered to be a *very poor summary* of the proof, S1 and S2 supplied a *poor summary* of the proof. S2, for example, provided the following summary of the proof:

> The aim of the proof is to show that if R is a finite integral domain, then R is a field. It then wants to show that R has a multiplicative inverse, then that the kernel of $f_a: x \rightarrow ax$ to be trivial. The prof then shows that $x = 0$ since if $ax = 0$ then a or x is 0 but a is not, thus $\ker f_a = \{0\}$ so f_a is injective. Thus, $|R| = |f_a(R)|$, which shows it is surjective. It then proves a has a multiplicative inverse, so R is a field.

S2's summary is incoherent and appears to duplicate some parts of the proof word for word. Moreover, her summary includes way too much unnecessary information; for example, she repeats the argument for the triviality of f_0. While S2's summary does mention some *key ideas* that are noted in the expert's summary, it doesn't make the logical connection between those *ideas*. In fact, S2 appears to have the logic of the proof backward, as she seems to think the existence of multiplicative inverse is what guarantees the triviality of the kernel of f_0.

While no one provided a *good summary* of the proof, three students—S4, S7, and S10—provided a *satisfactory summary* of the proof. S7, for instance, summarized the proof as follows:

> First it is important to show each nonzero element of *R* has a multiplicative inverse. Then we consider a nonzero element $a \in R$ and the map of f_a. We use the kernel of f_a to prove f_a is injective. Then from the fact that f_a is injective and therefore $|R| = |f_a(R)|, f_a$ is also surjective. Finally, we show $f_a(x) = 1_R$ hence a has a multiplicative inverse and therefore *R* is a field.

Evidently, S7's summary above has significant resemblance to the expert's summary of the proof. In particular, S7 does mention some *key ideas* of the proof. However, she did not indicate the fact that the surjectivity of f_0 depends on the finiteness of *R*, which was a crucial idea that was noted in the expert's proof. Furthermore, the last line of her summary is incorrect in the sense that f_a is not identically equal to the identity 1_R. Also, based on what is stated at the very end of her summary, S7 does not seem to have understood how a (the fixed nonzero element) has a multiplicative inverse. However, S7's summary overall does bear some resemblance to the expert's summary and suggests a satisfactory understanding of the proof. On the whole, while nearly all students provided a *poor* or a *very poor* summary of proof, no one provided a *good summary.* Indeed, only S4, S7, and S10 managed to provide a satisfactory summary of the proof.

Results on Undergraduates' Ability to Recognize or Appreciate the Scope of a Proof's Method

No undergraduate demonstrated why $\boldsymbol{R}$ must be finite for the proof to be valid. When asked why the method of the proof would fail if *R* was assumed to be infinite, six out of eleven undergraduates offered no response or said "I don't know…" The other five students pointed incorrectly to an assertion that would fail if *R* is infinite. Table 2 below illustrates the various responses they provided:

Table 2 Reasons undergraduates provided for why R must be finite

Reason why R must be finite	Participants
R would not be commutative (line two)	S1
There wouldn't be exactly be the same number of	S3 elements in each
f_a would not be injective (line seven)	S2, S8, S5
No response/I don't know/Not sure	S4, S6, S7, S9, S10, S11

Table 2 shows that participants failed to pinpoint a specific assertion in the proof that would fail—the argument in line eight—if *R* was infinite. That is to say, if *R* is infinite, $f_a(R) \subseteq R$ and $|R| = |f_a(R)|$ taken together would not guarantee that $f_a(R) = R$, which would not make f_a surjective.

To summarize, Mejia-Ramos and colleagues (2012) maintain that being able to provide a good summary of a proof is a key indicator of comprehension. However, undergraduates in this study showed a limited comprehension of the proof. In particular, in their proof summary undergraduates failed to highlight the proof's main idea. For a large number of participants, their proof summary was essentially a replica of a few sentences that appeared in the proof. Further research is needed to identify why undergraduates fail to summarize a proof using the proof's main ideas.

Appendix 1

Claim: Let *R* be a finite integral domain. Then *R* is a field.

Proof.

1. Let *R* be a finite integral domain whose multiplicative identity is 1_R and whose additive identity is 0_R.
2. Since *R* is a commutative ring, it suffices to show that every nonzero element in *R* has a multiplicative inverse.
3. Let *a* be a fixed nonzero element of R $(a \neq 0_R)$. Consider the map $f_a: R \to R$ defined by $f_a: x \to ax$. We first show that the kernel of f_a is trivial.
4. Note that kernel of $f_a = \{x \in R: f_a(x) = 0_R\} = \{x \in R: ax = 0_R\}$.
5. Since R has no proper zero divisors, $ax = 0_R \Longrightarrow a = 0_R$ or $x = 0_R$. But, $a \neq 0_R$ thus $x = 0_R$.
6. Therefore kernel of $f_a = \{0_R\}$ and so f_a is injective.

7. Next, note that $|R| \geq |f_a(R)|$. Since f_a is injective, it follows that $|R| = |f_a(R)|$.
8. Because $f_a(R) \subseteq R$ and $|R| = |f_a(R)|$, we have that f_a is surjective.

STUDENT UNDERSTANDING OF THE GENERAL BINARY OPERATION CONCEPT

Kathleen Melhuish
Texas State University
melhuish@txstate.edu

Michael Hicks
Texas State University
mh1653@txstate.edu

In this paper, we address the variety of ways in which students conceive of binary operations and the metaphors they might leverage when working with binary operations in group theory. We use open-ended surveys paired with interviews to qualitatively explore student's conceptions of binary operation. Through this analysis, we identified three central metaphors (function, arithmetic, and structure), as well as a number of attributes related to binary operation that students perceive as critical. This work has implications for our treatment of binary operation in advanced mathematics, and the messages we send about operation in the K-12 setting.

Keywords: Advanced Mathematical Thinking, Algebra and Algebraic Thinking, Post-Secondary Education

Binary operations are threaded throughout the mathematics curriculum starting with a focus on arithmetic, and then expanding to operations such as matrix multiplication and function composition. Although binary operations are prolific throughout mathematics in K-12, it is not until advanced courses in undergraduate mathematics that binary operation is formally defined. In courses such as group theory, students are put in a position to generalize the binary operation concept to better understand the structures that underlie our mathematical systems. Despite this occurrence, and the prevalence of binary operation mathematics, little research attention has been given to the general binary operation. This is disconcerting for two reasons: (1) according a survey of expert instructors, binary operation is considered to be one of the most important topics in group theory (Melhuish & Fasteen, 2016); (2) binary operations are one of the core concepts that can be connected back to the K-12 curriculum (Melhuish & Fagan, in press).

However, the survey of expert instructors also revealed a possible cause for the lack of treatment. They identified binary operation as a topic with low difficulty level (Melhuish & Fasteen, 2016). Yet, we found evidence to suggest that students' conceptions of binary operations can significantly interfere with performance on group theory tasks (Melhuish & Fasteen, 2016). This evidence was the impetus to study student understanding of binary operation more directly. In this paper, we address the variety of ways in which students conceive of binary operations and the metaphors they might leverage when working with binary operations across a number of task types. We present a qualitative study, guided by variation theory, in which we elaborate on the critical attributes of binary operations that students attend to while engaging with related tasks.

Literature Review

Binary operation has uneven treatment throughout the literature. Before we unpack this literature, we define what we mean by binary operation. Informally, binary operations can be thought of as rules that combine two elements within a set and produce a single element of the same set. For instance, addition is a binary operation on the set of integers because addition can be thought of as a rule for combining two integers to produce a single integer. Formally, binary operations are often defined as follows:

A *binary operation* $*$ on a set S is a function mapping $S \times S$ into S.

This formal definition situates operation as a type of function. We therefore outline literature across three categories: (1) arithmetic and other specific operation literature, (2) function literature, and (3) literature pertaining to the general binary operation.

As most literature on student mathematical thinking connects to operation in some way, we focus on a few key theoretical contributions (that go beyond the specifics of a particular arithmetic operation.) One such example is the *operation sense* framework developed by Slavit (1998), which unpack a series of stages built around familiarity with standard arithmetic operations. In this framework, operations represent a standard process, such as the process of combining groups underlying the operation of addition. Slavit's work documented a path of increasing sophistication that could support students' in developing operation sense that moved beyond particular arithmetic process metaphors to an understanding of operation without a need for concrete referents. Such understanding can support students' transition from arithmetic to algebra. Gray and Tall (1994) provided a different view on this abstractness focusing on operation as a *procept*. That is, an operation can be conceived as a process and a concept. An expression such as "3+2" is both the object (the sum) and the process (adding the two numbers.) In light of this literature base, we identify (1) students may struggle to move beyond arithmetic operations on concrete referents and (2) students need to conceive of operations as processes and objects (which is non-trivial.)

We next turn to the literature on function to identify ways in which function understanding may be relevant to binary operation. First, there is a large amount of existing literature documenting the complexities of function (Oehrtman, Carlson, & Thompson, 2008). Students have been shown to possess numerous conceptions throughout their K-16 education. Due to space limitations, we note two that provide insight beyond arithmetic literature. First, students may interpret functions as necessarily having a written rule (Vinner & Dreyfus, 1989). Such an interpretation limits students' ability to leverage or make sense of non-symbolic representations. Additionally, function conceptions are tied to a wide range of metaphors (Zandieh, Ellis, and Rasmussen, 2017). One such metaphor is the ubiquitous input/output machine metaphor (Tall, McGowen, & DeMarois, 2000). In light of binary operations being a special case of function, we conjectured that similar representation and metaphor preferences might exist.

Finally, we attend to the literature on the general, abstract, binary operation concept. While majority of research related to abstract algebra and linear algebra implicitly treat binary operations (e.g., Larsen's (2009) work having students reinvent groups), few studies have explicitly focused on binary operation. These few studies are primarily theoretical breakdowns (with empirical instantiations) that are part of a larger attempt to map student conceptions. Brown, DeVries, Dubinsky, and Thomas (1997) and more recently Wasserman (2017) presented genetic decompositions of binary operations in which individuals may have an action (requiring concrete actions with individual inputs), process (seeing a binary operation as a general process on a domain), or object (seeing binary operation as something that can be acted on) conception of binary operations. Alternately, Novotná, Stehlíková, and Hoch (2006) use lens of *structure sense* to produce a framework of binary operation capturing shifts of attention where students can first recognize binary operation in familiar settings, then make sense of properties like closure, engage with unfamiliar operations, and compare differing representations. Other notable results include students have limited representational flexibility (Ehmke, Pesonen, & Haapasalo, 2010), and have limited example spaces (Zaslavsky & Peled, 1996). While these contributions provide some insight into student conceptions around binary operation, many questions remain.

As a whole, the body of research points to substantial reasons to identify binary operation as a potentially troubling topic with its nature as a function and operation. In the next section, we outline a theoretical lens that has aided us in further parsing students' activity and conceptions around binary operaiton: variation theory (Marton & Booth, 1997).

