EXPANDING STUDENTS' CONTEXTUAL NEIGHBOURHOODS OF MEASUREMENT THROUGH DYNAMIC MEASUREMENT

Debasmita Basu

Nicole Panorkou
Montclair State University
panorkoun@montclair.edu

This study is part of a larger project exploring students' thinking of Dynamic Measurement (DYME), an approach to area measurement that engages students in dynamic digital experiences of measuring rectangular surfaces through sweeping lengths. The goal of this study was to evaluate the extent to which students could bridge the mathematical knowledge they gained from these dynamic experiences to other activities that are more static in nature. A classroom of 19 third grade students participated in an 8-period design experiment (DE) centered on DYME. Data to evaluate the bridging were obtained from pre- and post-assessments administered before and after students' participation in the DE. The results suggest that by working with the DYME tasks, students were able develop a conceptual connection between multiplicative reasoning and area measurement that were able to apply to solve static tasks.

Keywords: measurement, technology, situated learning, learning trajectory

> *Researcher*: So, what did you learn from interacting with these tasks?
> *Student*: We learned how to paint inside the lines.
> (*Excerpt from a design experiment after a series of sessions using DYME tasks*)

As researchers, we carefully design tools and tasks to engage students in experiences that would support their learning of mathematics. However, similar to the excerpt above we notice that "unfortunately mere experience is not sufficient for learning, for integrating into one's functioning, or for making, more and more effective actions available to be enacted in the future" (Mason 2015, p. 334). Indeed, students learn how to play with the tool, engage with the task and make some generalizations, which a researcher may describe as powerful for developing advanced mathematical ideas, yet there is "little evidence that students can abstract beyond the modeling context" (Doerr & Pratt 2008, p. 272) or whether students are able to use this knowledge to make sense of other tools or apply it in other contexts.

In fact, many researchers have tried to describe the situated nature of the generalizations that students develop as they engage with contextual problems and digital tools. An example is the work of Hoyles and Noss (1992) on the notion of "situated abstractions" in which they describe the gap between the generalizations that students form in one context but not in others. Many researchers tried to describe this as a failing "transfer" of knowledge. For instance, Broudy (1977) discussed transfer as the ability of students to apply their prior knowledge in order to solve new problems, while diSessa and Wagner (2005) discussed it as re-using the knowledge gained in one situation (or class of situations) to a new situation (or class of situations).

In exploring students' transition from a constructionist learning environment to formal algebra, Geraniou and Mavrikis (2015) raised the issue of what exactly is that "knowledge" being transferred, and chose to focus on "bridging" instead, a metaphor first used by Perkins and Salomon (1988) to describe "a process of abstraction and connection making" (p. 28). Following this notion, Geraniou and Mavrikis (2015) designed a series of "bridging activities" which assisted students in making the connections between the digital tool and the mathematics. These bridging activities included *consolidation tasks* that asked students to reflect on their interactions with the software, *collaborative tasks* that focused on asking students to justify whether their rules were equivalent or not to each other, *tool-like paper* tasks that looked like the software tasks but were on paper, and finally textbook or exam-like tasks. This variety in the design of the bridging activities can be seen as aiming to expand what Pratt and Noss (2010) refer to as students' *contextual neighborhood*, or the range of contexts and variety of circumstances in which the students' knowledge is made relevant and accessible.

In this paper, we describe our efforts in assisting students to expand their contextual neighborhood of measurement through dynamic measurement (which we describe in the next section), and discuss how our task design may have helped them bridge their dynamic digital experiences with typical static measurement tasks.

Dynamic Measurement (DYME)

DYME draws on research on visualizing area as 'sweeping' (e.g. Lehrer, Slovin, Dougherty, & Zbiek, 2014; Thompson, 2000) to engage students in digital experiences of visualizing the multiplicative relationship of length *times* width that underlies the area formula of a rectangle. To understand this approach, imagine a paint roller of length *a* being swept over a distance of *b* (width) to generate a rectangle of area *ab* (Figure 1). DYME presents area as a continuous dynamic quantity that depends on both the length of the roller and the length of the swipe. Aiming to explore students' DYME reasoning for area, we conducted two cycles of design experiments (DE) (Cobb, Confrey, Lehrer, & Schauble, 2003) and developed an interactive book of tasks on Geogebra [www.montclair.edu/csam/DYME] and a learning trajectory (LT) (Simon, 1995), illustrating how students' thinking of DYME may progress over time.

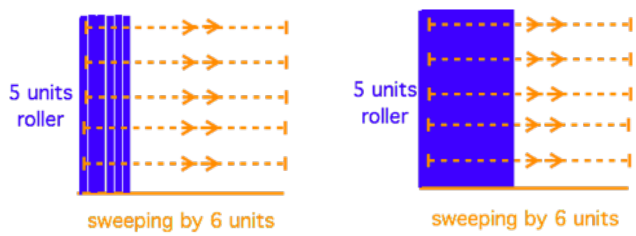

Figure 1. Area as a continuous structure using the 'sweeping' approach (Panorkou, 2017)

Table 1 presents the LT, which consists of a set of DYME constructs from less sophisticated to more sophisticated (levels), a sample Geogebra task for each construct, and a set of observable student generalizations that are more likely to occur at each construct. The goals of Levels 1-3 are for the students to build the idea of 2D space by visualizing area as a continuous structure that can change dynamically through 'sweeping,' recognize that the measurement of a surface requires the coordination of two dimensions (e.g. Reynolds & Wheatley, 1996), and recognize the multiplicative relationship between the two dimensions of a rectangle and its area (Izsak, 2005). To help students identify this relationship, the tasks involve the use of a 1-inch roller to paint shapes of different lengths and widths and constructing a repeating pattern for covering the shape (e.g. Outhred & Mitchelmore, 2000), by considering the distance covered in one swipe with the number of swipes. Subsequently, Levels 4-6 present an exploration of what else is possible to learn after students develop their DYME thinking, therefore they do not follow a specific order (although in this paper we refer to them "levels".) For instance, in Level 4 students use their DYME knowledge of area to identify the effects on the dimensions when the area of a shape is scaled, or in Level 5 students explore dimensions as factors that may give the same area.

Table 1. The hypothetical learning trajectory for DYME

Stage	Example of a task from the Geogebra book	Example of Students' behavior
1. Exploring dimensions and area as continuous attributes: Students visualize area as a continuous structure that can change dynamically.	Drag the paint roller to paint each shape. How far did you drag the paint roller to paint each shape? 	**a.** Students recognize that the dimensions, length of the roller and the distance dragged, define how big or small a shape is, e.g. "*The more I drag the roller, the more space I cover*" "*The longer the roller, the more space it covers.*" **b.** They also form relationships between the dynamic action of painting and the dimensions of the shape being painted, e.g. "*The length of the roller needs to be the same as the height of the rectangle*" "*The distance of paint is same as the base of the rectangle.*"
2. Coordinating two dimensions to compare area: Students recognize that the measurement of a surface requires the coordination of two dimensions.	Modify the envelope to fit the size of the card! How big is the envelope you created?  What do we need to change? What stays the same?	Students recognize that to compare two shapes, they need to compare both dimensions, e.g. "*The height needs to change, the base needs to stay the same.*"
3. Multiplicative Relationship of length, width and area: Students recognize the multiplicative relationship between the two dimensions of a rectangle and its area.	Students are asked to use a 1-inch roller to paint surfaces of different lengths and widths.  How far did you drag the roller? How many swipes did you need to cover the wall? How much space did you cover?	**a.** Students use the multiplicative 'times' language to find the space covered, e.g. "*This is 30 because the base is 10 and we are going to swipe three times.*" **b.** Students recognize that a roller of size *l* covers the same area as *n* rollers of size *l/n* dragged for the same distance, e.g. "*A 3-inch roller covers the same as three 1-inch rollers. If we cut it into 3 parts and you go across one time it is 10 and then if you go across another time it will be 20 and if you go one more time it will equal 30.*" **c.** Students recognize that the space covered can be found by the length of the roller *times* the base of the rectangle or the distance of swipe, e.g. "*The length of the roller is 3 and the distance is 10, so area is 3 times 10.*" **d.** Students using "length of roller" and "height" interchangeably, and this intuitively leads to *height times base*, e.g. "*The length is 3 and the base is 10. To find area, I did 3 times the base, which is 30.*"
4. Multiplicative Coordination of length and area: Students recognize that length, width and area are coordinated through multiplicative comparisons.	How can you make the parking place twice as big as it is now? 	**a.** Students identify that they can double or triple areas by multiplying only one of the dimensions by the same factor, e.g. "*To double the area, we can double the length or the width.*" **b.** Students recognize that in order to split area (fractional thinking), they need to split the length or the width, e.g. students create a cafeteria which is 1/4 of an 8 by 5 inches garden and argue: "*If we split this [the height of the cafeteria] into four parts, then one of the parts will be the cafeteria. It would be 2 inches because the if we use only 1-inch roller it would go 8 times across but if you use 2-inch roller then it would go 1,2,3, and that would go 4 parts.*"
5. Identifying area as a multiple of its dimensions: Students recognize area as a multiple of its dimensions and identify factors that give same area.	Please design the stores in such a way so that each of the food stores will have an area of 12 sq. meters. Also, each food store should have different length and width from the other stores! 	**a.** Students use the commutative property to compare areas, e.g. "*A rectangle with length 4 and width 3 has the same area with a rectangle of length 3 and width 4.*" **b.** Students identify factors that give same area, e.g. "*Length 4 and width 3 is doing 4 swipes of 3. This is same as two swipes of 6, so length 2 and width 6*"
6. Multiplicative Coordination of relative areas: Students recognize that if a shape is 1/n of another shape, then its area is 1/n of the area of that shape.	Make the robot as fancy as you like but its area should be no more than 190 sq. inches. 	Students recognize that if a right triangle is half a rectangle, then the area of that triangle is half the area of the rectangle, e.g. for calculating the area of each blue leg, the students argued: "*You have to do a half of 7 and 2. We do 7 times 2 and a half of that.*"

The first two cycles of DE showed DYME's potential for making the multiplicative relationship of the area formula more intuitive and accessible to students (e.g. Panorkou, 2017). However, the nature of DYME tasks is very different than any of the measurement tasks that students encounter in their classrooms and many of the generalizations they make are situated in the specific context of DYME. Therefore, in Cycle 3 we wanted to test out whether students could connect these situated experiences to their other measurement experiences. Our task design and questioning included many tasks that could help them do that. First, we used consolidation tasks that asked students to reflect on their interactions with the software, reflect on their learning in every session and generalize their strategies. An example of the latter was when we asked the students to advise a painter of how to measure the space of any rectangular surface. Second, we used whole class discussions at the end of each session that included collaborative tasks asking students to share different strategies of solving a task and discuss why different strategies generate the same answer. For instance, finding the space of a rectangular surface of 4 inches by 5 inches, by using 4 one-inch swipes of 5 inches or 2 two-inch swipes of 5 inches or using 4 inches *times* 5 inches. Third, in contrast to Geraniou & Mavrikis (2015) that used software-like paper tasks, we used paper-like dynamic tasks, that are similar to what students would encounter on paper but with technological affordances, such as presenting them with a rectangular surface which they can make bigger or smaller by modifying the length and width through dragging (e.g. Level 2 task in Table 1). We conjectured that this kind of design would help students build connections between DYME and other types of measurement.

Aims

This article describes our efforts to investigate how a whole class design experiment (DE) (Cobb et al., 2003) on DYME could help students develop their thinking of area as a multiplicative relationship and whether students are able to transfer knowledge gained from interacting with the DYME tasks to the static traditional area tasks they would encounter in the classroom. More specifically, our goals were to explore:

1. To what extent did the students develop their thinking of area as a multiplicative relationship as a result of the design experiment and the use of the DYME tasks?
2. To do extent did the students bridge the experiences gained from the dynamic environment of DYME tasks to traditional area tasks they encounter in the classroom?

Methods

Nineteen third-grade students from an elementary school in the Northeast participated in the whole class DE (Cobb et al., 2003). The students already had formal instruction on multiplication and area measurement using the common approach of using square units. The DE consisted of six 50-minute periods of instruction using the DYME Geogebra tasks.

Assessment Design

To answer our research questions, we designed and administered an assessment to students at the very beginning of the DE and at the end of the learning experience. The items in both pre- and post-assessments were identical aiming to create an initial and final "profile of strengths and weaknesses" (Huhta, 2008, p. 470) for each student. The assessments were pilot tested with a separate group of students and revised before they were used for the present study. Aiming to examine both the development of students' thinking of area and the extent of bridging, we designed the items based on typical measurement assessments used in the literature (e.g. Battista, 2004) and on questions found in standardized test assessments, such as PARCC. All the items were aligned to a level of the LT and were designed to provoke responses that could indicate how students' reasoning has changed following their interaction with the tasks during the DE.

For example, one of the DYME goals is for students to recognize that *a* swipes of *b* cover the same amount of space as *b* swipes of *a*, what we refer to as commutativity in DYME. To do that, we engage students in dynamic tasks, such as the one presented in Figure 2 (left), where they use paint rollers of different orientations (horizontal/vertical) in order to find area and generalize that 4 swipes of 5 cover the same space as 5 swipes of 4. Instead, typical measurement assessments evaluate the commutative property in static tasks similar to the Question A in Figure 2 (right), which assesses if students recognize that a 3ft by 4ft tabletop has the same area as a 4ft by 3ft tabletop. Question A was used as an item in our pre- and post-assessment. Each assessment included three to four items corresponding to each construct of the LT and these items were evenly distributed throughout the paper so that no two consecutive items were associated with the same LT construct.

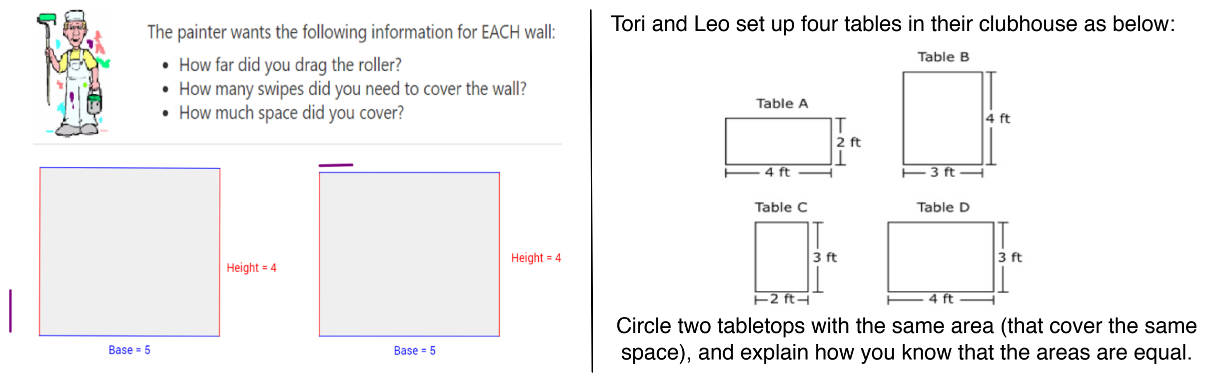

Figure 2. DYME Geogebra task (left); Question A, adopted from the PARCC assessment (right).

Assessment Analysis

For analyzing the students' work, we read every student's response and generated categories to capture the themes in their responses. We then developed a scoring protocol to measure the range of sophistication in their responses. To score the responses, we adopted Norton and Wilkins' (2012) suggestion: 1 for indication of a particular reasoning level and 0 for counter-indication of a particular reasoning level. The levels of reasoning adopted were consistent with the LT levels in Table 1. For instance, a response showing a Level 5 understanding was receiving a point for Level 5, while a response showing a Level 3 understanding was receiving a point for Level 3. The responses were scored by four researchers independently and then negotiated aiming to maximize reliability.

For an illustrative example of the whole process, consider Question A in Figure 2 (right). Table 2 presents the scoring rubric we developed for Question A. In this question, we noticed three different levels of reasoning corresponding to constructs 2, 3 and 5 of the LT. Depending on how the student responded, they would get a point for that construct. For example, if a student used the commutative property to find equal rectangles, they received a point only under level 5.

Results

After each student response was scored, we summed the total scores received by all students under each level (L1 - L6) and color-coded the responses based on these scores in a contingency table (Norton & Wilkins, 2012) (Table 3). As aforementioned, each assessment included three to four items corresponding to each level of the LT. For instance, we included four different items in which students could use level 5 reasoning to respond. If a student received 3 points of level 5 that meant that the student used level 5 reasoning to respond to 75% of the level 5 questions.

Table 2. Rubric for Question A created based on students' responses

Rubric	Example of students' responses	Scoring justification
The student expresses commutative reasoning to find the two rectangles with same area. (1pt for Level 5)	"Table B and table D, because 3x4 = 12, 4x3=12."	Response is aligned to LT level 5. The student exhibits an understanding of the commutative property.
The student multiplies the length and width of the rectangles and compares their area to find rectangles of equal area. (1pt for Level 3)	"I know they are equal because if you multiply them they have the same area."	Response focuses on students' calculation and comparison of area (LT level 3), but does not explicitly state that the commutative property is used.
The student coordinates the length and width of rectangles simultaneously to make judgement about their area. (1pt for Level 2)	"They are same because there is a 4 and a 3."	Response focuses on the numerical values of the sides of the rectangles to make judgements (LT level 2), but does not discuss the order of the numbers.
The student answers correctly but provided vague or no reasoning. (0 points)	"Because when I circle the table. So, I think I should circle the same table."	Response does not provide any description of students' thinking.
The student answers incorrectly. (0 points)	6x5, 3x5, 6x3, 5x6.	Response is illegible.
The student does not respond. (-)		No response.

If a student's overall raw score for a given level was above 60%, then it was inferred that the student reached proficiency in that level and the cell under that level was colored dark grey. If a student's overall score for a particular level was between 30%- 60% the cell was colored grey. For students whose total scores in any level of understanding were less than or equal to 30%, the cells were colored light grey to indicate that students showed some instances of the particular level of understanding. Some students did not answer all of the questions, and thus white cells indicate missing responses. Dotted lines (--) indicate students who did not take the assessment. Table 3 compares students' responses to the pre- and post-assessments showing the extent to which the students' thinking of area as a multiplicative relationship was developed due to their interaction with the DYME tasks. As Table 3 illustrates, out of the 19 third-grade students in the whole class design experiment, only 3 were able to think multiplicatively about area in the pre-assessment (represented by level 3). However, in the post-assessment, 15 students showed an understanding of area as a multiplicative relationship of length *times* width. These results showed that not only students' thinking of area as a multiplicative relationship was developed by engaging with the DYME tasks, but also, that they were able to use their DYME experiences to solve traditional area tasks.

Table 3 also shows that in each level, students understanding was developed from the pre-assessment to the post-assessment (with the exception of level 1 showing that students moved beyond that level.) This is illustrated both by the darker shading, which is more prominent for the post-assessment, and also by the increase in the average score in every level in post-assessment compared to pre-assessment. For instance, in level 3, students scored an average of .2 during pre-assessment, which increased to 2.0 during post-assessment. Similar development in students' thinking of area is observed in other levels, especially in level 4, 5, and 6 where the average score of students' responses increased from 0 to 0.6, 0.14 to 1 and 0.07 to 0.6 respectively.

Table 3. Contingency table showing the total scoring of the assessment questions

Student	Pre-assessment						Post-assessment

S												
Average	1.35	1.93	0.2	0	0.14	0.07	1.11	1.94	2	0.6	1	0.6

Although students exhibited an overall improvement in their level of understanding in the post-assessment compared to the pre-assessment, we found some exceptions in some students' responses. For instance, though students E and J showed proficiency in coordinating the two sides of a rectangle (Level 2) during pre-assessment, they showed a decrease in their responses in the particular level during the post-assessment. This was most likely because during the post-assessment, the level of understanding of the two students in the certain questions moved beyond level 2 and they showed a higher degree of understanding in level 3 and 5. Another case is student L, who reached level 5 during the pre-assessment but did not proceed beyond level 4 during the post-assessment. On further analysis, we found that student L did not answer the last 9 questions in the post-assessment, which explains the decrease in the level of understanding.

Significance

Researcher: What have you learned all these days?
Student 1: I learned that there are other ways to measure length and width. You can use objects like paint rollers.
Student 2: Yes, and that to double area we need to double one of the measurements.
(*Excerpt from a design experiment after a series of sessions using DYME tasks*)

The findings from the pre- and post-assessment analysis show that students' engagement with the DYME tasks helped them improve their understanding of area. The data analysis also showed that students were able to bridge their DYME experiences and generalizations with typical area tasks. Students extended their contextual neighborhood of measurement to include sweeping-based reasoning as well as reasoning about area as length *times* width. Students not only developed their understanding of area as a multiplicative relationship but they also used this knowledge to respond to more advanced questions in levels 4-6. Among our future goals are to examine the order in the upper LT levels (4-6) and also to further examine the type of activities that assist students in bridging these connections between DYME and other area generalizations.

ENTERING EQUATIONS: COMPARISON OF HANDWRITING RECOGNITION AND EQUATION EDITORS

Gabrielle A. Cayton-Hodges

James Fife
Educational Testing Service
jfife@ets.org

Once a novelty, Digitally-Based Assessments (DBA) have become commonplace in the USA. With mathematics, it is often a necessity to include items that require the student to input a mathematical formula, equation, or expression. Many of these responses, especially in the upper grades, cannot be input with a standard keyboard, but must use some type of equation entry. In this study, we compare ninth-graders' entry of mathematical expressions using an equation editor versus using handwriting recognition on a tablet. While neither method is currently without flaws, we discuss the benefits and drawbacks of each as well as potential methods for improvement and the implications for mathematics assessment.

Keywords: Assessment and Evaluation, Technology

Introduction

Mathematics has long been a subject of paper and pencils. Scratch work, diagrams, and mark-ups are all parts of solving mathematical problems that need to be addressed as part of developing Digitally-Based Assessments (DBA). One artifact of the paper-and-pencil world is that of the mathematical response itself. Most mathematical formulae, equations, and expressions cannot be input properly using a standard keyboard. Even at the elementary level, a simple fraction requires an equation editor, as most students are used to seeing the numerator directly above the denominator ($\frac{1}{2}$), not the orientation that would result from a sideways slash (1/2). At the middle-school level, exponents, square roots, and π further complicate the mix. Finally, at the high-school level, all of these are combined together in various embedded formats that can confuse even those who are comfortable with the individual symbols.

The most common solution to this open-ended response problem is to use an equation editor (see Figure 1).

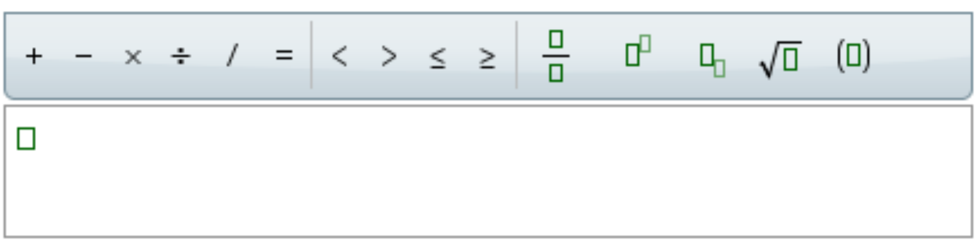

Figure 1. Sample Equation Editor Entry Box

While equation editors allow for precise entry of mathematical expressions, they do add an extra burden on the student. These additional difficulties can be both construct-related (i.e., students who struggle with mathematics may struggle more to use the equation editor due to not understanding the various mathematical symbols, orders of entry, etc.; see Noyes, Garland, & Robbins, 2004) and construct-irrelevant (i.e., students who have less exposure to equation editors, regardless of mathematical ability, may require extra time to identify and select the proper symbols and where to click or type; see Leeson, 2006). Hargreaves et al. (2004) also showed that students may solve problems differently when presented assessments through different media.

Tablets and other devices that allow for handwritten digital entry could resolve some of this burden, but unless those handwritten responses can be automatically scored with the same ease as the typed equation editor responses, the cost (in both time and money) of scoring the assessment becomes too great for this to be a reasonable solution. Thus, we cannot administer assessments with digital handwritten entry without automated handwriting recognition. In this paper, we discuss a study intended to be the first in a series of experiments aimed at first identifying differences between equation editor entry and automatically translated handwritten entry and then addressing the challenges of each towards the development of a solution that provides the most authentic experience as possible for students that minimizes construct-irrelevant difficulties.

Study and Research Questions

As stated above, this study describes the first year of a multi-year study aiming to understand and improve equation entry for mathematics assessments. Our goal for the first year of the project was 1) to demonstrate that we can score equations and expressions that have been captured on a tablet (Apple iPad) via handwriting with a stylus, then automatically translated into MathML (Ausbrooks et. al., 2010) via the translator MyScript (Vision Objects, 2017) and 2) to determine if there is a difference in performance when students enter responses on a computer, using an equation editor (WIRIS, see Maths for More, 2017), versus entering responses on a tablet. If we suppose that prior evidence with paper and pencil is an appropriate stand-in for tablets, research would suggest that it is easier for students to handwrite responses on a tablet using a stylus than to enter them on a computer using an equation editor and that students are less likely to make construct-irrelevant errors (see Hargreaves et al., 2004). The ability to administer assessments on a tablet, and to score the responses automatically, will increase flexibility and the attractiveness of digitally based assessments to both stakeholders and test-takers. For this study, we had students copy equations directly from a screen to study only the entry of the equation itself and minimize any effect that the method of entry may have on the solution strategy prior to equation entry.

We designed a study to answer the following research questions:

1. What are the potential causes of errors and variability in score differences with automatically scored equation responses that have been captured on a tablet via handwriting with a stylus?
2. Is there a difference in student performance between responses handwritten on a tablet and automatically translated into MathML and responses typed on a computer using the equation editor WIRIS?
3. Are the error rates of the handwriting recognition comparable to (or better/worse than) the errors students make when entering equations into an equation editor?

Methods

We developed two parallel forms (termed Form A and Form B) of a mathematics assessment that would each be administered on computer (using an equation editor) and on an iPad (using handwriting recognition). In both forms, students are asked to copy equations directly from the screen. The forms had different equations, yet we developed them to be as parallel as possible in terms of mathematical complexity, the necessary use of equation editor templates, and the number of characters. For the first half of the assessment, students are looking at the equation while they copy it, and for the second half, students must hide the stimulus while copying, but they are allowed to go back to view the stimulus as many times as necessary. All students took both forms. One-half of the participants handwrote their responses to the item on the first assessment on a tablet with a stylus and entered their responses to the items on the second assessment on a computer using an equation editor. The other half of participants completed the two assessments in the opposite order. The two groups of students were further subdivided into Form A or Form B and counterbalanced for order. Thus there were four groups, into which participants were randomly assigned (see Table 1).

Table 1: Counterbalanced design

	First Task: Computer Second: iPad	**First Task: iPad Second: Computer**
Form A: iPad Form B: computer	Group 2	Group 1
Form A: computer Form B: iPad	Group 3	Group 4

In each form, students were asked to copy 20 mathematical equations that ranged from very simple to enter (e.g., 6+2=8) to complex (e.g., one form of the quadratic formula). No equation exceeded in difficulty or complexity that which a student would see as part of a typical Algebra I class. For the computer (equation editor) form, all responses were automatically scored using a proprietary mathematical scoring engine (m-rater) that works through MathML. For the tablet (handwritten responses), all responses were automatically translated into MathML and then scored using the same scoring engine. For this study, we used the WIRIS equation editor, which is widely used in K-12 mathematics assessments and the MyScript Handwriting recognition tool, which has a popular iOS handwritten mathematics calculator and is also used in various mathematical contexts by some leading tech designers.

See Figure 2 for the process of translating the handwritten responses into MathML.

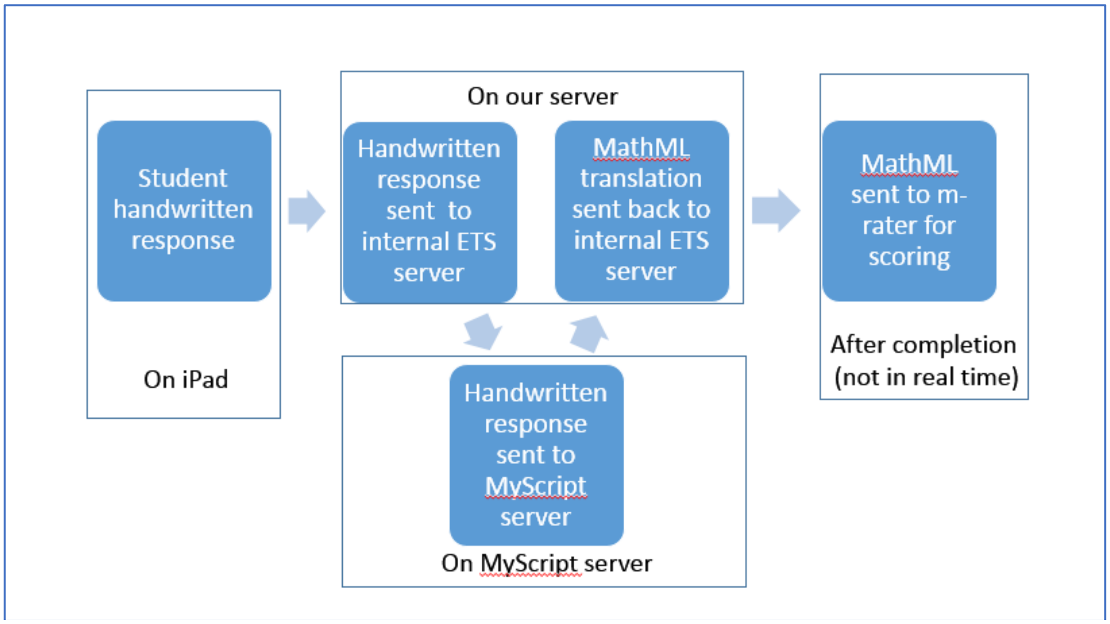

Figure 2. Handwriting to MathML process

Sample and Data Collection

We recruited 9th-grade students from 4 high schools in the USA from racially, culturally, and socioeconomically diverse areas (35% of students qualified for Free/Reduced Lunch of those that reported). Overall, 474 9th-grade Algebra students completed the study (204 Male, 265 Female, 5 Nonreported). The final sample was 45.8% White, 25.9% African American, 10.1% Asian American, 9.7% Hispanic/Latino, and 8.4% other). All students participated during their regular mathematics class and we randomized the experimental groups to which students were assigned within classes (i.e., each class had students placed into each of the four groups). We encountered some connectivity issues discovered after administration whereby 143 students in varying classes and schools did not receive MathML translations from the MyScript server as well as some various missing data with 22 students. Therefore, analyses were conducted with the remaining 309 students so as to maintain the counterbalanced design.

Results

The students received one point for each response that was an exact match to the target equation (in the case of the handwritten responses, one point was given per response in which the computer translation was an exact match to the target). No credit was given for partial responses. Overall, the automatically-produced scores were higher with the equation editor than with the translated handwriting (Form 1: iPad average 10.96 (out of 20), Computer Average, 15.46 (out of 20); $t(156) = 13.4$; $p < .001$; Form 2: iPad average 10.59 (out of 20), Computer Average, 15.5 (out of 20); $t(145) = 11.5$; $p < .001$).

It is worth reiterating that these scores are a reflection of the computer translated handwriting not a score obtained from the writing itself. In other words, we are not comparing what a student wrote with what they typed, but rather how well their handwriting translated into the correct scoreable form versus what they typed. Thus, we can state that the student responses entered via equation editor far outperformed the computer translated handwritten responses, but we make no statement as to the writing on the iPad itself and whether it would have been scored correct or incorrect by a human rater. We do this because it is that final translated response that is the subject of the viability of this as an option for large-scale assessment, which is the focus of this multi-year project.

Despite the higher overall scores for the equation editor, not all items are created equal. For some items, scores between the conditions were about equal (and not significantly different) while for others there were large differences. Figure 2 shows the differences for all scores in both Form A and Form B. As can be seen, both forms produced very similar scores per item, no differences between Forms are significant.

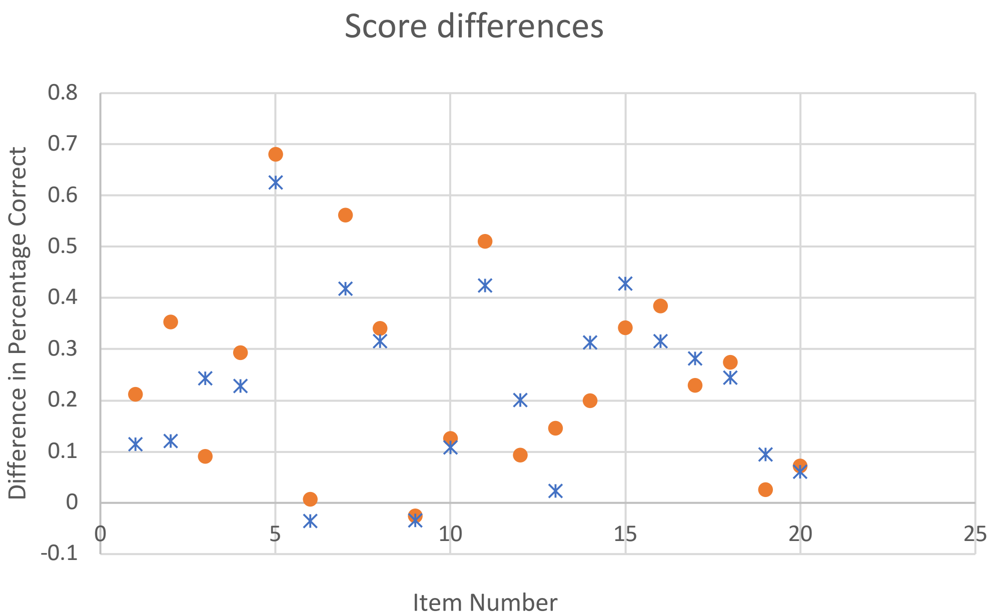

Figure 3. Score differences, equation editor minus tablet (Form A in blue square and Form B in orange circle)

As stated in our first research question, we wished to not only look at overall performance, but to better understand the potential causes of the variability in score differences. To do so, we looked at individual examples of high and low difference items. As an illustration, Table 2 lists the three items with the smallest and largest differences in percentage correct over both Form A and Form B.

Table 2: Items with Greatest and Smallest Differences in Percentage Correct

Item	Equation editor mean	Handwritten mean	Difference (Equation Editor minus Handwriting)
Smallest Differences			
$x+y=y+x$	87.4%	86.7%	0.7
$4 \times 2 = 8$	88.7%	86.3%	2.4
$y = ax^2 + bx + c$	75.4%	78.0%	-2.6
Greatest Differences			
$28 \div 4 = 7$	98.7%	30.7%	68.0
$36 \div 4 = 9$	92.0%	29.4%	62.6
$x(y+z)=xy+xz$	84.9%	28.7%	56.2

In taking a deeper dive into the characteristics of the equations with higher and lower handwriting recognition rates, we found that while variables (x and y) were recognized reasonably well, the multiplication symbol (×) was occasionally recognized as an x. Additionally, the equation $y = ax^2 + bx + c$ was one of the only items in which the handwritten mean was higher than the equation editor mean, largely because many students had difficulty using the template for the superscript, thus resulting in errors such as $y = ax^{2+}bx + c$ and similar errors.

As can be seen in two of the examples with the greatest difference in response type, the division symbol (÷) had a fairly low recognition success rate, and even though variables were recognized well, once parentheses were used along with the variables, recognition dropped substantially.

However, this is clearly only one part of the story. As part of this exploration of the differences, we felt it was also important to look at timing differences. Our rationale was that if equation editors do allow for higher performance but also take much longer to use, there may be some tradeoff between time and accuracy.

Figure 3 shows the difference in average time taken on the item for both Form A and Form B (computer minus iPad). As can be seen in Figure 3, timing scores for both forms were nearly identical, with both forms having high outliers for items 1 and 11. Both of these items occurred at the beginning of a new section in each form, and thus it appears that the time difference is more a product of the students on computers taking longer to read the directions and begin typing than it is of the item itself. For the rest of the items, differences tended to range between zero and ten seconds, though we did see a great amount of variability between students such that some students had virtually no difference while others took much longer for the computer entry than the iPad. The exploration of individual student characteristics will be the focus of a future analysis.

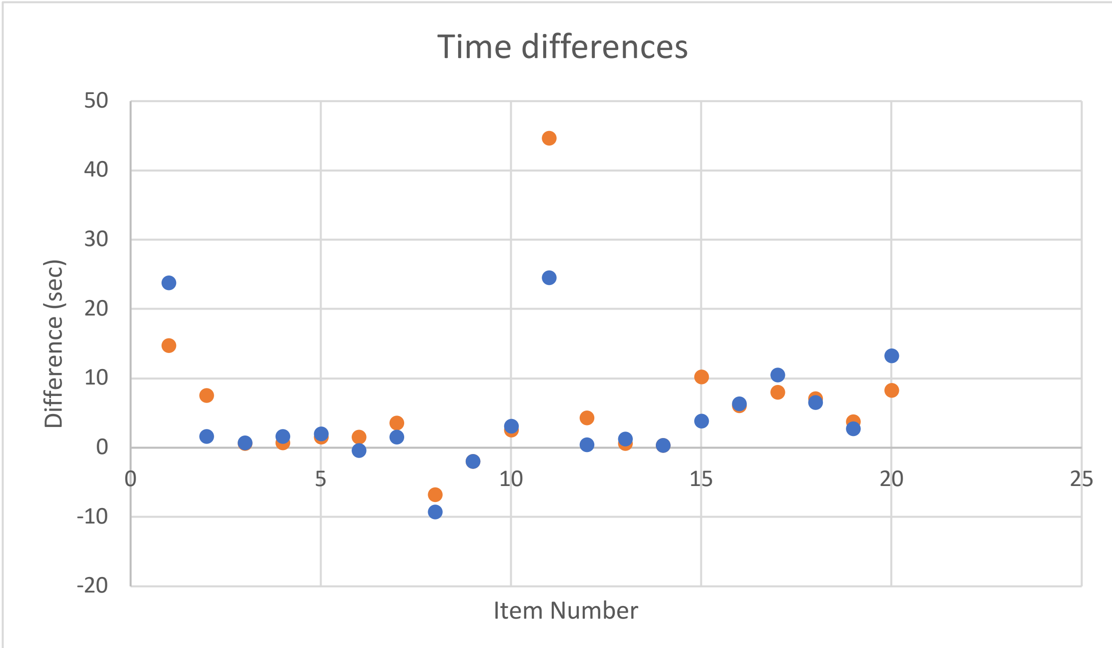

Figure 4. Timing Differences, equation editor minus tablet (Form A in blue and Form B in Orange)

Overall, using current technology, automatically produced scores were much higher when equations were entered using a standard equation editor than when using handwriting recognition software. While those equations did take slightly longer to enter, the timing differences were not large enough for this mode of entry to result in more than a few minutes of extra testing time (depending on the number of equations being entered). One caveat is that this was for copying equations. It would be interesting to see if timing differences were similar when students were asked items in which they had to generate equations, as we could see some compounded differences with uses of scratch paper, etc.

Discussion

What should we conclude about the future of DBA mathematics response entry on the basis of this study? While on the surface, we seem to have found that equation entry is currently superior to handwritten responses, we also uncovered important difficulties with equation editor responses that are particularly troubling considering this is the current preferred response method. For example, equation editor responses ranged between 70% and 95% correct. Considering that students were copying equations, a 70% correct response rate means that 30% of students did not accurately copy an equation using a typical editor that has been the standard of DBA. While these rates did outperform translated handwriting, we see this as more of an indicator that handwriting translation technology needs to be improved so that it can eventually replace the much troubled equation editors, as opposed to an indicator that equation editors are superior for response.

We are currently planning a follow-up study in which students are able to see their handwritten translations in real time and make corrections to their writing to see if this capability enables students to raise their own rates of recognition. We are also looking into ways to limit the lexicon of the recognition software to only include those characters which are part of the Algebra I curriculum (i.e., exclude most Greek letters, integrals, and derivatives). We also plan to see if a tutorial on how to use the equation editor may improve equation editor responses. These improvements to both of these entry methods would need to be considered along with how much time it may cost the test-taker. For instance, watching a tutorial would be a one-time cost of a few minutes, while the ability to see the handwriting translation could potentially cost test-takers a lot of time if they need to correct every individual item (some more than once).

Conclusion

Overall, it is true that we should have some concerns about responses to DBA mathematics items that require students to enter mathematical equations or expressions, regardless of entry mode. Equation editor items should potentially allow for some leeway in scoring on responses that indicate the student may have had entry difficulties (e.g., where it appears students have had trouble knowing how and where to use a template). Additionally, we should also not discount the future of handwritten entry, though the technology is not currently up to the state it should be for assessment use. Since DBA mathematics assessment is here to stay, and growing in use, we need to continue this line of work to improve the entry capabilities to the point that they seamlessly allow students to show what they truly know in the mathematics and not be limited by the technology.

En este estudio se analizan y contrastan acercamientos que futuros profesores de matemáticas de bachillerato muestran al resolver problemas de palabras con el uso de papel y lápiz y, posteriormente, con el uso de un Sistema de Geometría Dinámica (SGD). Se analizan los recursos, representaciones, estrategias y formas de razonamiento matemático que exhiben los participantes cuando utilizan GeoGebra en el proceso de resolución de los problemas. Los resultados muestran que el uso de la herramienta favorece la exploración dinámica de los conceptos involucrados, la formulación de conjeturas y la búsqueda de distintos argumentos para validar la solución.

Palabras clave: Resolución de Problemas, Álgebra y Pensamiento Algebraico, Tecnología

Introducción

Los problemas verbales o de palabras aparecen en los planes y programas de estudio desde el nivel básico y representan un reto para los estudiantes en términos de desarrollar conceptos y estrategias eficientes para resolverlos. Este tipo de problemas, en general, se destacan como una forma de aplicar los contenidos que se estudian a ese nivel con la resolución de problemas situados en contextos de la vida real (Verschaffel, Depaepe, & Van Dooren, 2014). En este sentido, en algunos libros de texto se propone a los estudiantes un camino que se considera es el que debe seguir para resolver los problemas verbales de manera competente: 1) comprender el problema; 2) identificar los datos conocidos y desconocidos; 3) asignar a un dato desconocido la incógnita (generalmente representada con la letra x); 4) expresar los datos desconocidos que restan en términos de la incógnita; 5) formular la ecuación; y, 6) resolver la ecuación y comprobar el resultado (Rees & Sparks, 2005). Sin embargo, cuando un estudiante se enfrenta a la resolución de problemas verbales, la primera fase (comprender el problema) suele carecer de sentido, ya que los enunciados tienden a usar palabras clave como “más” o “la diferencia de” que guían inmediatamente la selección de alguna operación aritmética, fórmula geométrica o expresión algebraica (Verschaffel, Greer, & De Corte, 2000), la cual se resuelve sin contemplar la situación planteada. En este sentido, se identifica una necesidad por promover tareas que involucren problemas verbales donde los estudiantes puedan dar significado a los conceptos u objetos matemáticos involucrados en los problemas. De acuerdo con Santos-Trigo y Reyes-Martínez (2014), el uso coordinado de las tecnologías digitales puede ser un factor fundamental para alcanzar los objetivos deseados en la enseñanza de la matemática, ya que ofrece la posibilidad de representar, explorar, identificar, formular y resolver problemas. Además, Santos-Trigo, Reyes-Martínez y Aguilar-Magallón (2015) resaltan que, “los sistemas escolares en todo el mundo se enfrentan a un desafío de incorporar sistemáticamente la utilización coordinada de las tecnologías digitales en las propuestas curriculares y entornos de aprendizaje" (p. 298). ¿En qué medida el uso de un Sistema de Geometría Dinámico (SGD) influye en el desarrollo de recursos, estrategias y formas de razonamiento matemático en los estudiantes cuando resuelven problemas verbales? ¿Qué tipo de razonamiento matemático (representaciones, exploraciones, conjeturas, explicaciones parciales, etc.) caracterizan los acercamientos basado en el uso de tecnologías digitales? Con el objetivo de responder estas preguntas, en este estudio se presenta una ruta donde se incorpora el uso de un SGD en la resolución de problemas verbales y se analizan las formas de razonamiento que los estudiantes desarrollan sobre los conceptos y la manera en que influye en las actividades que caracterizan a la resolución de problemas.

Marco Conceptual

Resolución de problemas y el uso de tecnología digital

Schoenfeld (1985) propuso un marco que explica el comportamiento de los estudiantes en la resolución de problemas. Éste se centra en el domino de conocimiento conceptual y procedimental (recursos), estrategias de búsqueda para el análisis y transformación de problemas que aumenten la probabilidad de encontrar una solución (heurísticas), monitoreo y control de los procesos cognitivos (metacognición) y actitudes y emociones positivas hacia la tarea que se está desarrollando (creencias). No obstante, el marco se diseñó en un ambiente donde las herramientas principales eran el papel y lápiz. Cuando se incorpora el uso de tecnologías digitales en la resolución de problemas, no solo facilita aspectos como representar, buscar patrones o invariantes entre los objetos de un problema, que es esencial para que los estudiantes identifiquen relaciones y planteen conjeturas, sino también simplifica la implementación de estrategias y ayuda a extender el repertorio de heurísticas (Santos-Trigo, 2008).

Con base en estas ideas, Santos-Trigo y Camacho-Machín (2013) propusieron un marco que, además de permitir analizar los procesos que siguen los estudiantes cuando resuelven problemas con el uso de tecnología digital, da la posibilidad de transformar problemas rutinarios en no rutinarios. El marco consta de cuatro episodios: 1) comprensión: identificar los conceptos que se relacionan con el problema y plantear algunas preguntas que orienten la actividad; 2) explorar el problema: valorar diferentes caminos para alcanzar la solución; 3) búsqueda de distintas soluciones: analizar y discriminar los distintos resultados encontrados para proponer una solución argumentada, así como plantear nuevos problemas a partir de dichos resultados; y, 4) integración y reflexiones: discutir en torno a las actividades y resultados obtenidos.

Bajo este enfoque, los modelos dinámicos de los problemas se vuelven importantes para explorar comportamientos matemáticos de una familia de objetos. En este camino, la construcción de un modelo dinámico ofrece una oportunidad para que los estudiantes busquen y exploren relaciones entre los elementos del problema vía el uso de estrategias que involucran el movimiento controlado de objetos, la generación de lugares geométricos, la cuantificación de atributos y la búsqueda de propiedades que validan relaciones y soluciones de los problemas (Santos-Trigo, Reyes-Martínez, & Aguilar-Magallón, 2015).

Metodología

En este estudio participaron ocho estudiantes de un curso de resolución de problemas que forma parte de un programa de Maestría en Educación Matemática. Se trabajó durante diez semanas, una sesión de tres horas por semana. El desarrollo de las sesiones se llevó a cabo en un aula de computo donde cada estudiante tuvo acceso a una computadora con el SGD, GeoGebra, instalado. Durante las primeras dos sesiones, se implementaron tareas que tenían la finalidad de que los estudiantes comenzaran a familiarizarse con GeoGebra, posteriormente, se abordaron diversos problemas (rutinarios y no rutinarios) con el objetivo de que los estudiantes desarrollaran diversas estrategias durante el seguimiento de los episodios planteados por Santos-Trigo y Camacho-Machín (2013). En este reporte se analiza el trabajo de los estudiantes en un problema que se abordó en dos sesiones al final del curso.

El problema

Un grupo de deportistas efectúan un recorrido de 380 km en siete horas durante una expedición de caza. Durante cuatro horas viajan a lo largo de una carretera pavimentada y el resto del tiempo por un camino de herradura. Si la velocidad media en el camino de herradura es de 25 km/h menor que la velocidad media en la carretera, encuéntrese la velocidad media y la distancia recorrida en cada uno de aquellos tramos de camino (Rees & Sparks, 2005, p. 60).

La implementación de la tarea se dividió en dos momentos: (1) primero se les solicitó a los estudiantes resolver el problema solamente con papel y lápiz y, (2) después, se les pidió que lo resolvieran con el uso de GeoGebra. Los datos se recolectaron a través de los reportes escritos, las videograbaciones de las sesiones, archivos de GeoGebra con las construcciones dinámicas que elaboraron los estudiantes y las notas de campo de los investigadores.

Resultados

En esta sección se discuten los recursos, estrategias y formas de razonamiento que exhibieron los estudiantes al resolver el problema: (1) con el uso de papel y lápiz; y, (2) con el uso de GeoGebra. En la Tabla 1 se muestran las principales características de los acercamientos que llevaron a cabo los estudiantes.

Tabla 1: Resultados con el uso de papel y lápiz y con el uso de GeoGebra.

Estudiante	Resultados con el uso de papel y lápiz	Resultados con el uso de GeoGebra (primer modelo)
Felipe	- Plantea un sistema de ecuaciones con ambas velocidades. - Encuentra la solución.	- Representa dinámicamente las condiciones del problema. - Encuentra solución de manera empírica. - Analiza el lugar geométrico que describe el punto (distancia del camino pavimentado, diferencia entre las velocidades) - Justifica algebraicamente la solución encontrada en el modelo dinámico.
Homero	- Diagrama (segmento de recta). - Plantea ecuación en términos de la velocidad del camino pavimentado. - Encuentra la solución.	- Representa dinámicamente la condición de las distancias. - No construye el modelo dinámico de manera individual.
Alfonso	- Plantea ecuación en términos de la velocidad del camino pavimentado. - Muestra dificultades procedimentales. - No encuentra la solución.	- Representa dinámicamente las condiciones del problema. - No presenta un análisis del comportamiento de los objetos matemáticos involucrados.
David	- Diagrama (áreas relacionando tiempo y distancia). - Plantea ecuación a partir del diagrama (interpretación errónea). - No encuentra la solución.	- Representa dinámicamente las condiciones del problema. - Encuentra solución de manera empírica. - Justifica algebraicamente la solución encontrada en el modelo dinámico.
Rocío	- Diagrama (segmento de recta). - Expresa las velocidades en términos de las distancias sin llegar a plantear la ecuación correspondiente.	- Representa dinámicamente las condiciones del problema. - No presenta un análisis del comportamiento de los objetos matemáticos involucrados.

	- No encuentra la solución.	
Raúl	- Diagrama (segmento de recta). - Plantea ecuación (relaciona la suma de las velocidades con la velocidad promedio). - No encuentra la solución (Figura 1).	- Representa dinámicamente las condiciones del problema. - Encuentra solución de manera empírica. - Analiza el lugar geométrico que describe el punto (distancia del camino pavimentado, diferencia entre las velocidades)
Uriel	- Diagrama (segmento de recta). - Plantea ecuación en términos de la distancia recorrida en el camino de herradura. - Muestra dificultades procedimentales. - No encuentra la solución.	- Representa dinámicamente las condiciones del problema. - Encuentra solución de manera empírica. - Justifica algebraicamente la solución encontrada en el modelo dinámico.
César	- No muestra la solución al problema.	- Representa dinámicamente las condiciones del problema. - Encuentra solución de manera empírica.

Se observa que, en los distintos acercamientos con el uso de papel y lápiz, el diagrama es insuficiente en la búsqueda de la solución. En general, cinco de los estudiantes usan esta estrategia (los diagramas son muy similares) y, aunque solo uno de ellos obtuvo la solución correcta, en ningún caso el diagrama aportó un dato relevante para resolver correctamente el problema, por ejemplo, el acercamiento propuesto por Raúl (Figura 1). De los estudiantes restantes, que no hicieron un diagrama, solo uno resolvió correctamente el problema. Al respecto, Schoenfeld (1985) menciona que el uso de heurísticas no garantiza la solución de un problema si no se cuenta con los recursos necesarios, sin embargo, en los problemas verbales parece tener mayor peso el dominio de recursos (procedimientos rutinarios) que los otros aspectos que se consideran en la resolución de problemas. También, se observan dificultades para representar la situación problemática mediante ecuaciones. Por ejemplo, Raúl plantea la igualdad entre la suma de las velocidades y la velocidad promedio, y David plantea la igualdad entre la suma de los productos de tiempos por distancias y distancia total recorrida. Es decir, ambos casos carecieron de sentido.

Respecto a los acercamientos con el uso de GeoGebra, se observa que todos los participantes lograron representar geométricamente las condiciones iniciales que se deben cumplir en el problema: distancias y tiempo (Figura 2). Cinco de los estudiantes encontraron la solución de manera empírica mediante la exploración del modelo dinámico del problema. Únicamente dos participantes realizaron un análisis dinámico del lugar geométrico que describe el punto que relaciona, de manera funcional, la distancia del camino pavimentado y la diferencia entre las velocidades. Por último, la justificación algebraica de la solución encontrada en el modelo dinámico solo fue presentada por tres estudiantes.

El primer modelo dinámico del problema sirvió de plataforma para la construcción de un segundo modelo dinámico basado en recursos, estrategias y formas de razonamiento diferentes a los planteados en el primero. Estos modelos dinámicos se describen en las siguientes secciones.

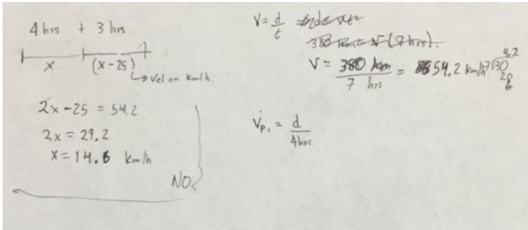

Figura 1. Diagrama y ecuación propuestos por Raúl.

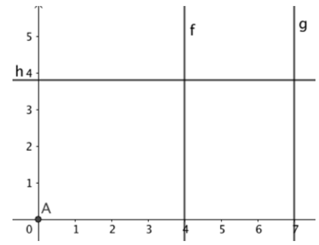

Figura 2. Representación de datos conocidos en el sistema cartesiano.

Acercamientos con el uso de un SGD

Cuando los estudiantes comenzaron a resolver el problema con GeoGebra, tuvieron que pensar el problema en términos de propiedades y los comandos de la herramienta. Por ejemplo, se plantearon preguntas como: ¿de qué manera se pueden representar el tiempo, distancia y la velocidad en este ambiente?, ¿cómo se construye un modelo dinámico asociado al problema?, ¿qué estrategias permiten llegar a la solución? Para resolver el problema los estudiantes desarrollaron dos modelos dinámicos, el primero, fue común entre los estudiantes (Figura 3), mientras que el segundo (Figura 4) fue desarrollado con la guía del investigador e implica una solución distinta a la que puede obtenerse en un ambiente donde solo se utiliza papel y lápiz. Ambos modelos se basaron en el uso del sistema cartesiano, donde se representaron las unidades de tiempo en el eje x y en el eje y la distancia recorrida (dividida entre 100 para facilitar la construcción y análisis del modelo dinámico). Las condiciones iniciales del problema: recorrido de 380 km en siete horas, de las cuales cuatro fueron en carretera pavimentada y el resto del tiempo por un camino de herradura, fueron representadas como rectas perpendiculares a los ejes que pasaban por el valor numérico correspondiente al dato conocido (Figura 2).

Primer modelo

Este modelo parte de la idea de representar las distancias como segmentos sobre el eje y (Figura 3a) con la finalidad de satisfacer la condición de que sumen 3.8, la cual está relacionada con la distancia total que se recorre. Para lograrlo, un estudiante coloca un punto sobre el eje y y define los segmentos AB y BC como las distancias recorridas en la carretera pavimentada y el camino de herradura, respectivamente. Enseguida, traza una perpendicular sobre el eje y que pasa por B, esta recta está asociada a la distancia del primer tramo del camino, y construye los segmentos AD y DE, en los cuales obtiene las pendientes que interpreta como las velocidades de cada tramo (Figura 3b).

Una vez que cuenta con el modelo dinámico, se enfocó en encontrar la posición del punto B en la que se satisface la condición: la velocidad media en el camino de herradura es de 25 km/h menor que la velocidad media en la carretera, es decir, la diferencia de las pendientes (m-m_1) es 0.25 (Figura 3c). El estudiante encuentre y analiza el lugar geométrico del punto F que relaciona la ordenada del punto B y la resta de las pendientes, e identifica que la solución al problema es cuando el lugar geométrico interseca a la recta y=0.25 (Figura 3d).

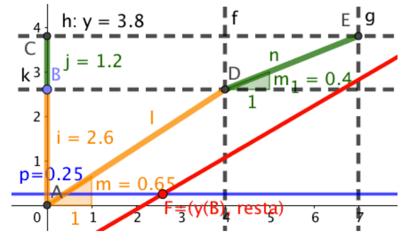
c)



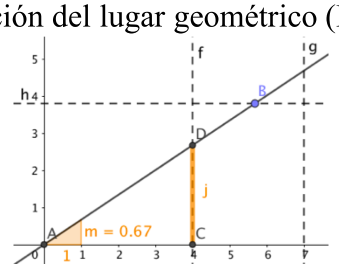
d)

Figura 3. Construcción del primer modelo dinámico.

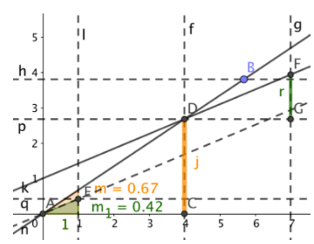
Para justificar el modelo dinámico, los estudiantes representaron algebraicamente la idea desarrollada en GeoGebra. Para encontrar la ecuación del lugar geométrico escribieron la *resta* en términos de la variable (en este caso $y(B)$ que denotaron como x). Luego, expresaron las pendientes como $m=\frac{y(B)}{4}=\frac{x}{4}$ y $m_1=\frac{3.8-y(B)}{3}=\frac{3.8-x}{3}$. Así, la función que define a la recta es $f(x)=m(x)-m_1(x)=\frac{x}{4}-\frac{3.8-x}{3}=\frac{3x-15.2+4x}{12}=\frac{7x-15.2}{12}$. Para buscar la solución, encontraron la coordenada en x del punto de intersección de $f(x)$ y la recta p (definida como $y=0.25$), resolvieron la ecuación $\frac{7x-15.2}{12}=0.25$ y obtuvieron que la solución se obtiene en $x=2.6$, es decir, 260 km recorridos en el primer tramo. Con este resultado obtienen las demás respuestas.

Segundo modelo

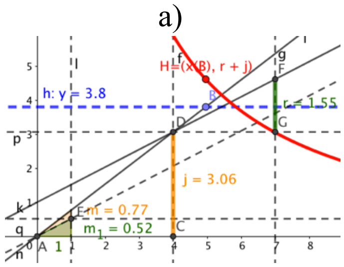
La idea esencial detrás de este modelo fue interpretar las velocidades como pendientes asociadas a rectas. El camino inicial que siguió un estudiante fue definir el punto B sobre la recta h, trazar la recta AB y medir su pendiente (Figura 4a), que está relacionada con la velocidad del primer tramo recorrido. Para representar la velocidad en el segundo tramo del recorrido, el estudiante construyó un triángulo rectángulo con base igual a una unidad y altura igual a $m-0.25$, lo que le permitió trazar la recta AE cuya pendiente es $m-0.25$ (Figura 4b). Luego, trazó una recta paralela a la recta AE que pasara por el punto D y una perpendicular al eje y que también pasara D. Así, trazó el segmento FG, el cual está relacionado con la distancia recorrida en el camino de herradura. Posteriormente, analizó el comportamiento del punto H, que relaciona la abscisa del punto B y la suma de las distancias de los recorridos (segmentos r y j) mediante la visualización del lugar geométrico (Figura 4c).



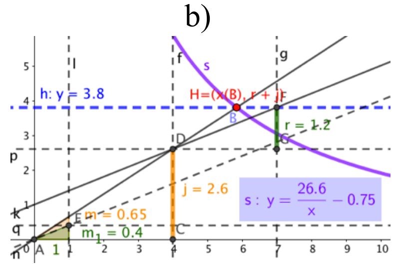
a)



b)



c)



d)

Figura 4. Construcción del segundo modelo dinámico.

De esta manera, encuentra que la solución es cuando el lugar geométrico se interseca con la recta $y = 3.8$. Con base en estas ideas y exploraciones, el estudiante fue capaz de representar algebraicamente este acercamiento. Representó con x la coordenada de la abscisa del punto B, el cual está asociado a la pendiente m. Para obtener la función debe expresarse a $j + r$ en términos de x, es decir, dado que $m = \frac{3.8}{x}$ y $m = \frac{j}{4}$ entonces al igualar y despejar j se obtiene que $j = \frac{15.2}{x}$. Similarmente, dado que $m_1 = m - .25$ y $m_1 = \frac{r}{3}$ entonces $r = \frac{11.4}{x} - .75$. Así, la función asociada al lugar geométrico descrito por H es $f(x) = \frac{26.6}{x} - .75$. Al igualar la función a 3.8, se tiene que $x = \frac{26.6}{4.55} \approx 5.84$. Cuando se grafica en GeoGebra la función encontrada, es posible corroborar que se los resultados coinciden (Figura 4d).

Discusión de los resultados

Cuando los estudiantes intentan resolver el problema en un ambiente donde solamente cuentan con papel y lápiz, se observa que para llegar a la solución es necesario que posean los recursos que les permitan plantear las ecuaciones adecuadamente y, mediante procedimientos rutinarios, obtener el resultado correcto. Sin embargo, si no logran comprender la situación problemática será difícil que logren plantear la ecuación o modelo matemático que les permita llegar a la solución e incluso implementar la heurística de representar el problema por medio de un diagrama para observar cómo se relacionan los datos del problema.

Cuando se incorporó GeoGebra para resolver el problema, se observó que el nivel de apropiación del SGD y los recursos con los que contaba cada estudiante determinaba el tipo de estrategia que desarrollaban. De manera general, los dos modelos dinámicos que se construyeron involucraron recursos y conceptos matemáticos diferentes, lo que implicó el desarrollo de diferentes formas de razonamiento. Cada uno de los modelos permitió que los estudiantes interpretaran geométricamente las condiciones que se deben cumplir en el problema planteado. Así, el SGD permitió que los estudiantes dieran significado a los conceptos y objetos matemáticos involucrados en el problema y, a través de la exploración de los modelos dinámicos, encontraran la solución sin necesidad de plantear un acercamiento algebraico de manera inicial. En la Tabla 2 se presenta una comparación de las actividades matemáticas que se llevaron a cabo en cada uno de los modelos exhibidos por los estudiantes, con base en los episodios propuestos por Santos-Trigo y Camacho-Machín (2013).

Tabla 2: Comparación de los modelos dinámicos del problema

Episodio	Primer modelo	Segundo modelo
Comprensión	Interpretar las distancias geométricamente como segmentos sobre el eje *y* que sus longitudes sumen 3.8 y representar las velocidades en términos de las distancias.	Interpretar las velocidades geométricamente como pendientes de rectas donde una sea 0.25 unidades menor a la otra y representar las distancias en términos de las velocidades.
Exploración del problema	Buscar para qué longitudes de los segmentos se cumple la condición de las velocidades (pendientes).	Buscar para qué pendientes de las rectas se cumple la condición de las distancias (segmentos).
Búsqueda de distintos acercamientos a la solución	Soluciones empíricas obtenidas por: - Analizar los valores numéricos de los atributos del modelo - Visualizar lugar geométrico (recta) que relaciona la longitud del segmento AB con la diferencia de las pendientes m y m_1 (ver Figura 2d)	Soluciones empíricas obtenidas por: - Analizar los valores numéricos de los atributos del modelo - Visualizar lugar geométrico (hipérbola) que relaciona la abscisa del punto B con la suma de los segmentos j y r (ver Figura 3d) Solución algebraica obtenida por:

	Solución algebraica obtenida por: - Representar el modelo dinámico mediante ecuaciones.	- Representar el modelo dinámico mediante ecuaciones.
Integración y reflexión	Dar sentido a la resta de velocidades respecto a la situación problemática.	Relacionar la pendiente de rectas verticales con la indeterminación de la función.

En la Tabla 2 se puede observar que hay recursos y estrategias que coinciden en cada episodio de ambos modelos con el uso del SGD. En el primer episodio, fue importante el uso del sistema cartesiano para representar los datos del problema geométricamente y para, posteriormente, analizar las relaciones y atributos de la construcción. Lo anterior, implicó aplicar una escala en el eje de las ordenadas para tener la posibilidad de visualizar el modelo con mayor facilidad y explorarlo. También, cobró sentido el concepto de pendiente cuando se interpretó geométricamente la razón de dos cantidades (como es el caso de la velocidad). El episodio de exploración del problema es resultado de implementar la heurística de punto con movimiento controlado que permite el SGD. Es decir, a partir de un punto que se definió sobre una recta o un eje, se construyó un modelo dando la oportunidad de explorar y analizar las relaciones entre los atributos de la construcción. En el tercer episodio, utilizar la herramienta de lugar geométrico es una estrategia esencial para encontrar soluciones geométricas en términos de la covariación de atributos de la configuración dinámica, que conlleva a plantear conjeturas por medio de la observación y, por lo tanto, a buscar argumentos. Por último, el cuarto episodio se centra en el dominio del problema donde se reflexiona sobre el comportamiento y la interpretación del modelo para todos los valores del punto móvil. Por otro lado, se evidencian las diferencias de ambos acercamientos que muestran los conceptos que se enfatizan y los distintos caminos que involucran reflexiones diferentes para interpretar la solución del problema.

La construcción y exploración de los modelos dinámicos permitió que los estudiantes lograran representar algebraicamente el problema al dar seguimiento a los pasos de la construcción. Específicamente en el segundo modelo dinámico, se desarrolló un modelo algebraico que no sería fácil de plantear sin la exploración de la construcción. De esta manera, los estudiantes pudieron interpretar y contextualizar las expresiones algebraicas, y dar sentido a diferentes objetos y conceptos matemáticos como la pendiente.

Conclusiones

El uso del SGD para la resolución de problemas verbales permitió que los estudiantes prestaran más atención a la comprensión del problema para poder construir el modelo dinámico del problema y a la exploración del problema, para analizar el comportamiento de los objetos matemáticos involucrados. La búsqueda de distintos acercamientos a la solución favoreció el desarrollo de diferentes formas de razonamiento, especialmente, se observó un tránsito de lo empírico a lo formal cuando los estudiantes llevaron su solución dinámica a la representación algebraica. Al integrar y reflexionar sobre las estrategias de solución, fue posible analizar, dentro del contexto del problema, estrategias que se identificaron en las exploraciones como la resta de velocidades, además de ideas matemáticas como la indeterminación de una función.

In this study we analyze and contrast approaches that future high school math teachers show when solving word problems with the use of pencil and paper and later, with the use of a Dynamic Geometry System (DGS). The resources, representations, strategies and forms of mathematical reasoning that the participants exhibit when they use GeoGebra in the process of

problem solving are analyzed. The results show that the use of the tool favors the dynamic exploration of the concepts involved, the formulation of conjectures and the search for different arguments to validate the solution.

Keywords: Problem Solving, Algebra and Algebraic Thinking, Technology.

Introduction

Word problems are an important theme in school plans and programs of study from the basic level and represent a challenge for the students in terms of developing concepts and strategies to solve them. This type of problems, in general, stand out as a way of applying the contents that are studied at that level by solving problems situated in real-life contexts (Verschaffel, Depaepe, & Van Dooren, 2014). Likewise, in some textbooks students are encouraged to follow a path that involves the following stages: 1) understand the problem statement; 2) identify known and unknown data; 3) assign the unknown to an unknown data (usually represented by the letter x); 4) expressing the unknown data remaining in terms of the unknown; 5) formulating the equation; and, 6) solving the equation and check the result (Rees & Sparks, 2005). However, when a student is faced with solving word problems, the first phase (understanding the problem) is often meaningless, since statements tend to include keywords such as "more" or "difference" that push them immediately the selection of some arithmetic operation, geometric formula or algebraic expression (Verschaffel, Greer, & De Corte, 2000), that then is solved without making sense of the situation posed. In this way, a need is identified to promote tasks that involve word problems where students can give meaning to the concepts or mathematical objects involved in the problems. According to Santos-Trigo and Reyes-Martínez (2014), the coordinated use of digital technologies can be a fundamental factor in achieving the desired objectives in the teaching of mathematics, since it offers the possibility of representing, exploring, identifying, formulating and solving problems. In addition, Santos-Trigo, Reyes-Martínez and Aguilar-Magallón (2015) highlight that, "school systems throughout the world face a challenge of systematically incorporating the coordinated use of digital technologies in curricular proposals and learning environments " (p. 298). To what extent does the use of a Dynamic Geometry System (DGS) affect the development of resources, strategies and ways of mathematical reasoning in the students, when they solve word problems? What kind of mathematical reasoning (representations, explorations, conjectures, partial explanations, etc.) characterize the approaches based on the use of digital technologies? In order to answer these questions, this study presents a route that incorporates the use of DGS in the word problem solving and discusses the forms of reasoning that students develop about concepts and the way in which it influences the activities that characterize the problem solving.

Conceptual Framework

Problem Solving and the use of digital technology

Schoenfeld (1985) proposed a framework that explains the students´ behavior in problem solving. It focuses on the domain of conceptual and procedural knowledge (resources), search strategies for the analysis and transformation of problems that increase the probability to find a solution (heuristics), monitoring and control of cognitive process (metacognition) and attitudes and positive emotions towards the task that is been developed (beliefs). However, the framework was designed in an environment where the main tools were paper and pencil. When the use of digital technologies is incorporated into problem solving, it not just facilitates aspects such as representing, looking for patterns or invariants among objects of a problem, which is essential for the students to identify the relationships and raise conjectures, but also it simplifies the strategies implementation and helps to extend the heuristics repertoire. (Santos-Trigo, 2008).

Based on these ideas, Santos-Trigo and Camacho-Machín (2013) proposed a framework that besides allowing the analysis of procedures that the students follow when they solve problems with the use the digital technology, it gives the possibility to transform routine problems into non-routine problems. The framework consists of four episodes: 1) understanding: to identify the concepts that relate to the problem and ask some questions that guide the activity 2) explore the problem: to evaluate different ways to find the solution 3) search for different solutions: to analyze and discriminate the different results found to propose an argued solution, as well as to pose new problems from these results 4) integration and reflections: to discuss about the activities and the results obtained.

Under this approach, the dynamic models of the problems become important to explore mathematical behaviors of a family of objects. In this way, the construction of a dynamic model offers an opportunity for the students to search and explore relationships between the elements of the problem through the use of strategies that involve the controlled movement of objects, locus generation, attributes qualifications and the search of properties that allow relationships and solutions to problems. (Santos-Trigo, Reyes-Martínez, & Aguilar-Magallón, 2015).

Methodology

In this study, eight students participated from a problem solving course that is part of a Master´s program in Mathematics Education. It worked for ten weeks, with a session of three hours per week.

The development of the sessions was done in a computer lab where each student had access to a computer with the DGS, GeoGebra, installed. During the first two sessions, tasks aimed at getting the students familiarized with GeoGebra were implemented, after that, various problems (routine and non-routine) were addressed with the aim of having the students develop various strategies during the follow-up of the episodes proposed by Santos-Trigo and Camacho-Machín (2013). In this report it is analyzed the students' work in a problem that was addressed in two sessions at the end of the course.

The Problem

A group of athletes make a 380 km tour in seven hours during a hunting expedition. For four hours they travel along a paved road and the rest of the time by a bridle path. If the average speed in the bridle path is of 25 km/h lower than the average speed on the road, find the average speed and the distance traveled in each of those road sections. (Rees & Sparks, 2005, p. 60).

The implementation of the task was divided in two stages: (1) the students were first asked to solve the problem just with the use of pencil and paper and (2) later, they were asked to solve it with the use of GeoGebra. The data was collected through the written reports, the video recordings of the sessions, GeoGebra archives with the dynamic constructions created by the students and the field notes of the researchers.

Results

In this section are discussed the resources, strategies and ways of thinking that the students showed when they solve the problem: (1) with the use of pencil and paper; and, (2) with the use of GeoGebra. Table 1 shows the main characteristic of the approaches carried out by the students.

Table 1: Results with the use of pencil and paper and with the use of GeoGebra.

Student´s Name:	Results with the use of pencil and paper	Results with the use of GeoGebra (first model)
Felipe	- He proposes a system of equations with both speeds. - He found the solution.	- He represents in a dynamic way the conditions of the problem. - He found the solution in an empiric way. - He analyses the locus that describes the point (paved road distance, difference between speeds) - He justifies algebraically the solution found in the dynamic model.
Homero	- Diagram (line segment). - He proposes an equation in terms of the speed of the paved road. - He found the solution.	- He represents in a dynamic way the conditions of the distances. - He does not create the dynamic model in an individual way.
Alfonso	- He proposes an equation in terms of the speed of the paved road. - He has procedural difficulties. - He does not find the solution.	- He represents in a dynamic way the conditions of the problem. - He does not present an analysis of the behavior of the mathematical objects involved.
David	- Diagram (areas relating time and distance). - He proposes an equation from the diagram (wrong interpretation). - He does not find the solution.	- He represents in a dynamic way the conditions of the problem. - He found the solution in an empiric way. - He justifies algebraically the solution found in the dynamic model.
Rocío	- Diagram (line segment). - She expresses the speeds in terms of the distances without proposing the corresponding equation. - She does not find the solution.	- She represents in a dynamic way the conditions of the problem. - She does not present an analysis of the behavior of the mathematical objects involved.
Raúl	- Diagram (line segment). - He proposes an equation (he relates the sum of the speeds with the average speed) - He does not find the solution (Figure 1)	- He represents in a dynamic way the conditions of the problem. - He found the solution in an empiric way. - He analyses the locus that describes the point (paved road distance, difference between speeds)
Uriel	- Diagram (line segment). - He proposes and equation in terms of the distance traveled in the bridled path. - He has procedural difficulties. - He does not find the solution.	- He represents in a dynamic way the conditions of the problem. - He found the solution in an empiric way. - He justifies algebraically the solution found in the dynamic model.
César	- He does not find the solution.	- He represents in a dynamic way the conditions of the problem. - He found the solution in an empiric way.

It is observed that, in the different approaches with the use of pencil and paper, the diagram is insufficient in the search of the solution. In general, five of the students used this strategy (the diagrams are very similar) and, although just one of them obtained the correct solution, in no case the diagram gave relevant data to solve correctly the problem, see for example, the approach proposed by Raúl (Figure 1). Of the remaining students, who did not make a diagram, just one of them solved correctly the problem. According to that, Schoenfeld (1985) says that the use of heuristics does not guarantee the solution of a problem if the necessary resources are not available, however, in the word problems, the domain of resources (routine procedures) seems to have greater weight than the other aspects that are considered in the problem solving. Also, there are some difficulties as to represent the problematic situation through equations. For example, Raúl proposes the equality among the sum of the speeds and the average speed, and David proposes the equality among the sum of the products of times by distances and the total of distance traveled. In other words, both cases suffered from lack of meaning.

Regarding the approaches with the use of GeoGebra, it is observed that all the participants managed to represent geometrically the initial conditions that must be satisfied in the problem: distances and time (Figure 2). Five of the students found the solution in an empiric way through the exploration of the dynamic model of the problem. Only two participants did a dynamic analysis of the locus that describes the point that relates, in a functional way, the distance of the paved road and the difference between the speeds. Finally, the algebraic justification of the solution found in the dynamic model was only presented by three students.

The first dynamic model of the problem was used as a platform to the construction of a second dynamic model based on resources, strategies and different forms of reasoning to the ones proposed in the first one. These dynamic models are described in the following sections.

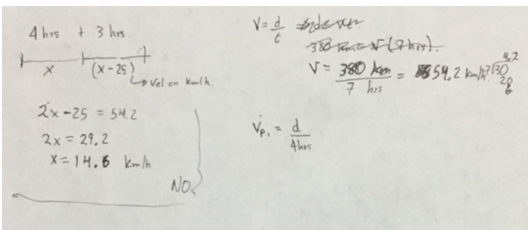


Figure 1. Diagram and equation proposed by Raúl.

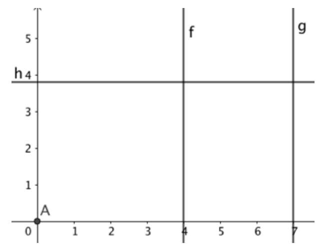

Figure 2. Representation of known data in the cartesian system

Approaches with the use of a Dynamic Geometry System

At the moment that the students started to solve the problem with GeoGebra, they had to think the problem in terms of properties and the commands of the tools. For instance, they asked questions like: In which way the time, the distance and the speed in this environment can be represented? How does a dynamic model related to the problem is constructed? What strategies allow to reach the solution? In order to solve the problem the students developed two dynamic models, the first one, was common among the students (Figure 3), while the second one (Figure 4) was developed with the guide of the researcher and it involves a different solution to the one that can be obtained in an environment where is only used pencil and paper.

Both models were based on the use of a cartesian system, there were represented the time units in the *x*-axis and in the *y*-axis the distance traveled (divided between 100 to facilitate the construction and analysis of the dynamic model). The initial conditions of the problem: 380 km route in seven hours, in which four of them were traveled in a paved road, and the remaining time by a bridle path, were represented as perpendicular lines that pass through the numerical value corresponding to the known data (Figure 2).

First model

This model is based on the idea of representing the distances as segments on the y-axis (Figure 3a) with the objective of satisfying the condition that they sum 3.8, which will be related to the total distance traveled. To achieve this, a student places a point on the y-axis and defines the segments AB and BC as the distances traveled in the paved road and in the bridle path respectively. Then, trace a perpendicular to the y axis that passes by B, this line segment is associated to the distance of the first section of the road, and they build the line segments AD and DE, from which they obtain the slopes that are interpreted as the speed of each section. (Figure 3b).