Theoretical Framework

One way to conceptualize learning is the perception of new attributes of a phenomenon or experiencing a phenomenon in a new way. Such an approach leverages a variation theory (Marton & Booth, 1997) lens. For a given individual, their understanding of a concept reflects which attributes of the concept are foregrounded for them. Students become aware of attributes through experiences of concepts (and non-examples of concepts) where attributes may be foregrounded via contrast. If a student never experiences a non-example of a binary operation with one or three inputs, they may not perceive two inputs as a critical attribute of binary operation. Alternately, if all examples students encounter have certain commonalities such as associativity, students may perceive associativity as a critical attribute of binary operation. In this way, variation theory ties learning tightly with the role of experiences and particularly contrasting experiences where students may discern attributes of a particular object.

From a variation theory stance, we then leverage several key ideas including: *object of learning*, *critical attributes*, and *metaphors*. Variation theory provides a complimentary tool to traditional cognitive or social investigations of learning via shifting from cognition to perception (Dahlin, 2001). This shift leads to questions about: What are the critical attributes of a given object of learning? What opportunities do students have to perceive (through variation) the critical attributes of an object? And ultimately, what critical attributes are in the *lived* object of learning for a student?

Vikström (2008) has expanded the use of variation theory to also attend to metaphors as the means for which students structure and communicate their lived object of learning. As students become aware of critical attributes of a phenomenon, metaphors are the mechanism to integrate and connect with the abstract notion of a particular concept. When students engage in tasks, they then rely on metaphors to connect a given situation to their greater understanding of a concept.

In accordance with this view on learning, the research questions guiding our study are: (1) What are the metaphors leveraged by students when communicating about binary operation?; (2) Which attributes are students attending to when engaged in binary operation related tasks?

Methods

Participants and Data Collection

The participants in this study consisted of students enrolled in three introductory, undergraduate-level abstract algebra classes (n =9, n = 12, and n = 12 respectively). Additionally, we interviewed six students, four of which come from the surveyed class, two from another class (that received a shortened survey that is not reported here.) Classes span two institutions and three unique instructors. Surveys were created to cover a variety of binary operations and non-binary examples. In particular, the questions were crafted in accordance with the following activity domains:

1. *Is or is not*. Determining if a given instantiation is an example of a concept (e.g. Ehmke , Pesonen, and Happasalo, 2011)
2. *Same or different*. Determining if two instantiations are mathematically the same (e.g. Novotna, Stehlikova, and Hoch, 2006)

3. *Properties*. Determining what properties an example may or may not have. (e.g. Dubinsky Dautermann, Leron, & Zazkis, 1994)
4. *Generating*. Creating an example meeting some criteria (e.g. Zaslavsky & Peled, 1996).

Table 1: Example Survey Prompts

Category	Is or Is not	Same or Different	Property	Generating
Prompt (shortened)	$(a) = a^2$, on $\boldsymbol{R}$	$\boldsymbol{Z}_3$ and $\boldsymbol{Z}_6$ (presented tabularly)	Is ½(a+b) associative?	Define a binary operation on {1,2,4}
Purpose	Critical attribute: closure; Missing: 2 inputs	Calls on attribute: element-wise defined	Missing varying attribute: *E-O-E* formatting	Calls on varying attribute: non-symbolic representation

Each of the questions was open-ended and provided a prompt for the students to explain their reasoning. Across the classes, the surveys contained ten common questions, along with several variations designed to test the robustness of response types. For the scope of this report, we focus on the common questions.

In addition to the surveys, six semi-structured interviews were conducted to gain deeper insight into the students' mathematical thinking as they worked through the survey. The purpose of the interviews was twofold: (1) to validate our interpretations of written responses and (2) allow for a closer inspection of metaphors that are leveraged in verbal communication (and not always immediately apparent in written responses.)

Analysis

The analysis of the survey data was driven by methods of phenomenographic content analysis (Trigwall, 2006). Student responses were disconnected from the individual. The goal was to identify patterns in the different ways that students experience a given phenomenon. Each task was then analyzed for patterns in responses beginning with broad open codes. These were condensed to categories reflecting critical attributes of binary operation as experienced by students. We then independently coded all survey responses resolving all disagreements via discussion. After this analysis, we determined the degree to which a given student's attention to attributes was consistent across tasks. In the results section, we share the dominant critical attributes from student responses, as well as reports on consistency.

For the interview data, we analyzed transcripts to identify the metaphors they leveraged to communicate about binary operation. For each transcript, we identified each instance that a student communicated directly about binary operation noting varying patterns in language. We then returned to the literature to categorize metaphor clusters: arithmetic, function, and structure. We used these metaphors to code the transcripts to determine which of the three metaphors occurred in a given individual's communication.

Results

We begin by discussing the three metaphors that underlined students' communication.

Metaphors

Function Metaphor Cluster. We define the function metaphor cluster as being enacted whenever a student communicates about binary operation as if it were a function, that is, a mapping with inputs and outputs. Indicators include: reference to a domain and range, input/output language, mapping language, and referencing function specific properties such as one-to-one. An example of a student using this metaphor is the following description of a binary operation, "[the binary operation] takes two inputs and returns an output based on the operation." Notice this language evokes traditional function metaphor language where there is something (akin to a function machine) that takes inputs and produces outputs. Other examples of using the function metaphor include: "[The binary operation] does take two of the numbers and it will return a third," and "The division binary operation is going to take me from the Reals to the Reals." Such metaphors occurred across all of the interviews (see Table 2).

Table 2: Interviewed Students' Metaphors for Binary Operation

Metaphor	Function	Arithmetic	Structure
Student 1 (Class B)	x	x	x
Student 2 (Class B)	x	x	x
Student 3 (Class C)	x	x	x
Student 4 (Class C)	x	x	x
Student 5 (Class D)	x	x	x
Student 6 (Class D)	x	x	

Arithmetic Metaphor Cluster. We define the arithmetic metaphor as being enacted whenever a student communicates about binary operation as if it was an arithmetic operation. In arithmetic contexts, we tend to leverage a combining metaphor. For example, when adding 2 and 3, one metaphor would be combining collections of 2 items and 3 items to produce 5 times. This action is internal to the inputs rather than taking inputs and mapping to something new (as in a function metaphor.) Indicators of this metaphor include language around "answer" and "combining." For example, a student described the action: "Two numbers, take them, combine them". Another described comparing two operations on particular elements with: "They are not the same answer." As in the case of function, these metaphors occurred in all interviews (see Table 2).

Structure Metaphor Cluster. We define the structure metaphor cluster as being enacted whenever a student communicates about a binary operation as a mechanism for structuring a set. The structure may be noticed based on prior exposure to mathematics (such as a binary operation on a set forming a group) or the student may spontaneously create the structure (such as noticing a pattern or explicitly searching for a pattern within a set of outputs). Indicators include language about overall behavior, patterns, or structural properties. The structure metaphor tended to emerge in tasks in which students were asked to compare two binary operations to determine whether they were the same. For example, one student asked, "What pattern do we have going on there?" and another commented, "These two groups behave rather similarly." This metaphor can be quite productive when considering structural properties of a given set. Structure metaphors were frequent, occurring in five of six interviews.

These results reflect that the three metaphors are not a mutually exclusive categorization of a student's thinking about binary operations. A student can enact any of three metaphors depending on the task they are engaged with, and in fact it was common of the students to enact all three at some point. Furthermore, the same metaphors can be supportive or unsupportive depending on the critical attributes the metaphor is structuring.

Critical Attributes

In this section, we unpack some of these critical attributes. Our focus is on the survey results, but we note that are interview subjects provided similar profiles in terms of critical attributes. We cover two definitional properties (closure, two input elements), one additional critical attribute (binary operations are defined at the element level), and two non-critical representational attributes (symbolic rule and element-operator-element (E-O-E) formatting).

Table 3: Survey Responses when Determining if an Instantiation is a Binary Operation

	Attended to Closure			Attended to Two Input Elements		
	Always	Inconsistently	Never	Always	Inconsistently	Never
Class A	5 (62.5%)	2 (25.0%)	1 (12.5%)	0 (0%)	0 (0%)	8 (100%)
Class B	5 (41.7%)	5 (41.7%)	2 (16.7%)	1 (8.3%)	1 (8.3%)	10 (83.3%)
Class C	4 (33.3%)	2 (16.7%)	6 (50.0%)	6 (50.0%)	3 (25.0%)	3 (25.0%)
Total	14 (43.8%)	9 (28.1%)	9 (28.1%)	7 (21.9%)	4 (12.5%)	21 (65.6%)

Closure. The first of the critical attributes is closure. It was common for students to attend to closure of a binary operation on a set when asked to determine if a given operation was binary or not (see table 3). For example, when asked if $*(a) = a^2$ defined on $\mathbb{R}$ is a binary operation, one student responded, "yes, if a is real, the square of a is also real."

Two input elements. The second critical attribute is that a binary operation must be defined on two elements (or ordered pairs.) Some students perceived this critical attribute (as seen in Table 3). For example, when asked to determine if $\sqrt{a}$ on $\mathbb{Z}$ is a binary operation, one student responded, "No, only a is used, not both inputs." However, it was far more common for students to ignore this critical attribute and only attend to closure (as in the prior example).

Table 4: Survey Responses when Determining if two Given Operations were the same

	Attended to Element-Wise Differences		
	Across Prompts	Element-Defined Prompt Only	Never
Class A	4 (50%)	3 (37.5%)	1 (12.5%)
Class B	1 (8.3%)	8 (66.7%)	3 (25%)
Class C	6 (50%)	4 (33.3%)	2 (16.7%)
Total	11 (34.4%)	15 (46.9%)	6 (18.8%)

Defined element-wise. A particular binary operation is determined by where any two elements are mapped. However, students inconsistently treated this as a critical attribute of binary operation. This became clear on tasks comparing two operations. For example, when provided Cayley tables representing addition modulo 3 and 6 and asked if they were the same binary operation, one student responded they were not because whenever they "plug in 1 and 2 into both these operations [they] will get different results" reflecting attention to individual elements. In contrast, another student claimed that the binary operations were the same because the elements "behave the same." Over half of the students either never attended to element-definedness or only when provided a binary operation already defined that way (see Table 4).

Table 5: Survey Responses when Asked to Create a Binary Operation on {1,2,4}

	Non-symbolic Representation	Symbolic Representation	No Answer
Class A	0 (0.0%)	6 (66.7%)	3 (33.3%)
Class B	1 (8.3%)	4 (33.3%)	7 (58.3%)
Class C	9 (75.0%)	3 (25.0%)	0 (0%)
Total	10 (39.4%)	10 (39.4%)	13 (30.3%)

Symbolic Format. Students across the dataset reflected a preference for symbolic representations. In fact, the most commonly skipped tasks across all prompts where those in alternate representations. This preference was most notable in the final prompt asking students to generate a binary operation for set {1,2,4}. As seen in table 5, well over half of the students did not create a binary operation. Instead they often attempted to build a symbolic rule without any success. This desire for a symbolic rule is well documented in terms of functions, and it seems that students perceive a similar attribute as critical to binary operation.

Table 6: Survey Responses when Treating Associativity of ½(a+b) binary operations

	Focused on EOE Portion(s) of Operation (addition/multiplication)	Focused on Entire Operation
Class A	4 (44.4%)	5 (55.6%)
Class B	5 (41.2%)	7 (58.3%)
Class C	9 (75.0%)	3 (25.0%)
Total	18 (54.5%)	15 (45.5%)

E-O-E Format. The desire for a symbolic rule manifested further with students' perceiving a particular format as critical. This preference was seen throughout the survey responses but was most prominent when addressing the prompt to determine if ½(a+b) was associative. As seen in table 6, when placed in a situation without this formatting, students often defaulted to focusing on addition and multiplication as separate binary operations rather than holistically. Through the follow-up interviews, students who responded this way indicated that they could not discern the operation "rule" or that the operation was the "plus" portion reflecting the perception that E-O-E symbolism was critical.

Discussion and Conclusion

In this paper, we have addressed a variety of ways in which students conceive of binary operations in terms of critical attributes and identified metaphors they might leverage when working on tasks with binary operations. In particular, we found three metaphors that were commonly enacted by students: the function metaphor, the arithmetic metaphor, and the structure metaphor. Such metaphors can serve to be productive when they are robust and developed. However, that requires students to also have perceived the critical attributes of binary operation that can be structured and communicated via the metaphors. When leveraging a function metaphor, students may naturally attend to function attributes (such as the need for inputs), and not perceive a binary operation specific attribute (needing exactly two inputs). Similarly, students with an arithmetic metaphor may generalize from arithmetic examples and perceive attributes like E-O-E formatting as critical for general binary operations. As variation theorists have noted, variations are perceived not just synchronically, but also "by remembering earlier related experiences (diachronic simultaneity)" (Vikström, 2009, p. 212). As students structure their knowledge using metaphors, they are likely integrating attributes perceived from many prior experiences related to function and arithmetic in their earlier mathematics experiences.

While the links to function and arithmetic are immediate, the structure metaphor's link to prior experience is a less direct. Notably, the structure metaphor is a dominant metaphor for determining when mathematical structures are isomorphic. However, this is a new treatment at the undergraduate level. Yet many structural treatments exist throughout education such as finding patterns when adding even numbers, or connecting operations like multiplication and division. In fact, this played out robustly in our data. Many students identified multiplication and division as the same operation because of their similar behavior. A structural metaphor can support attending to important varying features (such as a structural property), but can also limit students' attention to the critical attribute of binary operations being element-defined.

These results have several implications. First, binary operations are not a trivial despite instructors classifying it as such. Instructors may wish to increase attention to binary operation in classes with this focus (such as abstract algebra and linear algebra.) Second, students may not perceive many critical attributes such as the need for two elements, and may perceive non-critical attributes as critical such as E-O-E formatting. From a variation standpoint, a potential solution is to expose students to examples, non-examples, and non-standard examples so that they have opportunities to contrast instantiations with varying critical and non-critical attributes. This type of activity can foreground these features so that students may perceive them. From a research standpoint, we may want to consider the degree to which these three metaphors, and attention to specific attributes may underlie student activity across the K-16 spectrum as they engage with common binary operations such as number arithmetic or function composition.

REPRESENTATIONAL SAMENESS AND DERIVATIVE

Alison Mirin
Arizona State University
amirin@asu.edu

This study focuses on students' understanding of multiple representations of functions. It examines student responses to a task in which calculus students are asked to evaluate the derivative at a point of the cubing function when represented piecewise. Results suggest that attending to the graph of the piecewise function does not improve students' ability to differentiate it. Results also suggest that students tended to view a piecewise-defined function not as a singular function, but as a set of instructions for which function to use.

Keywords: function, derivative, multiple representations

Introduction and Literature Review

Multiple representations of functions play an important role in mathematics and mathematics education. There is a body of literature addressing college students' difficulties linking multiple representations of functions, and some studies suggest that post-secondary students struggle translating between different representations (Even, 1998; Gagatsis and Shiakalli, 2004; Chinnappan and Thomas, 2001). The literature on multiple representations tends to focus on translation between multiple *types* of representations (e.g., graphical, analytical, and verbal), rather than multiple representations of the same type. However, working with multiple representations of the same type is also a crucial part of mathematics. Although there is no body of literature specifically devoted to within-representation-type translation, some authors have highlighted the importance of this for specific types of representations. For example, Moore and Thompson (2015) make the point that math students should be able to move flexibly between different coordinate systems, being able to recognize when the same graph has two different visual representations.

I argue in Mirin (2017) that students' understandings of sameness of representation of function, by which I mean student assessments of which function representations represent the same function, are inextricably linked to their concept of function. We can see how one's concept of sameness-of-representation-of-function and the function concept itself are interlinked when we consider how a student might view derivative. If a student views a derivative as operating on a function, then his concept of function is inextricably tied to his concept of derivative. For example, his criteria for determining whether two function representations share a derivative might be influenced by his criteria for determining whether those representations refer to the same function. This leads us to the following research question: What are students' understandings of multiple analytic representations of a single function as it relates to derivative?

We follow Thompson's (1982) constructivist approach of being sensitive to student understanding by asking, "What is the problem that this student is solving, given that I have attempted to communicate to him the problem I have in mind?"(p.153). This is akin to Harel, Gold, and Simon's (2009) description of the "interpreting" mental act; in analyzing students' responses to a task, we, as researchers, pay careful attention to how students interpret a task. Thompson makes the point that, when referring to representations *of* something, we ought to be clear about *to whom these are representations* of whatever "something" is (Thompson & Sfard, 1994). In the case of this study, there is a representation of the cubing function *to us* (as mathematicians), but to students, it may not be. So, we ought to be sensitive to the fact that a student might agree with the assertion that two representations of the same function share a derivative, but these students might have non-standard understandings of what "same function" is. In fact, this is precisely the sort of reasoning a particular student used to determine that sharing a graph was not sufficient for sameness of functions; she concluded that two particular representations of functions share the same graph but do *not* share a derivative, leading her to conclude that, to be the same function, having the same ordered pairs on the graph is not sufficient (Mirin, 2017).

Task Design and Methodology

This study arose from an anecdote that Harel and Kaput (1991) share in which calculus students, when prompted to differentiate the function g defined piecewise by $g(x) = \sin x$ if $x \neq 0$ and $g(x) = 1$ if $x = 0$, answered with $g'(x) = \cos x$ if $x \neq 0$ and $g'(x) = 0$ if $x = 0$, appearing to use the constant rule. To these students, the only aspect of the representation as relevant for determining the value of $g'(0)$ is the second line of the piecewise function definition. It seems reasonable to believe that, if the definition of g were modified to instead have $g(x) = 0$ if $x = 0$ (resulting in a nonstandard representation of the sine function) students would answer identically. However, given the anecdotal nature of Harel and Kaput's claim, there is no data available to substantiate how common such errors are or why they occur.

This paper undertakes the task of studying this phenomenon more systematically. I designed the following task to address this issue:

Let f be the function defined by

$$f(x) = \begin{cases} x^3 & \text{if } x \neq 2 \\ 8 & \text{if } x = 2 \end{cases}$$

Evaluate $f'(2)$, and provide an explanation of your answer.

Figure 1. The Task on which This Study is Based (Quiz A)

Henceforth, the task of evaluating $f'(2)$ for f defined piecewise as above will be referred to as "The Task". Notice that the function f is simply the cubing function, but represented in a non-standard way. Whether students see it that way is part of the investigation.

Subjects and Methods

Initially, The Task, exactly as pictured in Figure 1, was given to 240 introductory calculus students during the last week of the semester at Anonymous State University (ASU). Referred to as "Quiz A", it was administered in an exam environment by course instructors as part of the course, where students were required to work silently and independently. I conducted follow-up interviews of eight individual students. I collected and coded their responses before performing the interviews, and, informed by the interviews, re-coded the responses to reflect students' rationales as suggested by the interviews.

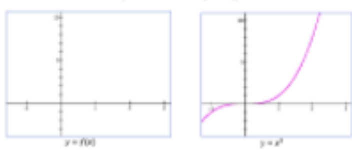
The interviews each lasted 60-90 minutes. The interviews operated according to clinical interview methodology (a la Clement, 2000) and served as establishing students' rationale for their responses to The Task. Additionally, students were given similar problems, as well as asked to graph the function *f* and asked to make sense of their answer to The Task with their graph of *f*.

Results, Quiz A vs. Quiz B

Results of Quiz A suggest that Harel and Kaput (1991)'s anecdote is indeed indicative of a wider phenomenon, as only 18.3% of students gave the correct answer. Like in Harel and Kaput's story, the majority (53.6%) of students claimed that the answer was "0". Further, many students (41.2% of total) explicitly cited the constant rule.

Now that we have established that there is a larger phenomenon, the next natural question to ask is, "why"? It is possible that some students erred due to inattention or carelessness, rather than a major misconception. That is, they might have simply seen the "8" and applied the constant rule out of habit or simply not realized that 2^3 is 8 and that the given function is in fact continuous. This would explain why some students answered "undefined," and it is also consistent with some of the graphs that students volunteered (graphs with removable discontinuities). Further, it might not have occurred to students to compare the graph of *f* with that of the cubing function - as discussed earlier, the piecewise-defined *f* is a representation of the cubing function to *us*, but perhaps not to students.

Suppose *f* is the function defined by $f(x) = x^3$ if $x \neq 2$, $f(x) = 8$ if $x = 2$.
1. Calculate 2^3
2. Below to the right is a graph of $y = x^3$. On the blank axes provided, graph $y = f(x)$ for the function *f* defined above.



3. Evaluate $f'(2)$ for f defined above. Please provide a 1-3 sentence explanation of your answer. (a)0, (b)8 (c)12, (d)undefined, (e)0 if $x = 2$, and 12 if $x \neq 2$, (f) 0 if $x = 2$, and undefined if $x \neq 2$.
4. Suppose g is a function and h is a function. What does it mean for g and h to be the same function?