Once a dynamic model is obtained, they were focused to find the position of the point B in which the condition is satisfied: the average speed in the bridle path is of 25 km/h less than the average speed in the paved road, in other words, the difference of the slopes (*m-m$_1$*) is 0.25 (Figure 3c). The student finds and analyses the locus of the point F that relates the ordinate of the point B and the subtraction of slopes, and identifies that the solution to the problem is where the locus intersects the line y=0.25 (Figure 3d).

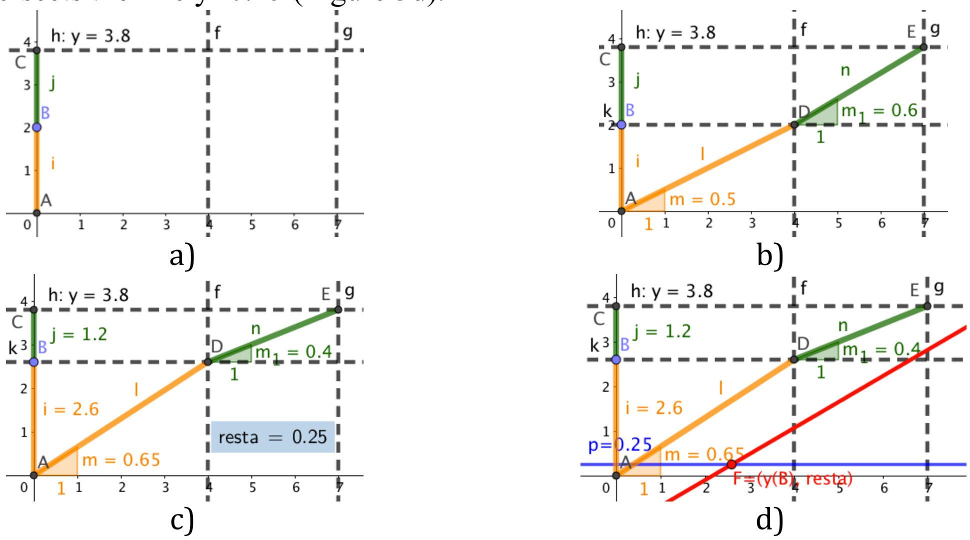

Figure 3. Construction of the first dynamic model

In order to justify the dynamic model, the students represented algebraically the idea developed in GeoGebra. To find the equation of the locus they wrote the subtraction in terms of the variable (in this case *y*(*B*) that is denoted as *x*). Later, they express the slopes as $m = \frac{y(B)}{4} = \frac{x}{4}$ and $m_1 = \frac{3.8-y(B)}{3} = \frac{3.8-x}{3}$. Hence, the function that defines the line is $f(x) = m(x) - m_1(x) = \frac{x}{4} - \frac{3.8-x}{3} = \frac{3x-15.2+4x}{12} = \frac{7x-15.2}{12}$. To look for the solution, they found the coordinate in x of the intersection point of $f(x)$ and the line p (defined as $y = 0.25$), they solved the equation $\frac{7x-15.2}{12} = 0.25$ and got that the solution is obtained in $x = 2.6$, in other words, 260 km were traveled in the first section. With this result they got the others answers.

Second Model

The essential idea of this model was to interpret the speeds as slopes related to straight lines. The initial path that a student followed was to define the point B on the line *h*, trace the line AB and measure its slope (Figure 4a), which is related to the speed of the first section traveled. To represent the speed in the second section of the travel, the students built a right triangle with a base equal to one unit and height equal to $m - 0.25$, which gave him the opportunity to trace the line AE, its slope is $m - 0.25$ (Figure 4b). After that, he traced a line parallel to the line AE that goes through the point D and a perpendicular to the y-axis that also goes through D. In this way, he traced the segment FG, which is related to the distance traveled in the bridle path. Later on, he analyzed the behaviour of the point H that relates the abscissa of the point B and the sum of the distances of the travels (segments r and j) through the visualization of the locus (Figure 4c)

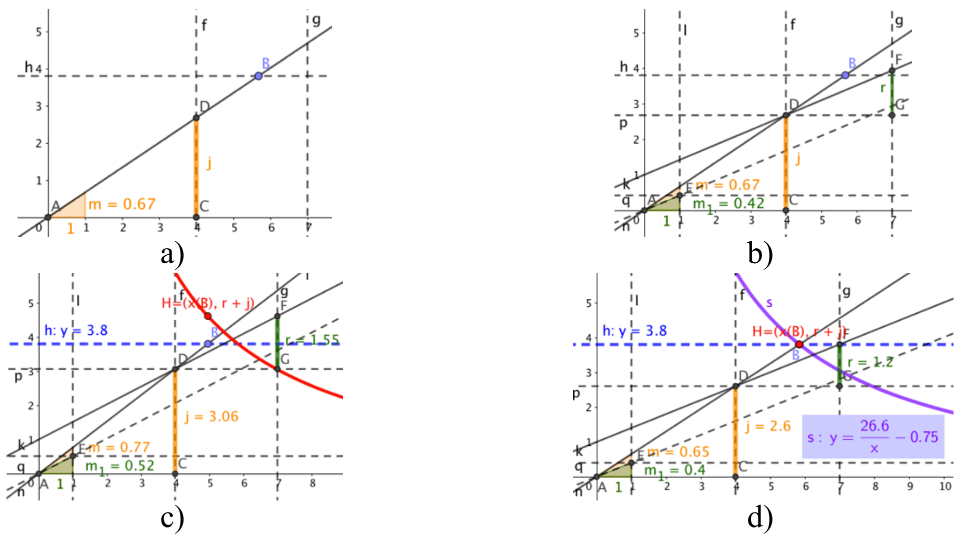

Figure 4. Construction of the second dynamic model.

In this way, he finds that the solution is when the locus intersects the line $y = 3.8$. Based on these ideas and explorations, the students were able to represent this approach algebraically. He represented with x the coordinate of the abscissa of the point B, which is associated with the slope m. In order to get the function, $j + r$ must be expressed in terms of x, in other words, since $m = \frac{3.8}{x}$ and $m = \frac{j}{4}$ then when equalizing and clearing j we obtain that $j = \frac{15.2}{x}$. Similarly, since $m_1 = m - .25$ and $m_1 = \frac{r}{3}$ we get $\frac{11.4}{x} - .75$. In this way, the function associated to the locus is described by $\frac{11.4}{x} - .75$. At the moment to equalize the function to 3.8, we obtain that $x = \frac{26.6}{4.55} \approx 5.84$. When the function found is plotted in GeoGebra, it is possible to corroborate that the results match (Figure 4d).

Discussion of the Results

When the students try to solve the problem in an environment where they can only use pencil and paper, it is observed that in order to get the solution is necessary that they have the resources that allow them to propose the equations in a correct way and, through routine procedures, to get the correct result. However, if they do not understand the problematic situation it will be difficult for them to manage to propose the equation or mathematical model that allows them to find the solution and even, to implement the heuristic of representing the problem by a diagram to observe how the data of the problem is related.

When GeoGebra was incorporated to solve the problem, it was observed that the level of appropriation of the DGS and the resources that each student could use determined the type of strategy that was developed. In general, the two dynamic models that were built involved different resources and mathematical concepts, which in turn involved the development of different ways of reasoning. Each model allowed the students to interpret geometrically the conditions that must be fulfilled in the problem given. So, the DGS allowed students to give meaning to the concepts and mathematical objects involved in the problems and through the exploration of the dynamic problems, they found the solution without the need to propose an algebraic approach from the beginning.

Table 2 presents a comparison of the mathematical activities that were done in each model showed by the students, based in the episodes proposed by Santos-Trigo and Camacho-Machín (2013).

Table 2: Comparison of the dynamic models of the problem

Episode	First model	Second model
Understanding	To interpret the distances geometrically as segments on the y axis such that all its lengths sum 3.8 and represent the speeds in terms of the distances.	To interpret the speeds geometrically as slopes of straight lines where one is 0.25 less than the other and represent the distances in terms of the speeds.
Exploration of the problem	To search for which lengths of segments does the condition of the speeds is met (slopes).	To search for which slopes of the straight lines does the condition of the distances (segments) is met.
Search of different approaches to the solution	Empiric solutions obtained by: - Analyzing the numeric values to the model attributes. - Visualizing the locus (line) that relates the length of the segment AB with the difference of the slopes m y m_1 (see Figure 2d) Algebraic solution obtained by: - Representing the dynamic model through equations.	Empiric solutions obtained by: - Analyzing the numeric values to the model attributes. - Visualizing the locus (hiperbola) that relates the abscissa of the segment B with the sum of the segments j and r (see Figure 3d) Algebraic solution obtained by: - Representing the dynamic model through equations.
Integration and reflection	To give sense to the subtraction of the speeds related to the problematic situation.	To relate the slope of the vertical line with the indetermination of the function.

In Table 2 it can be observed that there are resources and strategies that match in each episode in both models with the use of the DGS. In the first episode, it was important the use of the Cartesian system to represent the data of the problem geometrically, and after that to analyze the relations and attributes of the construction. The last process, involved the application of a scale on the axis of the ordinates to get the possibility of visualizing easier the model and explore it. Also, the concept of the slope got sense when it was interpreted geometrically as the ratio of two quantities (as in the case of the speed). The episode of the exploration of the problem is the result of implementing the heuristic of the point with controlled movement that allows the DGS. In other words, from a point that was defined on a line or an axis, a model was built giving the opportunity to explore and to analyze the relations between the attributes of the construction. In the third episode, to use the locus tool is an essential strategy to find the geometric solutions of the covariation of the attributes of the dynamic setting, that allows to propose conjectures through the observation and hence, to search arguments. Finally, the fourth episode is focused on the handling of the problem where is analized the behavior and the interpretation of the model for all the values of the free point. On the other hand, the differences between both approaches are pointed out, these shows the emphasized concepts and the different ways that included different reflections in order to interpret the solution of the problem.

The construction and exploration of the dynamic models allowed the students to achieve to represent algebraically the problem by following the steps of the construction. Specifically, in the second model it was developed an algebraic model that will not be easy to propose without the exploration of the construction. In this way, the students could interpret and contextualize the algebraic expressions and give sense to different mathematical concepts and objects as the slope.

Conclusions

The use of DGS for the solution of verbal problems allowed the students to pay more attention to the understanding of the problem in order to build the dynamic model of the problem and the exploration of it, in order to analyze the behavior of the mathematical objects involved. The search for different approaches to the solution promotes the development of different forms of reasoning, especially, it was observed a change from the empiric to the formal when the students carried their dynamic solution to the algebraic representation. By integrating and reflecting about the strategies of the solution, it was possible to analyze in the context of the problem, strategies that were identified in the explorations as the subtraction of the speeds, and also the mathematical ideas as the indetermination of a function.

The research study examined the ways participants analyzed students' mathematical thinking in a massive online open course focused on teaching mathematics with technology. Across units, participants' posts showed increased attention to student thinking and less focus on issues related to technology.

Keywords: Technology, Teacher Professional Development

Introduction

Effective professional development is intensive, ongoing and connected to practice. It connects to teachers' professional practice and develops relationships among teachers (Darling-Hammond, Wei, Andree, Richardson, & Orphanos, 2009; Loucks-Horsley, Hewson, Love, & Stiles, 1998). Research provides support for seven key features that are essential for providing effective professional development for teachers (e.g., American Federation of Teachers, 2002; Borasi & Fonzi, 2002; Darling-Hammond, et al., 2009; Garet, Porter, Desimone, Birman & Yoon, 2001; Sparks & Hirsh, 1997). These features include assurance that professional development: broaden and deepen teachers' understandings of the content they are teaching; strengthen teachers' pedagogical skills specific to teaching a particular discipline; provide opportunities for teachers to understand how students learn and appreciate differences in student thinking; be connected to the practice of teaching (lesson planning, assessing student thinking, curriculum development, implementation of activities); be ongoing, job-embedded and site specific and continuously interwoven in the daily work of teachers; engage teachers in ongoing discussions within professional communities focused on content, teaching, and learning; provide supports for change that include personnel, materials, equipment, and time.

With technology rapidly changing, teachers often seek out professional development opportunities to learn about new tools. However, research shows that just adding technology to the classroom is not sufficient (e.g., Ertmer, 1999). Teachers need to understand how technology can be used to support students' mathematical thinking. This requires teachers to attend carefully to students' work and thinking.

Building on the work of van Es and Sherin (Sherin & van Es, 2005; van Es & Sherin, 2002; van Es & Sherin, 2010) who examined teachers' noticing of student thinking from video recordings of classrooms, Wilson, Lee, and Hollebrands (2011) developed a model for characterizing prospective teachers' attention to students' work and actions and interpretations of students' mathematical thinking while analyzing a video of students' work with technology. The model facilitated the identification of four distinct processes teachers use to make sense of student work and thinking: describing, comparing, inferring, and restructuring. **Describing** is characterized by an explicit focus on the actions and words of students. Teachers may repeat the same words that were spoken by the students or provide a detailed account of the menus that were selected while using the technology. **Comparing** is characterized by teachers considering their own work on the task with students' actions, either implicitly or explicitly. **Inferring** involves teachers in making assumptions about students' mathematical knowledge to make inferences about what students are thinking. The final category, **restructuring**, occurs when teachers' own knowledge about mathematics, teaching, or technology is modified based on their analysis of students' work and thinking.

The purpose of this study was to examine what teachers focused upon when attending to student work and thinking while participating in online discussion forums within a teaching mathematics with technology professional development course. When teachers focused on student thinking, we were interested in examining the processes teachers used to make sense of students' work with technology.

Context

With a focus on strengthening teachers' pedagogical skills, knowledge of technology, and appreciating differences in student thinking, the first two authors and members of the design team created a Massive Open Online Course, "Teaching Mathematics with Technology." The goals of the course are for teachers to become more familiar with different types of technology and pedagogical strategies that can be used to support mathematics teaching and learning. In addition, we desire for teachers to become aware of the ways students reason and think by providing opportunities for them to analyze videos of students' working on mathematical tasks with technology. A summary of the course and opportunities included for teachers to analyze students' thinking is included in Table 1.

Table 1: Description of Units and Opportunities for Teachers to Analyze Student Thinking

Unit Title	Opportunities to Analyze Student Thinking
Unit 1: Affordances of Technology for the Teaching and Learning of Mathematics	Two video recordings of pairs of students completing the Penny Circle task are provided. In one video students use Demos, in the other video students use paper and pencil to complete the task.
Unit 2: Capitalizing on the Power of Technology	A video recording of a pair of students completing the "Three Animals" task using Geogebra is provided.
Unit 3: Interacting with Engaging Mathematical Tasks	A video of two students completing a "Mystery Transformations" task using WebSketchpad is provided. Three videos of students solving a geometry, statistics, and algebra task are also provided. Teachers can select one to view and analyze.
Unit 4: Using Multiple-Linked Representations	An animation of a classroom scenario involving a discussion of a statistics task using CODAP is provided.
Unit 5: Assessing Students' Mathematics Thinking	A video of a class using Plickers to conduct formative assessment is provided.

The course was first offered in Fall 2016. The first unit opened October 3rd. Subsequent units were opened weekly and the entire course remained open until mid-December. Each unit contained two discussion forums where participants were encouraged to respond to prompts and to each other. One discussion forum was included in the "Essential Exploration" section where a technology-based mathematical task was presented for teachers to solve. It was followed by a video or animation of students' work on that same task. The second discussion forum was included in the "Connect to Practice" section where additional tasks and/or videos of students or classrooms were provided. Although each unit was opened weekly, participants could work at their own pace and choose to complete activities that were of interest to them. Participants interested in obtaining a certificate of completion were required to access the Essentials (readings and videos), complete the Essential Exploration, and post at least one discussion or comment in each of the two discussion forums within each unit.

Participants and Methods

A total of 534 individuals registered for the course, while 337 accessed the course and 236 posted to the discussion forums. At the conclusion of the course, all discussion forum posts were downloaded into a .csv file. Data were cleaned to remove html codes and personal identifiers. Because we were interested in how participants analyzed student thinking, we focused on discussion forum posts from units 1, 2, and 3 that included opportunities for participants to analyze student thinking. This included five discussion forums (two from Unit 1, one from Unit 2, and two from Unit 3) resulting in 271 discussion threads. From these 271 discussion threads, a decision was made to focus on 35 participants who posted in two or more of the five forums.

These 35 participants resided in four countries, with the majority in the US (89%). Within the US, most of the participants resided in the South (48%), while 23% lived in the Midwest, 19% resided in the Northeast, and 10% resided in the West. The majority were female (89%). The highest degree completed by 23% of the participants was a 4-year college degree, while most held advanced degree (69% and 9% had obtained a master's degree and PhD, respectively). The majority of participants were classroom teachers (82%); other participants included administrators (6%), undergraduate and graduate students (3%), university faculty (3%), and other (6%). Participants background with respect to number of years of experience was diverse, with a mean of 14.59 years and a median of 11.5 years. Most of the participants specialized in high school (46%) and middle grades (37%), while others specialized in post-secondary or a combination of the specialization already mentioned.

The data were organized by each of the 35 participants to examine their posts across units. A total of 174 posts made by the 35 participants were analyzed across three units. Of those 174 posts, 79 came from Unit 1, 27 from Unit 2, and 68 from Unit 3. With a total of 174 posts and 35 participants, the average number of posts per participant across all units was 4.97.

Each post was then coded to indicate whether the post was about student thinking or not (yes or no), what the post was focused on (technology, task, students, mathematics, teaching) and if the post was about student thinking the way they were analyzing student thinking (describing, comparing, inferring, restructuring, other).

The **describing** category was used if the post provided details about what the students did or said. For example, one participant posted, "The technology using pair of students used interactive coordinate plane, click and drag (mouse) digital data tables." **Inferring** was defined as a post that includes an assumption about student thinking or motivation. For example, one participant posted "The technology option allowed them to see the patterns much easier and with more possibilities." **Comparing** was defined as a post that included a direct relationship between the work of the participant and the work of the student. For example, one participant posted, "When I was doing the task, I was trying to ask myself the same questions the boys asked in the video." **Restructuring** was defined as a post that included evidence that the participant learned something about mathematics, teaching, or student thinking from their analysis of student thinking. For example, one participant wrote, "What I noticed with the video of the students who used paper and pencil, they actually collected data for various circles. They used this data to create a graph. By looking at the data, they determined that a quadratic equation was a best fit for the data. I think that the students should do this activity first and then go to Desmos to determine the equation that would be a best fit of the data." We also had a code, **Other**, that was used to code posts that did not fit the four existing categories. Within the Other category there were two themes: **contrasting paper/pencil to technology** and **anticipating or comparing to own students or students in general**. This post was coded as contrasting paper/pencil to technology, "The paper-pencil method definitely took a lot longer and there was not enough data to be seen." The following post was coded comparing to students, "I have a similar issue with my students and it is tough to not give them too much, but enough to get them exploring to a point they have enough to make good conjectures on."

The researchers coded an initial subset of posts collaboratively. Once there was consistency in coding, each post was coded by three researchers, these codes were discussed until a consensus was reached. If there was disagreement about a particular code, definitions were refined to provide greater clarity.

The Focus of Teachers' Attention

For those posts that were focused on student thinking 66% were about students or task, which is not surprising. For those posts that did not address student thinking, the focus was somewhat equally distributed among technology, teaching, task, and students (See Figure 1).

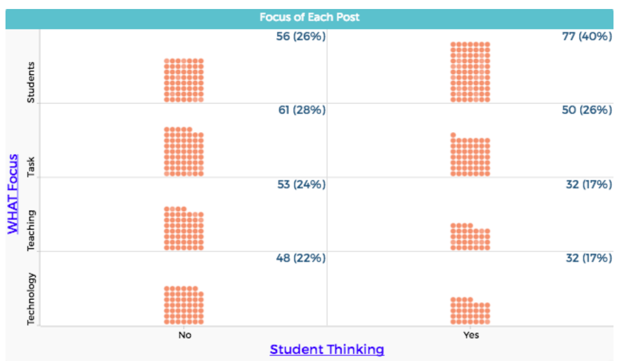

Figure 1. The focus of each discussion forum post and its consideration of student thinking.

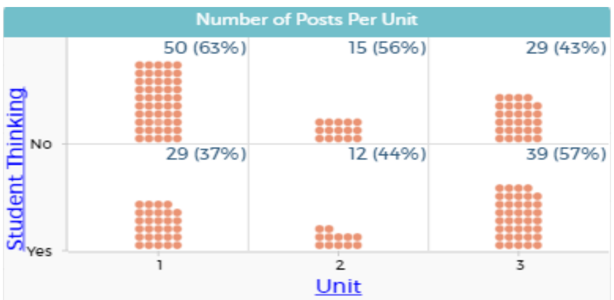
It appears that when participants did not address student thinking, they still attend to task but focus more attention on issues related to teaching and technology. Themes within the posts that did not address student thinking were: participants own solution of the task with technology, contrasting paper/pencil and technological approaches, general discussion about students' mathematical work, teaching concerns.

Several posts referred to teachers' own work with technology. For example, one participant noted, "I also had difficulties with software, but it means I need to practice more." Another participant stated, "I started with the linear model too! The exponential model got crazy large. I like that when I picked that one, the simulation questioned that one and prompted me to go back." Participants also discussed how different tools (paper/pencil, technology) can be used to support students' learning. For example, one participant exclaimed, "Yes! I agree that students need a combination of both methods as technology should enhance the experience and not do it completely for them!" and another participant commented, "The technology allows learners to use more functions and visualise the circle with unlimited pennies and may notice the large difference when the functions and graph are done by hand writing." Several posts addressed general teaching concerns such as, "I teach developmental math at college level. I think technology is good for teaching and learning. But I have classes in a room without computers. So

I mostly think about using technology and demonstration on the screen for the whole class to see." While others referred to students in a general way, "Students sometimes have a hard time figuring out if their predictions are good or bad. With this program, they are able to immediately determine if the estimates were good or bad."

Because opportunities to analyze students' thinking were included in each unit, teachers' attention to student thinking across the units was examined. As shown in Figure 2a, there was increased attention to student thinking across units (from 37% to 44% to 57%). While the majority of the posts were identified as "not student thinking" in Units 1 and 2 (63% and 56%, respectively), the majority of the posts were identified as "student thinking" in Unit 3 (57%). In addition to analyzing whether a post was about student thinking or not, researchers examined the focus of each post across units. In Figure 2b, it is evident that of all the posts that were coded as focusing on technology, the majority occurred in Unit 1 (61%) and decreased in Units 2 and 3.



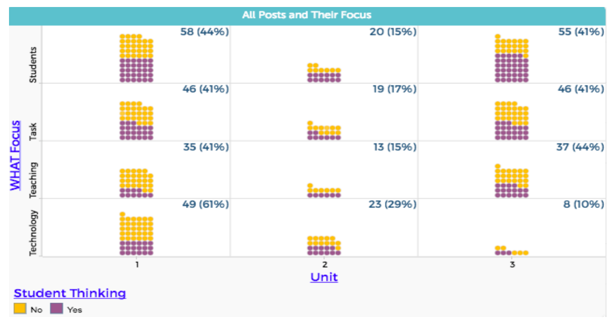


Figure 2a. Number of discussion forum posts focused on student thinking across units.

Figure 2b. Proportion of coded discussion forum posts in each of the units.

Focusing only on those posts that were coded as addressing student thinking, we see that the number of posts that also address technology increased from Unit 1 to Unit 2 and then decreased in Unit 3 (Figure 3a). Although not as drastic, there was a similar result for the discussion of tasks, where 59% of the discussion in Unit 3 of the posts identified as student thinking were also discussing the task, whereas those percentages were slightly higher in Units 1 and 2 (76% and 75%, respectively- Figure 3b). In addition to discussing the technology and the task related to student thinking, participants also discussed students and teaching. Posts about teaching and student thinking increased from Unit 1 to Unit 2 (See Figure 3c) and posts about students and student thinking stayed fairly consistent across units (Figure 3d).

One of the purposes of this research study was to examine what teachers focused upon when attending to student work and thinking while participating in online discussion forums within a teaching mathematics with technology professional development course. We found an increase in the number of posts that analyzed student thinking across units. When posts were not focused on student thinking, they tended to address teaching or technology. Within posts that addressed student thinking we saw different trends in the ways teachers discussed technology, teaching, task, and students.

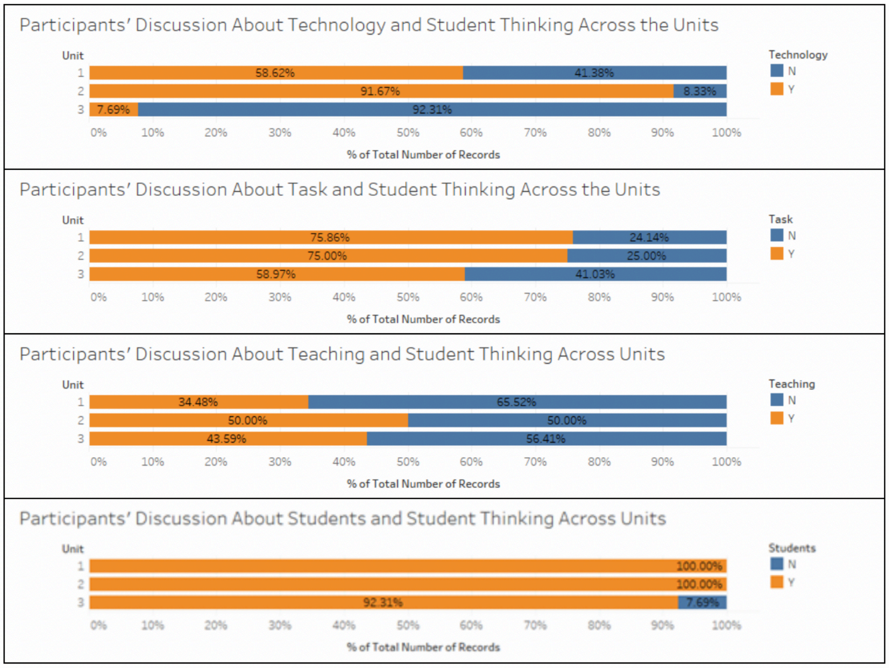

Figures 3a-3d. Focus of posts coded student thinking.

The other purpose of this study was to examine processes teachers used when examining student thinking. If a post was coded as addressing student thinking, it was coded for the process that was used (describing, comparing, inferring, restructuring, and other) to make sense of student thinking. Findings to this question are presented in the following section.

How Teachers Analyze Students' Work and Thinking

Posts that included an analysis of student thinking were coded in terms of describing, comparing, inferring, restructuring or other. Many of the teachers analyzed student thinking and responded by: 1) describing and inferring, 2) inferring and restructuring, or 3) describing, inferring, and restructuring. However, others indicated that they had solved the task themselves using technology, anticipated student strategies, made comparisons to their own thinking, and/or described/made inferences about student thinking (See Figure 4). We found that some teachers made two other types of comparisons: comparisons to their own students or students in general.

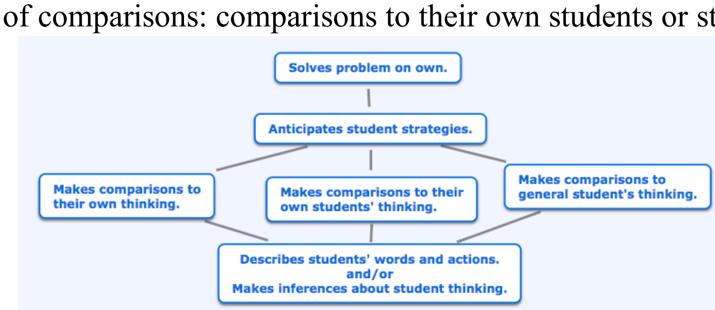

Figure 4. Teachers' patterns of analysis of student thinking.

Across all units, posts typically included inferences about students. They also included descriptions of students' actions or words. Less often, we saw instances of restructuring (Figure 5).

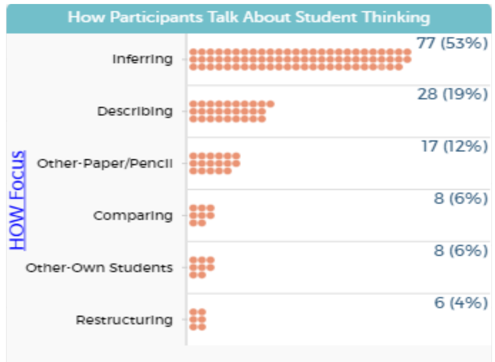

Figure 5. How teachers made sense of student thinking in discussion forum posts.

If we look at the processes used in the posts across units, posts are identified as "Inferring" 61% of the time in Unit 3, whereas the percentages are lower in Units 1 and 2 (45% and 57%, respectively). Discussion forum posts are also more likely to compare the paper/pencil students to the technology students in Units 1 and 2, whereas only 2% of the posts were assigned this code in Unit 3. This is not surprising since we noted earlier that the posts focused more on technology first two units, and this decreased in Unit 3. Additionally, posts were more likely to compare the students in the video to their own students in Unit 3 (about 11% of the time), than in Units 1 and 2 (about 2% and 0%, respectively).

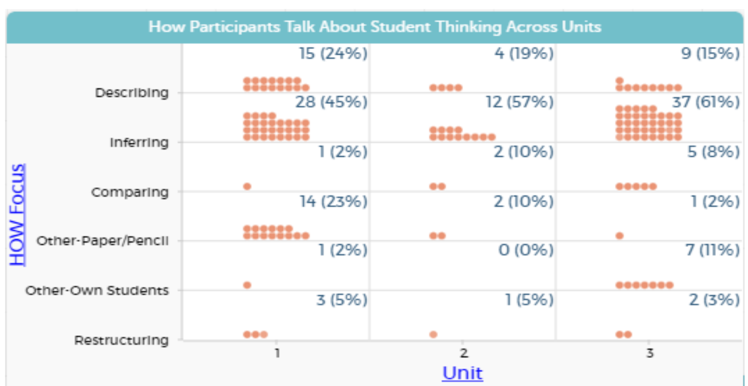

Figure 6. How participants discuss student thinking across units.

Discussion

With more content and courses for teachers available online, it is likely that this will be a venue where teachers seek out professional learning experiences. Massive open-online courses transcend geographic distances and time zones to bring people together around a common interest across the globe. With asynchronous MOOCs, teachers can make decisions about when and how to participate. While research provides evidence about how teachers can improve in their ability to notice and analyze students' thinking in face-to-face professional development, little research is available that examines how this transpires online.

Other studies that examined how participants noticed classroom events while participating online found a shift in attention from factors related to classroom implementation to features of the task (McGraw, Lynch, Koc, Budak, & Brown, 2007) or a shift in the sophistication of analysis of student thinking about specific mathematics (Fernández, Llinares, & Valls, 2012).

Our study provides evidence that in our online course teachers' attention to student thinking increased over time. In addition, teachers' posts provided evidence of going beyond what students were doing with the technology to making inferences about students' thinking. We also found that while many of the initial posted focused on issues related to the technology, this shifted over time to focus on other aspects related to mathematics teaching and learning.

In support of standards for the learning and teaching of mathematics and statistics that advocate for the use of technology to promote reasoning and sense making, and to elicit student thinking, we draw on the use of authentic student work in the form of video case instruction to develop prospective secondary mathematics teachers' [PSMTs] knowledge of students' understanding, thinking, and learning with technology in mathematics. Specifically, we draw on the extant literature related to TPACK, video cases as learning objects, and noticing to propose a set of design principles intended to guide the development of materials to support PSMTs' acquisition of TPACK. Here we explicate six design principles situated in the literature, provide an example of a module designed based on these principles, and share findings from pilot studies utilizing the module.

Keywords: TPACK; Professional noticing; Preservice teacher education

The National Council of Teachers of Mathematics (NCTM, 2000) has long advocated that "technology is essential in teaching and learning mathematics; it influences what is taught and enhances students' learning" (p. 24). Given the impact that meaningful incorporation of technology tools can have on students' understanding of mathematics, it is important for teachers to develop a model of teaching and learning that goes beyond the specifics of a technology tool so they are able to make informed decisions about appropriate use of technology to develop mathematically proficient students. This was most recently articulated in the Association of Mathematics Teacher Educator's (AMTE) *Standards for Preparing Teachers of Mathematics* which states, "well-prepared beginning teachers of mathematics are proficient with tools and technology designed to support mathematical reasoning and sense making, both in doing mathematics themselves and in supporting student learning of mathematics" (2017, p. 11). This requires teachers to not only be proficient users of technologies, but also to understand how to use technology in meaningful ways to support students' thinking about mathematics. Whether or not the use of technology will enhance students' learning depends on teachers' decisions when using technology tools to design and implement meaningful tasks. These decisions are informed by teachers' knowledge of mathematics, technology, and pedagogy.

Consider the context of teaching trigonometric functions in high school. Teachers need to know how triangle and unit circle models of trigonometric functions are related and connected to each other (knowledge of content). They also need to know how to use technology to create connected representations of right triangle models, unit circle models, and representations of trigonometric functions (knowledge of technology specific to the content). Finally, teachers need to be able to design activities that align with the approaches that students might take when asked to make sense of the connections between right triangle and unit circle models of trigonometry (knowledge of pedagogy specific to the content). The intersection of these forms of knowledge has been identified as technological pedagogical content knowledge (TPACK).

Building off of the work of Grossman (1989), Niess (2005) articulated four components of TPACK: 1) an overarching conception of what it means to teach a particular subject while integrating technology in the learning; 2) knowledge of instructional strategies and representations for teaching particular topics with technology; 3) knowledge of students' understandings, thinking, and learning with technology in a specific subject; and 4) knowledge of curriculum and curriculum materials that integrate technology with learning in the subject area. It is the third component, knowledge of students' understandings, thinking, and learning with technology in a specific subject that is the focus of this paper. Specifically, drawing on the extant literature related to TPACK, video case instruction, and professional noticing we propose a set of design principles for the development of video-enhanced modules for PSMTs with an eye toward the development of their *knowledge of students' understandings, thinking, and learning with technology in mathematics,* an important aspect of TPACK.

Theoretical Foundations

Technological Pedagogical Mathematical and Statistical Knowledge

Within teacher education, many have built upon Shulman's (1986) idea of teachers' pedagogical content knowledge (PCK). Research and teacher education in mathematics education have been greatly influenced by Simon's hypothetical learning trajectory (1995), Even's (1990) work on the essential features of subject matter knowledge in mathematics (particularly for functions), and Ball and colleagues (e.g., Ball, Thames, & Phelps, 2008) work on the components of mathematical knowledge for teaching. However, none of this work considered the knowledge that comes with teaching with technology. The particular knowledge needed when technology is added has been identified as TPACK (e.g., Niess, 2005). This construct has been used by several researchers as a frame for their work to describe the development of PSMTs' abilities in using technology in mathematics teaching (e.g., Hollebrands, McCulloch, & Lee, 2016; Lee, Kersaint, Harper, Driskell, & Leatham, 2012).

When considering TPACK within the context of preparing prospective secondary mathematics teachers [PSMTs], we believe it is *most* essential to focus on the intersections of content (mathematical and statistical) knowledge with technological and pedagogical knowledge. So although we acknowledge the importance of general knowledge of technology and pedagogy, we focus on thinking about mathematics and statistics content, and the use of technology tools specific to teaching mathematics and statistics, as well as pedagogical and technological knowledge that is central to teaching and learning mathematics and statistics (Figure 1). This means developing specific types of knowledge for teaching secondary mathematics/statistics with technology: 1) Mathematics/Statistics Knowledge (Content Knowledge of mathematics and statistics); 2) Technological Mathematical/Statistical Knowledge (Technological Content Knowledge with appropriate tools used in mathematics and statistics); 3) Pedagogical Mathematical and Statistical Knowledge (Pedagogical Content Knowledge for teaching mathematics and statistics); and 4) Technological Pedagogical Mathematical and Statistical Knowledge (as a specific type of Technological Pedagogical Content Knowledge). With a focus on content, notice that the largest circle represents our approach in that mathematics/statistics knowledge is foundational to developing the other three knowledge types. In designing modules to focus on examining students' mathematical practices with technology, we also necessarily concentrate on increasing undergraduate PSMTs' Mathematical and Statistical Knowledge (MSK) and Technological Pedagogical Mathematics and Statistics Knowledge (TPMSK).

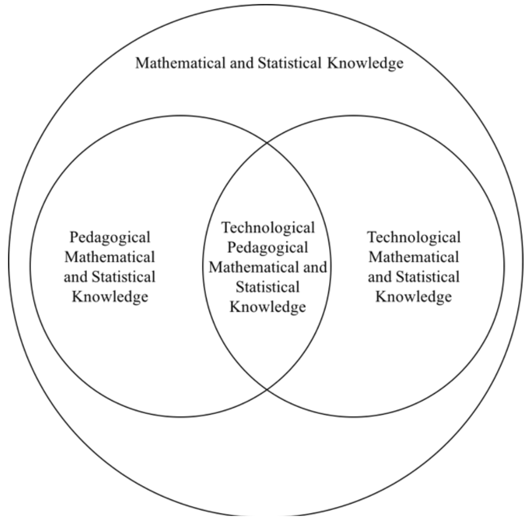

Figure 1. Framing Technological Pedagogical Mathematical and Statistical Knowledge

Analyzing Student Work

Research has pointed to the important role that students' mathematical thinking plays in high-quality instruction (e.g., Jacobs & Spangler, 2017). This points to the need for PSMTs to have opportunities to grapple with and make sense of how students think about mathematics. NCTM's publication, *Principles to Action*, identified "elicit and use evidence of student thinking" as one of the eight mathematics teaching practices (2014, p. 10). For PSMTs this skill must be purposefully developed via teaching practice. One method that has been shown to help PSMTs develop an understanding of student thinking is analysis of authentic student work (e.g., Jansen & Spitzer, 2009; Philipp, 2008).

Authentic student work can come in the form of written artifacts or video cases. Here we focus on video cases and their corresponding written artifacts as together they provide insight to student thinking as they are engaged in mathematical work. Video cases have been shown to improve PSMTs' ability to critically observe classroom practice, attending to teacher choices and student thinking rather than merely content delivery (e.g., Star & Strickland, 2008; Sherin & van Es, 2005). Additionally, a focus on student thinking through video case analysis has been shown to improve PSMTs' abilities to draw attention to and describe teachers' instructional moves to make student thinking visible, to reason about impact of teacher's decisions on student learning, and to propose alternatives to what was observed in the video (Santagata & Guarino, 2011).

While video case instruction has been shown to be very beneficial for PSMTs, researchers caution that the *selection* of video clips (e.g., Kurz, Llama, & Savenye, 2005; Sherin, Linsenmeier, & van Es, 2009) and *how* video cases are used is critical to promoting teacher learning (e.g., Brophy, 2004). To this end, Sherin et al. (2009) articulated a framework for selecting video clips to develop cases that attend to the extent to which a clip provides a *window* into student thinking, the *depth* of student thinking, and *clarity* of student thinking. To ensure the best video clip possible they suggest that all three criteria are considered. It is also suggested that cases be designed so that they focus on aspects of student work in which there are elements of confusion or surprise (Shulman, 1996; Sherin et al. 2009). Once video clips are selected, the activities that surround their use must be carefully designed, articulating clear goals to focus the analysis of the video (Borko, Jacobs, Eiteljorg, & Pittmann, 2008). A method often used to guide PSMTs' analysis of student work in video cases is the *professional noticing* construct developed by Jacobs, Lamb and Philipp (2010). The three components of the professional noticing construct are attending to students' strategies, interpreting students' mathematical thinking, and deciding how to respond on the basis of students' understandings.