Figure 2. Quiz B (Visually Condensed)

Accordingly, informed by Quiz A results, Quiz B (Figure 2, above) was created to test this possibility that inattention accounts for student responses. Quiz B involves The Task (multiple choice form), except, prior to attempting The Task, students are prompted to calculate 2^3 and to graph $y = f(x)$ aside a provided graph of $y = x^3$. Also included on Quiz B is a task asking students to state their definition of when a function *g* is the same function as a function *f*. If inattention accounts for student responses, then the following hypotheses should hold:

(1) Overall, students will perform significantly better on The Task in Quiz B than Quiz A, leaving open the possibility that inattention or carelessness could account for students' tendency to do poorly on The Task in isolation. Students might, because of the prompting, be more likely to compare *f* to that of the cubing function.
(2) Quiz B students who answered "12" would be more likely than Quiz A students who answered "12" to provide a justification involving the comparison of *f* with the cubing function.
(3) Students who provided a mathematically normative definition of function sameness (Problem 4) would be more likely to answer "12" than students' who did not.

As discussed earlier, a student's criteria for determining whether two function representations share a derivative might be influenced by his or her criteria for determining whether those representations refer to the same function. If a student believes that having the same set of ordered pairs is sufficient for function h to be the same as function g, then it seems she is more likely (than a student who does not believe this) to conclude that because g and h are the same function, their respective derivatives are the same function. These hypotheses center on the idea that if students are positioned to compare the ordered pairs on $y = f(x)$ to that of $y = x^3$, they are more prone to answer The Task correctly.

Table 1: Student Answers to Quiz A and Quiz B

	0	**8**	**12**	**Undefined**	**Multiple answers**	**Other**	**Blank**	**Total**
Quiz A %, n	56.3%, 135	4.6%, 11	18.3%, 44	5.8%, 14	(8.3%, 20) 0&12: (5.8%, 14) 0&undef: (2.5%, 6)	5.4%, 13	1.3%, 3	100%, 240
Quiz B %, n	40.2%, 41	7.8%, 8	23.5 %, 24	9.8%, 10	(18.7%, 19) e: (12.8%, 13) f: (5.9%, 6)	N/A	0%, 0	100%, 102

The data reveal no evidence to support that inattention could account for student responses. Although there was a slight improvement in correctness rate from Quiz A to Quiz B (see Table 1), this improvement was not statistically significant (χ^2=1.21, p>.05), contrary to (1). In other words, prompting students to compare the graph of $y = f(x)$ to that of $y = x^3$ *did not* appear to cause improvement, suggesting that students did not err simply due to inattention to the function's graph. Moreover, the Quiz B students who answered "12" were no more likely than the Quiz A students who answered "12" to draw an explicit comparison between *f* and the cubing function (4.2% of Quiz A students who answered 12 did, whereas only 2.9% of Quiz B students did so), contrary to (2). Also, the students who provided a mathematically normative definition of function sameness were no more likely to answer "12" than those who did not, contrary to (3). These results suggest that, contrary to my hypotheses, prompting students to compare *f* to the cubing function did not appear to encourage them to infer that *f* and the cubing function share a derivative at 2. This naturally led to the emergent question: if inattention to the graph of *f* does not account for students' tendency to answer incorrectly, then why are students answering the way they are answering?

Phenomena and Student Rationale

To answer this question, we turn to the student graphs together with the student interviews. Normatively, two graphs (of functions) are the same if and only if they consist of the same ordered pairs. It seems reasonable to believe that some students might *not* have this criterion for sameness of graph; indeed, interviews suggested that some students viewed a graph of x^3 with an extra "dot" placed at (2,8) as different from a graph of x^3 without one. Some students referred to the point (2,8) as "separate". Accordingly, a sub-category (category B) of "correct" was created: mathematically normative graphs that highlighted (2,8) in the sense that they had a dot on (2,8) that was more prominent than any other dots. The remaining "correct" graphs - those that were correct but indicated nothing special about (2,8) - were grouped together as category. The remaining graphs were classified as follows: those with a single dot at (2,8) (2.0%), those with just a graph of $y = 8$ (6.9%), those with a removable discontinuity at x=2 (6.9%), blank (4.9%), those with graphs of both $y = 8$ and $y = x^3$ (2.9%), and other (8.8%). Among the correct graphs (A and B), graph A students were more likely than graph B students to answer "12" on The Task (χ^2=3.932, p<.05), suggesting some sort of difference (in the graph B students' minds) between *f* and the cubing function. How students understand their graphs in relation to The Task will be further elaborated below.

Now we turn to the qualitative data: the student interviews, which shed light on why students answer the way they do. Musgrave and Thompson's (2014) construct of "function notation as idiom" was useful in accounting for student responses. A student views function notation idiomatically when he or she views "$f(x)$" in its entirety as a name for a function (Musgrave & Thompson, 2014). Such students might view "$f(x)$" as no more than another name for "*y*" (Thompson, 2013). It appeared that many students used this way of thinking when evaluating $f'(2)$, as students seemed to view "*8*" and "x^3" as names of functions with "$f(x)$" referring to both of these functions. Another common theme, appearing both on the written quizzes and in the interviews, was the viewpoint that the "if $x \neq 2$" served as a *restriction* on the domain for students, rather than as a condition.

Since there is not space to discuss every student in detail, we provide insight from the interviews that is consistent with various student responses. The following subsections should be viewed as *descriptions and illustrations* of student thinking that explain students' answers, rather than rigorous evidence of such phenomena. Moreover, we discuss only the parts of the interviews that explain why students answered the way they did originally, rather than elaborating on the in-depth portions that were more exploratory. Each subsection begins with a direct, written quote from a student, which provides a concise summary of the way of thinking described in the subsection. We also discuss how, for the students, the point (2,8) was special and the way students made sense of their graphs. Additionally, we discuss how students' ways of thinking are reflected in their responses to the interview prompt to find *h'(5)* for the function *h* defined by $h(x) = x^3$ if *x≠5*, $h(x) = x^2 + 100$ if *x=5*.

Students who answered "0"

"When the graph is at the point *x=2*, the function is determined by the piecewise part '*8*'. So, $f(x)$ *itself* equals *8*. When *8* is derived, it becomes 0" [Pete, Quiz B student (emphasis added)]. The rationale summarized by Pete appears to exemplify a common way of thinking amongst students who answered "0". For these students, the "$f'(2)$" tells them that they are in the situation "$x = 2$," which serves as an instruction to use the function "*8*". Here, the "*8*" serves as a name of a function rather than a particular output, suggesting an idiomatic conception. Many of these students provided a category B graph of *f* (graph of $y = x^3$ but a special dot at (2,8)) and found no issue with the fact that they couldn't "see" that $f'(2) = 0$ in their graph; when asked to explain graphically, they would provide a graph of $y = 8$ and explained why its derivative at 2 is 0.

Interviewed students extended this way of thinking to evaluating *h'*(*5*) for the function *h* defined by $h(x) = x^3$ if *x≠5*, $h(x) = x^2 + 100$ if *x=5*. It was common for students to answer "10" by evaluating the derivative of $x^2 + 100$ as 2*x* and substituting *x*=5 to result in 10, with the rationale that "Um I used this part, the part that makes the parabola [$y = x^2 + 100$]. Because we're interested in the time when x equals 5. And that's kind of the rule here, when *x* equals 5 to use the parabola" [Jennifer, Quiz A student]. She elaborated: "The derivative of *h* when *x* equals 5 is gonna be *2x* um…..if *x* were to equal some number other than 5, you would use this (underlines x^3) function up here, but because *x* is 5 we use this one." Jennifer's rationale exemplifies the way of thinking that led students to answer "$f'(2) = 0$": viewing the conditions on a piecewise-defined function as instructions for which function to use, and a piecewise-defined function involving two different functions.

$f'(2) \rightarrow x = 2 \rightarrow y = 8 \rightarrow$  $\rightarrow y' = 0$

Figure 3. Student rationale for answering "0"

Many of these students (Pete included) provided a graph of *f* that was like $y = x^3$ but with a dot at (2,8) (category B graph). It seems that students viewed the dot at (2,8) as separate or independent from the rest of the graph. For example, one student recreated his graph during the interview, explaining his reasoning as follows: "At the point (2,8) I draw a circle to show there is an opening there, there's a gap. I'm excluding that point from what it is we are talking about in this point in time." He elaborated: "So the *two*...they're existing on the same coordinate system but *existing independent of each other*" (emphasis added).

Students who answered both "12" and "0"

"If *f(x)* does not equal 2, the function is x^3. The derivative of x^3 equals $3x^2$, then substitute 2 for *x,* $3(2)^2=12$. However, if *x* is allowed to be 2, then the derivative of *8*=0" [Carlos, Quiz A student]. The case of Carlos illustrates how a student can reason idiomatically to get the answers 0 and 12. In the interview he reiterated his reasoning: "If *x* isn't 2 then the function is x^3. The derivative of x^3 is $3x^2$. Then substitute 2 for *x* here and you get 12. However, if *x* is allowed to be 2, then the derivative of *8* is 0". For Carlos, the "if *x=2*" condition told him that he was in the case in which "the function" is the function "$f(x) = 8$," and that the "if $x \neq 2$" condition told him he was in the case in which "the function" is x^3. Carlos did not even make the connection that the "2" in "$f(2)$" told him he was in the case where "$x = 2$"; for him, the "$f(x)$" was just a shorthand for "*y*". When prompted to graph *f*, he provided a graph of (what he thought was) *y=8* as well as a graph of $y = x^3$, indicating that he viewed himself as graphing two separate functions. When asked how $f'(2)$ can be 12 while he had said prior that it was 0, he explained: "this is an *entirely different function"*, indicating that the conditions on the piecewise function were instructions about which function to use.

Two cases: $x = 2,\ x \neq 2$

$x = 2 \rightarrow y = 8 \rightarrow$  $\rightarrow y' = 0 \rightarrow f'(2) = 0$ if $x = 2$

$x \neq 2 \rightarrow y = x^3 \rightarrow$  $\rightarrow y' = 12 \rightarrow f'(2) = 12$ if $x \neq 2$

Figure 4. Student Rationale for answering "0 if $\boldsymbol{x = 2}$, 12 if $\boldsymbol{x \neq 2}$"

Carlos' way of thinking was confirmed when he was asked to calculate *h'*(*5*) when *h* is defined by by $h(x) = x^3$ if $x \neq 5$, $h(x) = x^2 + 100$ if *x*=*5*. He graphed $y = x^3$ and $y = x^2 + 100$ on the same axes (Fig.4). When prompted to find the value of *h'*(*5*), he differentiated x^3 and plugged in 5 to get 75, and then he differentiated $x^2 + 100$ and plugged in 5 to get 10. When asked which was the value of *h'*(*5*), he exclaimed confidently, "both! 75 and 10!".

Students who answered both "0" and "undefined"

"If just looking at $f(x) = 8$, the derivative of a constant would make $f'(2) = 0$. If just looking at $f(x) = x^3$, the derivative would be undefined because $f(2)$ is not on the graph of x^3.

There is a hole at x=2" [Eric, Quiz B]. Eric's reasoning exemplifies how students could have come to select choice "f" in Quiz B. A different student, Sarah, explained her reasoning in detail in the interview. Sarah initially answered that "both" are undefined, but during the interview, she revealed that she interprets "0" to mean the same thing as "undefined" (which was a common trend in student responses). Like Carlos, she viewed two functions as being involved, which was again confirmed when she was asked about the piecewise-defined function "h". She appeared to reason about two different functions, and calculated $f'(2)$ by treating the first function as "$y = x^3, x \neq 2$", and the second function as "$y = 8, x = 2$". She interpreted the "$x \neq 2$" as a restriction on the *first* function, and the "$x = 2$" a clarification that such a restriction did not exist on the *second* function. Thus, for the first function, $f'(2)$ is undefined, and for the second function, $f'(2)$ equals 12.

Two cases, two functions

$y = x^3, x \neq 2 \rightarrow$  $\rightarrow f'(2)$ undefined if $x \neq 2$.

$y = 8, x = 2 \rightarrow y = 8$ and x can be 2 $\rightarrow$  $\rightarrow f'(2) = 0$ if $x = 2$.

Figure 5. Student Rationale for answering "0 if $x = 2$, undefined if $x \neq 2$"

Conclusions and Discussion

The results of Quiz A showed us that Harel and Kaput's (1991) anecdote is indeed indicative of a larger phenomenon: many students appeared to differentiate a piecewise function formally by differentiating each expression as a separate function. By comparing the results of Quiz A to Quiz B, we confirmed that this phenomenon cannot be attributed merely to inattention. The interviews, together with the Quiz B results, suggest that a non-normative understanding of piecewise function notation, stemming from a view of function notation as idiom and the conditions on the domain as either instructions or as restrictions, accounts for many students' responses.

This study shows that students do not view the same function, represented in two different analytic ways, as sharing a derivative at a particular value. However, this last sentence was ambiguous; when we say "a function", we are not being clear if students view these function representations as referring to the *same* function. Students might, for example, consider it possible for two *distinct* functions to share a graph, and we can ask: do students believe that same graph implies same derivative? The answer to this appears to be "no," as many Quiz B students provided normative graphs of f yet did not evaluate $f'(2)$ normatively. Yet, we run into another ambiguity: what students view as "same graph" might not be consistent with the normative notion of "same graph," as suggested by students' insistence that the point (2,8) being highlighted. This means that, although it is tempting to conceptualize this study as one about students' understanding of derivative, its results highlight how students think about function notation. To illustrate this point consider the way of thinking that accounted for students answering "0." It arose from a misconception of function notation: no matter how strong of a meaning the student has of "derivative", the student was still reasoning with the graph of "$y = 8$", leading to an answer of "0".

As discussed earlier, it seemed reasonable to hypothesize that students who provided normative definitions of what it means for functions g and h to be the same (Problem 4, Quiz B) would be more likely to correctly evaluate $f'(2)$; this is because it seems these students would be more likely to assess piecewise-defined *f* and the cubing function as "the same," positioning them to infer that *f* and the cubing function share a derivative. In light of the interviews and students' ways of thinking, the counter-intuitive result – that this hypothesis did not hold – makes sense. This is because, to students, *f* was not a function in the same way that the cubing function is; instead, *f* was *two functions*. Having a strong criteria for sameness of functions did not help students evaluate $f'(2)$ because *f* was not in the category of "functions" to which sameness can apply!

BUSINESS CALCULUS STUDENTS' INTERPRETATIONS OF MARGINAL CHANGE IN ECONOMIC CONTEXTS

Thembinkosi P. Mkhatshwa
Miami University
mkhatstp@miamioh.edu

Despite the overwhelming amount of research on students' interpretations of rates of change in real-world physical science contexts, similar studies in real-world economic contexts are sparse. Contributing towards addressing this gap in knowledge, this study reports on how 12 pairs of business calculus students interpreted marginal change (marginal cost and marginal revenue) in different economic contexts and function representations while solving two optimization tasks. Analysis of task-based interviews conducted with the students revealed that a majority of the students interpreted marginal change as an amount (the difference) and not as a rate (the difference quotient). A few students interpreted marginal change as the derivative. Implications for instruction are discussed.

Keywords: rates of change, marginal change, business calculus, optimization problems

Much research has reported on students' difficulties with interpreting rates of change (average rate of change and instantaneous rate of change) in real-world physical science contexts such as in fluid dynamics, kinematics, and thermodynamics (e.g., Carslon, Jacobs, Coe, Larsen, & Hsu, 2002; Prince, Vigeant, & Nottis, 2012). However, research on how students, especially at the undergraduate level, interpret rates of change (herein referred to as marginal change) in real-world economic contexts is limited, which is the motivation for this study. According to Gordon (2008), more than 300,000 students take business calculus in the United States each year. Understanding marginal change in a business context is vital in fields such as marketing, managerial accounting, supply chain management, finance, and economics. This study reports on business calculus students' interpretations of marginal change while reasoning about two optimization tasks (shown in the methods section), which are situated in two different economic contexts that have different function representations. Our study was guided by this research question: How do business calculus students interpret marginal change when solving optimization problems that have different function representations and are situated in different economic contexts?

The term marginal change, as used in this study, refers to marginal cost or marginal revenue. Marginal cost is the cost per additional unit produced and marginal revenue is the revenue generated per additional unit sold. Mathematically, marginal change can be calculated as an average rate of change where the length of the interval of change is one unit. Marginal change can be approximated using the instantaneous rate of change.

Related Literature

Rates of Change in Context

Several studies have reported on students' tendency to conflate the rate of change of a quantity with either the amount of the quantity or the amount of change of the quantity when solving application problems that are situated in real-world physical science contexts (e.g., Lobato, Hohensee, Rhodehamel, & Diamond, 2012; Prince et al.,2012; Rasmussen & Marrongelle, 2006). A majority of the 373 engineering students in Prince et al.'s (2012) study had difficulty distinguishing between the rate of change and the amount of change of a quantity in a thermodynamics context. Rasmussen and Marrongelle (2006) reported on students who failed to make "a conceptual distinction between rate of change in the amount of salt and amount of salt" (p. 408) in a differential equations course. In a remote-controlled airplane task where the amount of change had the same numerical value as the rate of change (as it is in the economic context of marginal change), Lobato et al. (2012) reported that a majority of the 24 students who participated in their study confused the distance traveled by the airplane in the task with the speed of the airplane. The study reported in this paper extends the body of research on students' reasoning about rates of change from the physical sciences to economic contexts by examining students' interpretations of marginal change in two different profit maximization contexts.

Rates of Change in Multiple Function Representations

The importance of the concept of function in students' learning of calculus cannot be overemphasized. Oehrtman, Carlson, and Thompson (2008) argued that "the concept of function is central to undergraduate mathematics, foundational to modern mathematics, and essential in related areas of the sciences" (p. 27). In his review of research literature on students' understanding of functions, Thompson (1994c) argued that "tables, graphs and expressions might be multiple representations of functions" (p. 23) to instructors and researchers, but that they are not "multiple representations of anything to students" (p. 23). Thompson's argument is well supported by evidence from research on students' understanding of rates of change in multiple function representations (e.g., Klymchuk, Zverkova, & Sauerbier, 2010; Villegas et al., 2009). Much of the existing research on students' understanding of rates of change in multiple representations is limited to graphical, algebraic, and textual representations of functions. This study extends the literature on students' understanding of rates of change by reporting on students' interpretations of rates of change in two functional situations, one that is based on a numerical table of values and another that is algebra-based.

Theoretical Perspective

The current study draws on the theory of quantitative reasoning (Thompson, 1993; Thompson, 1994b; Thompson, 2011). Quantitative reasoning is the analysis of a situation in terms of the quantities and relationships among the quantities involved in the situation (Thompson, 1993). Thompson (2011) described three tenets (a quantity, quantification, and a quantitative operation) that are central to the theory of quantitative reasoning. A quantity is a measurable attribute of an object. Thompson (1993) distinguished between a quantity and a numerical value: a quantity has a unit of measurement, and a numerical value does not. Examples of quantities in this study include marginal cost and marginal revenue.

Quantification is the process of assigning numerical values to quantities (Thompson, 1994d). A quantitative operation is the process of forming a new quantity from other quantities (Thompson, 1994b). In economics, for example, comparing (by way of finding the difference) marginal revenue and marginal cost with the intent to find the excess of marginal revenue against marginal cost otherwise known as marginal profit is a quantitative operation known as a quantitative difference. We designed two mathematical tasks (shown in the next section) that provided students with opportunities to reason about quantities and relationships among quantities. The interview protocol used during data collection engaged pairs of students in reasoning about relationships among quantities. We believe that having pairs of students share ideas while solving the tasks helped to reveal students' interpretations of the concept of marginal change in detail, something that could have been harder to achieve when interviewing individual students. The interviewing of pairs of students further shifted the students' focus from the researcher to the tasks.

Methods

Setting, Participants, and Data Collection

The study participants were 24 undergraduate students at a research university in the United States who had recently completed a business calculus course. The students were chosen based on their willingness to participate in the study, their major (business or economics), and their prior exposure to the ideas of marginal cost and marginal revenue through the course textbook and course lectures. The cumulative grade point averages (GPAs) of the 24 students had a mean of 3.43 on a 4.0 scale, a standard deviation of 0.37, and a range of 1.56. All but two of the students had earned at least a B grade in their business calculus course. The students were recruited from five different sections of a business calculus course.

We remark that the concept of marginal change was poorly presented in the course textbook and in course lectures. Specifically, in both the textbook and in course lectures, marginal change was defined as a rate (the difference quotient) and interpreted as an amount (the difference) (Mkhatshwa, 2016). As we will show in the results section, we argue that defining marginal change as a rate and interpreting it as an amount as was done in course lectures and in the textbook had an influence on students' reasoning about the units of marginal change in Task 2 (and likely in the other tasks we gave to the students) that appears in the following section. Part of the difficulty is that the numeric value of the difference is the same as the numeric value of the difference quotient since the denominator is one in the case of marginal change, a difficulty also noted by Lobato et al. (2012) in a kinematics context. In many cases the "per additional unit" may have been held implicitly by the students when giving units of marginal change in dollars instead of dollars per additional unit. We further remark that students' opportunities to reason about marginal change in course lectures and via the course textbook were mainly limited to the use of algebraic tasks.

Data for the study consisted of (1) transcriptions of audio-recordings of task-based interviews (Goldin, 2000) conducted with 12 pairs of students and (2) work written by the 12 pairs of students during each task-based interview session. Each interview lasted for about one hour and fifteen minutes. The interviews covered four economic tasks, and this study reports on two of the tasks (herein referred to as Task 1 and Task 2). Both tasks are situated in a profit maximization context. In addition, while both tasks are textually represented, Task 1 is also algebraic and Task 2 is numeric (table-based). We describe the design of each of the two tasks:

Task 1 (Haeussler, Paul, & Wood, 2011, p. 617): A manufacturer can produce at most 120 units of a certain product each year. The demand equation for the product is $p = q^2 - 100q + 3200$ and the manufacturer's total cost function is $c = \frac{2}{3}q^3 - 40q^2 + 10{,}000$, where q denotes the number of units that are produced and sold. Find the maximum profit.