Much of the research on PSMTs analyzing student work has been completed through the lens of professional noticing. Within professional noticing work more attention has been paid to professional noticing of whole class video (e.g., Krupa, Huey, Lesseig, Casey & Monson, 2017; McDuffie et. al, 2013), with less on prospective teachers' noticing of student written work (e.g., Dick, 2017; Goldsmith & Seago, 2011). In terms of PSMTs' professional noticing of students' understanding, thinking, and learning mathematical tasks in technological environments, very few studies have been conducted (e.g., Wilson, Lee & Hollebrands, 2011).

The seminal work on PSMTs' professional noticing of students' understanding, thinking, and learning of mathematics with technology comes from Wilson et al. (2011). They not only indicated that engaging preservice teachers in analyzing video cases of students' technological mathematical work resulted in identifying different ways of constructing models of student thinking, but also made a call for the need of research to more fully understand the role of these models in the development of PSMTs' TPACK. Even so, a broad search of the literature (including unpublished dissertations) indicates there has been very little continued work in this direction. This might be due to the complex nature of designing such materials for PSMTs. To address this, and support others who are aiming to support PSMTs in their development of TPMSK, we draw on the literature described here to propose a set of design principles for engaging PSMTs in professional noticing of students' mathematical technological practices.

Design Principles for Supporting Professional Noticing of Students' Technological Mathematical Practices

The design principles we propose draw on the integration of the literature on developing TPACK, video case pedagogies, and the construct of professional noticing. Specifically, we propose that by beginning with the philosophy of an integrated approach to develop skills in a specific content area, pedagogy and technology, the development of MSK and TPMSK can be done through the use of video cases of student practices on technology-based mathematics and statistics tasks. Guiding PSMTs' analysis of video cases is the use of the professional noticing construct. Specifically, we propose the following design principles.

1. PSMTs need to observe secondary students engaged in technology-based tasks of high-cognitive demand. As such, the selected tasks must be of high cognitive demand (Smith & Stein, 1998) and position the use of technology to develop mathematical or statistical understanding (Dick & Hollebrands, 2011).
2. Video clips (and associated written artifacts) should focus on aspects of student work in which there are elements of confusion or surprise, as is suggested by Sherin et al. (2009) and Shulman (1996).
3. Final clips should be selected based on Sherin et. al's (2009) recommendations for dimensions of video clips that support teacher discussion of students' mathematical thinking (i.e., *window* into student thinking, *depth* of student thinking, and *clarity* of student thinking). This includes use of picture-in-picture so that students' technological work is visible as well as any gestures they are making in relation to their technological work (e.g., pointing).
4. To support PSMTs' development of TMSK they must engage with the technology-based task first as learners (Lee, Hollebrands, & McCulloch, 2015).

5. To support PSMTs' development of TPMSK through the analysis of video clips, guiding questions should be designed based on Jacobs et al. (2010) framework for professional noticing. This means specifically asking PSMTs to attend, interpret, predict, and make pedagogical decisions based on their analysis of the video cases.

We conjecture that careful selection of tasks, technology, video case clips, and the questions included in a video case will work together to provide PSMTs an opportunity to develop their knowledge of students' understandings, thinking, and learning with technology in mathematics.

An Example: The Function Concept - Functions and Non-functions

To illustrate our vision for video cases that can promote PSMTs' professional noticing of students' technological mathematical practices we provide an example. We begin by having PSMTs engage with a preconstructed GeoGebra applet designed to provoke a dilemma in relation to their understanding of function (Design Principle 4) PSMTs are asked to engage with this applet and answer questions related to their own understanding of function, representations of function, and consider how they might use the applet with students. (Figure 2). This applet has been designed using a vending machine metaphor so that PSMTs grapple with making sense of function, domain, and range in a context that does not use traditional algebraic representations (Design Principle 1) (see McCulloch, Lovett, & Edgington (2017) for a full discussion of the design of this applet and one study of its use with undergraduate students).

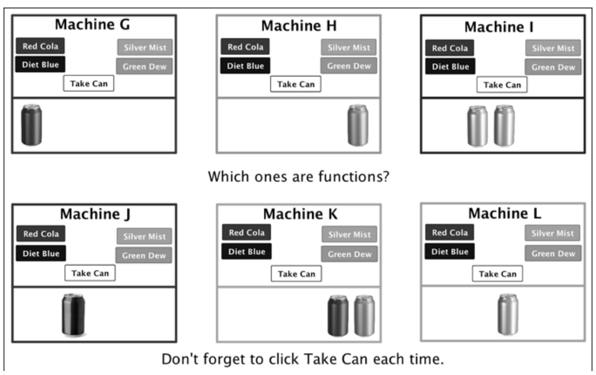

Figure 2. Vending machine applet

Figure 3. Students working on the applet

A second version of the Vending Machine task was designed specifically for secondary students (Design Principle 1). It was designed to be used as an introduction to function with students who had no previous experience with the term *function*. The goal of this version of the task is that students develop a definition of function based on their exploration of the machines in the applet. The applet was then implemented in an 8th grade math class with pairs of students working together and their work on the task was screen captured. Next, the students' videos were analyzed for the purpose of selecting examples of work. This included identifying video clips for episodes of confusion or surprise, followed by the analysis of the window, depth of student thinking, and clarity of student thinking (Design Principle 2 & 3). Once video episodes were selected, they were packaged as a case with questions designed based on Jacobs et al. (2010) professional noticing construct (Design Principle 5). For example, PSMTs were asked to attend to and interpret the coordination of student thinking and technological actions when analyzing the video cases. Further, they were asked to make predictions about student thinking and technological action based on their attending and interpreting. Using these materials, the video case was implemented with PSMTs as follows:

- PSMTs were asked to discuss revisions they would make to the original applet if they intended to use it with secondary students to develop the definition of function.
- After exploring the version of the applet that was used with secondary students, PSMTs anticipate how secondary students would engage with the task - considering actions with the technology and students' verbal and written responses to task prompts.
- PSMTs then analyze carefully selected screen capture clips of multiple pairs of students engaging with the applet (and their associated written work). These video clips show the pairs of students' engagement with some of the machines in the applet, but not all. PSMTs then predict how each student pair might identify each machine as a function or non-function and how they might engage with the remaining machines given their analysis of the first few.
- Given written definitions of function from five pairs of secondary students, PSMTs select which they would use to start a class discussion of the definition of function, why they selected that sample, and which machines in the applet they would draw upon for the discussion given their selection.

As is evident, the video case provided ample opportunities for the PSMTs to consider their own and students' technological mathematical work through engaging with a carefully selected task and analyze carefully selected video cases of students' technological mathematical work by engaging in professional noticing.

Discussion

Our proposed design principles for the development of professional noticing of students' technological mathematical practices are grounded in the literature and have been successfully used to frame the design of a module for PSMTs in the context of the use of a vending machine applet to build an understanding of the function concept. The vending machine task module has been piloted with 98 PSMTs in secondary mathematics education methods courses at six different universities. Data included PSMTs' pre and post function definitions, screen casts of their own mathematical work with the vending machine task, and written artifacts from the analyzing student work assignments. These studies indicate that this module was successful in eliciting PSMTs' MK, TMK, and TPMK (Lovett et al., Under Review). Specifically, within the realm of TPMK, not only were PSMTs able to show an understanding of *students' understandings, thinking, and learning with technology in mathematics*, but also as they stated their predictions of students' technological mathematical work they showed evidence of being able to conceive of how technology can support mathematical thinking (Lovett et al., Under Review), both important aspects of TPACK (Niess, 2005).

Pilot study results also indicate the use of professional noticing to frame the analysis of the video cases was important in that it elicited the specific ways in which prospective teachers drew upon different aspects of student work evident in the video cases. We found that some drew only upon students' spoken and written words, others drew upon only students' actions with the technology. However, those that coordinated both aspects of the students' work were better prepared to predict students' responses on related tasks and to make decisions to support student learning (Lovett, Dick, McCulloch, Sherman, & Martin, 2018). This coordination was especially important as they were making sense of a particular video clip in which students were confused.

Finally, it was found that PSMTs' knowledge of the mathematics deepened through their own engagement with the vending machine task as a learner, and for many this knowledge was expanded even more through their analysis of the video cases (Lovett et al., 2017). Thus, we have substantial evidence that these proposed design principles for developing video cases for examining students' practices with technology are promising.

Conclusion

Strong preparation of mathematics teachers must include opportunities to engage with technology-based mathematics tasks as learners as well as opportunities to develop an understanding of how to support students' learning in mathematical technological environments. As we consider the conference theme, *looking back* and understanding theories and methods that have been successful in supporting prospective teachers as they learn to make sense of student thinking can help us *look ahead* and move forward by drawing on this work to propose new theory about continuing this development in technological contexts. In this paper we have articulated a set of 6 principles to frame the design of video case materials to support PSMT development of TPACK. Results from pilot studies provide empirical support for the promise of these design principles. We now challenge ourselves and others in the field to keep these principles in mind as we work to ensure PSMTs are well-prepared to teach with technology in ways that support students' mathematical reasoning.

RESOLUCIÓN DE PROBLEMAS Y USO DE TECNOLOGÍAS DIGITALES EN UN MOOC: DISEÑO E IMPLEMENTACIÓN

PROBLEM SOLVING AND THE USE OF DIGITAL TECHNOLOGIES IN A MOOC: DESIGN AND IMPLEMENTATION

En este estudio se analizan y discuten los elementos del diseño y resultados de la implementación de un curso masivo abierto en línea (MOOC) que promueve la resolución de problemas basado en el uso de tecnología digital. Los resultados muestran que el diseño de las actividades, la intervención del equipo de diseño del MOOC en los foros de discusión y la interacción entre los participantes permitió y favoreció la creación de un ambiente de colaboración en la resolución de problemas. Los participantes compartieron y discutieron sus ideas matemáticas como parte de una comunidad virtual de aprendizaje, lo que les permitió formular conjeturas, explorar y buscar propiedades para sustentar relaciones y comunicar resultados.

Palabras clave: Resolución de Problemas, Tecnología.

Introducción

Durante o después de sus clases, es común que los estudiantes consulten diversas plataformas digitales en Internet para acceder a información sobre contenidos disciplinarios, compartir y discutir ideas, tomar cursos especializados en algún tema e interactuar con expertos. Así, los espacios y tiempos en los que se produce aprendizaje han cambiado y han sido alterados por la conectividad en la red (Gros, 2016).

Diversas universidades han puesto a disposición del público general, Cursos Masivos Abiertos en Línea (*Massive Open Online Course*, MOOC por sus siglas en inglés) a través de diversas plataformas digitales. La comunidad virtual que participa en estos cursos comprende un conjunto grande (generalmente miles) de personas con diferentes niveles de estudios, edad, dominio o conocimiento previo de la materia, entre otros. En el desarrollo de las actividades de un MOOC no existe un profesor encargado de responder o dar seguimiento puntual a cada participante. Cada integrante define su grado de compromiso y participación en las actividades. Para este estudio, se construyó el MOOC: Resolución de Problemas Matemáticos y uso de Tecnologías Digitales, basado en los marcos: resolución de problemas (Santos-Trigo, 2014) y RASE (Churchill, King, & Fox Churchill, 2016). Churchill, et al., (2016) argumentan que un ambiente de aprendizaje en línea debe incluir elementos que permitan a sus participantes trabajar y colaborar en equipo con otros. Las actividades deben fomentar la participación activa de los estudiantes en un ambiente de reflexión, de discusión y centrarse en un contexto donde las tareas involucren a los estudiantes en los episodios de resolución de problemas: formulación de preguntas, búsqueda de diversos métodos de solución, exploración de diferentes representaciones, búsqueda de patrones, variantes y relaciones entre objetos matemáticos, presentación de argumentos, comunicación de resultados, planteamiento de preguntas y formulación de nuevos problemas (Santos-Trigo, 2014). El uso sistemático de tecnologías digitales resulta importante en la representación, exploración, comunicación y comprensión de conceptos matemáticos en la resolución de problemas (Santos-Trigo, Moreno-Armella, 2016).

En este estudio interesó analizar el diseño de las actividades matemáticas y la formas de razonamiento de los participantes relacionado con: (1) el planteamiento de preguntas y la búsqueda de diversas maneras de responderlas; (2) la formulación de conjeturas basadas en el movimiento de objetos matemáticos y la cuantificación de atributos como medida de segmentos, ángulos, áreas, etc.; y (3) la búsqueda de argumentos que validen esas conjeturas transitando desde los argumentos empíricos y visuales hasta la construcción de argumentos geométricos y algebraicos. Así, la pregunta de investigación que sirvió de guía para el desarrollo de este estudio fue ¿De qué manera el diseño e implementación de las actividades en un MOOC basado en resolución de problemas y uso coordinado de tecnologías digitales influye en la construcción y el desarrollo del pensamiento matemático de los participantes?

Marco Conceptual

La construcción del pensamiento matemático está relacionada con la resolución de problemas ya que es un medio que permite identificar, explorar, probar y comunicar las estrategias de solución (Santos-Trigo, 2014; Schoenfeld, 1992). Diversas tecnologías digitales ofrecen a los estudiantes diversos caminos para representar y explorar conceptos y problemas matemáticos que extienden aquellos acercamientos basados en el uso de lápiz y papel (Santos-Trigo, 2014; Aguilar-Magallón & Poveda, 2017).

Un Sistema de Geometría Dinámica (SGD) puede utilizarse para integrar los procesos que intervienen en la resolución de problemas ya que permite generar representaciones o modelos dinámicos de los problemas matemáticos donde el movimiento de objetos particulares (puntos, rectas, segmentos, polígonos, etc.) puede ser explorado y explicado en términos de relaciones matemáticas. Así, el uso sistemático de tecnologías digitales resulta importante en la representación, exploración, comunicación y comprensión de conceptos matemáticos en la resolución de problemas.

Churchill et al. (2016) argumentan que se necesita un modelo para el diseño de ambientes de aprendizaje que proporcione, a profesores e investigadores, pautas para utilizar tecnologías digitales en el contexto de la enseñanza y aprendizaje. Proponen el modelo de diseño RASE que integra Recursos, Actividades, Soporte y Evaluación. Los Recursos, se refieren a los materiales disponibles para los estudiantes: videos, imágenes, documentos digitales, calculadoras, herramientas para la representación de situaciones matemáticas, etc. Las Actividades deben permitir a los estudiantes involucrarse en procesos de discusión, análisis y reflexión en colaboración con otros.

El Soporte establece que se deben incluir diversos medios de consulta y comunicación entre los estudiantes con el objetivo de que puedan obtener ayuda o retroalimentación en el momento en que lo necesiten y, así, fomentar su independencia del profesor o tutor. La evaluación debe favorecer que los estudiantes mejoren constantemente su aprendizaje, por ello, es necesario que cuando expresen sus ideas, analicen la retroalimentación recibida, a través de los medios de soporte, para refinar o ampliar los conceptos o ideas iniciales.

En un MOOC, los foros de discusión se convierten en un medio de conversación entre sus participantes y les ofrece la oportunidad de plantear, aclarar, conocer, contrastar ideas propias y de otros (Poveda & Aguilar-Magallón, 2017). Ernest (2016) argumenta que en la conversación intervienen: un hablante/proponente, un oyente/crítico y un Texto Matemático. El hablante/proponente plantea una idea (Texto Matemático) y el oyente/crítico responde proporcionando su punto de vista, aceptando o modificando la idea original. Posteriormente, el hablante/proponente puede asumir el rol de oyente/crítico, de esta manera, se alternan sus roles.

Metodología

El objetivo del diseño de las actividades del curso fue enfatizar que el aprendizaje de las matemáticas requiere problematizar o cuestionar las tareas o situaciones, pensar distintas maneras de resolver un problema, comprender y utilizar diversas representaciones, interpretar la solución y comunicar los resultados. Mediante este proceso, la formulación de preguntas se convierte en un medio que permiten a los participantes construir, desarrollar, refinar, o transformar sus formas de comprender y resolver problemas.

Los Recursos incluyeron representaciones o modelos dinámicos de problemas construidos en GeoGebra, vínculos a la plataforma Wikipedia y videos de KhanAcademy para el estudio y consulta de conceptos o relaciones matemáticas. Las Actividades comprendieron tres etapas: 1) *Movimiento*: los participantes tuvieron la oportunidad de explorar un modelo dinámico que representa un problema y explorar el comportamiento de algunos de sus objetos que resulta al mover otros elementos, 2) *Conjetura:* el objetivo es que, a partir del movimiento, los participantes formularan conjeturas que puedan ser sustentadas o refutadas a partir de argumentos visuales o empíricos y 3) *Justificación*: se buscó que toda conjetura fuera justificada mediante argumentos que involucraran propiedades y resultados matemáticos.

Se utilizó el foro de discusión para que los participantes tuvieran la posibilidad de plantear sus dudas e ideas las veces que consideraran necesarias. Así, el trabajo de los integrantes puede ser un punto de referencia para que otros retomen o extiendan las ideas, las contrasten y las discutan. Además, en los foros de discusión los participantes pueden recibir retroalimentación acerca de las ideas que plantean, esto puede favorecer el análisis y reflexión como parte del proceso de Evaluación.

Implementación del MOOC, sus participantes y procedimientos

El MOOC se construyó e implementó en la plataforma *Open edx* (https://open.edx.org/about-open-edx), tuvo una duración de siete semanas y estuvo compuesto por cinco Actividades. El requisito fue estar cursando o haber terminado estudios del nivel K-12. Participaron 2669 personas. Al inicio del curso, únicamente estuvo visible la Actividad 1, una semana después se mostraba la Actividad 2 y así sucesivamente, sin restringir el acceso a las anteriores.
Durante las siete semanas en que el curso estuvo disponible a los participantes, el equipo de diseño (ED) monitoreó el desarrollo de las Actividades y la participación en los foros. El trabajo consistió en lo siguiente:

1. Al inicio de la Actividad (primer y segundo día), clasificó los comentarios en cuatro categorías: respuestas a las preguntas que planteaba cada Actividad, acercamientos hacia la solución del problema (correctos e incorrectos), nuevas preguntas planteadas por los integrantes y propuestas para extender el problema. Posteriormente, se eliminaron los comentarios con ideas similares; se tomaron dos o tres de cada categoría y fueron colocados de tal forma que se mostraran al inicio de las conversaciones, así los participantes les podrían dar prioridad en su análisis.
2. Durante la Actividad intervenía en los foros solo cuando se requería orientar y extender la discusión. Nunca se respondía de manera directa a las preguntas de los participantes, sino que, se planteaban preguntas con el objetivo de generar discusión y que ellos mismos buscaran diferentes formas de solucionar la situación.

3. Al final de la Actividad se plantearon preguntas para promover la ampliación del tema y que los participantes buscaran extender los problemas iniciales.

Los datos de este estudio se recolectaron por medio de los foros de discusión. La unidad de análisis fueron las conversaciones de los participantes en cada Actividad. Al finalizar el curso, el equipo de diseño analizó y documentó cómo el diseño de las Actividades, la discusión e interacción entre los participantes y las acciones que tomó el equipo de diseño en el foro influyeron en el desarrollo de los episodios de resolución de problemas, según el marco de resolución de problemas y uso de tecnologías digitales de Santos-Trigo (2014).

Presentación de Resultados

Se discute una de las Actividades propuestas en el MOOC: Dos granjeros desean sembrar un terreno que tiene forma de un cuadrado. ¿Cómo dividir el terreno para que cada granjero siembre exactamente la misma área? La Actividad consistió desarrollar dos soluciones del problema, en cada una se proporcionó un modelo dinámico y un conjunto de preguntas para guiar el trabajo de los participantes. La Tabla 1 muestra la etapa en donde los integrantes del MOOC tuvieron la oportunidad de mover objetos en búsqueda de relaciones o invariantes y un resumen de las conversaciones en el foro.

Tabla 1: El movimiento y los primeros resultados de la exploración dinámica.

El movimiento y la exploración	Resultados de las interacciones en los foros
 **Movimiento:** Al mover los puntos A, B, P y Q ¿Qué ocurre con las áreas de las regiones? ¿Dónde situar los puntos P y Q para que las áreas de las regiones AQPD y QBCP sean las mismas?	Todos los participantes: 1. Coincidieron que, al mover los puntos P y Q, es posible obtener regiones de áreas iguales, sin importar la medida del lado del cuadrado. 2. Se basaron en el movimiento de objetos y la medición de áreas para determinar algunas soluciones: $P = C$ y $Q = A$; $P = D$ y $Q = B$; y PQ mediatriz de DC. En esta parte de la Actividad, los participantes no lograron observar que una solución general es cuando PQ pasa por el centro del cuadrado.

La siguiente pregunta que se planteó a los participantes fue: ¿Resulta importante el centro del cuadrado y la posición de la recta que divide al terreno en regiones de la misma área? Todos formularon su primera conjetura basada en argumentos visuales y empíricos (mediciones de las áreas de $AQPD$ y $QBCP$): "*Si la recta PQ pasa por el centro del cuadrado ABCD entonces lo divide en dos áreas iguales*". El ED cuestionó: *"¿Cuántas soluciones existen?*" Las respuestas coincidieron en que existe un número infinito de soluciones.

En la búsqueda de una justificación de la conjetura, se cuestionó a los participantes: ¿Qué conceptos, propiedades y recursos matemáticos se pueden usar para sustentar la conjetura? Todos coincidieron, en las conversaciones, en que era necesario trazar las diagonales del cuadrado y utilizar sus propiedades (Justificación 1 de la Tabla 2).

El participante P_1 presentó otra forma de justificar la conjetura: construyó un modelo dinámico, planteó sus ideas, contestó las dudas de otros y proporcionó retroalimentación a los que decían no comprender la justificación (Justificación 2, Tabla 2).

Tabla 2: Recursos y estrategias de exploración y solución.

Justificaciones	Recursos y estrategias de exploración y solución
Justificación 1 	**Recursos:** Propiedades del cuadrado y sus diagonales, ángulos entre paralelas, ángulos opuestos por el vértice y congruencia de triángulos. **Estrategia**: Colocar un punto móvil P sobre el lado DC, construir la recta PO y trazar las diagonales del cuadrado. **Justificación:** $\Delta DOP \cong \Delta BOQ$ (ALA), así $DP = BQ$, por lo tanto, los trapecios $AQPD$ y $QBCP$ son congruentes y tienen área igual.
Justificación 2 de P_1 	**Recursos:** Propiedades del cuadrado, congruencia de triángulos, ángulos entre paralelas, propiedades de rectas paralelas y perpendiculares. **Estrategia:** Colocar el punto móvil P sobre DC, trazar la recta PO y construir rectas perpendiculares a DC y AB que pasan por P y Q, respectivamente. **Justificación:** $\Delta QKP \cong \Delta PLQ$ (LAL) y los rectángulos $AQKD$ y $LBCP$ son congruentes (no proporciona argumentos). Preguntas de los participantes en el foro: (1) *¿Qué sucede si P=C y Q=A?* P_1: "*Se tienen dos triángulos rectángulos congruentes*", (2) "*¿Cómo sabes que AQ=PC?*". P_1 hizo referencia a la Justificación 1.

La siguiente parte de la Actividad guio a los participantes en la exploración y búsqueda de otra solución, los detalles se muestran en la Tabla 3.

Tabla 3: La importancia del movimiento y la exploración.

Etapas de la Actividad	Interacciones en los foros
P es un punto móvil dentro del cuadrado. **Movimiento.** ¿Qué regiones se les puede asignar a los grajeros para que cada uno siembre la misma área?	Los participantes coincidieron en que: • Al mover P se pueden obtener las soluciones cuando: P coincide con alguno de los vértices, P es el punto medio de un lado o P es el centro del cuadrado. • Otra solución es cuando P pertenece a una de las diagonales del cuadrado o a la recta que une los puntos medios de AB y DC. Luego de las conclusiones anteriores, un participante mencionó que la suma de las áreas de los triángulos ABP y CDP se mantiene contante e igual a la mitad del área del cuadrado. Los demás estuvieron de acuerdo y afirmaron que no habían visto dicha invariante.

Conjetura: ¿Al variar la posición del punto P, qué ocurre con la suma de las áreas de los triángulos ABP y CDP?	Los participantes formularon la conjetura: "*Si P es un punto que está dentro del cuadrado, la suma de las áreas de los triángulos opuestos es la mitad del área del cuadrado $ABCD$*". Retroalimentación: "*Al mover P se forman 4 triángulos*", respuestas: "*Mueve el punto P de tal forma que coincida con un vértice, o bien, coloca P sobre sobre uno de los lados*".

Luego de que los integrantes formularon la conjetura, la siguiente parte consisitió en buscar relaciones matemáticas para justificarla, por ello, se incluyó, en el modelo dinámico del cuadrado, las rectas FH y EG. Los participantes discurtieron y presentaron la Justificación 1 que muestra la Tabla 4. La Justificación 2 de la Tabla 4 fue construida y compartida por el participante P_2. Los demás aprobaron las ideas y construyeron modelos algebraicos como otra ruta para sustentalo.

Tabla 4: Recursos y estrategias de exploración y solución.

<table>
<tr><th>Justificación de la Solución 2</th><th>Recursos, estrategias y justificación</th></tr>
<tr><td>
¿Qué propiedades son importantes para presentar un argumento que sustente la conjetura? ¿Qué propiedades tienen los triángulos que se generan al trazar las rectas perpendiculares a los lados que pasan por el punto P?</td><td>Recursos: Propiedades de rectas paralelas y perpendiculares, triángulos rectángulos congruentes
Estrategia 1: Trazar las rectas EG y FH perpendiculares a los lados del cuadrado que pasan por P.
Justificación 1. $\Delta AGP \cong \Delta AFP$ (LLL) y $\Delta GBP \cong \Delta HBP$ (LLL), del mismo modo $\Delta CEP \cong \Delta CHP$ y $\Delta EDP \cong \Delta FDP$. Por lo tanto, $Area\, \Delta DCP + Area\, \Delta ABP = Area\, \Delta BCP + Area\, \Delta DPA$.
Estrategia de P_2. La suma de las alturas de ΔAGP y ΔDPE, sin importar la posición de P, es constante e igual a BC.
Justificación de P_2: La suma de las alturas de ΔPCD y ΔABP es igual a la suma de las alturas de ΔDAP y ΔBCP, además, los 4 triángulos tienen la misma base, por lo tanto, $Area\, \Delta PCD + Area\, \Delta ABP = Area\, \Delta DAP + Area\, \Delta BCP$.</td></tr>
</table>

El ED cuestionó en el foro: *"¿Existe otra forma de solucionar el problema? ¿Qué otras preguntas se pueden plantear?"*. El participante P_3 retomó las ideas P_2 (Jjustificación 2 de la Tabla 4) y construyó un modelo dinámico del cuadrado con otra solución (Justificación 1 de la Tabla 5). Los demás participantes aprobaron las ideas de P_3 y discutieron otra forma de sustentar la conjetura (Justificación 2, Tabla 5). Todos los participantes validaron las ideas expuestas y proporcionaron ayuda a otros.

Tabla 5: Otra solución del problema.

<table>
<tr><th>Otra solución</th><th>Recursos, estrategias y justificación</th></tr>
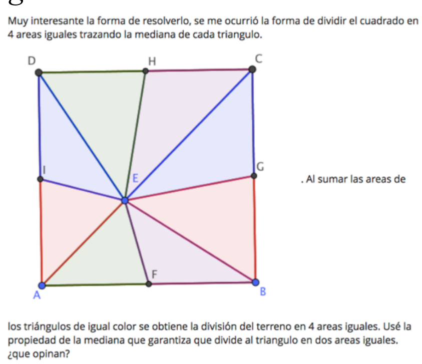
<tr><td></td><td>Recursos: Propiedades de rectas paralelas y perpendiculares.
Estrategia: Colocar un punto móvil E sobre DC, trazar la recta m perpendicular a DC que pasa por E. Colocar dos puntos móviles F y G sobre m.
Justificación 1 de P_3: La suma de las alturas de ΔAFD y ΔBCG es constante e igual a AB sin importar la posición de E, F y G, por lo tanto, $Area\ \Delta AFD + Area\ \Delta BCG$ es la mitad del área del cuadrado.
Justificación de otros participantes: Trazar rectas paralelas a los lados que pasan por los puntos móviles para obtener triángulos congruentes.</td></tr>
</table>

La Tabla 6 muestra dos de las preguntas que formularon los participantes y las respuestas que encontraron.

Tabla 6: Nuevos problemas planteados por los participantes.

<table>
<tr><th>Preguntas formuladas</th><th>Justificación</th></tr>
<tr><td>Extensión 1
“¿Cómo dividir el terreno en 4 regiones con la misma área?”.


</td><td>En la búsqueda de respuestas, un participante utilizó la propiedad: Al trazar una mediana de un triángulo, éste queda dividido en dos áreas iguales. Así, construyó y presentó un modelo dinámico similar al de la Solución 2 y en donde trazó la mediana de cada triángulo (EI, EH, EG y EF). Al sumar las áreas de los triángulos DEI y CGE, se obtiene que su valor es un cuarto del área del cuadrado.
Los demás participantes en la conversación estuvieron de acuerdo con las ideas y recalcaron el uso de un SGD en la exploración y búsqueda de soluciones.</td></tr>
<tr><td>Extensión 2
“¿Será posible determinar un cuadrilátero inscrito dentro de cualquier otro tal que sea la mitad de su área?”.</td><td>Otro participante compartió información de Wikipedia relacionada con el teorema de Varignon: En cualquier cuadrilátero, los puntos medios de los lados forman un paralelogramo cuya área es la mitad de la del cuadrilátero original.</td></tr>
</table>

Discusión de los resultados

El diseño de las Actividades guio el trabajo de los participantes hacia la búsqueda de diversas formas de explorar los modelos dinámicos. Cada modelo representó para los participantes un punto de partida que les permitió identificar conceptos, plantear conjeturas basadas en el movimiento de los objetos matemáticos presentes en la configuración dinámica y sus relaciones o invariantes. El uso de los foros de discusión favoreció la comunicación, análisis y contraste de ideas matemáticas, además permitió a los participantes proporcionar u obtener retroalimentación de otros. Lo anterior fue importante para que transitaran de soluciones visuales y empíricas (asociadas con el uso de las herramientas como movimiento de objetos dentro de la configuración, la cuantificación de atributos como medida de segmentos, ángulos, áreas, etc.) hacia la presentación de argumentos geométricos y algebraicos en la validación de las conjeturas formuladas.

Durante el desarrollo del curso, el monitoreo que realizó el ED en la clasificación y la jerarquización de los comentarios favoreció la discusión, refinamiento de conceptos e ideas matemáticas y los episodios de la resolución de problemas. Por ejemplo, los participantes formularon conjeturas, presentaron argumentos para justificarlas y formularon nuevos problemas. El planteamiento de preguntas que presentó el ED fomentó la discusión de las ideas matemáticas, la formulación de nuevas soluciones y extensiones del problema (Ver Tabla 2, 5 y 6).

Algunas personas participaron en el foro asumiendo el rol específico de proporcionar retroalimentación a las preguntas de otros, esto, junto con el diseño de las actividades, promovió el trabajo colaborativo y fomentó la independencia de los participantes en el proceso de la construcción y su desarrollo del pensamiento matemático.

Conclusiones

Los resultados muestran que las diversas tecnologías digitales utilizadas en este estudio y la integración de los componentes Recursos, Actividades, Soporte y Evaluación basados en la resolución de problemas permitieron crear un ambiente de trabajo colaborativo. La plataforma digital permitió incluir representaciones dinámicas de los problemas elaboradas en GeoGebra, en las cuales los participantes tuvieron la oportunidad de explorar, identificar conceptos, buscar conjeturas y diversos argumentos para sustentarlas. En este proceso, utilizaron estrategias asociadas con el uso de la herramienta como movimiento de objetos dentro de la configuración dinámica y la cuantificación de sus atributos (longitudes y áreas).

Durante el desarrollo de las Actividades, un grupo de participantes proporcionó retroalimentación a otros, lo que favoreció aclarar o refinar dudas o ideas relacionadas con conceptos matemáticos, con la exploración del modelo dinámico, con la formulación de conjeturas y su justificación. Lo anterior permitió a los participantes avanzar en el desarrollo y comprensión de las Actividades en forma colaborativa y sin depender de un tutor.

Las acciones que tomó el ED en sus intervenciones en los foros expandieron las discusiones en tres direcciones: (1) favorecieron la creación de grupos de trabajo donde se discutían los diferentes episodios de la resolución de problemas, (2) dirigieron las discusiones y fomentaron la comprensión de conceptos e ideas matemáticas y (3) permitieron a los participantes formular preguntas y buscar respuestas, esto los llevó a plantear nuevas soluciones y extensiones al problema. Es importe reconocer que durante la etapa del diseño y la implementación de un MOOC se debe buscar que los participantes creen la conciencia de que ellos mismos monitoreen sus avances en la comprensión y uso de las ideas matemáticas en la resolución de problemas.

Un factor por considerar en el trabajo a futuro es la posibilidad de que los participantes construyan y presenten sus propios modelos dinámicos de los problemas, ya que, en este estudio, pese a que no se solicitó explícitamente, algunos construyeron y compartieron sus construcciones dinámicas fomentando la discusión de ideas, las formas de resolver y extender el problema.

In this study, the elements of the design and results of the implementation of a Massive Open Online Course (MOOC) based on the problem solving and the use of digital technology are analyzed and discussed. The results show that the design of the activities, the intervention of the MOOC design team in the discussion forums and the interaction among the participants allowed and favored the creation of a collaborative environment in problem solving. Participants shared and discussed their mathematical ideas, as part of a virtual learning community, which allowed them to formulate conjectures, explore and search properties to sustain relationships, and communicate results.

Key Words: Problem Solving, Technology.

Introduction

During and after their lessons, it is common for the students to use different digital platforms on Internet to have access to information about disciplinary contents, share and discuss ideas, take specialized courses in a topic and interact with experts. The spaces and times in which the learning is developed have been changed and altered by the connectivity of the network (Gros, 2016). Some universities have made available to the general public Massive Open Online Courses through different digital platforms. The virtual community that participates in these courses comprises a large group (usually thousands) of people with different levels of studies, age, domain or prior knowledge of the subject, among others. In the development of the activities of a MOOC there is not a professor in charge to answer or provide timely follow-up to each participant. Each member defines their degree of commitment and participation in the activities. For this study, the MOOC: Mathematical Problem Solving and use of Digital Technologies was built, based on the frameworks: Problem Solving (Santos-Trigo, 2014) and RASE (Resources, Activities, Support and Evaluation) (Churchill, King, & Fox Churchill, 2016). Churchill, et al., (2016) argue that an online learning environment must include elements that allow its participants to work and collaborate in team with others. The activities must motivate the active participation of the students in a reflecting environment of discussion and focus in a context in which the tasks involve the students in the episodes of problem solving: formulation of questions, search for different solution methods, exploration of different representations, search for patterns, variables, and relations between mathematical objects, arguments representation, communication of results and formulation of new problems (Santos-Trigo, 2014). The systematic use of digital technologies is important in the representation, exploration, communication and understanding of mathematical concepts in problem solving (Santos-Trigo, Moreno-Armella, 2016).

In this study, it was interesting to analyze the design of the mathematical activities and the forms of mathematical reasoning of the participants related to: (1) the question formulation and the search for different ways to answer them (2) the formulation of conjectures based on the movement of mathematical objects and qualification of attributes, e.g. measure of segments, angles, areas etc. and (3) the search for arguments that validate those conjectures moving from the empiric and visual arguments to the geometric and algebraic arguments. In this way, the research question that guided the development of this study was: How does the design and implementation of activities in a MOOC based on problem solving and coordinated use of digital technologies influence the construction and development of the participants' mathematical thinking?

Framework

The construction of the mathematical thinking is related to problem solving because it is a way that allows to identify, explore, test and communicate the solution strategies (Santos-Trigo, 2014; Schoenfeld, 1992). Diverse digital technologies offer the students different ways to represent and explore concepts and mathematical problems that extend those approaches based on the use of pen and paper (Santos-Trigo, 2014; Aguilar-Magallón & Poveda, 2017).

A Dynamic Geometry System (DGS) can be used to integrate the processes that are present in problem solving that allow to generate representations or dynamic models of the mathematical problems where the movement of particular objects (points, lines, segments, polygons, etc.) could be explored and explained in terms of mathematical relations. Hence, the systematic use of digital technologies is important in the representation, communication, and understanding of mathematical concepts in problem solving.

Churchill et al. (2016) argue that a model is needed for designing the activities that provides professors and researchers, guidelines to use digital technologies in the teaching and learning context. They propose the design model RASE, the Resources refer to the available materials for the students: videos, images, digital files, calculators, tools for the representation of mathematical situations, etc. The Activities must allow the students to be involved in the processes of discussion, analysis and reflection in collaboration with others.

The Support establishes that some means of consultation and communication must be included between the students, with the objective that they can get help or feedback at the moment that they need it and, in this way, to promote the independence from the professor or tutor. The Evaluation should encourage the improvement of the students' learning, therefore, it is necessary that when they express their ideas, they analyze the feedback received through support media, to refine or expand the initial concepts or ideas. In a MOOC the discussion forums become a mean of conversation between their participants and give them the opportunity of proposing, getting to know, contrast own ideas and those of others (Poveda & Aguilar-Magallón, 2017). Ernest (2016) argues that in the conversation are involved: a speaker/proponent, a listener/critic and a Mathematical Text. The speaker/proponent proposes an idea (Mathematical Text) and the listener /critic answers by giving his point of view, accepting or changing the original idea. After that, the speaker/proponent can assume the listener /critic role, in this way the roles are reversed.

Methodology

The objective of the activities design of the course was to emphasize that the learning of mathematics requires problematizing or questioning the tasks or situations, thinking about different ways to solve a problem, understanding and using different representations, interpreting the solution and communicating the results. Through this process, the formulation of questions becomes a medium that allows the participants to build, develop, re-think or transform their ways to understand and solve problems. The Resources included representations or dynamic models of problems built in GeoGebra, links to the Wikipedia platform and the videos of KhanAcademy for the study of mathematical concepts and relationships.

The activities included three stages: 1) *Movement*: the participants had the opportunity to explore a dynamic model of a problem and the behaviour of some of its parts that results from the movement of other elements, 2) *Conjecture*: the objective is that from the movement, the participants will formulate conjectures that can be supported or refuted from visual or empirical arguments and 3) *Justification*: it was tried that all conjectures were justified through arguments that involved mathematical properties and results. The forum was used to give the participants the possibility to propose their doubts and ideas to others as many times as needed. In this way, the students' work can be used as a reference point for others to take up or extend the ideas, contrast them and discuss them. In addition, in the forums the participants can receive feedback about their proposed ideas, it can be useful for the analysis and reflection as part of the Evaluation process.