We designed Task 1 to examine students' reasoning about optimization problems similar to those given in their textbook and in course lectures. We used this task to examine students' interpretation of marginal change in a profit maximization context when given a task that has an algebraic representation. We also designed this task to examine students' reasoning about relationships among four quantities: the number of units produced and sold, total cost, total revenue (which can be obtained by multiplying the demand equation given in the task by q, the number of units that are sold), and profit (which can be obtained by finding the difference between total revenue and total cost).

Task 2: The following table shows the marginal revenue (MR) and marginal cost (MC) at various production and sales levels (q) for SciTech, a company that specializes in producing and selling computer chips. The company knows that total revenue is greater than total cost at all the production and sales levels shown on the table.

q (units)	400	401	402	403	404	405
MR (marginal revenue)	58	56	55	54	53	51
MC (marginal cost)	52	54	55	57	60	62

What advice can you give to the management of the company about when to increase or decrease production and sales of computer chips?

We designed Task 2 to examine students' reasoning about relationships among four quantities: the number of computer chips produced and sold, marginal cost, marginal revenue, and profit. We used this task to examine students' interpretations of marginal change (e.g., the cost of producing the 401st computer chip) in a profit maximization context when given a task that has a numeric (table-based) representation. We also used Task 2 to examine students' reasoning about the units of marginal change, that is, as a rate (the difference quotient) or as an amount (the difference).

Data Analysis

Data analysis was done in two stages. In the first stage, we carefully read through each interview transcript and coded instances where pairs of students interpreted marginal change (marginal cost or marginal revenue) while they reasoned about each of the two tasks. Some of the codes that emerged from the data (through an inductive process) include interpreting marginal change as an amount i.e. the difference (e.g., saying the units of marginal cost in Task 2 are dollars), interpreting marginal change as a rate i.e. the difference quotient (e.g., saying the units of marginal cost in Task 2 are dollars per unit), and interpreting marginal change as the derivative (e.g., saying the derivative of the total cost function in Task 1 is marginal cost).

In the second stage of our analysis, we did a comparison across tasks to see how interpretations of marginal change given by pairs of students changed (or did not change) across the representations and contexts of the tasks they were given. For example, if a pair of students interpreted marginal change as the derivative in Task 1 (a task with an algebraic representation) and marginal change as an amount in Task 2 (a task with a numerical representation), we concluded that the students' interpretations of marginal change varied with the representation and context of the task they were given. The comparison made in the second stage provided answers to our research question: - How do business calculus students interpret marginal change when solving optimization problems that have different function representations and are situated in different economic contexts?

In light of the tenets of the theory of quantitative reasoning, and as we would show in the next section, some of the students mentally performed quantitative operations such as by conceptualizing the quantity of marginal cost as the derivative of the total cost function given in Task 1. We state as a remark that a majority of the students in this study performed a quantitative operation by conceptualizing a measure of profit as the amount of excess revenue above cost when creating a formula for the quantity of profit. These students engaged in the process of quantification (assigning a numerical value for the quantity of profit) by evaluating the profit formula at a particular production and sales level to find the amount of profit at that level. In our previous work (Mkhatshwa & Doerr, 2018), we showed that some of the students in this study performed a quantitative operation by conceptualizing a measure of the quantity of marginal profit as the difference between marginal revenue and marginal cost while working on Task 2.

Results

Analysis of interview transcriptions and work written by students revealed three findings. Because of space limitations, this paper reports on two of the findings. First, nearly all the pairs of students interpreted marginal change as an amount (the difference) and not as a rate (the difference quotient). Second, three pairs of students interpreted marginal change as the derivative.

Interpreting Marginal Change as an Amount

With the exception of one pair of students (Yuri and Kyle), all the other pairs of students indicated that the units of the marginal cost (MC) and marginal revenue (MR) values given in Task 2 would be in dollars. When asked to justify why the units would be in dollars, a majority of these students indicated that "since we are in the United States," the units must be in dollars. We interpreted the students' claim that the units would be in dollars to mean that they interpreted marginal change as a change (the difference), and not as a rate of change (the difference quotient). A critical reader may argue that this may have been less of a conceptual issue and more of a language issue. For example, it is common for people to speak of marginal cost in units of dollars while holding the "per unit" implicitly. However, these students consistently referred to marginal cost in terms of units of a change in total cost (i.e. dollars) and never mentioned the "per additional unit" while reasoning about marginal cost in other tasks. While this may have been a language issue, we argue that because of the consistency at which the students referred to units of marginal cost as dollars and not as dollars per additional unit that the students were interpreting marginal cost as an amount (the difference) and not as a rate (the difference quotient). As noted earlier, part of the difficulty may have been that that the numeric value for the difference and the numeric value for the difference quotient are equal since the denominator in the difference quotient is one in the case of marginal change.

Yuri, however, stated that the units of the MC and MR values in the table shown in Task 2 would be in "dollars per unit" suggesting that he interpreted marginal change as a rate (the difference quotient). The following excerpt illustrates Yuri and Kyle's reasoning about the MC and MR values in Task 2.

Researcher: What are the units of these numbers [pointing at the MR and MC values in Task 2]?
Kyle: Dollars
Researcher: Yuri?
Yuri: Dollars per unit
Kyle: or cents
Researcher: Yuri, why did you say dollars per unit?
Yuri: Marginal revenue is additional, extra revenue per unit
Researcher: Tell me more about that

Yuri: [Silence]

Yuri's statement that "marginal revenue is additional, extra revenue per unit" in the above excerpt suggests that Yuri interpreted marginal change as a rate, the rate [R(q+1)-R(q)]/1, for a total revenue function R(q) where q is the number of units sold. Kyle's initial response that the units of the marginal cost and marginal revenue values are "dollars" suggests that he was interpreting marginal cost and marginal revenue as total cost and total revenue respectively. This was confirmed later in the interview when Kyle stated that the company mentioned in Task 2 breaks even (i.e., total cost equals total revenue) at a production and sales level of 402 computer chips in the table shown in the task when, in fact, marginal cost equals marginal revenue. However, when he added "or cents" after Yuri had said that the units of marginal cost and marginal revenue would be "dollars per unit," Kyle was either agreeing with Yuri that the units were dollars per unit or cents per unit, or he was still interpreting marginal cost as total cost. Regardless of the units given by each of the 24 students for marginal cost and marginal revenue, the fact that these students assigned units to the marginal cost and marginal revenue values suggests that they interpreted marginal cost and marginal revenue as quantities and not as numerical values.

Interpreting Marginal Change as the Derivative

In this study, interpreting marginal change as the derivative refers to an understanding of the quantity of marginal cost (or marginal revenue) as the result of differentiating a cost function (or a revenue function) and not as a quantity that has rate-related units such as dollars per unit. Three pairs of students interpreted marginal change as the derivative while reasoning about Task 1 and Task 2. Two of these pairs of students interpreted marginal change as the derivative only in an algebraic representation (Task 1) and the other pair of students interpreted marginal change as the derivative only in a tabular representation (Task 2). None of these three pairs of students consistently interpreted marginal change as the derivative in both tasks (Task 1 and Task 2) or even in the other two tasks reported in the larger study (Mkhatshwa, 2016). Alan and Sarah are representative of the two pairs of students who interpreted marginal change as the derivative while reasoning about how to solve the problem posed in Task 1. The following excerpt, which occurred early in the interview, illustrates how Sarah and Alan reasoned about what they needed to do in order to answer the question posed in Task 1.

Sarah: Take the derivative of the demand equation $[p = q^2 - 100q + 3200]$
Researcher: What do you get when you take the derivative of the demand equation?
Alan: Is it the marginal?
Sarah: That would be the marginal cost
Researcher: What is marginal cost?
Sarah: The derivative of the total cost [function], right?
Alan: Yah yah, you are right

In the above excerpt, Alan wondered if taking the derivative of the demand equation would give them "the marginal" while Sarah stated that by taking the derivative of the demand equation what they will get "would be the marginal cost." Alan's wondering about the derivative of the demand equation being "the marginal" and Sarah's assertion that marginal cost is "the derivative of the total cost" were taken by the researchers to be the students' interpretations of the derivative of the demand equation by Alan (or the total cost function by Sarah) as marginal cost. Alan and Sarah, did not reason any further about the idea of marginal cost in solving the problem posed in Task 1. It would appear that these students associated the act of taking the derivative of an equation (e.g., the total cost function in the case of Sarah) with the term "marginal."

Joy and Nancy are the only pair of students who interpreted marginal change as the derivative while reasoning about the units of the MC values and MR values in Task 2. The following excerpt, which occurred towards the end of Task 2, illustrates how Joy and Nancy reasoned about the units of the MC and MR values in Task 2.

Researcher:	What do you think are the units of these numbers [pointing at the MR and MC values in Task 2]?
Nancy:	Oh, dollars.
Joy:	Dollars.
Researcher:	How do you know it's dollars?
Joy:	Because revenue and cost is dealing with money
Researcher:	But that's marginal cost and marginal revenue, is it the same thing?
Nancy:	Yah
Researcher:	Joy?
Joy:	I think, if you like take the, like if you take the derivative of the revenue it gives you the marginal revenue…

Joy's statement that "if you take the derivative of the revenue, it gives you the marginal revenue" suggests that she was interpreting the marginal revenue as the derivative of the revenue function. There is, however, no evidence that Nancy also thought the same way even though she did not object to Joy's statement about the derivative of the revenue function being the marginal revenue. Joy and Nancy went on to calculate differences between the marginal revenue values and marginal cost values at each production and sales level shown in the table that appears in Task 2. They referred to these differences as "profit," suggesting that these students also interpreted marginal cost as total cost and marginal revenue as total revenue as profit is generally defined as the difference between total revenue and total cost, and this is how profit was defined in the textbook used by the students and during course lectures.

Discussion and Conclusions

Nearly all the pairs of students who participated in this study interpreted marginal change as an amount (the difference) and not as a rate of change per unit of one (the difference quotient). These students stated that the units of marginal cost and marginal revenue in Task 2 would be dollars instead of dollars per unit. Throughout their reasoning about marginal change in other tasks (including two other tasks not included in this paper), the students consistently referred to marginal change in units of dollars and not in units of dollars per unit. We argue that part of the difficulty in this may have been the fact that in the case of marginal change, the numeric value for the difference and that of the difference quotient are equal as the denominator in the difference quotient is one. Only one student interpreted marginal change as a rate of change per unit of one. This student stated that the units of marginal cost and marginal revenue in Task 2 would be dollars per unit. As noted earlier, similar results were reported by Lobato et al. (2012) in a kinematics context. To some extent, the students' interpretation of marginal change as both a difference and a difference quotient can be attributed to the opportunities in the textbook they had to learn about marginal change. Specifically, marginal change was defined as a rate per unit of one (the difference quotient) and interpreted as an amount (the difference) in the textbook used by the students (Mkhatshwa, 2016). Also, the presentation of marginal change in course lectures closely followed the presentation of marginal change in the textbook (Mkhatshwa, 2016).