Development of activities, participants and procedures

The MOOC was built and implemented in the platform *Open edx* (https://open.edx.org/about-open-edx), it has a duration of seven weeks and it was composed by six activities. The only requirement for registration was that interested individuals had a minimum schooling level equivalent to grade 12. 2669 people signed up for the MOOC. At the beginning of the course, only Activity 1 was visible, Activity 2 was shown one week later and so on, without restricting access to the previous ones. During the seven weeks in which the course was available to the participants, the Design Group (DG) monitored the development of the activities and the participation in the forums. The work consisted in:

1. At the beginning of the activity, the comments were classified in four categories: answers to the questions that were proposed in each activity, approaches to problem solving (correct and incorrect), new questions asked by the members and proposals to extend the problem. Later, the comments with similar ideas were eliminated, two or three were chosen from each category and were placed in such way that they were shown at the beginning of the conversations, in this way the participants could give them priority in their analysis.
2. During the Activity, it intervened in the forums only when it was necessary to orient and extend the discussion. Questions from the participants were never answered directly, but some different questions were asked in order to generate more discussion and to allow the participants to find different ways to create the solution by their own.
3. At the end of the activity, questions were raised to promote the extension the topic and for the participants to look to extend the initial problems.

The data of this study were collected through the discussion forums. The unit of analysis were the conversations of the participants in each activity. At the end of the course, the design team analyzed the conversations. Interested to analyze and document how the activities design, the discussion and interaction between the participants and the actions that the design team took in the forum influenced in the development of the episodes of problem solving, according to the framework of the problem solving and the use of dynamic technologies of Santos-Trigo (2014).

Presentation of results

One of the Activities proposed in the MOOC is discussed: Two farmers want to plant land that is shaped like a square. How to divide the land so each farmer can plant exactly the same area? The activity consisted in developing two solutions to the problem, in each one a dynamic model was given and a set of questions to guide the work of the participants. Chart 1 shows the stage in which the members of the MOOC had the opportunity to move the objects to look for relations or invariants and a summary of the conversations in the forum.

Chart 1: The movement and the results of the dynamic exploration.

The movement and the exploration	Results of the interaction in the forums
 **Movement:** When we move the points A, B, P & Q, what happens with the areas of the regions? Where to place the points P and Q so that the areas of the $AQPD$ & $QBCP$ regions are the same?	All the participants pointed: 1. It is possible to move the point P and Q and obtain regions of same areas regardless of the size of the square side. 2. The object movement and the measurement of the areas can give some solutions: $P = C$ y $Q = A$; $P = D$ y $Q = B$ & PQ perpendicular bisector of DC. In this part of the activity, the participants could not observe that a general solution is when $O \in PQ$ ($O$is the square center).

The next questions asked to the participants was: Is the center of the square and the position of the line that divides the land in regions of the same area important? All of them made their first conjecture based in visual and empiric arguments (measurement of the areas $AQPD$ y $QBCP$): "*If $O \in PQ$ then it divides the square into two figures of the same area*".

The DG asked: *"How many solutions are there?"* The answers agreed that there is an infinite number of solutions. In the search for a justification of the conjecture, the participants were asked: What concepts, properties and mathematical resources can be used to support the conjecture? In the conversations all of them pointed out the need to trace the diagonals of the square and use its properties (Justification 1, Chart 2).

The participant P_1 presented a way to justify the conjecture: he built a dynamic model, answered the doubts of others and gave feedback to the people that could not understand the justification. (Justification 2, Chart 2).

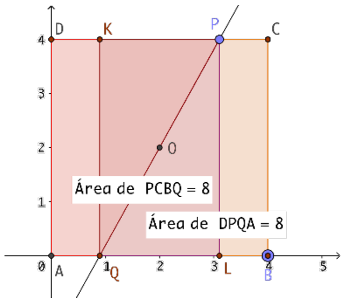
The next section of the activity guided the participants in the exploration and searching of another solution, the details are showed in Chart 3.

Later, the members formulated the conjecture, the next section consisted in searching for mathematical relationships to justify it, therefore, in the dynamic model of the square the lines FH and EG were included. All the participants discussed and presented the Justification 1 that is shown in Chart 4.

Chart 2: Resources and strategies of exploration and solution.

Justifications	Resources and strategies of exploration and solution
Justification 1 	**Resources:** Properties of the square and its diagonals, angles between parallel lines, angles opposed by the vertex and congruence of triangles. **Strategy:** Put P on the side DC, build the line PO and trace the diagonals of the square. **Justification:** ΔDOP≅ΔBOQ (SAS), so $DP = BQ$, therefore, the polygons $AQPD$ y $QBCP$ have equal area.

<table>
<tr>
<td>Justification 2 of P_1



</td>
<td>Resources: Properties of the square, congruence of triangles, angles between parallel lines, properties of parallel lines and perpendicular lines.
Strategy: Placed P on DC, trace the PO line and build perpendicular lines to DC and AB that pass through P and Q, respectively.
Justification: $\Delta QKP \cong \Delta PLQ$ (SAS) and the rectangles $AQKD$ and $LBCP$ are congruent (arguments are not given). Participants' questions in the forum: (1) What happens if P=C & Q=A? P_1: "We have two congruent right triangles", (2) "¿How do you know that AQ=PC?" P_1 reference Justification 1.</td>
</tr>
</table>

Chart 3: Movement and exploration importance

<table>
<tr>
<th>Stages of the activity</th>
<th>Interaction in the forums</th>
</tr>
<tr>
<td>
P is inside the square.
Movement. What regions can be assigned to the farmers so that each one can plant the same area?</td>
<td>Ten participants pointed out some solutions:
1. P matches with any vertex, P is the central point of a side or P is the center of the square.
2. P belongs to a diagonal of the square or to the line that joins the middle points of AB and DC.

In this part of the activity, none of the participants observed solutions based on the movement of objects, for instance, the solution is obtained for any position of point P inside the square.</td>
</tr>
<tr>
<td>Conjecture: Is it possible to identify any relationship between the values of the areas? When varying the position of the point P, what happens to the sum of the areas of the triangles ABP and CDP?</td>
<td>All participants formulated and shared the conjecture: "If P is a point that is inside of the square, the sum of the areas of the opposite triangles is the half of the square ABCD". Some participants gave feedback to others, for example, someone mentioned: "P always generates four triangles", it was suggested: "Move point P in such a way that it matches with a vertex, or P over one of the sides".</td>
</tr>
</table>

The Justification 2 of Chart 4 was built and shared by participant P_2. The other participants approved the ideas and built algebraic models as another way to support it.

Chart 4: Resources and strategies of exploration and solution.

Justification of the Solution 2	Resources, strategies and justifiaction
 What properties are important to present an argument that supports the conjecture? What properties have the triangles that are generated when we trace the perpendicular lines to the sides passing through the point P?	**Resources:** Properties of parallel and perpendicular lines, congruence of triangles. **Strategy 1**: Trace the perpendicular lines EG and FH to the sides of the square that pass by P. **Justification 1.** $\Delta AGP \cong \Delta AFP$ (SSS) and $\Delta GBP \cong \Delta HBP$ (SSS), at the same time $\Delta CEP \cong \Delta CHP$ & $\Delta EDP \cong \Delta FDP$. Therfore, Area ΔDCP + Area ΔABP = Area $\Delta BCP + Area\Delta DPA$. **Strategy of P_2.** the sum of ΔAGP and ΔDPE, without taking into account the position of the point P, is constant and equal to BC. **Justification of P_2:** The sum of the heights of ΔPCD and ΔABP is equal to the sum of the heights of ΔDAP y ΔBCP, so, the four triangles have the same base and Area ΔPCD + Area ΔABP = Area $\Delta DAP + Area\Delta BCP$.

The DG asked in the forum: Is there another way to solve the problem? What other questions can you ask? The participant P_3 revisited the ideas from Justification 2 of Chart 4 and built a dynamic model of the square with other solution (Justification 1 of the Chart 5). Other participants approved the ideas and discussed another way to support the conjecture (Justification 5 Chart 5).

Chart 5: Another Solution

Another solution	Resources, strategies and justification
	**Resources:** Properties of the parallels and perpendicular lines. **Strategy:** Placed the mobile point E on DC, trace the perpendicular line m to DC that passes by E. Placed two mobile points $F$and G on m. **Justification 1:** The sum of the heights of ΔAFD and ΔBCG is constant and equal to AB for all positions of E, F and G, therefore, Area ΔAFD + Area ΔBCG is half of the square's area. **Justification 2.** Trace parallel lines to the sides that pass by the mobile points F & G to generate congruent triangles.

The Chart 6 shows two of the questions the participants formulated and the answers they found.

Chart 6: Extensions of the problem.

Formulated questions	Justification
Extension 1 *"How to divide the land into 4 regions with the same area?".*  	During the search for the answers, one participant used the property: Each median divides the area of the triangle in half. In this way, he built and presented a dynamic model similar to the one of the Solution 2 where he traced the medians of triangles ($EI, EH, EG \& EF$). The sum of the areas of triangles DEI and CGE is a quarter of the square's area.
Extension 2 *"Is it possible to determine a quadrilateral inscribed within any other such that it has half of its area?".*	The participants shared information of Wikipedia related to the theorem of Varignon: *The midpoints of the sides of an arbitrary quadrilateral form a parallelogram. If the quadrilateral is convex or concave, then the area of the parallelogram is half the area of the quadrilateral.*

Discussion of the Results

The activity design guided the participants' work towards searching different ways to explore the dynamic models. Each model represented to the participants a starting point that allowed them to identify concepts, propose conjectures based on the movement of the mathematical objects present in the dynamic setting and their relationships or invariants.

The use of discussion forums helps the communication, analysis and the contrast of mathematical ideas, in addition, they allowed the participants to give and receive feedback from others. This was important for transiting from visual and empirical solutions (associated with the use of tools such as movement of objects within the setting, quantification of attributes as measures of segments, angles, areas, etc.) to the presentation of geometric and algebraic arguments in the validation of the formulated conjectures.

During the development of the course, the monitoring that the DG did in the classification of the comments helped the discussion, re-think of mathematical concepts and ideas and the episodes of problem solving. For example, the participants formulated conjectures, they presented arguments to justify them and also proposed new problems. The proposal of questions made by the DG helped the discussion of mathematical ideas, the proposal of new solutions and extensions of the problem. (See Chart 2, 5 and 6).

In addition, a group of participants assumed the role of giving feedback to the questions of other people, this promoted the collaborative work and fomented the independence of the participants in the construction process and the development of mathematical thinking.

Conclusions

The results show that the different digital technologies used in this study and the integration of the components: Resources, Activities, Support and Evaluation based in problem solving allowed to create a collaborative work environment. The digital platform allowed the inclusion of dynamic representations of the problems elaborated in GeoGebra, in which the participants had the opportunity to explore, identify concepts, look for conjectures and different arguments to justify them. In this process, they used strategies associated with the use of the tool like object movement within the dynamic setting and the quantification of its attributes (lengths and areas). During the development of the Activities, a group of participants provided feedback to others, which helped to clarify ideas related to mathematical concepts, with the exploration of the dynamic model, with the formulation of conjectures and their justification. This allowed the participants to advance in the development and understanding of the activities in a collaborative way and without depending on a professor or tutor.

The actions taken by the DG in its interventions in the forums increased the discussions in three directions: (1) they helped the creation of working groups where the different episodes of problem solving were discussed, (2) led discussions and fomented the understanding of mathematical concepts and ideas and (3) allowed the participants to propose questions and look for answers, this led them to propose new solutions and extensions to the problem. It is important to recognize that during the design and implementation stage of a MOOC, participants should be expected to create an awareness that they themselves monitor their progress in understanding and using mathematical ideas in solving problems.

One factor to be considered in future work is the possibility for participants to build and present their own dynamic models of the problems, since, in this study, although it was not explicitly requested, some built and shared their dynamic constructions helping the discussion of ideas, the solutions and extensions for a problem.

Introducción

La resolución de problemas es un tema importante en la agenda de investigación en Educación Matemática. Actualmente se reconoce que el uso de tecnologías como un Sistema de Geometría Dinámica (SGD) genera oportunidades para desarrollar conocimiento matemático, pero también permite transformar escenarios de enseñanza alrededor de la resolución de problemas (Santos-Trigo, Reyes-Martínez & Aguilar-Magallón, 2016). Un principio fundamental de este enfoque de resolución de problemas y uso de tecnologías digitales es que el individuo reconozca la resolución de problemas como una oportunidad para plantear preguntas relevantes de forma constante y sistemática que le ayude en su actividad matemática (Santos-Trigo, Reyes-Martínez & Aguilar-Magallón, 2015). Para este estudio, resultó importante investigar en qué medida el uso de un SGD (GeoGebra), permite a los participantes involucrarse en actividades de planteamiento de problemas. En este camino, la pregunta de investigación que guio el desarrollo de este estudio es: ¿Cuáles son las heurísticas y estrategias que exhiben profesores y futuros profesores en el proceso de construir representaciones dinámicas de la figura presente en un problema geométrico de demostración?

Marco Conceptual

Por un lado, la formulación de preguntas relevantes o actitud inquisitiva al enfrentarse a situaciones problemáticas es un aspecto central de la actividad matemática de un individuo. Comúnmente el planteamiento de preguntas durante todo el proceso de resolución de problemas conduce a la formulación de nuevos problemas (Osana & Pelczer, 2015). Por otro lado, el planteamiento de preguntas y problemas es importante no solo para el desarrollo de habilidades matemáticas en profesores y futuros profesores, sino también para el desarrollo de habilidades didácticas. En la literatura se reconoce que, en general, profesores y futuros profesores tienen serias dificultades al enfrentarse a tareas de planteamiento de problemas (Rosli et al., 2015).

¿Cuál es el papel de las herramientas digitales en el planteamiento de preguntas y problemas y en la formación de profesores para desarrollar habilidades de formulación y reformulación problemas? Leikin (2015) argumenta que el uso de un SGD es útil para formular preguntas y problemas relacionados con el análisis de relaciones matemáticas presentes en figuras que se usan para resolver problemas geométricos. Aguilar-Magallón y Poveda-Fernández (2017) afirman que las permisibilidades de un SGD (como el arrastre de objetos, la medición de atributos, el uso de deslizadores y la visualización de lugares geométricos) en conjunto con heurísticas de resolución de problemas (como relajar las condiciones del problema, analizar casos particulares y visualizar patrones e invariantes) pueden motivar diversos episodios de formulación y resolución de problemas.

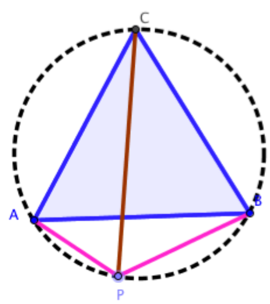
Metodología

Participantes

En este estudio participaron nueve estudiantes de un curso de Maestría en Educación Matemática durante cuatro sesiones semanales con duración de tres horas cada una. El grupo estuvo conformado por seis profesores en servicio y tres futuros profesores. Todos los participantes tenían formación académica relacionada con matemáticas.

El problema

Para este reporte se analizan los episodios de formulación y resolución de problemas que surgieron a partir del análisis de la figura presente en un problema geométrico de demostración (Figura 1).



Sea ABC un triángulo equilátero y P cualquier punto de la circunferencia que lo circunscribe, demostrar que $AP + BP = CP$.

Figura 1. El problema

Resultados

En esta sección se expone un episodio de formulación y resolución de problemas que fue motivado por el uso de GeoGebra. En particular, el análisis se centró en las formas de razonamiento, recursos y heurísticas que exhibieron los participantes en este proceso.

Construcción de una representación dinámica del problema

¿Cómo obtener una representación dinámica del problema utilizando el SGD? Los participantes formularon dos problemas relacionados con dos caminos para obtener una representación dinámica del problema: 1) construir un triángulo equilátero y luego trazar su circunferencia circunscrita y 2) inscribir un triángulo equilátero en una circunferencia dada. En la Tabla 1 se muestra un acercamiento dinámico a la solución del segundo problema mostrado por los participantes. Este acercamiento estuvo basado en la heurística de relajar las condiciones del problema y la visualización de lugares geométricos por medio del arrastre de objetos de la configuración dinámica. Los participantes trazaron un triángulo que cumplía de forma parcial con las condiciones del problema; trazaron un triángulo equilátero con dos vértices móviles sobre la circunferencia. Posteriormente, mediante el movimiento de la configuración plantearon las condiciones necesarias para resolver el problema.

Tabla 1: Acercamiento dinámicos y solución empírica mostrada por los participantes.

Configuración	***Análisis***
 1. Puntos C y D móviles. Se traza el triángulo CDE equilátero por medio de circunferencias. Lugar geométrico descrito por el punto E cuando se mueve el punto C.	***Recursos.*** Triángulo equilátero y lugar geométrico. ***Estrategia dinámica.*** Relajar las condiciones del problema. EL triángulo CDE es equilátero, pero tiene sólo dos vértices inscritos en la circunferencia. Así la estrategia de exploración consiste en mover el punto C hasta que el punto E pertenezca a la circunferencia inicial. ***Solución empírica.*** La intersección del lugar geométrico descrito por el punto E con la circunferencia inicial definen uno de los vértices del triángulo equilátero inscrito (otro es el punto D y el último se encuentra por construcción).

En este acercamiento se observa el uso de lugar geométrico como herramienta para resolver problemas, sin embargo, en una primera instancia la solución se quedó en un nivel visual y empírico debido a la imposibilidad de GeoGebra para intersecar lugares geométricos. Para poder intersecar lugares geométricos (en GeoGebra) se requiere transformarlos en objetos geométricos robustos; en otras palabras, que su construcción dependa de ciertos elementos bien definidos. Por ejemplo, para robustecer un lugar geométrico que se supone circunferencia se necesita su centro y radio. En la búsqueda del centro para trazar de forma robusta la supuesta circunferencia usada en el acercamiento dinámico de la Tabla 1, los participantes se dieron cuenta que la intersección F de la mediatriz del segmento variable DE con la circunferencia original era invariante (Figura 2). Así supusieron que el punto F era el centro de la circunferencia y midieron la distancia al punto E para verificar que era constante. La detección de invariantes en la exploración del modelo dinámico de la Tabla 1 permitió a los participantes encontrar una solución sintética (que puede obtenerse con regla y compás) al problema (Tabla 2).

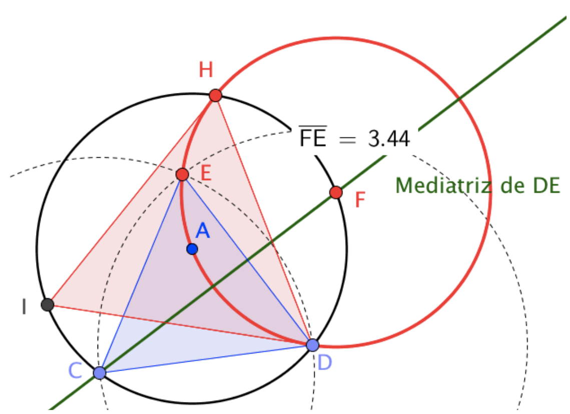


Figura 2. El punto $\boldsymbol{F}$ de intersección de la mediatriz de $\boldsymbol{DE}$ con la circunferencia inicial es invariante y es el centro de la circunferencia descrita por el punto $\boldsymbol{E}$.

Hodges, T.E., Roy, G. J., & Tyminski, A. M. (Eds.). (2018). *Proceedings of the 40th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Greenville, SC: University of South Carolina & Clemson University.

Tabla 2: Solución sintética encontradas por los participantes al analizar modelo dinámico.

Solución sintética	***Descripción***
 1	Punto C cualquiera sobre la circunferencia inicial de centro en A. Circunferencia con centro en C y radio CA. Los puntos de intersección E y D de las dos circunferencias formarán uno de los lados del triángulo equilátero inscrito. El tercer vértice F se encuentra con la circunferencia de centro en D y radio DE.

Discusión de resultados

Con ayuda del SGD, los participantes pudieron encontrar tres tipos de soluciones al problema de inscribir un triángulo equilátero en una circunferencia: soluciones empíricas, robustas y sintéticas. En una primera instancia, debido a que en GeoGebra no se pueden intersecar lugares geométricos, las solución encontrada fue empírica. En esta dirección, para encontrar la solución robusta (en términos de intersecciones) se requirió transformar (robustecer) el lugar geométrico. Posteriormente, la exploración de las propiedades del lugar geométrico mostrado en Tabla 1 permitió a los participantes encontrar una solución sintética al problema, es decir, una solución que puede obtenerse con trazos básicos de regla y compás. Tanto para las soluciones empíricas como para las soluciones exactas (robustas y sintéticas), fueron importantes las heurísticas de visualizar patrones o lugares geométricos, explorar casos particulares y detectar invariantes.

Conclusiones

Existe una gran variedad de problemas geométricos en los cuales la información o condiciones son presentados por medio de figuras o configuraciones geométricas. Comúnmente, cuando se resuelven problemas de forma tradicional (con papel y lápiz) la tarea de reconstruir las figuras que aparecen en los enunciados no es relevante, pues únicamente interesan las relaciones matemáticas implícitas en dichas figuras. Cuando se trabaja dentro de un SGD resulta primordial pensar en las formas de obtener representaciones dinámicas para explorar los problemas. Así, los resultados del estudio mostraron que considerar distintas maneras de representar una situación problemática puede motivar episodios de planteamiento de problemas.

This document reports the analysis of problem-solving and problem-posing episodes related to constructing dynamic configurations in a Math Education Masters course. What are the heuristics and strategies that teachers and prospective teachers exhibit in the process of constructing dynamic representations of the figure in a geometric problem? The results show that the use of GeoGebra motivates teachers to pose and solve problems. In this way, some important strategies were to relax the conditions of the problem, the exploration of particular cases, the search of patterns and invariants and the visualization of loci of intersection points.

Keywords: Problem Solving, Technology, Geometry and Geometric and Spacial Thinking, Teachers` Preparation in Training

Introduction

Problem solving is an important issue in the research agenda for Mathematics Education. Currently, it is recognized that the use of technologies such as a Dynamic Geometry System (DGS) generates opportunities to develop mathematical knowledge, but also allows transforming teaching scenarios into problem-solving scenarios (Santos-Trigo, Reyes-Martínez & Aguilar-Magallón, 2016). A fundamental principle of this approach for problem solving and use of digital technology is that the individual should be able to recognize that it provides an opportunity to, constantly and systematically, formulate relevant, helpful questions in their mathematical activity (Santos-Trigo, Reyes-Martínez & Aguilar-Magallón, 2015). For this study, it was important to investigate to what extent the use of a DGS (GeoGebra) allows participants to get involved into problem-solving activities. The research question that guided the development of this study was: What are the heuristics and strategies that teachers and future teachers develop in the process of constructing dynamic representations of a figure in a geometric-demonstration problem?

Conceptual Frame

A critical characteristic in a mathematical activity is the capacity to formulate relevant questions or possessing an inquisitive attitude when facing problematic situations. Frequently, formulating questions throughout the problem-solving process leads to formulation of new problems (Osana & Pelczer, 2015). Furthermore, formulating questions and new problems is a key factor not only for developing mathematical skills in teachers and prospective teachers, but also for the development of didactic skills. Previous studies recognize that, in general, professors and prospective teachers have serious difficulties when facing problem-posing tasks (Rosli et al., 2015). What is the role of digital tools in formulating questions and problems, and in training teachers to develop problem-posing skills? Leikin (2015) argues that using DGS helps to formulate both questions and problems related to the analysis of existing mathematical relationships in figures used to solve geometric problems. Aguilar-Magallón and Poveda-Fernández (2017) affirm that the affordances of DGS (such as dragging objects, measuring attributes, use of sliders, and loci visualization) together with problem-solving heuristics (such as relaxing problem conditions, analyzing particular cases, and visualizing patterns and invariants) motivate diverse episodes of problem formulation and resolution.

Methodology

Participants

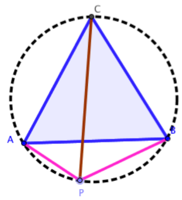
Nine students from a Math Education Masters course participated in this study, over four three-hour, weekly sessions. From this group, six were in-service teachers, and three were prospective teachers. All the participants had academic training related to mathematics.

The problem

The study consisted in analyzing the problems that emerged from the analysis of Figure 1, presented in a geometric-demonstration problem.

Results

This section presents an episode of problem posing and solving motivated by the use of GeoGebra. In particular, the analysis focused on the reasoning forms, resources and heuristics exhibited by the participants in this process.



Let ABC be an equilateral triangle and P be any point of the circumscribing circle, show that $AP + BP = CP$.

Figure 1. The Problem

Construction of a Dynamic Representation of the Problem

How to construct a dynamic representation of the problem using the DGS? The participants formulated two problems for obtaining dynamic representations of them: 1) construct an equilateral triangle and then trace its circumscribed circumference and 2) inscribe an equilateral triangle on a given circumference.

Table 1 shows a dynamic approach for the solution of the second problem. This approach was based on the heuristic of relaxing the problem conditions, and the visualization of loci through dragging objects allowed by dynamic configuration. Participants drew a triangle that partially met the problem conditions; they drew an equilateral triangle with two dynamic vertices on the circumference. Afterwards, through moving the configuration, they formulated the necessary conditions to solve the problem.

Table 1: Dynamic Approach and empirical solution shown by the participants.

Configuration	***Analysis***
 1. Dynamic Points C and D. The equilateral triangle *CDE* is traced through circumferences. Locus described by point *E* when the point *C* moves.	***Resources.*** Equilateral Triangle and locus. ***Dynamic Strategy.*** Relaxing the problem conditions. The triangle *CDE* is always equilateral, but only two of its vertices are inscribed in the circumference. Thus, the exploration strategy consists of moving point C until point E belongs to the initial circumference. ***Empirical Solution.*** The intersection of the locus described by point E with the initial circumference defines one of the vertices of the inscribed equilateral triangle (another one is point D and the last one is by construction).

In the participants' approach, the use of locus as a problem-solving tool is observed; however, in a first instance, the solution remained at a visual and empirical level due to the impossibility of GeoGebra to intersect geometric places. This intersection (in GeoGebra) is only possible if the objects are transformed into robust geometric objects; meaning that its construction depends on well-defined elements. As an example, in order to make robust a locus that is assumed as a circumference, its center and radius are required. While searching for the center, in order to draw the robust circumference used in this approach, participants realized that the intersection of the perpendicular bisector of the variable segment DE with the original circumference was invariant (point F in Figure 2). Thus, they assumed that point F was the center of the circumference, and measured the distance to point E to verify that it was constant. Detecting invariants while exploring the dynamic model shown in Table 1, allowed the participants to find a synthetic solution (which can be obtained with ruler and compass) to the problem (Table 2).

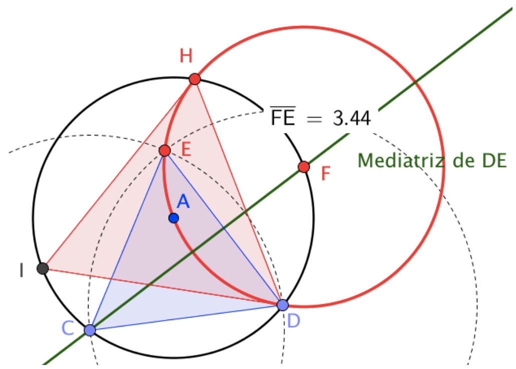


Figure 2. The intersection point, F, of the ED perpendicular bisector with the initial circumference is invariant and the center of the circle described by point E.

Table 2: Synthetic solution found by the participants when analyzing dynamic model.

Synthetic Solution	***Description***
 1	Dynamic Point C on the initial circumference with center in A. Circumference with center in C and radius CA. The points of intersection, E and D, of the two circles form one of the sides of the inscribed equilateral triangle. The third vertex F was found whit the circumference of center at D and radius DE.

Discussion of Results

Using the DGS, the participants were able to find three types of solutions to the problem of inscribing an equilateral triangle in a circumference: empirical, robust and synthetic solutions. The empirical solution was the first one to be found, since GeoGebra cannot intersect loci. In this direction, to find the robust solution (in terms of intersections), it was required to transform (make robust) the locus. Exploring the properties of the locus shown in Table 1 allowed the participants to find a synthetic solution to the problem, that is, a solution that can be obtained with basic rules and compass traces. For both empirical and exact solutions (robust and synthetic), three problem-solving heuristics were essential: pattern or loci visualization; exploring particular cases; and detecting invariants.

Conclusions

There are a variety of geometric problems in which the information or conditions are presented by means of figures or geometric configurations. Commonly, when problems are solved in a traditional way (with paper and pencil), reconstructing the figures that appear in the statements is irrelevant, since only the mathematical relationships implicit in these figures are important. When working within a DGS, it is essential to think about ways to obtain dynamic representations to explore problems. The study results showed that considering different ways of representing a problematic situation by dynamic models motivates the formulation and resolution of new problems.

This study investigated how a weekly mathematically-focused text message to parents, which shared 1) what children were learning about in mathematics class, and 2) an idea to build on this mathematics topic at home, were perceived and used by parents. We found that parents highly valued this regular communication, not only because they appreciated hearing from the school but because it connected them more with their child and their child's mathematical learning. Parents also shared that the texts influenced how they thought about their child's mathematical learning and increased mathematical talk at home.

Keywords: Elementary School Education, Equity and Diversity, Technology

Objective of the Study

The overarching goal of the study was to investigate how mathematically-focused text messages can be used to connect linguistically-diverse families with what their child is learning in mathematics. We first created relevant and mathematically-focused text messages that had the potential to support parents to build on their child's school mathematical learning. After creating the texts, our goal was to investigate how families used the texts at home to see if parents perceived them as supporting their child's learning, and how the texts affected parents' feelings of connection to schools and their children.

Perspective/Rationale

Home-school partnerships and communication are critical for educational growth and development in children (Epstein, 2001) and connecting the home and school settings develops a cohesive learning environment for children (Christenson, 2004). Essential to developing home-school partnerships is active, productive, effective, regular communication.

Although parents want better communication with teachers and schools (Miretzky, 2004), Davies (1991) found that families often wait for schools to initiate contact. Text messaging is one promising way to better communicate with parents. This innovative pathway for building home-school partnerships and communication opens an efficient, nearly universal avenue for schools to communicate with and engage parents. Ninety-one percent of American adults own cell phones (Rainie, 2013). Of these users, 98% can receive text messages of which 95% are opened (Ehrlich, 2013). Additionally, Hispanics (88%), African Americans (93%) and whites (90%) have similar cell phones ownership rates mitigating the Internet access gap that has plagued the use of other electronic communications such as email, student information systems, and websites (Rainie, 2013).

Studies on parent communications using text messages have promising results. York and Loeb (2014) found using text messages with tips for parent engagement in literacy increased parent engagement with their children's early literacy development and increased in student literacy assessment scores. Kraft and Monti-Nussbaum (2017) used text messages to engage parents as partners in successfully mitigating the summer slump in early literacy. While these results show potential, there is a dearth of literature implementing similar communication strategies and support for parents and teachers in developing early mathematics skills and concepts. Additionally, little of this research captures qualitative data from parent perspectives.

A review of the literature points to a need to investigate how mathematically-focused texts can be used to connect parents and teachers, which leads to the research questions: How do we create relevant and useful mathematically-focused text messages that support parents to build on students' mathematical learning? How do families use the texts at home? How do the texts affect parents' feelings of connection to schools and their children?

Methods

Context

The study took place in a culturally and linguistically diverse school. The school's student population during the 2017-18 academic year was almost 500 (43% Black, 35% Hispanic, 8% White, 9% Asian, 1% Native American, and 4% multiracial). The overall English language learner population was 40% (District Report, 2018). Of that population, about half are Spanish speakers, and the remaining ELL students speak Vietnamese, French, Lao, Nilo-Saharan, Bosnian, Burmese, Kru, Karen, Nepalese, Arabic, Kunama, Mabaan, Nuer, Swahili, Somali, Dinka, Tigrinya and Zapoteco (teacher communication, 2015). Ninety-seven percent of the school's students receive free or reduced lunch (District Report, 2018).

Within the school, the study worked with the school's four kindergarten teachers and their parents. During the two years of the study, seven to 12 different primary languages were spoken by kindergarten parents.

Participants

The researchers designed mathematically-focused text messages for the parents and/or guardians of four kindergarten classes throughout the school year. Data was collected during the 2016-2017 and 2017-2018 school years.

The four kindergarten teachers taught all the kindergartners in the school. Three of the teachers had taught kindergarten at the school for over 15 years and the fourth teacher, while new to the school and to kindergarten, had previously taught preschool for over 10 years in the same district.

All kindergarten students' parents or guardians were recruited to sign up for the text messages during the school's Meet-the-Teacher night, which was held the day before school began, and at parent conferences in fall and spring. During the 2016-2017 school year, 22 out of 62 parents signed up (35%). All text messages were sent only in English that year. During the 2017-2018 school, 43 parents out of 84 signed up for the texts (51%). This year, recipients were able to choose to receive text messages in English only (21 parents), Spanish only (5), or both languages (17). In both years, every parent asked has signed up to receive the texts, with one exception. The challenge was not convincing parents to participate in receiving the texts; the challenge was finding the parents to ask them.

The Text Messages

The researchers developed mathematically-focused text messages for the parents and/or guardians of students in the kindergarten classes at the school. The weekly texts included 1) what the children where learning about in mathematics class and, 2) an idea for how to engage in similar mathematics at home. These suggestions for engagement were designed to take only a short time to implement (3-5minutes) but could be adapted and repeated as often as a parent or child choose. Each text was limited to 128 characters, so being concise and clear was a challenge. An example from November 8, 2016 shares what the children were learning about in mathematics and a related activity:

> Text 1: In math class this week we've been counting and writing numbers up to 10.
> Text 2: Activity-Ask your child to write his/her name. Write your own name. Ask how many letters are in each name. Which name has more?

The mathematically-focused text messages were designed to encourage mathematical discussions between the parent and child at home. In this way, the child would have an opportunity to share his/her mathematical thinking with his/her parents and the parents will have an opportunity to extend their child's mathematical understanding.

Teacher Focus Groups and Classroom Observations

To ensure the text messages are aligned with the content, readable by parents, and relevant to the children, we conducted a teacher focus group to get feedback from the teachers on text message design and content. In year 1, we also visited each of the four classrooms two times per month to observe and take field notes of the mathematics that kindergartners were learning to align the text messages with the timing and nature of the content taught in the classroom.

Parent Focus Groups

Parent focus groups were held at two different points in the study (mid-year 2017-18 (n=7) and end-of-the-school-year 2016-17 (n=5); 2017-18 (n=10)) to gather information from parents about their perceptions and uses of the text messages.

Data Analysis

All the transcripts of parent and teacher focus group interviews were analyzed using NVivo software for qualitative research to support systematic procedures for coding and categorizing data. The data interpretation and reporting used an inductive approach incorporating systematic methods of managing data through reduction, organization, and connection (Dey, 1993). This approach allowed us to identify common themes, as well as divergent cases, looking across categories to see if there are underlying patterns to the responses.

Results

First, creating the first draft of the text messages involved reviewing the kindergarten curriculum and curriculum map for mathematics topics and timing, creating texts with specific activities, and reviewing these texts with the kindergarten teachers in a focus group to gather their feedback. We adapted the texts based on their feedback, which was primarily about aligning the math language to the math language they use in their classrooms and how they felt parents may understand the language. Then on a weekly basis, after observing in the classrooms and before the weekly texts were sent, we tweaked the texts again to make sure timing, activities, and language were aligned to the teachers' instruction.

Parent focus groups were held to gather information on parents' use and perspectives of the mathematically-focused texts. We discovered that parents found the text useful in fostering communication with their child; they appreciated knowing what their child was learning about in mathematics because it gave them background so they could discuss the content of what their child was learning about in school. As one parent said, "I really liked that, knowing what's going on. 'Cause he may, [child's name], may not be able to describe what's going on to me" (Parent focus group, May 30, 2017). Another parent shared a similar sentiment,

> When they come home I always ask them what they learned. And for their age, they're just like, "Um." And they just list all the fun stuff. 'We play. We ate.' And I'm just like, 'Okay.

> What did you actually learn?' The text messaging helped because I'm like, 'Okay, so you're making ways to make 10? Make five?' They're like, 'Oh yeah. We learned that.' So, then we started doing it. (Parent focus group, December 20, 2017)

Also, most parents shared ways that they adapted and extended the activities.

> We do [the math activity] in the car. And then um, when I do laundry on the weekends, my daughter's favorite thing to do is count out five dryer sheets to put in the dryer, because I always put extra. But she counts out five and then she looks at the knob and she puts it on 70 and turns it on. So, she's helping with chores while she's counting. (Parent focus group, December 20, 2017)

Parents said they felt more connected to their child's learning because of the texts and that it had increased their mathematical talk with not only their kindergarten child, but also other children in the family. "I put some stuff out for him to try and count and stuff and, and like she said, it's a learning thing because not only is my five-year-old learning, he, my two-year-old now is counting" (Parent focus group, December 20, 2017).

Conclusion

Using mathematically-focused text messages to communicate with parents is rare in the research literature. Working to communicate with linguistically diverse parents using texts is also rare in the educational research literature. These two gaps in the mathematics education research show the need for figuring out how we can use technology such as text messaging to better meet parents where they are and connect them more closely to their child's learning. This study began to address this need and found that receiving the texts made parents feel more connected to the school and their child's learning. Parents appreciated knowing what their child was learning, were able to do the math activities in the texts with their child, and often times incorporated the math ideas into regular household activities or extended the math ideas. Next year we are ready to expand beyond English and Spanish to the next three most popular languages in the school – Arabic, Swahili, and Vietnamese.

STUDENT ONTOLOGY AND EPISTEMOLOGY IN AXIOMATIC GEOMETRY USING TECHNOLOGY

Younggon Bae
Michigan State University
baeyoun3@msu.edu

In this theoretical paper, I address students' ontological and epistemological shifts that have been discussed in the existing literature of student learning of geometry. First, students make a shift in the ontological view of geometric models from Euclidean to non-Euclidean geometry, in which the geometric models are considered conscious artifacts of mathematical design. Second, students make a shift in the epistemological view of mathematical proofs from absolutism to fallibilism, in which proofs can be characterized with a variety of functions and forms. Drawing on the prior literature, I argue that making successful shifts can benefit students in axiomatic geometry and that such shifts can be facilitated by engaging in mathematical activities with supports of dynamic geometry environments. Examples of those activities that involve constructing and analyzing geometric proofs are illustrated.

Keywords: Epistemology, Geometry, Technology

The purpose of this theoretical paper is to address students' ontological and epistemological shifts that have been discussed in the existing literature of mathematics education regarding student learning of axiomatic geometry. Drawing on the prior literature, I argue that making successful shifts can benefit students in axiomatic geometry and that such shifts can be facilitated by engaging in mathematical activities with supports of Dynamic Geometry Environments (DGEs). In this paper, axiomatic geometry means a study of geometry with a focus on the axiomatic approach to understand various geometries with different axiomatic systems including Euclidean and non-Euclidean geometries.

A Shift in Ontology of Geometric Models for Axiomatic Geometry

In axiomatic geometry, students need to make a shift in ways of perceiving and interacting with geometric models. Understanding axiomatic systems and models involves knowing how geometric models are constructed with sophisticated mathematical designs, and why those models satisfy the given postulates of the systems. In many cases, especially for non-Euclidean geometry, the models are not just natural outcomes resulting from physical observations of existing figures. Rather, they are conscious artifacts produced by creative and elaborative mathematical design. This nature of non-Euclidean models indicates that students need to change their ways of perceiving geometric models, which have been developed through their prior experience in Euclidean geometry.

Hegedus and Moreno-Armella (2011) introduced *Euclidean ontology* in their analysis of historical development of non-Euclidean geometry. In Euclidean geometry, a student can draw a line on paper, which is an iconic representation of the pure abstraction of all lines. A diagram is merely a mirror of an *a priori* geometric figure. In axiomatic geometry, however, a diagram results from an interpretation of the figure in a given geometric model. For instance, Poincaré constructed a model of hyperbolic geometry with a particular interpretation of lines–arcs orthogonal to the unit circle–whereas Klein used Euclidean line segments inside the unit circle in his model. Those models are not natural beings that reflect abstractions of figures, rather artifacts to be constructed, verified, and explored by students investigating characteristics of the figures emerging across all possible interpretations.

The shift in ontology of geometric models from Euclidean to non-Euclidean geometry can be supported by DGE-activities that provides students with opportunities of conceptual embodiment of geometric models. The conceptual embodiment means to develop perceptual representations for figures in non-Euclidean geometry, which are not static mental images, rather dynamic mathematical structures that realize abstract concepts of geometry (Tall, 2008). In this regard, exploring behaviors of dynamic diagrams of figures in DGEs can facilitate students to develop perceptual representations of figures in non-Euclidean geometry. In this exploration, students can drag the figures and observe the dynamic responses to their manipulations. It enables students to build up their perceptual representations that they can access as engaging in formal reasoning. For example, Guven and Karatas (2009) showed that interactive diagrams of a DGE can support students' development of a conceptual embodiment of triangles in spherical geometry. In their study, the participants who engaged in DGE-activities investigating triangles on a sphere were able to create paper-and-pencil diagrams of spherical triangles in explaining the properties used in their proofs.

An Example: DGE-Construction of Poincaré Model

Constructing an interactive model of hyperbolic geometry in DGEs can provide an opportunity to experience both exploration of dynamic figures and design of mathematical models highlighted in the literature (Guven & Karatas, 2009; Otten & Zin, 2012). In this activity, students can develop perceptual representation of hyperbolic figures with its underlying mathematical structures and connect the observed properties of figures and mathematical structures. For example, students may recognize a hyperbolic line in Poincaré model becomes straight as the two distinct points getting close to a diameter of the unit disk (Figure 1). Knowing the underlying design of the lines in this model, students can explain this observation by imagining that the radius of the orthogonal circle diverges as the two points lie on the diameter. In addition, students can discover new concepts in hyperbolic geometry, which they have never seen in Euclidean geometry. For example, students can explore infinitely many parallel lines in hyperbolic geometry and discover particular set of parallel lines distinguished from others.

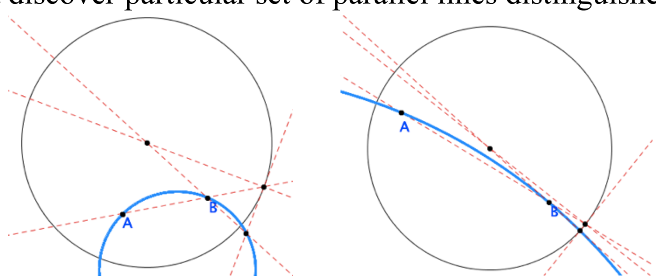

Figure 1. Hyperbolic lines in Poincaré model

A Shift to Fallibilist View of Mathematical Proof

In the axiomatic approach to geometry, college students encounter mathematical proofs less absolute and deterministic than what they have seen in their prior experience. Proving is not for generating an absolute certainty of a given mathematical statement as usually pursed in the absolutist view of mathematics. Instead, students can benefit from analyzing why a proof works in a system but not in others and investigating why a statement is not provable in a system. In this regard, students' views on proof in axiomatic geometry need a shift from the absolutist to the fallibilist view, which provide a variety of functions and forms of proofs.

Researchers have compared the two contrasting views of mathematics, absolutism and fallibilism, in terms of how proofs are perceived differently in each view (de Villiers, 1998; Ernest, 1991, Öner, 2008). In the fallibilist view, also frequently referred to as quasi-empiricist (Lakatos, 1976), mathematics is considered a product of social processes in which its concepts and proofs can be revised (Ernest, 1991). This view contrasts to the absolutist view, in which absolute certainty exists in mathematics. A proof in the absolutist view is a requirement for verification or conviction of mathematical knowledge. On the other hand, in the fallibilist view, personal conviction motivates one to seek a proof to convince oneself and/or intended audiences of the proof (Öner, 2008). As a quasi-empiricist, de Villiers (1998) argues that proving involves a variety of functions, including explanation, discovery, communication, and systematization, which constitute a broader set of mathematical activities.

These various functions of proofs in the fallibilist view can be promoted in axiomatic geometry by introducing an alternative form of proofs in DGEs. DGEs enable students to transform a written proof into a geometric construction. This visual and interactive proofs in DGEs is called a robust construction (Leung, 2008; Stylianides & Stylianides, 2005). Whereas a diagram in the written proof is a particular instantiation of generic objects from the abstract procedure of the construction, the constructed figures in DGEs serve as generic examples that can vary to represent any other particular example. This generalizability of the robust constructions in DGEs enables us to transform written proofs to geometric constructions without loss of generality. Creating and analyzing robust constructions provide students with opportunities to discover hidden assumptions, logical flaws in proofs, and axiomatic feature of the geometry.

An Example: Proof Analysis of Exterior Angle Theorem in Spherical Geometry

From the fallibilist view of proofs, I illustrate a DGE-activity of generating and analyzing robust construction of a proof for the exterior angle theorem–an exterior angle of a triangle is greater than either of the two opposite interior angles–that holds in Euclidean geometry but not in spherical geometry. Analyzing a proof of this theorem in those two geometries allows students to investigate the axiomatic natures of the systems related to the proof. By creating and interacting with robust constructions of a written proof in the two different geometric models (Figure 2), students can identify when the proof fails in spherical geometry as they stretch out the triangle. This activity can enable students to figure out what feature of the spherical geometry–two distinct lines intersect at two distinct points–causes this inconsistent result between two geometries. Furthermore, this activity can lead student to experience developing new mathematical knowledge. Students generate their own definitions of a family of triangles that do not satisfy the theorem in spherical geometry then refine the original statement by adding a specified condition describing such triangles.

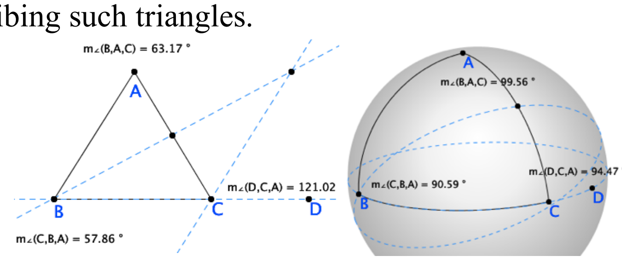

Figure 2. Exterior angle theorem in Euclidean (left) and spherical geometry (right)

Discussions

In this paper, I addressed students' ontological shift in geometric models and epistemological

Hodges, T.E., Roy, G. J., & Tyminski, A. M. (Eds.). (2018). *Proceedings of the 40th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Greenville, SC: University of South Carolina & Clemson University.

shift in mathematical proofs with respect to student learning of axiomatic geometry using technology. The DGE-activities illustrated in this paper show the potential of pedagogical role of technology in pursuing such goals in axiomatic geometry classrooms. To provide an implication to teaching practices, I propose an alternative way of mathematical communication promoting those activities–proving as performing. The act of proving in this view is not just to produce a tangible material (e.g., written proofs or images of geometric constructions), but can be to perform a proof that is transformed into the robust construction (Leung, 2008; Stylianides & Stylianides, 2005). Using screencast software, students can create video recording of their proofs in DGE and verbal annotation, showing how they created this generalizable geometric construction that is equivalent to the formal written proof.

Screencast presentations of DGE practices are beneficial for implementing student-centered and discourse-oriented geometry classrooms. First of all, video recordings afford a way for instructors to listen to their students verbally explaining their thinking while interacting with dynamic geometry construction. Second, practices of creating and sharing screencast presentations can empower teacher and students by establishing a mathematics register (Pimm, 1987) and enrich the communicative classroom community. The use of student-generated presentations can promote students' agency in classroom by sharing their own mathematics, understanding each other, and interpreting these ideas into formal statements. Lastly, screencast presentations can support equitable power dynamics between students (e.g., Esmonde & Langer-Osuna, 2013) in discourse-based geometry classrooms for all students by allowing them to share their voices with each other, especially for those who are marginalized in classroom discussions.

As the presence of instructional technology in secondary mathematics classrooms increases, the need for teacher resources supporting its use becomes of greater importance. Mathematics textbooks are one resource that teachers rely on for instruction, so it is important to know how they support teachers in this regard. We analyzed a nationally representative sample of 20 high school textbooks, including integrated/non-integrated and conventional/investigative curricula, to compare the level of technology integration and the types of technology utilized. Findings indicate a relatively low percentage of tasks integrating technology, and that calculators are the predominant technology within this sample.

Keywords: Technology, Curriculum, Curriculum Analysis, High School Education

A wealth of technologies exists for mathematics instruction, and research shows that the strategic use of technology has the potential enhance students' mathematical thinking and understanding (e.g., Hollebrands & Dove, 2011). As access to instructional technologies increases in secondary classrooms, the question arises as to the extent to which instructional technologies are integrated into contemporary curricula. As mathematics teachers rely on textbooks to guide their instruction (e.g., Banilower et al., 2013), it is important to understand how often and the types of technology that are included in mathematics curricula. This understanding may be used to guide professional development efforts and provide important guidance to curriculum developers.

This study examines the integration of technology use in current secondary mathematics curricula. We conducted a textbook analysis using a nationally representative sample of secondary mathematics curricula. We noted how often technology is incorporated and the types of technology used with respect whether the textbook was 1) Algebra 2 vs. Geometry vs. Integrated, and 2) investigative versus conventional.

Background

A number of textbook analyses have been published in the last ten years (e.g. Sherman, Walkington, & Howell, 2016; Otten, Gilbertson, Males, & Clark, 2014; Tarr, Grouws, Chavez, & Soria, 2013), but very few have examined the extent to which instructional technology is incorporated into curricula (Oner, 2009). We aim to address this gap in the literature regarding the content of current curricula.

In this study, we followed Stein, Remillard, and Smith (2007) in differentiating between two types of texts: "Investigative textbooks reflect a reform philosophy that is consistent with the recommendations of the *NCTM Curriculum and Evaluation Standards* (1989). Conventional textbooks refer to commercially developed textbooks that were not influenced by the earlier reform documents mentioned above" (Sherman et al., 2016, p. 118). Recent studies of integrated versus subject-specific curricula demonstrate an advantage for integrated over the subject-specific on standardized tests of student learning in high school algebra (Grouws et al., 2013) and geometry (Tarr et al., 2013)

Methods

This study examines current secondary mathematics textbooks to answer the questions: 1) how often do secondary textbooks incorporate tasks that utilize technology, and 2) what types of technologies are utilized?

To characterize technology use in secondary textbooks, a sample of twenty textbooks varying with respect to curricular focus, integrated versus non-integrated, and conventional versus investigative was chosen. Geometry and Algebra 2, and corresponding integrated textbooks, were selected because of the differing technologies that may be used. Textbook state adoption lists were examined for all states that had current, publicly available adoptions posted online. These criteria yielded in the sample noted in Table 1.

Table 3: Textbooks Used for Analysis

	Textbook Publisher/Series	Conventional/ Investigative/ # Texts	Reference Information
1	Carnegie Learning	Investigative (4)	Barte Dengler et al.
2	McGraw Hill	Conventional (2)	Carter
3	Houghton Mifflin Harcourt	Conventional (2)	Burger et al.
4	Houghton Mifflin Harcourt	Conventional (2)	Larson et al.
5	Pearson/Prentice Hall	Conventional (2)	Bass et al.
6	Pearson/Prentice Hall	Investigative (2)	CME Project
7	McGraw Hill	Investigative (2)	Hirsch & Fey
8	College Preparatory Mathematics	Investigative (4)	Dietiker et al. Kysh et al.

The unit of analysis for coding was a mathematical task. We were interested in tasks that could expect to be implemented in classroom instruction. To this end, main narrative sections, extensions of narrative sections, stand-alone labs, stand-alone activities were included, while exercise sections, review sections, summary sections, practice assessments, standardized test prep sections were excluded. Previous textbook analysis (Sherman et al., 2016), demonstrated that this distinction could be made reliably in a large set of textbooks. Each task was coded with respect to whether or not it included the use of technology, and the type of technology that was used. Secondary coding was conducted for each of these distinctions to ensure reliability.

Results

Across the 20 textbooks a total of 10,100 tasks were coded, with an average of 14.88% (*SD* = 8.25%) of tasks within a textbook using technology, ranging from 1.84% to 30.70% across the sample. Table 2 depicts how the inclusion of technology differed across textbook types and subjects.

Table 2: Technology Integration by Textbook Type and Subject

		% of Tasks Integrating Tech	Total Tasks
Conventional	Algebra 2	16.23%	2834
	Geometry	7.43%	2558
	Overall	**12.05%**	**5392**
Investigative	Algebra 2	14.98%	1202
	Geometry	7.61%	1262
	Integrated	17.47%	2244
	Overall	**14.19%**	**4708**

Mixed effects logistic regression models were fit to predict whether a given task utilized technology or not (coded as a 0/1) with textbook title as a random effect. Whether the textbook was conventional or investigative did not significantly predict the presence of technology tasks (p = 0.726). However, when comparing Geometry versus Algebra 2 versus Integrated texts, significant differences were found. Geometry texts were significantly less likely to include technology tasks than Algebra 2 texts (Odds = 0.39, d = -0,52, p = 0.0012) or Integrated texts (Odds = 0.33, d = -0.61, p < .001).

Technology tasks in each textbook were also coded for the type of technology used, as summarized in Table 3 below.

Table 3: Technology Type by Textbook Subject and Type

	Tech Tasks	Graphing Calculator	Scientific Calculator	DGS	Custom eTool	CAS	Sprea dsheet	Other
Algebra 2	640	69.53%	20.00%	0.31%	6.41%	1.09%	1.56%	1.09%
Geometry	286	14.69%	37.06%	26.92%	19.23%	0.00%	2.10%	0.00%
Integrated	390	52.05%	6.15%	11.79%	15.38%	4.87%	1.54%	8.21%
Conventional	650	55.08%	33.08%	8.15%	0.00%	1.08%	2.46%	0.15%
Investigative	666	49.85%	6.46%	10.81%	23.42%	2.85%	0.90%	5.71%

Conventional and investigative texts used graphing calculators and DGS at a relatively similar rate, while conventional texts were more likely to use scientific calculators. Although custom eTools constitute nearly a quarter of the technology tasks found in investigative texts, they are unique to the CPM texts.

Discussion

In terms of the quantity of technology integration in current curricula, across all textbooks, an average of about 15% of tasks utilized technology in some way, a result that indicates that the inclusion of technology in secondary mathematics textbooks is relatively rare. Regarding the types of technology utilized in texts, calculators are by far the most commonly used technology, while the use of DGS is much less common. The relatively rare use of DGS, even in Geometry texts, replicates earlier findings (Oner, 2008) for a larger and more current sample. Taken together, the potential of DGS to support exploring, generalizing, and conjecturing, the fact that Geometry texts use technology significantly less than Algebra 2 texts, and the predominant use of calculators in this sample of textbooks, suggest that technology might primarily be used as a computational tool, rather than for investigating and interacting with the mathematics. Furthermore, in light of current standards (NCTM, 2000; Common Core, 2010) articulating the important role of technology in a reformed vision of mathematics education, it is surprising that the investigative texts in this sample did not demonstrate a greater inclination toward integrating instructional technology. One of four components of Technological Pedagogical Content Knowledge (TPACK) articulated by Niess (2005) is "knowledge of curriculum and curriculum materials that integrate technology with learning in the subject area" (p. 511). Thus, these results should have important implications for mathematics teachers and teacher educators.

What the current study does not address is *how* these textbooks incorporate technology in reference to supporting students' high-level thinking. Our ongoing analysis of the tasks presented here includes the use of technology as an amplifier vs. reorganizer (Pea, 1985), as well as level of cognitive demand (Stein & Smith, 1998) in order to answer questions regarding the ways in which technology is used across this sample of texts.

USING TABLET TECHNOLOGY TO PROMOTE PARENT/CHILD MATHEMATICAL DIALOGUE

Emily Dennett
The Ohio State University
dennet.7@osu.edu

Theodore Chao
The Ohio State University
chao.160@osu.edu

As an important player in their child's education, parents should discuss mathematics with their young children. Since children who are read to regularly by their parents have higher literacy rates; we posit that positive interactions between children and their caregivers would increase children's competence in mathematics and lower rates of mathematics anxiety. We present findings from a design based experiment of original technology developed to encourage parents to engage in mathematical dialogue with their children. Three rounds of research were conducted with mother and preschool child pairs. Our findings indicated that an iPad app can present rich tasks for preschool children and prompts for the parents to encourage productive discussion.

Keywords: Early Childhood Education, Design Experiments, Pre-School Education, Technology

Mobile technology is now a constant part of our lives. These devices, particularly smart phones and tablets, can cause distraction and disconnection between parents and their young children if not used in a conscious and thoughtful manner (Park, 2016; Thorton, Faires, Robbins, & Rollins, 2014). As this technology continues to emerge and develop, parents face difficult decisions about the role they will allow these devices to play in their children's lives.
While parents and educators may be worried about the amount of "screen time" that children are exposed to, many also recognize that these devices have the potential to be powerful educational tools. The American Academy of Pediatrics posited recently that educational apps can be beneficial for children if "they are appropriately engaging, but not distracting; that they are designed to be used by a dual audience (i.e., both parent and child) to facilitate family participation in media use and modeling of more effective social and learning interactions" (Reid Chassiakos, Radesky, Christakis, Moreno, & Cross, 2016, p. e5). A randomized experiment conducted by Berkowitz et al. (2015) of 587 first-graders showed gains in mathematics competence after using an app that encouraged parents and elementary school children to solve word problems together.

We believe that educational apps that facilitate family mathematics interaction could also benefit younger children, yet such apps do not currently exist. However, a review of the apps available through Apple's App Store and Google Play revealed that the majority the mathematics apps for young children are based on math drills and memorization or have very little educational benefit (Reid Chassiakos, Radesky, Christakis, Moreno, & Cross, 2016)
In this paper, we present the preliminary development and analysis of an iPad app which fosters interaction between a parent and young child. This app, Family Math Moments, leverages the same mobile technology that modern parents are addicted to as a tool to help them utilize research-based mathematics education discussion techniques to unlock and support their child's deep mathematical thinking.

Our research asked the following questions during three research cycles:

1. How can a mobile app provide a tool for parents to better uncover and support their child's complex mathematical thinking?

2. What supports help parents engage their children in mathematical dialogue?

Theoretical Framework

Cognitively Guided Instruction (CGI), play-based mathematics in early childhood, and the importance of math talk to develop children's thinking frame this work. CGI in early childhood education emphasizes the child's thinking in their own learning of mathematics and posits that "eliciting and responding to children's mathematical ideas is central to supporting student learning" (Carpenter, Franke, Johnson, Turrou, & Wager, 2017, p. 98). Teachers using CGI in their teaching of young children are empowered to listen carefully to children's thinking and use questions to help students work from what they know. The task presented in the app was chosen because it was situated in a context familiar to young children and crafted to allow children to develop and visually explain their sophisticated mathematical thinking. The app provides a task and creates an environment for parents and child to engage in these necessary discussions.

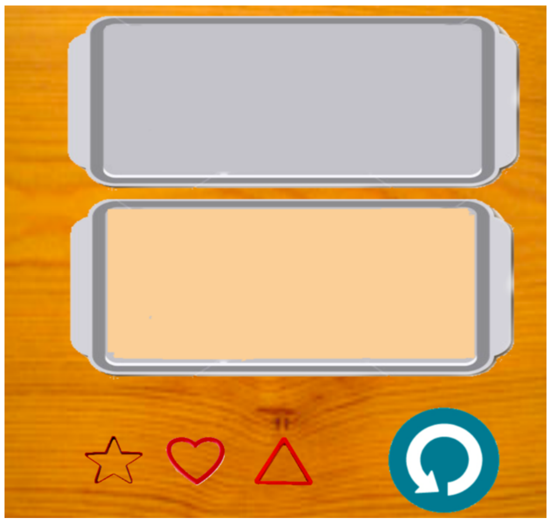

Figure 1. A Screenshot of the Cookies Activity in Family Math Moments. The child uses the cookie cutters to create cookies, with the goal of maximizing the amount of cookies made. The parent/family-member engages the child in mathematical discussion while the child explains their thinking.

Methods

This study used a design experiment methodology with lean thinking rapid iterations (Cobb, Confrey, DiSessa, Lehrer, & Schauble, 2003). Lean thinking allows for quick build-measure-learn feedback loops (Ries, 2011) that allow for research to be conducted on a minimum viable product (MVP) that is constantly updated based on the assessment from each research cycle. Before the research interviews began, an MVP prototype of this app was developed. The prototype was situated in the context of a mother and child baking cookies together. An opening page included cartoon figures and a voice-over that asked children if they would help the characters cut out as many cookies as possible out of a piece of cookie dough. Then the app transitioned to a screen that included a rolled out piece of cookie dough, cookie cutters, and an empty baking pan. Using the touch features of the iPad, the cookie cutters can be picked up and moved to the dough. After placing the cookie cutter on the dough, the user can move a cutout cookie to the baking pan. Figure 1 shows a screenshot of the app during the task.

Consistent with the CGI framework, the child is not provided with direct instructions on how to accomplish the task. In the spirit of play-based mathematics learning, the activity was intentionally not designed to be a video game experience. There is no scoring or time feature in the app. A child using the app is never designated as a "winner" or a "loser." The mathematics involved in this task includes counting, shape recognition, and optimization. The context of baking cookies was chosen based on the primary investigator's own experience as a parent.
To conduct the three research cycles, three mother/child pairs were recruited to complete interviews where the dyad tested the MVP and provided feedback. First, the lead author conducted a pilot round with her four-year-old son, Logan (all names used are pseudonyms). The other two pairs were four-year-old girls, Ada and Grace, and their mothers, Jessica and Amanda. All three children were enrolled in the same Pre-Kindergarten class. Table 1 provides demographic information about the participants.

Table 1: Participants

Research Cycle	Mother	Child
1 (Pilot)	First Author	Logan, 4 years old Considerable experience using iPad
2	Jessica Daycare administrator	Ada, 4 years old Limited experience using iPad
3	Amanda Works in Higher Education	Grace, 4 years old Limited experience using iPad

Results and Discussion

The results from this research are promising. The children were interested in using the app and engaged with the task quickly. The children and their mothers provided helpful feedback that could be quickly incorporated to improve the app's user experience. The feedback also advanced our understanding of how mobile technology can support parents to engage their children in mathematical dialogue. Table 2 provides and overview of the results from each research cycle and the impact that those results had on the development of Family Math Moments.

Table 2: Results

Participants	What Happened	Revisions
First Author and Logan	Logan liked that the task was not timed. Logan wanted to try the task multiple times.	Start over button added Parent handout created

Jessica and Ada	Jessica pushed parent handout to side Jessica focused on giving directions on how to use app. Researcher asked questions and Ada answered, Jessica never joined in the questioning.	Suggested questions were put on notecards
Amanda and Grace	Verbal introduction and tutorial was provided by researcher. Researcher handed Amanda notecards with questions to ask. Amanda initiated math talk with Grace.	Tutorial and “pop-up” questions for parents added to app

These first three cycles revealed that parents had difficultly discussing mathematics with their children without any direction, but when provided with sample questions they can use their intuition and knowledge of their child to extend the discussion and draw out their child’s thinking. The results from the first three research cycles will now be used to more fully develop iPad app.

Young children’s mathematical thinking is often diminished or dismissed. This study showed thinking that increases a parent’s understanding of their own children’s mathematical prowess. These results show that just as parent participation in reading to and with their children has led to a generational elimination of illiteracy in North America, an app such as Family Math Moments has the potential to further mathematical thinking for all children and eliminate mathematics anxiety.

PROMOTING COLLABORATION AND MATHEMATICAL ENGAGEMENT IN A DIGITAL LEARNING ENVIRONMENT

Alden J. Edson

sharma79@msu.edu

Promoting mathematics learning without developing students' engagement is a critical issue in the teaching and learning of mathematics. This study reports on the student and teacher perceptions on mathematics engagement in digital collaborative settings. Emerging themes arose through open coding of the student survey responses and the teacher interview. Findings revealed two themes: (a) the digital learning environment holds promise for promoting real-time collaboration and productive disciplinary engagement in mathematics and (b) in the digital learning environment, some students requested explicit opportunities for initial individual work before accessing a shared workspace on the digital platform.

Keywords: Technology, Problem Solving, and Middle School Education

Introduction

The 40th Annual Meeting of the North American Chapter of Psychology in Mathematics Education invites the mathematics education community to consider emerging opportunities related to technology use that can support each and every student. To this end, we are exploring ways in which digital technologies can support student learning of and engagement in mathematics. Through the use of design research methodologies, we report on initial work that offers promising directions for collaboration when teaching and learning mathematics.

Theory of Productive Disciplinary Engagement

While it often appears to educators and scholars that students are engaged in problems in the classroom, students may not be involved in the mathematical underpinnings of that engagement. Students are productive in their disciplinary engagement when they make intellectual progress or demonstrate change over time on the disciplinary learning goal (e.g., Hiebert, et al., 1996). This notion is referred to as productive disciplinary engagement. Four design principles of productive disciplinary engagement are needed to be embodied in learning environments: problematizing, authority, accountability, and resources.

Good problem solvers are not passive recipients of knowledge. If students are to engage in the content, issues, and practices of mathematics, then something must exist that is of genuine uncertainty for which there is sufficient space for students to make progress. Problematizing in mathematics (Hiebert, et al., 1996) involves addressing problematic situations that encourage learner "perplexity, confusion, or doubt" (Dewey, 1910, p.12).

If learners are involved in the content, issues, and practices of mathematics, then they must have some degree of intellectual authority when addressing problematic situations (e.g., Lampert, 1990). "As learners are authorized to share their thinking, they become recognized as authors of the ideas and contributors to the ideas of others, leading to students becoming local authorities on a subject" (Williams-Candek & Smith, 2015, p. 3).

Accountability refers to the notion that students are self-regulated in their learning. This means that they are responsible for how their ideas make sense amongst the ideas of others. The goal is that students will make ongoing revisions in their work, communicate their ideas, and consider how the ideas do or do not make sense in the discipline so that they are better positioned to improve them when more thoroughly challenged.

Learning environments need to provide access to sufficient resources so that students can engage in the other principles of productive disciplinary engagement. Resources might include sufficient time and location, technology tools, or classroom artifacts. Resources are going to vary dramatically as they depend on the topic, learning goal, classroom setting, and other factors.

Methods

This study is part of a larger design research (e.g., The Design-Based Research Collective, 2003) project focused on iteratively developing and enacting digital environments. The study is guided by thinking about how productive disciplinary engagement can be fostered in digital learning environments. The research reported in this study addresses the following research question: *In the digital learning environment, what are student and teacher perceptions of mathematics engagement in collaborative settings?* To this end, we report on data collected from four classes (approximately 25 students per class) that tested the developed digital resources over two days. The mathematics problem that was tested was from the seventh-grade unit, *Stretching and Shrinking: Understanding Similarity*. Problem 2.2 Hats Off to the Wumps: Changing a Figure's Size and Location comes from the *Connected Mathematics3* (CMP) curriculum materials (Lappan, Phillips, Fey, & Friel, 2014). While the teacher and students are familiar with CMP, the use of the prototype digital platform was the first experience for the students and the teacher. The platform supports students to make their thinking visible to others, to see and make changes in real time, and to publish their work (at any point in time).

The student survey was administered electronically after the testing of the mathematics problem. A total of 37 responses were captured from the students in the four classes. The teacher interview was also conducted after the testing of the mathematics problem. Interview questions focused on the experience using the digital platform and its features, student engagement in mathematics (problematizing, authority, accountability, and resources), student learning about similarity, and similarities and differences about the instructional model (Launch, Explore, Summary) from past teaching experiences. Student survey responses and teacher interview transcriptions were coded using an open coding approach (Strauss & Corbin, 1998). We report on the emerging themes on mathematical engagement in collaborative settings.

Findings

In this section, we report on findings of student and teacher perceptions on mathematics engagement in collaborative settings for an open mathematics problem.

Theme 1. The digital learning environment holds promise for promoting real-time collaboration and productive disciplinary engagement in mathematics.

From the analysis of the interview, the teacher spoke towards the positive aspects of the digital platform for student learning and engagement in mathematics. Below are excerpts of questions and responses between the interviewer (I) and the teacher (T).

As shown on Table 1, students found that the real-time collaborative digital resources were helpful for mathematics engagement and learning. However, some students raised issues on the technical lags (e.g., freezing and refreshing) and the cultural norms (i.e., hesitation of mistakes/errors now being public and sharing of the work as "copying" of others work). Although issues were raised, no students indicated they did not want to work collaboratively with the digital resources.

I: In your own words, tell me about the different features of the digital platform and the different ways you and your students used those features.
T: So, the main feature was the collaborative space screen, and the students slowly get used to using that to be able to share their thoughts and the answers on the same screen. When one student had an answer, they were able to input it and then share with their group and the whole class.
I: Did you notice changes in how students were accountable for their ideas, to the ideas of their group mates, or to the ideas of the class?
T: I think students were held a lot more accountable to each other and group. Because they think their work is much more visible, they cannot just write. They have to discuss, talk, and share. They were accountable to the whole class with the publish feature.
I: Have you noticed changes in how students share their thinking or contribute to the ideas of others?
T: They were just a lot more specific. They had things to reference. They felt a little more comfortable with each other. I am excited to see as we keep going how that changes. The next day, we did a lesson in class just out of the book paper pencil, I can still definitely feel the vibe of the cooperation thing as we were doing. So, I am interested in seeing this throughout the rest of this book if they continue to keep the same tightness they forced to do with the digital platform.

Figure 1. Teacher interview

Table 1: Select survey items and student responses

Did the technology help you be more confident, less confident, or as confident as usual in mathematics and in sharing your ideas with others? Explain why. (n=37)	More Confident 30%	Less Confident 22%	No Difference 40%	Other 8%
Was the technology helpful to explore similarity by producing similar and non-similar hats? Explain. (n=37)	Helpful 84%	Not Helpful 8%	Other 8%	
The technology allowed you to publish your work. Was this helpful or not? Explain. (n=37)	Helpful 62%	Not Helpful 30%	Other 8%	
The technology allowed you to look at your classmate's published work. Was this helpful or not? Explain. (n=37)	Helpful 65%	Not Helpful 24%	Other 11%	

Theme 2. In the digital learning environment, some students requested explicit opportunities for initial individual work before accessing a shared workspace on the digital platform.

Responses from the student survey surfaced an important consideration for working in collaborative groups. This consideration may be connected to an affordance of paper/pencil contexts. For example, below are sample student responses from students.

What changes, if any, would you like to see in the technology?

- *It should be individual and then you share your answers with your table group.*
- *You do a private thing then share with your group then publish*
- *I would make changes so that you can individually write things then discuss it with your group.*
- *I would have it work better; for example, everyone could have their own separate work and then share it when they were all done to compare answers.*

What did you not like about the technology?

- *It was hard to get work done because someone was trying to work on the table, and someone was working on the graph. I think each person should have their own interactive thing and then share with just their group of table.*

Figure 2. Sample of survey questions and students' responses

Discussion

In this study, we reported on student and teacher perceptions related to mathematics engagement in collaborative settings. Our analysis of the data was limited to student and teacher perceptions around one mathematical problem. The two themes highlight the pivotal role of accountability in the theory of productive disciplinary engagement. As Engle (2011) noted, developing and increasing accountability builds by asking learners to account for how their ideas make sense from the “inside out" - oneself, safer peers, more challenging peers, internal authorities providing increasing challenges, and external disciplinary authorities providing increasing challenges. In this version of the prototype, the digital platform began with the assumption that students would share a collaborative space. While students had the opportunity to create a space for themselves individually, it was an optional feature. The findings from the study suggest some need by students to work individually before moving to collaborative space. This finding may be interpreted as the students needing the opportunity to make sense of the problem themselves before sharing it with safe peers (group members). This study provides some evidence that resources and opportunities are needed to support accountability for the learner itself prior to moving outwards with others.

Despite the early stage prototype having technical glitches where students and the teacher had limited familiarity with the digital resources, this study underscores the important design consideration of collaboration when designing and enacting digital learning environments for promoting student engagement and learning of mathematics. Interestingly, the digital platform provided an option of an individual workspace for students (where group mates could not access their work), but its usage did not surface in our analysis of the survey.

While the digital learning environments reported in this study are different than paper/pencil contexts, students were still expected to be accountable to their ideas by justifying their work in their small group, to the whole class, and the teacher. Almost all students appreciated the value of working in a collaborative workspace, highlighting the benefits of real-time communication and sharing of work with others.

TEACHER KNOWLEDGE FOR TECHNOLOGY IMPLEMENTATION

Jaime Kautz	Hea-Jin Lee	Kui Xie
The Ohio State University	The Ohio State University, Lima	The Ohio State University
kautz.8@osu.edu	lee.1129@osu.edu	xie.359@osu.edu

This study is centered around a year-long professional development intended to improve teachers' technological, pedagogical, and content knowledge for middle school mathematics. Seven teachers' responses and asynchronous module work were analyzed to measure teachers' beliefs about their ability to implement technology in the classroom and the alignment between teacher interaction with technology and their understanding of mathematics. Results suggest that 1) teachers were more efficacious teaching mathematics without technology than with it; 2) teachers' beliefs about technology and their ability to implement it were generally positive and increased after professional development activities; 3) gaps in teacher knowledge and teachers' ability to use technology were evident.

Keywords: Teacher knowledge, technology, beliefs

Purpose of the Study

The use of technology in the classroom has gained momentum over the last decade, putting a focus on teachers' understanding and implementation of a technology-infused classroom. While much attention has been focused on building a framework of teachers technological, pedagogical, and content knowledge (TPACK), little attention has been paid to the possible factors that guide the implementation process. The year-long professional development (PD) focused on providing technological, pedagogical and content support for middle school mathematics teachers. The purpose of this study, then, is to examine possible factors influencing teachers' ability to implement technology in the middle school, mathematics classroom with two guiding questions: 1) What are middle school mathematics teachers' beliefs about their own ability to implement technology in the classroom? and 2) How do measures aimed at quantifying teachers' TPACK align with teachers' interaction with technology and their understanding of mathematics?

Theoretical Framework

In *Adding It Up,* the National Research Council (2001) calls out five components to effectively teach mathematics, three of which describe aspects of the knowledge base required to teach mathematics stemming from to the notion of Mathematical Knowledge for Teaching (MKT, Ball & Bass, 2003). While MKT theorizes the working parts of the knowledge required to teach mathematics, it does little to describe how technology integration fits into instruction. In an attempt to create a framework for the overlapping knowledges required to implement technology, Koehler and Mishra (2009) developed technological pedagogical and content knowledge (TPACK). To more effectively teach mathematics using technology, then, one must consider both frameworks. Only then can the influence of knowledge on technology integration be more fully understood.

Unlike MKT, most all measures of TPACK are related to teachers perceived levels of knowledge and are self-reported. While this can be reflective of actual levels of knowledge, there is clearly the possibility for disparity among the two levels. Instruments used to assess TPACK may be a better measure of beliefs than actual knowledge.

Hodges, T.E., Roy, G. J., & Tyminski, A. M. (Eds.). (2018). *Proceedings of the 40th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Greenville, SC: University of South Carolina & Clemson University.

In addition to the possible relationship between knowledge and beliefs, a compelling relationship between mathematical knowledge for teaching and instruction exists (Hill et al, 2008). Teachers with a strong knowledge of mathematics, a strong knowledge of how to teach it, and how to teach it within the context of a mathematics classroom were found to avoid mathematical content errors and implement more rigorous lessons. It would be unjust to assume that a relationship between MKT and implementation and not question the relationship between a measure of knowledge that includes technology integration and instruction.

Subsequent research also shows that teacher understanding of curriculum, a construct associated with both MKT and pedagogical content knowledge within TPACK, is an essential construct that must be addressed in future research on the relationship between knowledge and instruction (Hill et al, 2008). Therefore, the implementation of technology should be studied to fully understand how knowledge supports the integration of technology into classroom instruction.

Synthesizing the previous needs and findings, it becomes clear that too little research focuses on what factors support the integration of technology in a mathematics classroom. The impact of knowledge, beliefs and experience emerge as crucial constructs, as displayed in Figure 1, impacting how mathematics teachers select, evaluate, and implement technology into instruction.

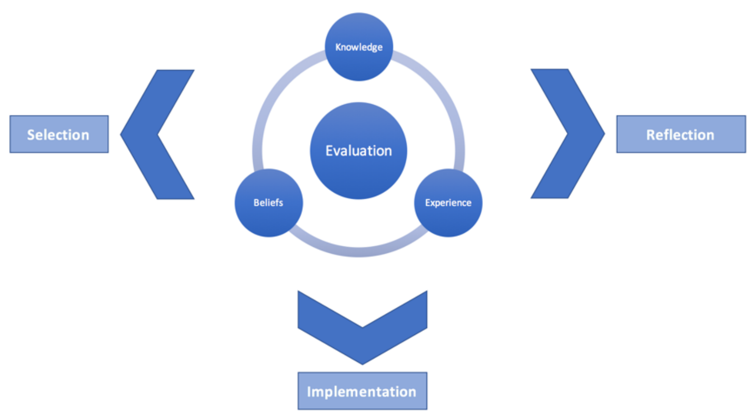

Figure 1. A theoretical framework for the implementation of technology in a mathematics classroom.

Methods

Participants

Middle school mathematics teachers from a large Midwestern city were recruited to participate in a year-long professional development. Five different school districts, spanning from urban to rural, provided 31 teachers and mathematics coaches to participate. For the purpose of this study, seven teachers were chosen to examine more closely. Emergent trends among the qualitative data were identified and analyzed.