A majority of the students' interpretations of marginal change tended to change within and across the tasks they were given. For example, Sarah and Alan interpreted marginal change as the derivative in Task 1 but then they switched to interpreting marginal change as an amount of change with units of dollars in Task 2. Given that the tasks had different function representations and were situated in different economic contexts, these results suggests that the students in our study had weak understandings of the idea of marginal change in different situations. Specifically, these results suggest that students' interpretations of marginal change varied in different economic contexts and representations of economic situations. As noted in our previous work (Mkhatshwa, 2016), opportunities for students to interpret marginal change (e.g., marginal cost) in the textbook and in course lectures were limited. We argue that by providing more opportunities for students to interpret marginal change in different economic situations and function representations, business calculus instructors and business calculus textbook authors might be able to support students towards developing a robust understanding of marginal change.

SPONTANEOUS GENERALIZATIONS THROUGH EXAMPLE-BASED REASONING IN A COLLABORATIVE SETTING

Katherine V. Pauletti

orit.zaslavsky@nyu.edu

This study explores the progression from student justification to generalization in the course of example-based reasoning. Data was collected through group interviews with high school students who were working collaboratively on a task of determining connections between perimeter and area of tile shaped patterns. The task called for making and justifying conjectures regarding patterns of specific number of tiles. Our findings show that the task elicited collaborative example-based reasoning that evoked spontaneous generalizations about patterns of any number of tiles. The findings point to the importance of collaboration in generalizing, as well as to the intuitive nature of generalizations.

Keywords: Reasoning and Proof, High School Education, Middle School Education, Geometry and Geometrical and Spatial Thinking

Background

The study reported in this paper is part of a larger study on the roles of examples in learning to prove (Knuth, Zaslavsky, & Ellis, 2017). The main goals of this study were to examine ways in which the use of examples may facilitate students' reasoning and proving. This approach reflects a shift from focusing on students' overreliance on examples as a stumbling block to learning to prove (Healy & Hoyles, 2000; Harel & Sowder, 2007), to exploring productive ways of using examples for proving. By example-based reasoning we refer to justifications that use examples to convince one's self or others regarding a certain assertion (Rissland, 1991; Zaslavsky & Shir, 2005). The data set of the study consists of transcriptions of videotaped task-based interviews, mostly with individual students and some with groups of two to three students. In this paper we focus on the group interviews and examine the interplay between example-based reasoning and generalization in a collaborative setting.

Conceptual Framing

Generalization is considered to be an important form of algebraic reasoning and an instrumental component of mathematics education reform (Kaput, 1999; National Council of Teachers of Mathematics, 2000; Ellis, 2007; Ellis, 2011). Early theories and frameworks characterized generalization as an individual act (Ellis, 2011), focusing on theories related to the static nature of transfer in which knowledge remains unchanged during the transfer process (Ellis, 2007). However, researchers have more recently considered the dynamic nature of transfer through an actor-oriented perspective in which generalization may be influenced by instructional environments and social interactions (Jurrow, 2004; Ellis, 2007; Ellis, 2011).

Jurrow (2004) and Ellis (2011) show that students can generalize through peer interaction. Jurrow (2004) describes *linking*, the process of creating and applying classification systems, as a way in which students use talk and interaction to generalize. Ellis (2011) identifies seven categories of generalizing-promoting actions within a collaborative setting, noting how student interactions support and shape the generalizing activities. Ellis (2007) also developed a taxonomy for categorizing generalizations in which a distinction is drawn between generalizing actions (*relating, searching, and extending*) and reflection generalizations (a student's ability to identify or use an existing generalization). Vinner (2011) emphasizes that most generalizations made by students are intuitive in that they are immediate, spontaneous, and rely on global impressions, rather than an analytical thought process. He points to this as one reason why generalizations often fail.

Students construct new knowledge through generalizing activities (Ellis et al, 2017). The generalization schema sorts through similarities and differences, forming a generalization through the similar examples (Vinner, 2011). Examples have been identified as the preferred way in which students justify the truth of their conjectures (Stacey, 1989; Ellis, 2007; Vinner, 2011). However, students may not scrutinize the similarities found in examples, leading to false generalizations (Stacey, 1989; Vinner 2011). Justification is an integral aspect of generalization (Kaput, 1999) helping students to establish conviction in their generalization, as well as to prove the generalization (Ellis, 2007); but students attempt to justify through the use of *empirical examples* rather than *generic examples* (Lannin, 2005). *Empirical* example-use is most often characterized by treatment that confirms or contradicts a given conjecture with no consideration of general structure, while *generic* example-use illuminates the general case through a particular case and may convey the main idea(s) of the relevant proof (Mason & Pimm, 1984; Stylianides, 2008; Leron & Zaslavsky, 2013). Ellis et al (2017) developed the Criteria-Affordances-Purposes-Strategies framework to characterize the ways in which students think with examples while investigating and proving conjectures. The CAPS framework identifies *generalization* as one of the affordances of example-use (Ellis et al, 2017).

Although Ellis (2007) contends that the connection between generalization and justification is bidirectional, existing literature is thin with regards to how students progress from example-based justification to develop a generalization. Our study contributes to this area of research.

The Study

In this part of the study we consider the questions: (*i*) How might students' example-based justification of a particular mathematical conjecture promote generalizations? (ii) What roles do peer interactions play in this process?

Research Instrument

The research instrument for this part of the study was "The Tile Task" - a task designed to elicit example-based reasoning in a geometric context. Participants were given the following information: "A design company offers Tile-Patterns in different sizes and shapes. Each tile is a square with a 1-unit length side. Tile-Patterns are constructed by combining some number of tiles so that each tile shares one full side with at least one other tile. No 'holes' are permitted, and no two tiles are allowed to share only part of a side." The following examples of acceptable tile-patterns were provided (Fig. 1):

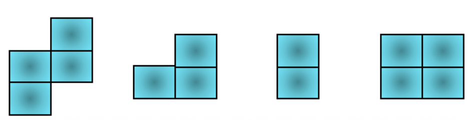

Figure 1. Acceptable tile patterns.

The two parts of the Tile Task that were analyzed for this paper (Question 4 and Question 5) were the same except for the number of tiles used. Question 4 asked: "For a tile-pattern that uses 8 tiles, what would be a shape of the pattern with the smallest perimeter? With the largest perimeter? How do you know?" Question 5 asked the same for a tile-pattern that uses 7 tiles.

While each of these questions could have been answered by using a previous part of the task in which students determined if the perimeter would increase, decrease, or remain the same by adding one tile, students were not directed to do so.

Data Collection

Students were randomly grouped for participation in four separate one-hour-long semi-structured, task-based clinical interviews. There was one individual interview ('Group 1' – one female), two dyad interviews ('Group 2' – one male one female; 'Group 3' – two females), and one triad interview ('Group 4' – three males). All interviews were recorded and transcribed, and any written work was also collected. Participants used Livescribe pens that captured audio, as well as pen strokes that can be replayed in real time.

Findings

This part of the study revealed that when asked to justify their answer, students attempted to generalize their findings to all tile-patterns regardless of the number of tiles used, with varying degrees of success. Students referred back to the examples they had generated when doing so. Two such instances, described below, occurred after student had identified the shapes of the pattern that would result in the largest and the smallest perimeters for tile-patterns using 8 and 7 tiles, respectively.

Case 1

S1, a 10th grade male, and S2, a 9th grade female, are working as a pair on the Tile Task. After reading Question 4, S1 immediately speaks in general terms about which tile-pattern would make the smallest and largest perimeters. As he speaks he sketches the tile-patterns as in Fig. 1.

> *S1*: Okay. Okay well I guess the largest, the smallest perimeter I guess would be the one that shows the least amount of sides, so...oh. Yeah so so if you have a really long one then that would be the most I think because you're showing as much of the tile as possible for each one and let me see.

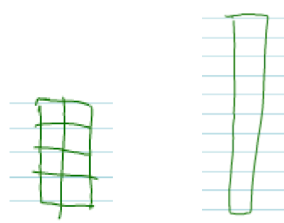

Figure 2. Tile pattern

S2 agrees with this assessment; they count the sides to determine that the smallest perimeter is 12 units and the largest is 16 units (this group incorrectly counted the largest perimeter as 16 while it really is 18 units). Once Question 4 is answered, they move onto Question 5.

> *S2:* I think the largest is still just a long one.
>
> *S1:* Yeah and this (Fig. 3) comes out to perimeter of twelve like this, so I don't know. I don't-

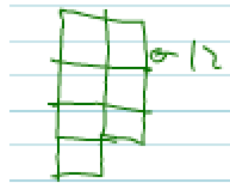

Figure 3. Another tile pattern

S2: I don't think there's anything you can do to make it smaller

S1: Yeah okay so that's smallest and the long one is largest.

Before leaving the Tile-Task, the interviewer asks S1 and S2 to talk about the shapes they used in Questions 4 and 5:

S1: Well the shortest one, or sorry the one with the smallest perimeter is usually in general stout, stouter I don't know how to describe it. Its length, its, the ratio of its length to width was smaller, no larger. I'm not, you put its length over its width it would be closer to one than if you put this length over this width is what I'm saying. So essentially when the closer to a square this gets or the closer to a figure where the ratio of length to width is one, the smaller its perimeter is**.** I think. Does that sound? (refers to Figure 2)

S2: Yeah

S1: So I guess yeah, if we needed to do a formula you could say as l over w approaches 1, the perimeter gets smaller. Or the less the, the less, the more the ratio, or I guess you say the ratio of length over width is inversely proportional to the perimeter. Yeah yeah okay because as the length over width, the ratio itself gets closer to one which is the biggest it can be, the perimeter goes down so yeah.

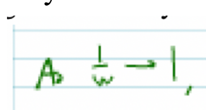

Figure 4. Formula

In describing the shapes used to determine the smallest perimeter, S1 attempts to generalize the relationship between a tile-pattern's length and width with regards to the tile-pattern's perimeter. By doing so, S1 is moving beyond the particular cases concerning tile-patterns that use 7 and 8 tiles into the general structure for all cases, regardless of the number of tiles used. Although S1 explicitly refers to the smallest perimeter, his attempt to generalize also captures all cases for the largest perimeter.

Case 2

The students below are both female, S3 is in 7th grade and S4 is in 9th grade. Each student begins working independently, drawing Figures 5 and 6.