Professional Development

Teachers began their PD experience with a six-day, summer institute that aimed to support teachers in building algebra content knowledge, building pedagogical content knowledge, and supporting the selection, evaluation, and implementation of digital resources in the mathematics classroom. Monthly, asynchronous modules were delivered online and modeled using the same focus as the summer institute. Email and site visits provided participants with additional support while they completed the online module portion of the project.

Data Collection

Initial pre-surveys were administered to measure participant TPACK, self-efficacy, and other measures of motivation. These surveys were again administered after the completion of the summer institute. Teacher work samples serve as a large component of the data set.

Results

Teacher beliefs

Teachers were given a survey with several items aimed at measuring their beliefs. With respect to self-efficacy to teach mathematics with technology versus without technology, five of the seven teachers had higher levels of self-efficacy for teaching mathematics without technology than with technology. All seven teachers had average scores over 3 (out of 5) for measures of self-efficacy to evaluate digital resources, self-efficacy to design, and perceived TPACK scores. Self-efficacy to evaluate digital resources, TPACK, self-efficacy to design curriculum, ability, expectancy, and attainment saw an increase after the summer institute.

Knowledge

Outcomes related to teacher content knowledge were mixed. Evidence suggests that while teachers understood basic slope content, other content provided more issues. Topics on exponents, multiple representations of equations, and fractions and rational numbers were littered with errors.

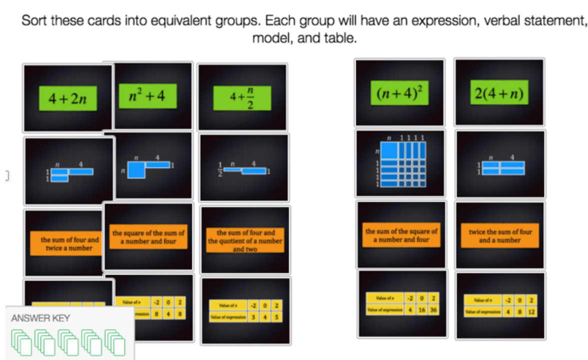

Figure 2. Work example of incorrect sorting of equivalent expressions.

The majority of teachers (4 out of 7) were unable to correctly match equivalent expressions that utilized different exponential rules. The teachers who were incorrect reported that they had difficulty remembering the rules associated with exponents. Figure 2 provides a different example, in which the teacher looks to be correct, but has switched two of the cards incorrectly. Similarly, the teacher did not fully submit their work due to difficulties utilizing the grouping mechanism of the digital resource.

Although teachers struggled with exponents, they excelled with notions of slope. Participants were able to correctly use and create slope triangles to answer questions about slope using Geogebra as demonstrated in the figure 3.

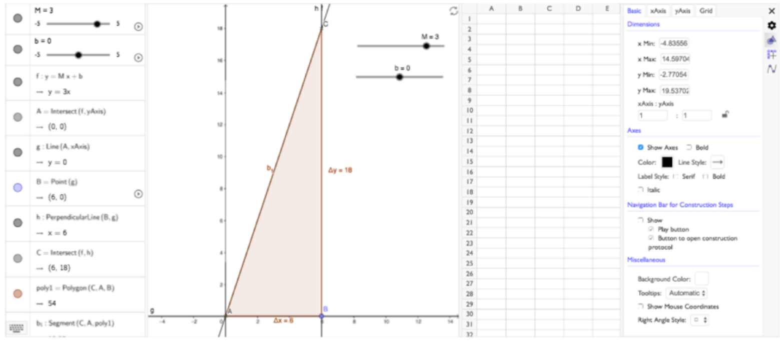

Figure 3. Example of the creation of a slope calculator using sliders.

Discussion

The study aimed to explore possible factors influencing teachers' ability to implement technology in the middle school, mathematics classroom. This study was unique in that looked at teachers' TPACK beyond popular survey methods by examining teacher work in asynchronous, online modules. While teachers reported above median values for TPACK, self-efficacy, and other measures, they reported more confidence in their ability to teach without technology. Teachers work in the asynchronous modules show teacher error in both content and technology utilization raising the question of whether erroneous responses were reflective of content knowledge or technology knowledge.

TEACHERS' IMPLEMENTATION OF VIRTUAL MANIPULATIVES AFTER PARTICIPATING IN PROFESSIONAL DEVELOPMENT

Lindsay Reiten
University of Northern Colorado
lindsay.reiten@unco.edu

The following study investigated why and how teachers implemented virtual manipulative (VM) tasks after participating in a professional development opportunity aimed at teaching with VMs. Findings indicate that teachers used VM tasks to support students' developing understanding and engagement and because they were supported in teaching with VM tasks. Mediating factors (e.g., time) influenced why and how teachers chose to use a particular technology tool.

Keywords: Professional Development, Technology, Middle and High School Education

Introduction

As access to various technology tools increases, so too has the expectation for teachers to use technology to enhance student engagement and understanding. Unfortunately, teachers often report that they are not prepared to use technology in an innovative manner and effectively in their instruction (Albion et al., 2015), a critical and longstanding issue in mathematics education. Effectively teaching *with* technology entails teachers using technology to promote opportunities for students to develop conceptual understanding through reflection and communication, as well as through using and connecting mathematical representations (Reiten, 2018). Which leads to the question, *when teachers are supported in teaching* with *a technology tool, why and how do they integrate the tool into their instructional practices?*

The following study highlights two teachers to report the findings of a professional development (PD) opportunity for secondary mathematics teachers aimed at supporting their efforts to teach *with* virtual manipulatives (VMs). A VM is an interactive, technology-enabled visual representation of a dynamic mathematical object, including all of the programmable features that allow it to be manipulated, that presents opportunities for constructing mathematical knowledge" (Moyer-Packenham & Bolyard, 2016). Visit http://bit.ly/VirtManips for an annotated list of VMs and http://bit.ly/VMTasks for a repository of VM tasks used during the PD. VMs were the focus of this PD due to the widespread availability of the tool and the increased attention that has been given to the development of VMs in recent years. Many VMs provide immediate feedback and the interactive environment can promote student perseverance and exploration for students who get frustrated or disengage with paper and pencil investigations (Moyer-Packenham & Westenskow 2013). Despite these benefits for using VMs, limited resources exist to support teaching *with* VM tasks (Reiten, 2018). A VM task is the VM and all accompanying instructions/prompts whether onscreen or in printed form.

Theoretical Background

Teachers' implementation of VM tasks were considered to be mediated by their mathematical goals for the task, the tools available related to their implementation, the students they teach, the teachers with whom they teach, and school/district initiatives. Therefore, to understand why and how teachers implemented VMs, the following study drew from activity theory (Engeström, 1999). An activity consists of a subject, object, and actions. The *subject* is the person or people engaged in an activity (i.e., the teachers in the PD). The *object* motivates the activity and gives the activity specific direction (i.e., teachers' practices related to implementing

VMs). *Actions* are goal-directed processes undertaken by the subject to achieve the object (i.e., teachers' instructional practices related to implementing VM tasks). Other aspects of this activity system include the tools/mediating artifacts (e.g., the VMs and tasks, the task analysis framework), rules (e.g., curriculum, instructional style), community (e.g., other teachers in the school), and division of labor (e.g., do teachers work collaboratively or primarily individually).

Methods

For the larger study, 14 mathematics teachers participated in the PD opportunity aimed at supporting their efforts to teach *with* VMs (see Reiten, 2018). The focus in this paper is on a 6th /7th grade mathematics intervention teacher (i.e., Tracy, 20 years of experience) and a high school Geometry/AP Statistics teacher (i.e., Daron, 21 years of experience). These participants were chosen due to representing different grade bands and student populations. Data collected included online background and final surveys, video and audio recordings of the PD sessions, and teachers' work during the sessions. Tracy also participated in semi-structured interviews at the beginning and end of the PD.

Transcripts, teachers' work, and their reflections were initially coded to identify themes related to how they used the tools introduced in the PD, how and why they implemented technology (codes drawing from literature), and related tensions (emergent codes). Focused coding (Saldaña, 2013) then progressed after sorting codes vis-à-vis components of the activity system (e.g., division of labor, community, tools, tensions, etc.), re-examining data within codes, and linking teachers' work during the PD with their conversations. This analysis gave insight into how and why teachers implemented VM tasks (i.e., the object of the activity system).

Findings and Discussion

The goal of the PD was to support teachers in teaching *with* VM tasks. Teachers' appropriation of tools (i.e., guiding questions, task analysis framework, annotated VM list, folder of tasks) used during the PD supported their implementation efforts (Reiten, 2018). Tracy implemented over 12 VM tasks and Daron implemented at least four VM tasks with students.

Why Teachers Implemented VM Tasks

Engagement and exploration. Teachers implemented VMs and tasks because they thought their students' learning might be enhanced due to students' engagement with the VM tasks. For example, during Tracy's final interview, she said

> It piques their interest, in all of it. All of a sudden we'll [i.e., the students] TRY because we're not writing on pencil and paper. Like the one that we did with the area and the perimeter when they're making the gardens [i.e., Fido's Flower Bed from ExploreLearning] all of a sudden, "*OH! A man walked by.*" Or "*Oh, did you see that dog?!*" You know, I mean … they get excited about it and they can compare [with each other].

On Daron's final survey, he said that he used the VM tasks because "students can discover and explore concepts in a dynamic way. [The VM tasks] allow for a deeper level of engagement and more efficient way to investigate deep mathematical ideas." Tracy's and Daron's reflections highlight how they were using VM tasks to give students opportunities to explore content in a more dynamic way and with less restrictions than if the task had been done with paper and pencil. Additionally, the interactive environment helped to promote students' engagement (e.g., Moyer-Packenham and Westenskow 2013) with the tasks as well as reflecting on the mathematics through comparing solution strategies with their peers.

Instructional guides. Many of the VM tasks that teachers chose to implement had accompanying guided questions or instructional guides to help students engage in the task and support their developing understanding. During the October PD session, Tracy said

> I just think that it [the VM with an instructional guide] is more GUIDED and that makes it a little more REAL to them where they are actually having to do what they would have to do on a math test, you know. That they are practicing those skills and writing it down and maybe making it a little more concrete than just click, click, click, click, click, click, click. And see if we get an answer eventually that says, *"Hey, you're right!"*

The accompanying questions or instructional guides supported teachers in how they may want to use a given VM task and assisted students' exploration of the given topic.

However, not all VM tasks had accompanying questions. Therefore, at times teachers developed instructional guides to accompany a VM. During the January PD, Daron said

> Some of the ones that I had been looking at don't really have a guide, so … I kind of keep these things in mind [i.e., the affordances in the task analysis framework] as I try to write a guide or put together some questions…to try to make sure as many of these were covered so it was a meaningful activity for them as well. Where otherwise you might just throw the questions out, you just, I think it allows you to think more like, "How do I move them up to those levels that we're trying to get them to?"

Therefore, teachers' efforts to develop instructional guides that further supported student learning and engagement were also supported via a tool introduced during the PD (i.e., the task analysis framework (Reiten, 2018)). Hence, when investigating why teachers choose to implement VM tasks, it is important to consider how teachers are supported in developing accompanying materials that they find helpful for supporting students' developing understanding.

How Teachers Implemented VM Tasks

Instructional role. Teachers used VM tasks for a variety of purposes or instructional roles. During the January PD session, Daron specifically looked for a VM exploring a confidence interval for a proportion to use in his AP Stats class that might enhance student understanding by connecting the confidence interval and the graph of a distribution. During the spring months, Tracy often looked for VM tasks that allowed students to investigate and develop area formulas (e.g., calculating the area of a parallelogram) rather than simply being told the area formula.

Implementation efforts. Although the PD aimed to support teachers in teaching *with* VM tasks, there was no requirement that teachers had to implement the VM tasks that they were critiquing and modifying during the PD session.

During the January PD session, Daron brought up his experience implementing a VM with his AP Statistics students. According to Daron, after doing the gizmo, students had less questions about the binomial theorem compared to years past and a better understanding of the formula. Students were not relying on their calculators to evaluate the formula and were not making some of the common errors that previous students had made (e.g., leaving off the beginning part of the binomial formula). After the PD session, Daron emailed the following thoughts related to his implementation of the Binomial Probabilities gizmo:

> I think students were much more engaged in learning the binomial pattern. They were able to see where the pattern was coming up from the most basic situation to more complex examples. I think students were able to see the pattern in the factorials and Pascal's triangles quickly, then were able to adapt them to more difficult problems. I asked for student feedback and they said they really liked using the gizmo and it helped them to see the pattern.

Daron's thoughts demonstrate how both he and his students found the VM helpful for students' developing understanding. This early positive experience implementing a VM task encouraged Daron to continue implementing VM tasks during the school year.

At times, teachers found it challenging to implement VM tasks. When asked during her final interview if there was something that prevented her from using VM tasks, Tracy stated, "Time!" Time related to having the instructional time within a class period as well as time for finding the tasks and getting them ready to implement with her students. Although the PD could not affect the instructional time teachers had, the PD provided teachers time to find, critique, and modify VM tasks specifically related to their upcoming units. As demands on teachers' time continue, integrating supported time within PD for teachers to find and develop VM tasks directly connected to their curriculum can help support teachers' integration efforts by strengthening the connection between the PD and teachers' instructional practices (Wilson, 2008).

Conclusion

Although VMs are not new, little resources exist to support teachers' efforts to teach *with* VM tasks. Therefore, this PD opportunity was developed to support teachers as they found, critiqued, and modified VM tasks to implement with their students. Teachers implemented VM tasks due to benefits they experienced in relation to their students' developing understanding and engagement, as well as the ways in which they were supported in designing instructional guides to support students' emerging understanding. The PD aimed to support teachers' efforts to teach *with* technology by providing teachers' the time and support needed to not only learn about VM tasks, but also time to critique the tasks and prepare the tasks to implement with their students. Supporting teachers to teach *with* technology goes beyond providing them with access to technology tools. Rather, it includes providing opportunities for teachers to interact with technology tools related to their current curriculum. Additionally, it means providing teachers resources that support their integration efforts and emerging understanding regarding knowledge growth in how to teach *with* technology. Supporting teachers also means acknowledging the tensions that exist related to integrating technology tools (e.g., time) student needs (i.e., community factors), tool limitations and supports (i.e., tools/mediating artifacts), etc.

MEASURING SELF-REGULATED LEARNING IN CALCULUS I

Benjamin D. Sencindiver

James.Folkestad@colostate.edu

Calculus 1 has been and continues to be a key gateway course to STEM majors, which contributes to a loss of students in the STEM pipeline. Self-regulated learning (SRL) competencies have widely been found to be related to academic achievement (e.g. Zimmerman, Moylan, Hudesman, White, & Flugman, 2011), though common tools to measure SRL have fallen under scrutiny (Winne & Jameison-Noel, 2002). Ways in which students interact in the learning process impacts performance and, in turn, the student experience. Using an SRL framework, online tools were designed to collect data that can be interpreted to create a behavioral SRL score based on in-course student activity. This brief report presents initial findings on the relationship between a behavioral SRL score and academic achievement in Calculus I.

Keywords: Metacognition, Measurement, Technology

Calculus I has often been identified as a gatekeeper course for STEM disciplines. Aside from incoming ability, evidence suggests that how students engage with their studies impacts their success (Vandamme, Meskens, Superby, 2007). This research aims to investigate the impacts of student's online interactions on academic performance by interpreting students' use of purposefully-designed online tools using a self-regulated learning (SRL) framework. For the purpose of academic performance prediction and at-risk student detection, SRL theory provides a lens to understand how students engage in online settings.

This brief research report will describe how an SRL framework can be used to more deeply understand students' behaviors in online settings and how student interactions with resources developed around SRL theory can be organized into a behavioral SRL score. We will then analyze relationships between this score and academic achievement in a Calculus I class.

Theoretical Framework: Self-Regulated Learning

SRL - "the self-directed process by which learners transform their mental abilities into academic skills" (Zimmerman, 2002, p. 65) - enables students to better understand how they engage with content and adapt their study strategies to overcome academic difficulties and become more successful students. For example, when a mathematics student receives a bad grade on a homework assignment, they often do not reflect on why or how to change their study habits to be more successful in the future. Zimmerman (2000) presents a three-phase process model of SRL describing an ideal process through which students can support their learning as they engage in a task. This model is cyclic, with each phase - forethought, performance, self-reflection - informing the next.

Forethought is the planning phase, which ties in a student's beliefs and motivation, such as self-efficacy, outcome expectations, and task value, around the task (Zimmerman, 2008). During this stage a student will analyze a task and determine goals and strategies to implement. Following forethought, the performance phase centers around the task itself. The student then implements planned strategies, observing and adapting strategies during the task (Zimmerman, 2000). Self-observations also provide information to the student about effectiveness of strategies on performance as students enter the self-reflection phase. The self-reflection phase analyzes the gathered information, drawing causal attribution to conditions surrounding the task so that adjustments and improvements can be made, informing future task cycles (Zimmerman 2000). As an example, consider a student preparing for an exam via a practice exam. Before sitting down, a self-regulating student would determine what resources are needed working on the practice exam (e.g. time, location, notes, textbooks, technology). They would identify test-taking strategies to use and then select ones that are relevant. During the practice exam, identified strategies are implemented and resources are used. Before sitting down, a self-regulating student would identify resources and strategies to use during the practice exam. After selecting and implementing these strategies, the student would reflect on their performance and process to make judgements regarding the effects of their methods on their performance and goals for the practice exam. Successful strategies could then be used in the subsequent exam, while others might be modified for future use.

Measuring SRL

The Motivated Strategies for Learning Questionnaire (MSLQ) is the most commonly used instrument for measuring SRL. The MSLQ is an 81-item self-report questionnaire that assesses "college students' motivational orientations and their use of different learning strategies for a college course" as well as their "goals and value beliefs" (Pintrich, Smith, Garcia, & McKeachie, 1991, p. 3). The MSLQ has primarily been used to study the relationship between components of SRL and academic performance (e.g. Pardo, Han, & Ellis, 2016). Unfortunately, self-reports do not always align with observed behaviors (e.g. strategy usage), which has caused the validity of the MSLQ to be called into question (Winne & Jamieson-Noel, 2002). To address this concern, we designed online tools specifically to coax evidence of the SRL phases into observable, measurable events that can be recorded and formed into a behavioral SRL score, which will be referred to as the *B-SRL score*.

Methods

As students often struggle with precalculus content (e.g. Carlson, Madison, & West, 2015), self-regulation around the task of assessing and addressing one's knowledge of precalculus topics at the start of the semester was the focus of this research. Three optional online tools were developed and made available to students through the university's learning management system (LMS) based on the three SRL phases: forethought, performance, and self-reflection.

The Prerequisite Self-Assessment (SA) was developed to capture evidence around the forethought phase. This eight-item survey asks students to rate their confidence in correctly answering questions on relevant prerequisite material on a Likert Scale from one (no confidence) to five (very confident). The SA determines if students are engaging in the task analysis component of forethought by assessing their confidence in precalculus topics.

Students' participation in the performance phase of SRL was determined by how they scored on the optional Prerequisites Content Quiz (CQ) - a 12-item multiple-choice and multiple-answer quiz about prerequisite material essential for Calculus I. Topics included in the SA and the CQ related to function notation, graphs of functions, algebra, and trigonometry. Upon completion, students received immediate feedback on the correctness of each response and, if incorrect, the relevant topic to review, as well as available resources (e.g. specially developed review videos).

The Prerequisite Reflection Tool (RT) was designed to provide evidence of students engaging in the self-reflection around their CQ performance. This five-item survey asks students to identify what precalculus topics they plan to revisit in light of their CQ performance, as well as how and when they plan to review. Student precalculus remediation was tracked through provided digital and physical resources. Subsequent follow through of remediation provides evidence of cyclic nature of SRL, capturing the transitions from reflection into forethought of remediation. As all tools and resources were optional for the students, their' mere use of these online tools and resources provide evidence of students engaging in the different phrases of SRL.

Formulating a Behavioral SRL Score

Using the data from the online tools, the B-SRL score was formulated by first categorizing the usage data for each online tool, and then coding each student's set of behaviors with the tools onto a six-point scale representing students SRL strategy usage. It is worth noting that SRL is a process that can stretch semesters, so the B-SRL score is a snapshot of the SRL process at the beginning of the semester around the task of assessing one's precalculus knowledge and potential remediation of skills within the first two weeks of class.

Since the online tools were all optional, each tool was either used by a student or not. For the both the SA and CQ, students who used the tool were further subdivided. Of students that used the SA, they were considered to have either high confidence (mean confidence score of three or greater) or low confidence. Students that completed the CQ were considered to have either high precalculus ability (score of eight or greater) or low ability. Results from the SA and CQ were combined with use of the RT (used or did not) and precalculus resource access (accessed or did not) to formulate a B-SRL score. Each set of behaviors was then evaluated using Zimmerman's three-phase model with the guiding question 'How appropriately is the student responding to the feedback about their impressions on their precalculus abilities?'. Further, the B-SRL score took into account whether or not the student was appropriately calibrated with regard to their confidence and academic ability, where more accurate calibration has found to be a product of SRL training in the literature (Zimmerman et al., 2011). Each behavior was assigned B-SRL scores of 0 (no self-regulation), 1, 2, 3, 4, or 5 (highly self-regulating).

To highlight the coding from behaviors into the B-SRL score, consider three students: Derek, Matilda, and Jay. Derek has high precalculus confidence, but low precalculus ability. Further Derek has not engaged with the RT nor the precalculus resources. His confidence and ability regarding precalculus ability are miscalibrated, and Derek is not using the low CQ score as a prompt to revisit precalculus material. For these reasons, Derek would receive a B-SRL score of two. If Derek were to instead use the RT and use one of the precalculus resources, he would receive a B-SRL score of four.

Matilda showed low confidence with precalculus content despite showing high precalculus ability. She then did not use the RT nor the precalculus resources. Matilda has high precalculus ability, so she does not need to remediate her precalculus abilities. Despite this, Matilda's ability and confidence are not appropriately calibrated since she has high ability but low confidence. Further Matilda has not reflected on her CQ performance, so she receives a B-SRL score of three. Were Matilda to reflect on the CQ (use the RT), she would receive a B-SRL score of four. Lastly, Jay is a student who uses none of the provided online tools. Though Jay may be self-regulating, there is no evidence of this. Hence, Jay would receive a B-SRL score of zero.

Data and Initial Findings

Data was collected from 376 consenting university Calculus I students who competed the course. Data sources included course performance data and B-SRL score data.

Toward considering the relationship of the B-SRL score with academic performance, DF rates were inspected for each set of students with a particular B-SRL score. For the 376 students, the DF rates for each B-SRL score generally tends to decrease as the B-SRL score increased. Particularly, the groups of students who received a B-SRL score of 0, 1, 2, 3, 4, and 5 had DF rates of 46.9%, 32%, 27.8%, 31.2%, 24%, and 17%, respectively. Note that the group with a B-SRL score of two deviates slightly from this pattern. It is worth noting that this B-SRL group is smaller compared to other B-SRL groups (n=18, compared to, on average, n=71.2). Further investigation of this group is warranted, but outside the scope of this report.

In comparing students who had high B-SRL scores (B-SRL score ≥ 3) with students with low B-SRL scores (B-SRL score < 3), Spearman's correlation revealed significant differences between the groups on all course exams and the final course grade ($0.14 \leq r \leq 0.23$ and $0.001 \leq p \leq 0.005$), suggesting that students with high SRL have higher scores than students with low SRL.

Discussion

These preliminary findings show promise for being able to use an SRL framework to develop tools that measure students' SRL through observable means. Using purposefully-designed tools, we developed a method for generating a B-SRL score for students by analyzing their online interactions, specifically those around prerequisite remediation and readiness for Calculus I. The relationship between B-SRL scores and academic performance metrics suggests that students who tend to self-regulate their precalculus abilities more tend to be more successful in Calculus I, which aligns with what is seen in the literature (e.g. Zimmerman et al., 2011; Zimmerman & Schunk, 2001). Similarly, students who self-regulate more tend to perform better on exams compared to those who self-regulate less.

Some foundational STEM courses implement 'gateway exams' at the beginning of a course to assess student readiness for the course. The methodology discussed in this paper expands on this strategy, going beyond just prerequisite content knowledge by incorporating student SRL strategies and remediation tendencies as well. The B-SRL score and discussed tools can further aid in early detection of at-risk students, informing intervention to support and improve student success in Calculus I and STEM. Future efforts in this project will be to utilize results to inform course design and pedagogical decisions to better support at-risk and underprepared students.

AN EXPLORATORY APPROACH TO ANALYZING STUDENTS' EYE MOVEMENTS WHEN SOLVING MATH PROBLEMS

Eye movement is important data to consider when studying students' cognition processes while solving math problems. However, the large amount of data makes it challenging for educators and researchers to discover meaningful patterns. Thus, this paper proposes using visualization and the Shneiderman visual information-searching theory —"Overview first, zoom and filter, details on demand"—to enable educators to easily and logically discover temporal and spatial patterns in eye movement data.

Keywords: Data Analysis and Statistics, Research Methods, Problem Solving, Technology

Introduction

Eye tracking is an important technology that has been increasingly used in recent education research. An eye tracking system can capture students' eye movements, reflecting their visual attention distribution in real time. From these data, researchers link students' eye movements to their internal cognition processes, which are also the processes of decision making. Eye tracking systems have successfully provided eye movement data support for educators to elucidate many aspects of students' cognition processes, such as visual attention (Takacs & Bus, 2016), problem-solving strategies (Thibaut & French, 2011), and comprehension and learning processes (Liu & Shen, 2011).

However, since the big data size challenges people's data exploration and analysis abilities, determining how to analyze eye movement data is difficult. Hundreds of data points per second are produced by eye tracking systems, making it impossible to analyze the data line by line. We need an effective method for simplifying the data and extracting valuable information. A typical method for simplifying eye movement data is choosing metrics such as fixation numbers and fixation duration to conduct statistical analysis (Lai et al., 2013). However, this method discards rich spatial and temporal information related to eye movement data. Here, the authors propose a method that uses information visualization techniques and a visual information-searching mantra to help teachers explore students' eye movement data efficiently. Specifically, this study applies the Shneiderman visual information-searching theory to educational eye movement data analysis in order to facilitate data exploration and pattern discovery. The Shneiderman visual information-searching theory introduced three steps for exploring visual data: "overview first, zoom & filter, details-on-demand" (Shneiderman, 1996). In the following sections, the authors apply visualization techniques to eye movement data from a mathematical problem-solving project to illustrate how this theory can be used to analyze eye movement data.

Methods

Stimuli and Participants

The computer program used in this study is a Conceptual Model-based Problem-Solving

(COMPS) tutor, which was developed to promote additive mathematics problem-solving. Figure 1 is a typical task that students were given. They were asked to represent the information from the word problem task in the Part-Part-Whole (PPW) diagram equation. Then, based on the PPW equation, students were required to set up the math equation. Ten third-grade students (five boys, five girls) participated in the study. Their eye movements were recorded by Tobii Pro X3-120 eye trackers during their interactions with the computer program.

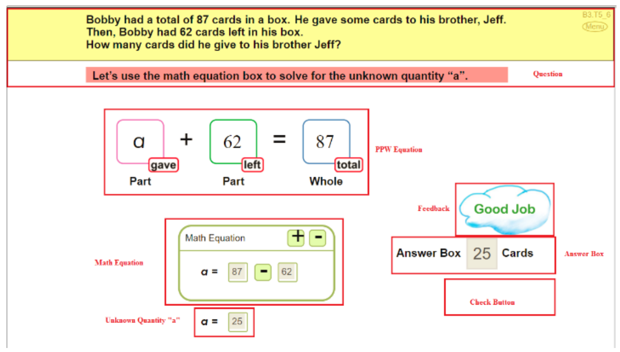

Figure 1. Layout of A COMPS Task with AOIs (Area of Interest)

Visualization Exploration

The visualization exploration process follows the Shneiderman information visualization-searching theory. First, the overview stage reveals students' eye movement patterns under each question structure. Then, zoom and filter closely observes eye movement data and discovers patterns worth future exploration. This process examines details on demand to investigate outliers, patterns, and differences. We hypothesize that by using Shneiderman, educators can quickly understand students' behaviors, identify concerns, and determine differences among them.

Overview first. Visualizing eye movements without considering the problem-solving context is neither accurate nor complete. Consolidating eye movement data within the context of the question and students' performance is necessary for obtaining an integrated and comprehensive view of students' attention distribution that reflects their internal cognitive process. In Figure 2, the first column signifies the task content. Each circle represents the length of time a student spent on the task. The outer ring of a circle is separated into arcs, according to the different stages of each student's interaction. For example, the light gray arc shows the percentage of time a student spent reading the question, while dark gray indicates the operating segment. The red/green arc is the feedback segment, and its color is determined by the correctness of the students' operation (incorrect-red /correct-green). Since students have two opportunities to try, some circles have two operation and feedback segments. The inner sectors indicate the total fixation duration of each interaction segment, while the color of each sector corresponds to the area of interest (AOI) color within which the fixations were distributed.

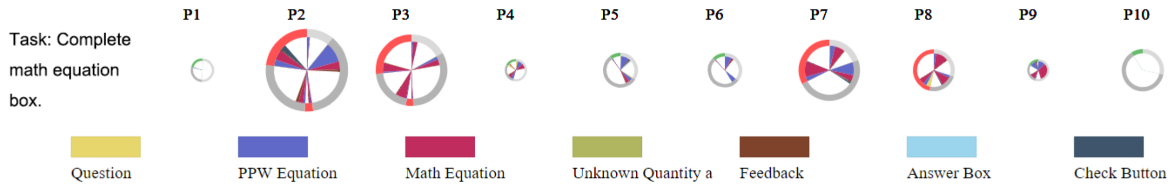

Figure 2. Students' Eye Movement Data Overview

As shown in Figure 2, six students completed the task fluently, indicating that they have no difficulty in transferring the PPW equation into the math equation. Four students failed the task. Two of them (P2 and P3) tried twice and still failed. It seems that, compared with the other students, those who struggled to solve the problems tend to spend much more time looking at the math equation area. To get more accurate information, we needed to zoom in and filter out unnecessary information.

Zoom and filter. The visual graphs of P4 and P5 are small in Figure 2, since students spent relatively less time on these tasks. Because of this, zoom is needed to observe the graphs. Even closer exploration can be supported by using filters. Figure 3 shows students' fixation distribution when reading the questions. Operation segment, feedback segment, and participants (P1 & P10) who have no eye movement data in the reading segment are filtered out. Obvious eye movement differences between high-performance and low-performance students can be observed. High-performance students focused on the filled PPW equation, while low-performance students spent little time on the PPW equation, indicating that they could not build connections between the PPW equation and equations. They looked at the math equation but were confused about how to fill it in. This pattern suggests that low-performance students have difficulty understanding abstract equations.

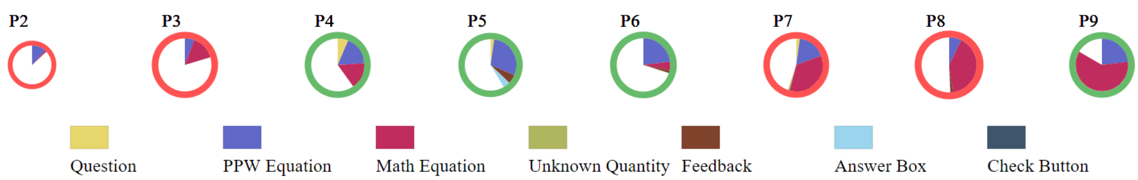

Figure 3. Fixation Distribution in Reading Segment

In the overview stage, educators gain a global understanding of students' performance and eye movement distributions. The zoom and filter techniques strengthen the exploration process by filtering noise and providing a clear view of information. Students' eye movement patterns can be observed at this stage. As the data is still aggregated, a more detailed exploration of the spatial and temporal acuities of the eye movement patterns is needed.

Details on demand. The "Zoom and Filter" stage reveals different fixation patterns between high- and low- students. Figure 4 pinpoints the moment when students' attention switches between the PPW equation and the math equation. This provides useful information: 1) all students looked at the math equation at the beginning of the task, but high-performance students switched their attention to the PPW diagram equation within two seconds, while low-performance students kept their attention on the math equation for at least three seconds; 2) Low-performance students kept looking back at the math equation during the reading segment and paid little attention to the PPW equation, while high-performance students focused on the PPW equation for a relatively long period of time. Although only four participants' visual graphs are presented in Figure 4 due to space limitations, similar patterns can be observed in all participants' eye movement visualizations. This suggests that the timing patterns extracted from this visualization can successfully capture differences between high- and low- performers.

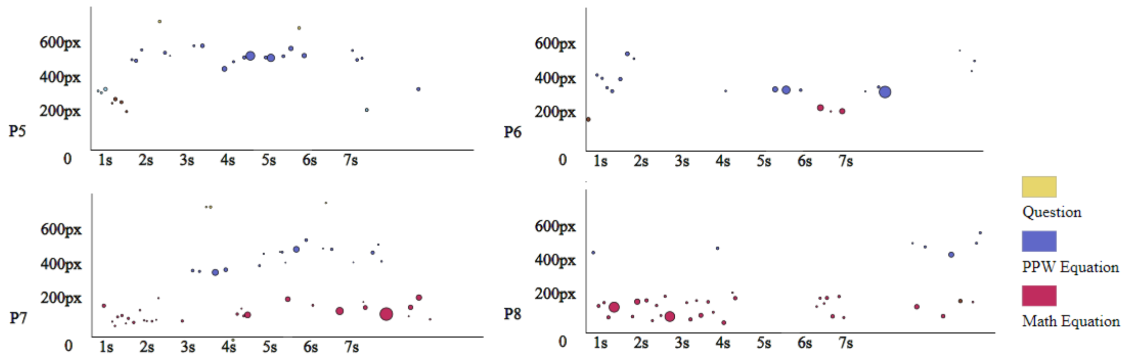

Figure 4. Visualizing Eye Movement Data from Reading Segment

Conclusion

This study presents a visual exploration approach to investigating students' eye movements when solving math problems. The visual exploration example from the COMPS project illustrates how the Shneiderman visualization searching-theory can be used to analyze complex eye movement data. In the past, research has relied exclusively on statistical models, causing valuable patterns to be ignored. The proposed approach can help educators and researchers track patterns in students' eye movements and discover valuable research directions related to students' cognition process.

In this study we investigate how students watch and learn from a set of calculus instructional videos focused on reasoning about quantities needed to graph the function modeling the instantaneous speed of a car. Using pre- and post-video problems, a survey about the students' sense-making and data about the students' interactions with the video, we found that many students did not appear to make significant gains in their learning and that students appeared to not recognize their own moments of confusion or lack of understanding. These results highlight potential issues related to learning from instructional videos.

Keywords: Technology, Instructional Activities and Practices, Post-Secondary Education

In recent years, "flipped" classrooms and massive open online courses have been promoted as effective ways to deliver content to students and to support active learning in the classroom (e.g., Schroeder, McGiveny-Burelle, & Xue, 2015). Although there is increased interest in using these techniques and a growing body of research literature on student learning in flipped classrooms (e.g., Maxson & Szaniszlo, 2015), there is still relatively little empirical data to support the claims of the efficacy of these instructional innovations.

With a few exceptions (e.g., Weinberg & Thomas, 2018), there have been virtually no studies that have investigated how students utilize the out-of-class resources or how students' experience with the videos supports their construction of particular mathematical meanings. Instead, the research has been based on an implicit empiricist epistemology, assuming that not only do students actually watch and learn from the out-of-class resources, but that the students uniformly construct the meaning the instructor believes the video to convey. Thus, it is important for us to investigate how students engage with and learn from instructional videos.
Our research questions are:

- How often do students pause or re-watch sections of the videos?
- What do students learn from watching instructional calculus videos? How is students' learning connected with their video-watching activity?
- What aspects of the calculus videos do the students find confusing? How is this connected to their learning?

Theoretical Framework

Sense-Making Gaps

Sense-making research (e.g., Dervin, 1983) has been used in the fields of information systems and, more recently, in mathematics education (e.g., Weinberg, Wiesner, & Fukawa-Connelly, 2014) to understand the ways individuals perceive, act within, and make decisions in situations. From this perspective, students experience gaps—moments of confusion or questions that must be answered or overcome in order to construct meaning for the video. Gaps are not a feature of the video, but rather are a product of the interaction between the video and the student's knowledge, beliefs, and purpose for watching the video.

Covariational Reasoning

To make sense of dynamic situations modeled by calculus, students construct relationships between conceived quantities that co-vary (i.e., change together), that is, they develop and apply *covariational reasoning* (e.g., Thompson & Carlson, 2017). Carlson, Jacobs, Coe, Larsen, and Hsu (2002) defined this as "the cognitive activities involved in coordinating two varying quantities while attending to the ways in which they change in relation to each other" (p. 354).

Methods

Video-watching was assigned in three of the authors' first-semester calculus classes. There were 29 volunteer student participants, with only 23 also completing the post-video survey. We describe student activity and learning from one set of three instructional videos that focused on graphing derivatives. The first video described how to use ideas about amounts of change to construct a distance-versus-time graph; the second video described how to construct and graph rates of change; the third video provided another example of constructing a graph of speed. All the videos were hosted on the Ximera online platform (https://ximera.osu.edu/), which recorded the timestamp of each student interaction with the videos—playing, pausing, and skipping backward or forward. In order to (potentially) identify places where students experienced a gap, we classified each pause and skip-back as a "revisit"—a place where the student felt that some aspect of the video was either important, unclear, or confusing.

Prior to watching the set of videos, students were presented with a graph of a cubic function $y=g(x)$ and asked to solve three problems related to approximating values of $g'(x)$. After watching the videos, the students were shown a graph of a quartic function $y=f(x)$ and asked to solve eleven problems that were similar in nature to those in the pre-video assessment. In order to further identify students' gaps, the students completed a sense-making survey in which they were asked to describe aspects of the video that were confusing or could use additional explanation. We used thematic analysis (Braun & Clarke, 2006) to generate initial descriptions and categories of the students' responses.