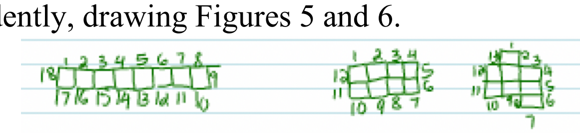

Figure 5. One student's work

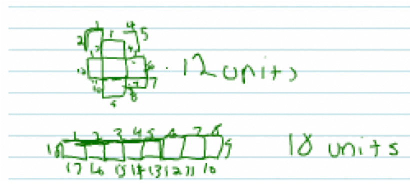

Figure 6. Another student's work

S3: What do you? I said smallest is 12 and longest is 18.

S4: Oh yeah. That's what I got too. But, yeah. I think that, I think that's, is that right? Let me, I'll just try something (Fig. 7).

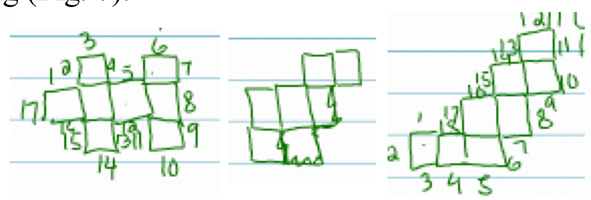

Figure 7. Student's work

S3: Yeah, lemme try a square (Fig. 8).

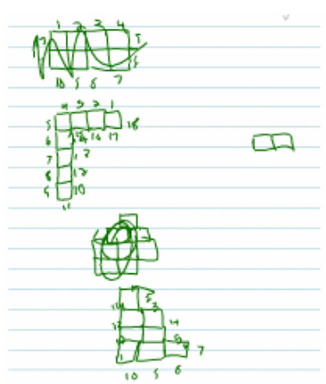

Figure 8. Student's work

S4: Yeah. I think the largest amount is 18.

S3: I'm good with that.

S4: Alright. I think our original answer is justified**,** um, the largest is 18 units and the smallest is twelve units, right?

The interviewer then asks S3 and S4 how they know that these are the largest and smallest perimeters.

S4: Um, I just personally, I experimented and I found that in um most structures most of the tiles had to only um be exposing to, or, 'cause I kept trying to make it so that each tile was exposing three sides, but um, it didn't work out because you have to plonk the other tile somewhere.

In trying to justify her results for Question 4, S4 talks about structural similarities found in the shapes of the various examples generated. The pair then moved onto Question 5, generating several tile-patterns using 7 tiles. After S3 and S4 were in agreement that the smallest perimeter was 12 and the largest 16, the interviewer asked: “How do you know?” The response of S3 is below:

> *S3:* Um. So I tried a different shape than what I did before and it still came in as 12. I feel like if the, um, like if it's larger than I guess 6 maybe, it's going to be, 12 I feel like is the smallest it can go if there's only like 6 tiles, like 5 tiles, the smallest it can go is 12 for the perimeter and then the highest it can go is 2 plus there like, you do 7 plus 7, it's 14 and it's 16, so like the perimeter would be 2 units more than what the number of tiles plus the number of tiles is. (refers to Fig. 9)

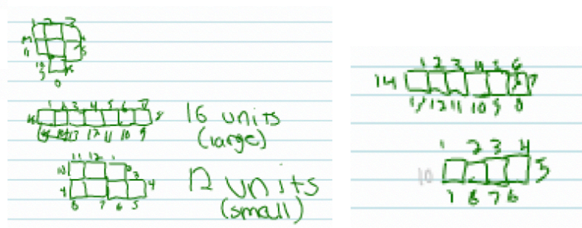

Figure 9. Student tried a different shape

The interviewer probes S3 further, asking if S3 is thinking about the largest perimeter in terms of any number of tiles; S3 replies: “yeah.” The following conversation between S3 and S4 ensued:

> *S4:* Then how would you split up the tiles when you're adding them together?
> *S3:* What do you mean, like?
> *S4:* If, if we had 7 tiles, how would you add them together? How would you split them to add them together?
> *S3:* To get a small perimeter or a large perimeter?
> *S4:* A large.
> *S3:* I just did a line and...
> *S4:* But, like applying your rule, how would you do it?
> S3: Um, I'm not really sure, but like it's the same thing as the 8 tiles. It came out to 18 for the largest and that's 2 plus 8 plus 8, which is 16, so it's 2 plus, that makes sense.
> *S4:* So it's the number, the number of
> *S3:* Tiles
> *S4:* tiles times two
> *S3:* Yeah.
> *S4:* plus two?
> *S3:* Yeah.
> *S4:* Ok.

Although S3 and S4 did not discuss the shape that would yield the largest perimeter, S3 sought to generalize the numerical value of the largest perimeter, regardless of the number of tiles used. S4 then engaged S3 in a conversation clarifying how to use the “rule” to find the largest perimeter, which further developed the algebraic generalization.

Discussion

The Tile Task was designed with the goal of characterizing students’ use of examples in conjecturing and proving when engaged in a task of a geometric nature. As expected, students generated their own examples in an effort to answer various questions regarding the size of the perimeter. The spontaneous example-use served to highlight what came naturally to students (Aricha-Metzer & Zaslavsky, 2017) with a goal of building an intuition regarding proving or disproving a conjecture (Zaslavsky, 2017). In addition to this, and as suggested by Vinner (2011), students spontaneously began to investigate the similarities found in their examples in order to make general statements beyond the particular case being considered. Students in each of the four groups, at some point during the Tile Task, engaged in a form of generalization that went beyond the scope of the question asked. This could reflect the intuitive nature of generalizations (Vinner, 2011).

The findings also reveal that students encounter difficulty when shifting from pattern recognition to pattern generalization (Ellis et al, 2017). According to Ellis (2011), students are aided in this shift by sharing ideas with their peers. While individual students initiated the attempt to generalize, the shift from pattern recognition to pattern generalization occurred when students shared their initial ideas with their peers. In case 1, this is evident when both students began to discuss S1's sketches in terms of exposed sides, which lead to an insight of how the length-to-width ratio can be used to determine the shape of a tile-pattern that results in the maximum or minimum perimeter. In case 2, S3 and S4 work individually (e.g. S3: "I tried… S4: "I just personally…") and then share their results. Through this sharing, S3 reveals that she recognizes a pattern between the numbers of tiles used and the largest perimeter of the tile-pattern. S4 propels the generalization forward by asking S3 how she would "split up the tiles" when adding them together. This discussion leads to a general algebraic formula that determines the size of the largest perimeter for a tile-pattern that uses a given number of tiles. Through a collaborative effort, each group volunteered a generalization related to Question 4 and Question 5.

It is also worth noting that while Question 4 and Question 5 discussed in the cases above could have been addressed by using information gained from Question 3, no group drew on this prior knowledge. Question 3 asked if the perimeter of a tile-pattern would increase, decrease, or remain the same following the addition of one tile. All three cases are possible depending on where the additional tile is placed: a) the perimeter decreases when one tile is added to a cavity, b) the perimeter increases when one tile is added to the end of another, and c) the perimeter remains the same when one tile is added to a corner. While only two of the four groups had concluded that the perimeter could decrease, all concluded that the other two cases were possible. However, none of the four groups used the information regarding the increased and constant perimeter when thinking about a shape that would yield the largest and smallest perimeters. The disjointed manner in which students advanced through the Tile Task warrants further exploration.

Pedagogical Implications

The results of this study have pedagogical implications with regards to example-based reasoning and student collaboration. This study shows how both can aid students with generalization. This study also points to the importance of engaging students in rich mathematical tasks.

VARIOUS MEANINGS A STUDENT USES FOR QUANTIFIED VARIABLES IN CALCULUS STATEMENTS: THE CASE OF ZACK

This study investigates one Calculus student's meanings for quantifiers in Calculus statements involving multiple quantifiers. The student was asked in a two-hour long clinical interview to evaluate and interpret the Intermediate Value Theorem (IVT) and three other statements whose logical structure was similar to the IVT except for the order of both the quantifiers and their attached variables. Four different meanings for variables attached to universal and existential quantifiers emerged from his responses at various moments of the interview. In this paper we detail these four meanings with empirical evidence and discuss implications of our findings to research and teaching of quantified variables in Calculus statements.

Keywords: Reasoning and Proof, Postsecondary Education, Cognition, Advanced Mathematical Thinking

The purpose of this study is to investigate students' mental processes associated with quantified variables. In particular, we focus on a Calculus student, Zack, and his quantifications for variables in the Intermediate Value Theorem (IVT) and similar statements as we answer the following research question: *What are the meanings for quantified variables that a student uses when interpreting statements from Calculus contexts?*

Literature Review

Quantifiers such as "for all" ($\forall$) and "there exists" ($\exists$) may be used to state important definitions and theorems in Calculus. For example, the Intermediate Value Theorem (IVT), the Mean Value Theorem (MVT), and definitions of limits and continuous functions may be stated with multiple quantifiers (Bartle & Sherbert, 2000; Stewart, 2003). Several studies have reported various student tendencies to mistreat quantifiers when analyzing quantified statements involving either the universal or existential quantifier (Barkai, Tsamir, Tirosh, & Dreyfus, 2002; Epp, 1999). For example, Barkai et al. (2002) reported that some participants of their study tended to suggest that a few examples are sufficient to prove that a statement involving a universal quantifier, in the form 'For all x, P(x),' where P(x) is a statement about x, is true. In the case of a statement involving an existential quantifier, in the form 'there exists x such that P(x),' students also rejected the notion that one example would suffice for proving such a statement (Tirosh & Vinner, 2004). One such explanation for why students tend to have these particular tendencies in their interpretations of quantified statements is that they may confound colloquial language with mathematical language (Epp, 1999). For example, colloquially we may state that "Every book on the bookshelf is French," and we would assume that there is at least one French book on the specified bookshelf. However, in mathematics, we could consider the case where the statement is vacuously true. Colloquial language may explain some student difficulties with quantification, but there may be other reasons why these tendencies exist that have yet to be noted in the literature that may be explained by classifying students' meanings for quantified variables.

Theoretical Perspective

In this section, we define some terms that we will use to describe one student's meanings for quantified variables. *Quantifiers* are phrases (e.g., "for all" and "there exists") used to indicate the number of elements, x, in the domain of discourse satisfying a predicate, $P(x)$. For example, consider the mathematical statement, "Every isosceles triangle x has congruent base angles." This statement is a quantified statement where the phrase "every" is a quantifier for the elements x within the domain of discourse, which is the set of isosceles triangles, satisfying the predicate, "x has congruent base angles." We refer to x as a *quantified variable*. We use the term *quantify* to mean that an individual is mentally searching for (or anticipating searching for) a specific number of, or quantity of, values of the variable x in the domain of discourse that satisfy the predicate $P(x)$. By *quantification*, we refer to an individual's mental search processes (or anticipated search processes) for a specific number of elements that satisfy the predicate.