Results

Student Learning

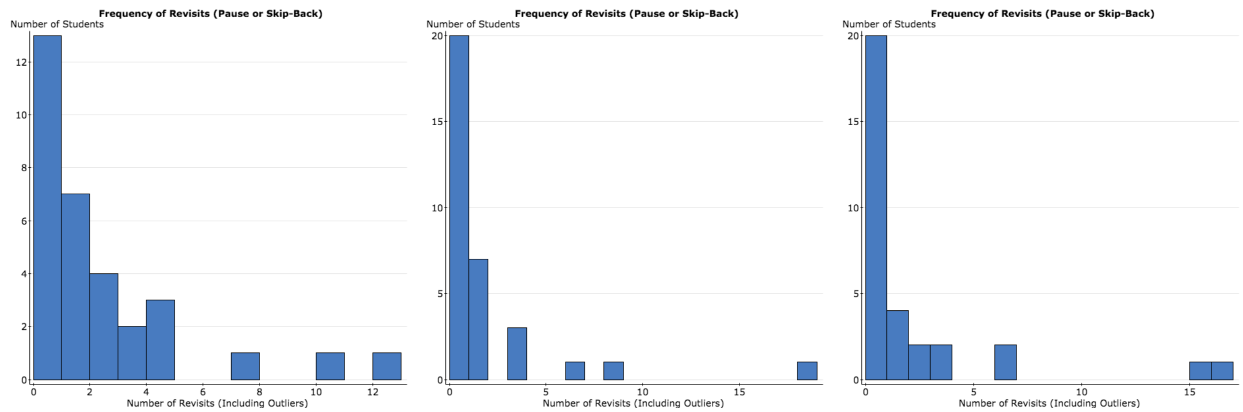
As shown in Table 4, the students correctly answered 41% of the pre-video problems and did not improve their scores significantly on their first attempt at the post-video problems ($t(28) = 0.9184$, $p=0.3662$)). Their mean score on their second attempt at the post-video problems was 82%, which was significantly higher than their pre-video scores ($t(28) = 7.7617$, $p<.0001$). The students' mean normalized gain (Bao, 2006) scores was 4.9% when comparing the pre-video problems and first attempt at the post-video problems and was 63% with the second attempt.

Revisits

The histograms in Figure 5 show the number of "revisits" (i.e., times each student paused or skipped backward) for Videos 1, 2, and 3. This shows us that, particularly in Video 2 and Video 3, most students never revisited during the video; in Video 1 roughly half of the students paused at least once. There were a handful of students for each video who revisited relatively frequently (i.e., their number of revisits was an outlier for the video).

Table 4: Student scores and normalized gains on the pre- and post-video problems

Group	Mean Pre-Video Score	Mean Post-Video Score (First Attempt)	Mean Post-Video Score (Second Attempt)	Mean Normalized Gain (Pre to First Post)	Mean Normalized Gain (Pre to Second Post)
Overall	41% (*SD*=30%)	46% (*SD*=17%)	82% (*SD*=15%)	4.9% (*SD*=37%)	63% (*SD*=34%)
Students with >50% on Pre		56% (*SD* =16%)	90% (*SD*=11%)	-22% (*SD* =32%)	47% (*SD* =49%)
Students with <50% on Pre		41% (*SD* =17%)	78% (*SD* =16%)	19% (*SD* =31%)	71% (*SD* =20%)



Video 1 Video 2 Video 3

Figure 5. Histograms of number of revisits by students per video.

Comparing Revisits and Learning

We performed a linear regression on the normalized gain scores (on pre-video problems to post-video problems) versus the number of revisits produced positive slopes; for the purpose of performing this regression, we eliminated one high-leverage data point (one student had a total of 46 revisits). When comparing the pre-video and first attempts at the post-video problems, the slope was not significantly different from zero (β =-.353, $t(26)$ = -0.353, p=0.727); this was also the case for the second attempt at the post-video problems (β = 0.00943, $t(26)$ = 0.649, p=0.522).

Survey Results

On the sense-making survey, 16 out of 23 students said that the video didn't need any additional clarification; these students only averaged getting 48% of the post-video problems correct on the first try, and only 85% after the second try. Of the six remaining students, three suggested clarifications that weren't directly related to graphing the derivative or the presentation of the video. The remaining three students indicated confusion about the triangle depicting amounts of change in distance and time together with a secant line; the relationship between the function increasing/decreasing and the derivative graph; and the relationship between the shape of the graph of the function and the shape of the derivative graph, respectively.

Discussion

The results for the students' performance on the pre- and post-video problems—in particular, their relatively poor performance on their initial attempts at the post-video problems—suggest that the students' learning was not particularly significant. Potential explanatory factors, such as the frequency of pausing or skipping backward (an indicator that the student experienced gaps in their understanding) were not associated with the students' normalized gain scores.

Most students never revisited the videos. In their responses to the sense-making surveys—which were written after the students had completed and received feedback on the post-video problems, the students indicated that they generally felt that the videos were clear. We found this surprising since the students tended to struggle with the post-video problems.

There are several potential explanations for these results. Perhaps the explanations in the video could be improved or there could be better alignment between the mathematical content of the video and the pre- and post-video problems. However, it also could be because the students didn't experience gaps or recognize their own lack of understanding thereby neglecting to revisit moments within the video that were critical for their own learning. Students' insistence that the videos were clear—even after they struggled with the post-video problems—could be attributed to either their inability to reflect on their own understanding and a propensity to attribute their struggle to a perceived inherent difficulty of mathematics.

Despite creating instructional materials guided by research-based recommendations, the students did not appear to construct an understanding of the underlying concepts sufficient for successfully solving to the post-video problems. This calls into question the effectiveness of instructional videos as stand-alone teaching tools. Moreover, that students did not experience gaps or recognize their lack of understanding exposes one of the most commonly-proposed benefits of a flipped class—the students' ability to re-watch videos. If students do not recognize their lack of understanding, they will not take advantage of this aspect of a flipped classroom. The scope of conclusions we can draw is limited by the relatively small sample size, the focus on a single calculus topic, and the use of a single set of videos. It is important to further investigate these conclusions by exploring how students watch, interact with, and learn from other instructional videos and other mathematical topics.

THE EFFECT OF A COMPUTER-ASSISTED MODEL-BASED PROBLEM-SOLVING PROGRAM FOR STUDENTS WITH LEARNING DIFFICULTIES IN MATHEMATICS

According to recent National Assessment of Educational Progress (2015), 60% of American 4th graders performed below proficiency level in mathematics. For students with disabilities, about 85% performed below the proficiency. In the meantime, there is a serious shortage of curriculum materials and teachers in providing high quality Response-to-Intervention (RtI) programs to students who are struggling in mathematics. The purpose of this single-case research design study was to evaluate the effect of a computer-assisted RtI program that emphasizes mathematical model-based problem solving on enhancing problem-solving performance of three elementary students with learning disabilities or difficulties. Findings from this study indicate promising effects of the program.

Keywords: mathematical model-based problem solving, computer-assisted instruction, students with learning difficulties, elementary mathematics problem solving.

Background and Conceptual Framework

While mathematics problem-solving skills are well recognized as critical for virtually all areas of daily life and for successful functioning in school, at home and in the community, many students with learning disabilities/difficulties in mathematics (LDM) fail to acquire key math concepts, such as additive and multiplicative reasoning, during the early school years. According to recent National Assessment of Educational Progress (NAEP, 2015), 60% of American 4th graders performed below proficiency level in mathematics. For students with disabilities, about 85% performed below the proficiency. In fact, about 5-10 % of school age children have been identified as having mathematics disabilities (Fuchs, Fuchs & Hollenbeck, 2007) and students whose math performance was ranked below the 20 to 35 percentile are often considered at risk for learning disabilities or for having learning difficulties in mathematics (LDM) (Bryant, et al., 2011). Given the increases in sophisticated and affordable technology for in and out of school, parents and teachers often turn to the many games, ‘apps,’ and web-based teaching/learning programs for help. However, there is a lack of intervention programs that focus on nurturing *conceptual understanding* of fundamental mathematical ideas--concepts that are essential to enabling students with LDM to understand and solve word problems.

Conceptual Model-based Problem Solving (COMPS) Tutor

Supported by National Science Foundation (NSF), we have developed a prototype of a computer-assisted COnceptual Model-based Problem Solving (COMPS) tutor, as a Response-to-

Intervention (RtI) program, to address the skill deficit of second- and third-grade students with LDM in meeting the challenging mathematics curriculum standards, particularly in the area of additive word problem solving. The COMPS-RtI program reflects a shift from traditional problem-solving instruction, which focuses on the *choice of operation* for solution, to a mathematical model-based problem-solving approach that emphasizes an understanding and representation of mathematical relations in algebraic equations. The explicit strategy teaching also makes the reasoning behind mathematics explicit to the students, so that they are able to make sense of what they are doing with mathematical models and abstract symbols.

The purpose of this study was to explore the effect of computer-assisted COMPS-RtI program that emphasizes mathematical model-based problem solving involving elementary students with LDM. Specific research questions were: (1) what was the functional relationship between the intervention delivered by the COMPS-RtI tutor and students' performance on solving addition and subtraction word problems measured by a researcher-developed criterion test?; and (2) were students able to transfer their learned strategy to solve problems with different story situations?

Participants and Setting

This study was conducted within the larger context of a National Science Foundation (NSF) funded project (Xin, Kastberg, and Chen, 2015). Participants were three 3rd graders with LDM, who enrolled in an urban elementary school in the United States. Three students (two girls and one boy) were included in the general education classrooms for 80-100% of the school day and they were all receiving Tier III Response to Intervention (RtI) support. All the instruction and testing were conducted in the school's computer lab during the afterschool program Monday through Thursday. Specific participant selection was based on the following criteria: (a) students identified as having difficulties in mathematics by the school and (b) students scored below the 25th percentile on the *Mathematics Problem Solving* subset of the Stanford Achievement Test (SAT-10; Harcourt Assessment, 2004).

Dependent Measures

The primary dependent measures is a researcher-developed *criterion test* (adapted from Xin, Wiles, and Lin, 2008) involving eight part-part-whole additive word problem solving items (including situations such as *combine*, *change-join*, and *change-separate* with unknown quantity placed at all possible positons), similar to problems included in the training module. The generalization test (adapted from Xin et al., 2008) not only includes part-part-whole problem structures but also additive comparison problem types (involving the "…more than..." or "…less than…" situations).

Experiment Design

An adapted multiple-probe-design (Horner & Baer, 1978) across participants was employed to evaluate potential functional relationship between the intervention and participants' word problem-solving performance. We chose a single-subject research design because the design provides a methodological approach well suited to conduct single case or group studies. In a multiple-probe-design, the intervention effects can be demonstrated by introducing the intervention to different baselines or participants at different points in time. "If each baseline changed when the intervention is introduced, the effects can be attributed to the intervention rather than to extraneous events" (Kazdin, 1982, p.126). The design included a *Baseline* (students were assessed on the criterion test and generalization [G] test), COMPS-RtI

Intervention (repeatedly measured on criterion test), followed by posttests and maintenance tests (criterion test and G test). Multiple equivalent test forms were used for the assessment during baseline, intervention, and post-intervention phases.

Procedure

All three participants completed one criterion test during the baseline condition. Then one student (Amelia) took another two equivalent criterion tests. Following the baseline, the intervention was first introduced to Amelia. Once the data for Amelia showed an accelerating trend, the intervention was introduced to the second student Sam immediately after he took two additional baseline tests. The same sequence was followed until all three participants were introduced to the intervention. Posttests and maintenance tests follow the intervention. Participating students worked with the COMPS-RtI tutor one–on-one on a laptop computer four times a week, with each session lasting about 20-30 minutes. Graduate research assistants supervised all the sessions. Their roles included administering pre-post assessment, recording computer/program's "bugs" and guiding students to appropriate part of the program after any unexpected "interrupt." Participants received about a total of 11-12 sessions during the spring semester.

Intervention Components

The COMPS-RtI program addresses Common Core State Standards (CCSS): Content.2.OA.A.1 *Represent and solve problems involving addition and subtraction*: "Use addition and subtraction within 100 to solve one- and two-step word problems involving situations of adding to, taking from, putting together, taking apart, and comparing, with unknowns in all positions, e.g., by using drawings and equations with a symbol for the unknown number to represent the problem" (CCSS Initiative, 2012). As part of the NSF-funded project, the COMPS-RtI tutor used in this specific study focused on solving part-part-whole problem types (e.g., *combine*, *change-join*, *change-separate*) but not comparison problems. Before solving real world problems, Part-I of the program engaged students in a series of activities involving the use of virtual manipulatives such as unifix cubes and coverings guided by a constructivist view of mathematics learning. The goal of this part of the program was to nurture fundamental mathematical ideas that are crucial for the development of additive reasoning and problem solving. It focuses on students' conception of "number as the composite unit" and the development of multi-digit numbers as quantities of tens and ones.

Building on these fundamental ideas, Part-II of the program focused on representing various additive word problem situations in a cohesive mathematical model equation. Part-III of the problem engage students in representing and solving contextualized real world problems using the mathematical model equation. The goal of Part-II and Part-III of the program was to engage students in constructing the big idea of "*Part* and *Part* makes up the *Whole,"* which leads to conceptual understanding of the mathematical model equation "P + P = W." Early in the program, Singapore bar models (Ramakrishnan & Soon, 2009) were used to facilitate students' transition from isolated unit of ones to the composite unit (CU); the bar model also facilitates students' conceptual transition to symbolic level of operation as they use the mathematical model equation to represent and solve various part-part-whole (PPW) word problems. The program engages students in decontextualizing mathematical relations from various real-world story problems, and then representing them in a single mathematical model, P + P = W, which *drives* the solution plan including the decision on the choice of operation.

Results and Discussion

All three participants' baseline performances were low and stable indicating the need for intervention. During the intervention, participants gradually improved their performance only after they worked with each part of the COMPS-RtI program. Although there are some variations across three participants in their performance after each part of the program, overall changes in performance during and after the intervention indicate students' improved performance following the COMPS-RtI intervention. Across all three participants' data path, there is no overlapping between baseline performance and the performance during the intervention as well as post-intervention assessment. This is an evidence of a strong treatment effect (Percentage of Non-overlapping Data [PND] = 100%, Scruggs & Mastropieri, 1998). In addition, all participants maintained their improved performance at an average of 90%, 87%, and 90% correct respectively during posttest and follow-up test phase. In addition, all three participants improved their scores on the generalization (G) test. However their performances were around 50 or 60% correct. It should be noted that the G test included additive comparison problem types that were not covered in the current version of the COMPS-RtI program. Systematic programing and training for skill transfer may be essential for students with LDM in particular.

INVESTIGATING SPATIAL AND TEMPORAL REASONING OF ELEMENTARY STUDENTS THROUGH GAMIFIED MATHEMATICS SOFTWARE

Sheunghyun Yeo
University of Missouri-Columbia
syhw6@mail.missouri.edu

The purpose of this study is to explore how elementary school students engage with the mathematical concepts embedded within "Spatial-Temporal" (ST) representations. I found a wide spectrum of conceptual understanding of ST Math, from strong connections with the mathematical concepts to little connections. When students had more access to the mathematical concepts and the explicit structure of the task, they tended to articulate the mathematical meaning of ST representations. However, some students appeared to make little sense of the apparent mathematical concepts. These findings suggest that ST Math tasks could improve engagement with the operational mathematical concepts, but a sense-making approach would additionally support a better relationship between ST representations and mathematical concepts.

Keywords: Technology, Elementary School Education, Number Concepts and Operations

Introduction

The integration of technology in mathematics education has increased; however, mathematical thinking is not driven by technology alone (Heid, 2005). Investigating the way students interpret technology through a mathematical lens and connect mathematical concepts is vital to use technology effectively. Regarding sense-making and reasoning, technologies can be categorized as either *conveyance* or *mathematical action tools*, based on their purposes within mathematics instruction (Dick & Hollebrands, 2011). *Conveyance technologies* are used to convey information such as presentation, communication, sharing/collaboration, and assessment/monitoring/distribution not oriented to mathematics content. *Mathematical action technologies* enable students to interact and receive feedback during the performance of mathematical tasks such as computational /representational tool kits, dynamic geometry environments, micro-worlds, and computer simulations.

Many researchers consider mathematical action tools as cognitive technologies which Pea (1985) defined as those which help users "transcend the limitations of the mind...in thinking, learning, and problem-solving activities (p. 168)." Also, these cognitive technologies are articulated either as *amplifiers* or as *reorganizers*. *Amplifiers* enhance the processes such as students' ability to solve problems in an efficient way, but do not change their thinking. *Reorganizers* engage cognitive processes by modifying the process of cognition (Barrera-Mora & Ryes-Rodriguez, 2013). This type of technology allows establishing the dialectic relationship among our actions, the forms of thinking, and the functions of technology which influence the acquisition of mathematical knowledge. According to What Works Clearinghouse (U.S. Department of Education, 2013), only one out of 40 mathematical programs pertained to high-quality elementary mathematics technology research. Much technology in the elementary school level is focused on drill-and-practice as *amplifiers* not conceptual understanding.

Recently, Spatial-Temporal (ST) Math, a game-based instructional software, is used in mathematics classrooms from kindergarten to middle school. In the same spirit of *reorganizers*, helping student's cognition enhance, the main feature of ST Math is to utilize interactive visual representations to build conceptual understanding with little language and symbols. ST Math is designed to aid students with learning spatial and temporal reasoning through visualized representations in which mathematical concepts are infused with dynamic action introducing mathematical concepts and procedures. Spatial and temporal reasoning means making a mental image and thinking ahead in space and time (Peterson et al., 2004). The game-style design and exercises are intended to get students engaged and motivated when solving each task (Rutherford et al., 2014). If students successfully complete a lower level in the task, then more challenging and difficult levels are proposed gradually.

This study aims to explore the spatial and temporal reasoning of elementary school students when they are engaged with ST Math software. In particular, this study seeks to examine the following questions: (a) What connections do students make between the spatial-temporal representations and the mathematical concepts they are meant to represent? (b) How do different activities appear to provide different access to the mathematical concepts?

Methodology

In a mathematics education methods course, elementary pre-service teachers (PSTs) participated in a series of one-to-one task-based interactions with elementary students in a Midwest elementary school. The goal of the interactions were for the PSTs to help support elementary students' mathematics learning and to make sense of children's mathematical thinking.

Twenty-one PSTs had a training session about how to use ST Math prior to an actual interview. PSTs selected specific ST Math tasks such as Pie Monster, How many petals?, and Building Expressions (Figure 1) based on the belief that which task was well-suited to their assigned student's mathematical proficiency level; the PSTs also prepared a script to use for questioning. PSTs interviewed the assigned child for 10-30 minutes and reported reflections on the interview as a course assignment. The audio and screen display were recorded via iPad's screen-casting function. This screen-casting enables the real-time recording of students' explanation about the task including their touching and dragging on the screen.

To analyze the elementary students' ST Math activity, I evaluated screen-casted videos and made a condensed file to extract information (e.g., task, level, attempted problems, and the rate of correct answers). Each video was transcribed and analyzed one at a time. A research memo was created and compared to find the common themes across the participants (Yin, 2013).

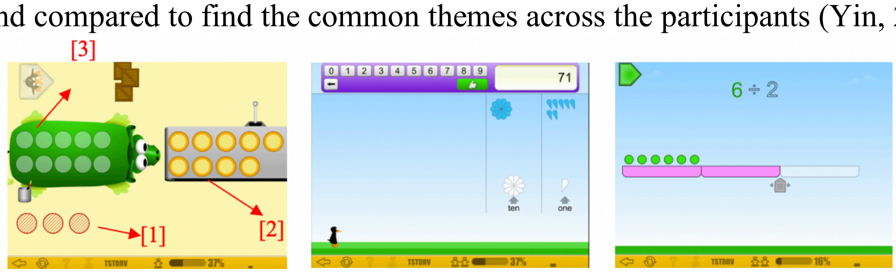

Figure 1. Pie monster (left), How many petals? (middle), and Building Expression (right)

Findings

Ways in which the students engaged with the spatial-temporal representations were analyzed by focusing on the mathematical interpretations students articulated when solving ST Math tasks. The following section presents the cases of one child (Amy) across the samples, selected on the basis of how children connected mathematical concepts with the ST representations in the given tasks.

Strong Connection with Mathematical Concepts

Clear relation to the ST representations. When some students solved the ST Math tasks, they exhibited strong connection with the mathematical concepts embedded within the ST representations. For example, the first level in Pie Monster task represents part-part-whole relationship (Carpenter et al., 2015). In the Pie Monster task, the problem type is separate and there are three types of direct modeled representations. The screen (see Figure 1- left side) represents three red-circles [1] as the *change* (subtrahend), nine orange-circles [2] as the *start* (minuend), and the white circles [3] in the Monster's belly as the result (difference).

Amy showed strong mathematical understanding in this task. To find a solution, Amy was supposed to figure out how many pies would be put in the Pie Monster's body once the amount of orange circles was reduced. She perceived that the discrete pie models represented as the *change* (red) to subtract from the *start* (orange) when she said, "So, you see the number at the bottom? Those are how much you're going to subtract." In addition, she had clear understanding of the structure of the task as subtraction. The function of the red balloons is to remove the number of orange pies as the number of red pies the student chosen. After she selected the pie models on Monster's belly, she noticed the animated effect of balloons. At that time, she explicitly described that the orange pies took away from the number of red pies: "If you do three, it's going to take away three of them… count the rest of them." This shows that she distinguished the between the change, the start and the result in the Pie Monster context. From the ST representations, she extracted her strategy to count the left over after subtracting.

Little Connection with Mathematical Concepts

Weak connection with mathematical concepts. The students' ability to explain the relationship between ST representation and mathematical concepts was not consistent across different ST Math tasks. For example, the *Building Expression* task begins with choosing the size of the group, selecting the number of groups, then deciding the result from division and multiplication respectively.

Though Amy explained well her problem-solving strategy in the Pie monster task, she was struggling with the Building Expression task. At first, Amy chose six green dots, matching the first number 6 on the screen (see Figure 1– right side). Then, she selected two groups of pink boxes. Here, she was possibly interpreting 6 ÷ 2 as two groups of six, or she might have been trying simply to represent the number 2 by manipulating the bar, without considering the meaning of the operation. In either case, Amy did not appear to be connecting the division symbol to the concept of division as she was engaged with the task. The result she selected was two groups of six, a total of twelve dots. When Amy was asked to explain her reasoning about the Building Expression task, she was relatively reluctant to express her idea from the beginning of the interview—unlike with the Pie Monster task. She was not engaging with solving the task or responding to probes from the interviewer. In order to explore Amy's understanding, the interviewer asked about the meaning of the pink box since Amy was struggling with making a decision between two big boxes and small parts boxes. She used the negative words five times such as "I don't know!" and "It doesn't matter." Even though she strived to solve the task with dragging and tapping at first, she was struggling with connection between the ST representations and mathematical concepts.

Discussion

With regard to the mathematical concepts, the students show the wide spectrum of understanding from the ST representations. Across the examples, most students showed the ability to quantify the pictorial representations with numbers and vice versa. For example, in the

Pie monster task, Amy could interpret the discrete representation as the total number. She perceived the discrete red-colored pies as the number 3 to take away from nine orange pies. Also, Amy could visualize the number with the concrete representations in the Building Expression task. She matched six green dots with the first number 6 and two pink boxes with the following number 2. This fundamental skill to solve ST Math tasks is to match the numerical value with the ST representations (Sarama & Clements, 2009). Potentially, the visual models in technology can help the children see such connections (Moyer, Niezgoda, & Stanley, 2005).

ST Math activities have potential to support engagement with the mathematical concepts operationally. For example, through the exploration between red, orange and white circles in the Pie Monster task, Amy was able to access the operational concepts of the relationship between minuend, subtrahend and difference. The impact on students' conception should be considered at the heart of the program (Webel, Krupa, & McManus, 2015). Meanwhile, to become reorganizer, the comprehensive approach is required such as sense-making of the ST representations, verbalizing what the students think, and concentrating on the animated feedback (Barrera-Mora & Ryes-Rodriguez, 2013).

SHEARING TRIANGLES AND PYRAMIDS IN AN IMMERSIVE VIRTUAL SPACE: A STUDY OF PRE-SERVICE TEACHERS' CONCEPTIONS

Camden Bock
University of Maine
camden.bock@maine.edu

Justin Dimmel
University of Maine
justin.dimmel@maine.edu

Keywords: Technology, Geometry and Geometrical and Spatial Thinking, Measurement

Pre-service elementary teachers (PSETs) have difficulties extending measurement concepts to from two-dimensional to three-dimensional figures (Tossavainen et al., 2017). This matters because how teachers understand mathematical topics shapes how they present those topics to their students (Murphy, 2012). If the geometry activities expected of young children are to move beyond shape recognition and naming tasks (Bruce & Hawes, 2015), PSETs need to be prepared for deeper investigations of the measurement properties of plane and solid figures. The affordances of immersive spatial displays –where participants can engage directly with virtual, three-dimensional figures – may provide new opportunities for PSETs to explore measurement concepts (Dimmel & Bock, 2018). We ask: How do the affordances of immersive spatial displays allow pre-service elementary teachers to reason about relationships between plane and solid figures?

Immersive spatial displays (i.e. HTC Vive) allow learners to interact with solid mathematical figures in their native dimension, visually explore parameters that grow without bound, and directly interact with figures. A pilot study found that pre-service teachers might draw connections between plane and solid figures when exploring shearing in immersive spatial displays (Bock & Dimmel, 2017).

In an ongoing study, we are conducting task-based, semi-structured interviews, during which participants work in small groups to explore the shearing of plane and solid virtual manipulatives. In the case of the triangle, participants can shear the triangle, watching its perimeter grow without bound, by standing in its plane. First person and mixed reality views of the environments will be recorded with the audio from participant dialog. These interviews will be analyzed with Balacheff's Conception-Knowing-Concept model of the conception (2013).

PRE-SERVICE TEACHERS' USE OF TPACK THROUGH THE CREATION OF VIDEO LESSONS USING IPADS

Fernanda Bonafini
The Pennsylvania State University
fcb5100@psu.edu

Younhee Lee
The Pennsylvania State University
yul182@psu.edu

Keywords: Video lessons, Tablet integration, iPad, TPACK.

Curriculum policies set expectations for technology to be incorporated in teaching of mathematics so that teachers can better support their students in comprehending mathematics using the technology. This scenario reinforces the importance in higher education to prepare future teachers to employ technology in their teaching to foster mathematical understanding of their future students. Pre-service teachers' creation of video lessons using iPads emerges as a new use of technology in which they can actively explore mathematical content and develop communication skills that will be required in their future practice (Niess & Walker, 2010). In this paper, we investigate how pre-service secondary mathematics teachers incorporate their knowledge of technology, mathematics, and pedagogy in a project of creating video lessons using an app called ExplainEverything (EE) on an iPad. We characterize their experiences using the TPACK framework (Mishra & Koehler, 2006).

The context of this study was a methods course focused on teaching mathematics with technology offered at a large mid-Atlantic university. Seven pre-service teachers participated in this study, and this paper presents results on three participants. Data sources include participants' lesson plans, video lesson files, their reflection upon their own videos, and online surveys. Using qualitative research methods, students' video lessons were analyzed by the researchers in tandem with their respective lesson plans, reflections, and surveys and coded by TPACK components.

Results and Implications

The project of creating video lessons provided an opportunity for pre-service teachers to use their mathematical, pedagogical, and technological knowledge in an integrated way towards developing their TPACK. In their video lessons, participants showed effective use of technology (e.g., EE, GeoGebra, CAS), pedagogical techniques (e.g., pausing, questioning, and building on students' prior knowledge), and mathematical representations using technology (e.g., graphical representations). Results suggested that pedagogical aspects of participants' TPACK were the most salient feature of their videos when compared to the other components. Implications from this study support that using video lessons in teacher preparation provides opportunities for instructors to give specific feedback and guidance for preservice teachers to learn and reflect upon their practice as suggested by the literature (e.g., Sherin & van Es, 2009). It is recommended that teacher educators implement a cycle of learning in which preservice teachers can refine their pedagogical strategies, the rigor in their mathematics, and their use of mathematical action technology, if a similar project is to be used in teacher education programs.

Gadanidis et al. (2016) expressed concerns that CT in the K-12 curriculum is often viewed as its own objective, rather than used to promote other subjects. According to Resnick et al. (2009) one of the benefits of CT is that it promotes "wide walls", meaning it allows for a variety of projects and learners to engage and benefit from CT skills. Gadanidis et al., propose that mathematical thinking is an appropriate context for these wide walls. In contrast, Wong et al. (2015) say learning must trigger a students' interest so that the interest can be extended to new areas. In our research we explored the concept of wide-walls using two different approaches, one which used CT skills to trigger interest and later used math as the framework for the walls of CT The first activities used both unplugged activities and SCRATCH and were highly engaging for the students. The class was able to understand and communicate the importance of learning the basics of CT. Through the activities the researchers noticed that, when students asked for help, they were willing to answer questions about the reasons certain pieces of code influenced the outcome and were willing to explain to the instructor and themselves how to go about finding a solution. This optimism persisted throughout the classes.

The next set of lessons required students to build on their understanding of how to calculate area and perimeter by making their own code There was a significant lack of interest from the students that became evident in the results. Only one third of students ended up completing the activity. One new component was introduced in this process but all students worked through this new process on their own. Phrases such as "I can't do it" began to be prevalent in the classroom. Our results suggest that caution should be exercised in defining wide walls of CT by preset curriculum. Seeing as wide walls are intended to allow all students to engage, when CT is incorporated into a subject where students are not fully engaged or the connection is forced, the future benefit of CT to the curriculum may be lost, as was observed in our research. This is not to say that triggering students' interest in the learning loop is not possible with mathematics as the starting point; of course, mathematical problems can be creatively contrived to do just that.

Room-scale virtual reality (e.g., the HTC Vive) is an example of an immersive spatial display—a technology where *space itself,* rather than a two-dimensional surface, is a canvas for making inscriptions (Dimmel & Bock, 2018). Spatial displays make it possible to readily interact with figures at different scales and explore them from new perspectives. Despite their educational promise, spatial displays are likely to follow the slow, complex process of technology acceptance and adoption that is standard in schools (Ertmer, 1999; Inan & Lowther, 2010). The objective of our research is to look ahead to a time when spatial displays are ubiquitous and to begin, now, to prepare teachers to adapt their instructional practices to these new technologies. If such adaptations are to be accepted by teachers, teachers themselves will have to play a generative role in their design (Cobb, Zhao, & Dean, 2009). We thus cast teachers as partners in the process of designing instructional activities that are possible with spatial displays. We ask: How do secondary mathematics teachers anticipate using spatial displays as instructional tools in their classrooms?

To investigate this question, we developed an immersive, gesture-based virtual environment that places users inside a 10x10x10 grid of points, each of which has integer coordinates. The resulting lattice is a three-dimensional analog of the Geoboard (Gattegno, 1954). The environment defines a spatial canvas where learners can use gestures to construct and investigate lattice polygons or polyhedrons. We convened focus groups of secondary mathematics teachers, during which participants explored the environment, critiqued its capabilities, and designed instructional activities students could engage in through the environment. Two groups of four secondary mathematics teachers participated in the focus group study. We report how participants' explored the environment, their discussion of its potential for use in mathematics classrooms, and the instructional activities they designed.

Teachers who adopt a strengths-based approach identify and rely upon the assumed valuable resources that students bring to their classroom communities (Aguirre et al., 2013; AMTE, 2017). While the rhetoric of a strengths approach is relatively easy to endorse, the intentional practice of interpreting and leveraging student actions as mathematical strengths is far more difficult to enact (Jilk, 2016), especially for prospective teachers (PTs) given the broader culture of power and exclusion that has persisted in U.S. classrooms for over 40 years (Louie, 2017). An enduring challenge for mathematics teacher educators is to develop course-based approximations of practice (Grossman et. al, 2009) that provide PTs with meaningful entry points into this work. Recent advances in technology-based methods of teacher preparation suggest that the Lesson*Sketch* (LS) platform is a promising medium for helping PTs to learn this complex practice (Amador et. al, 2016; Bannister et. al, 2018). Our research questions were: What do PTs notice and name about students' strengths in a LS experience before and after they are given explicit support for using strengths-based language? Are there any changes in the quality and quantity of the claims and evidence PTs used in their noticing statements?

We used a sentence frame intervention in the LS experience to explicitly help PTs learn how to notice and name students' mathematical strengths (Bannister et. al, 2018). We analyzed the quality and quantity of the claims 22 undergraduate PTs in an elementary mathematics methods course made about student strengths and the mathematical evidence they used to justify these claims. We found statistically significant increases in the quality of their claims and the quantity of evidence they used to support their claims, which provides empirical backing for a course experience that MTEs can use to approximate and support PTs to learn strengths-based practice.

To address the needs of children with learning difficulties in mathematics (LDM), a mathematics computer tutoring program was developed to nurture conceptual understanding of fundamental mathematical ideas in students with LDM (Xin, Kastberg & Chen, 2015). As an intervention for this study, we used the Numerical Structuring Module (NSM) of the mathematics computer tutoring program, which was designed for developing the composite unit in additive problem-solving by provoking changes in children's mental operations.

Steffe and Cobb (1988) suggested a model that explains how children come to understand quantity by proposing the stages of number sequence development. In each stage, children show unique counting acts (e.g., Double-counting). The composite unit, defined as a unit composed of unit items, is developed by the result of mental operations developed through challenges to counting acts (Olive, 2001).

The purpose of our study is to understand the learning paths of one student with LDM, Sofia, as she engages in NSM. Two research questions are posed in our study: 1) What strategies does Sofia use and how does she develop her strategies when she engages in NSM?

The sources of data for our analysis included pre- and post-tests, video recorded tutoring sessions, field notes and the performance data on NSM. We used constant comparative analysis to analyze the video recorded sessions and field notes.

Through her interaction with a computer tutoring program, our participant exhibited the use of the composite unit consistent with Steffe's idea although she relied on using perceptual material (i.e., her fingers) when she kept track of her counting acts. Our finding indicates that our participant developed the effective double counting strategy using a perceptual material for compensating her working memory challenges.

This study investigates students' help-seeking practices and their perceptions toward peer interactions as they solve mathematics tasks in a hybrid physical/virtual space. This pilot study paves the way for creating an equitable learning technology platform to facilitate classroom interactions and discussions in which ALL students participate with confidence.

In 2013, the report of Programme for International Student Assessment (PISA) suggested that students' poor mathematics performance relate to their mathematics anxiety. To deal with this anxiety, struggling students can seek help not only from their teachers but also their peers. Research has shown peers can provide rich and meaningful feedback for learning (Gielen et al., 2010; Colley & Windschitl, 2016). However, help-seeking practices can be intimidating to students. Therefore, we aim to understand what would occur as students interact with peers to get mathematics help in different contexts and how they perceive the practices.

Using design-based methodology and a clinical-interview protocol, we revised our tasks and questions each round based on participants' responses and interactions. This study involved six (two boys, four girls) children ranging from 3rd-7th grade over three sessions. The activities were mainly facilitated by the first author, a 10-year veteran elementary mathematics and science teacher. Each session including interviews lasted approximately 45 minutes. In the first round, two subjects were seated together. The math questions were presented to each participant on a sheet of paper. In the second round, three subjects were seated separately. Each child was provided with a laptop or tablet with math questions posted on a Google Doc. In the third round, three subjects were seated separately and asked to work on one same math problem in a simulation of collaborative virtual environment, i.e., Google Docs.

This pilot study reveals various factors that influence an individual's help-seeking practices. The virtual space, Google Doc, was tested but failed to serve as an effective means because students were impeded by the linguistic demands of conventional semiotic registers of standard virtual arenas. Moreover, some students were cautious about who they interacted with in virtual space, others were open to interact with someone they did not know. These findings inform us of how a safe and interactive online learning environment could be designed to help discover silent students' voice, facilitate quality discussions, and create a more equitable math classroom.

Keywords: Technology, Elementary School Education, Instructional Activities and Practices

As technology becomes more prevalent in the classroom, it is important that we fully explore how students interact with learning technology such as laptops and tablets through native or peripheral inputs. Prior research comparing the two found that user's proficiency with each device depended on their prior experience using computers with experts were more efficient with a mouse while beginners were more efficient with a touchscreen (Thomas & Milan, 1987). When estimating the performance of each input device, it is important to also consider how each will alter the student's learning experience. This paper explores how students interact with a dynamic technology using a touchscreen versus a traditional mouse and how that affects learning gains.

From Here to There! (FH2T) is a dynamic math game that uses perceptual based interventions to introduce foundational algebraic concepts (Ottmar et al., 2015). The FH2T program was given to 23 first grade students, all within a single classroom with a single teacher. Of the 23 first graders, 11 students used a mouse on a computer and 12 students used an iPad tablet. Our in-class observations noted that students struggled to use the computer mouse and would instead try to physically move numbers manually with their hands out of frustration. These findings support Thomas & Milan (1987) in that touchscreen devices are preferred by beginners than the traditional computer mouse. However, we examined learning gains using a two-tailed t-test on the pre and post assessment test scores. This data suggests that learning gains are not significantly affected by either input device. This could indicate that deployment on a regular computer is just as effective as on a touchscreen device, thus not hindering learning due to inaccessibility. We believe this is an important finding as touchscreen devices such as iPads are more expensive and are not as readily available as laptops and desktop computers in schools.

MATHEMATICAL OPPORTUNITIES FOR LEARNING IN FREELY AVAILABLE PBS APPLICATIONS

Amy Noelle Parks
Michigan State University
parksamy@msu.edu

Laura Tortorelli
Michigan State University
ltort@msu.edu

Although recent evidence suggests that well-designed applications can positively impact mathematics learning (Foster, Anthony, Clements, Sarama & Williams, 2016; Schacter & Jo, 2017), few studies have examined the impact of mathematics applications that teachers or parents can find for free on the internet. Yet, these sorts of resources often get used in schools and at home. Broadly, the goal of this study is to explore the affordances of freely available resources by answering the question: What opportunities for learning mathematics do mathematics applications designed and made available by the Public Broadcasting Company make possible for urban kindergarteners?

This poster reports Phase 1 of the study, which included a mathematical content analysis of PBS applications, an analysis of initial teacher feedback, and a preliminary analysis of usage data that revealed how frequently children engaged with mathematics games in their classrooms. The study is not yet complete, but Phase 2 will include an ANOVCA analysis to identify relationships between usage and performance on district mathematics assessments. This mixed methods study began when national PBS educators produced a suite of 26 games with mathematics content and the ability to collect user analytics (such as duration of use, answers, etc.) Mathematics educators then reviewed the games to identify mathematics content. This analysis identified 10 games likely to provide productive mathematical interactions for kindergarteners. Treatment tablets were loaded with these math games, while control tablets contained only literacy and drawing games. Approximately 900 tablets were distributed to all kindergarteners in a single district.

The results of the content analysis demonstrated that about half of the designed games were not mathematically productive. For example, one application allowed users to succeed by repeatedly clicking the mouse to fill a given container without requiring attention to size or quantity. Another application asked users to wash, dry, and cut a character's hair. The only mathematics was the labeling of the steps as first, second, and third, and a character reciting the counting sequence while having his hair washed. For this reason, only ten math games were loaded onto tablets. Initial analysis of the usage data and of conversations with teachers suggests that teachers are regularly using these games. For example, about one month after distribution, approximately 300 unique users played the games in a two-day period. This analysis suggests that teachers are willing to incorporate technology into their instruction and feel comfortable doing so on their own, but that initial assessments of the quality of resources are important. Once the assessment data is collected as part of this study, we will have been insight about whether the games identified as potentially productive had any impact on student mathematical performance.

Keywords: Function, Calculus, Technology

For students studying upper-level mathematics, particularly those majoring in STEM fields, having a robust concept definition of function is an essential part of their continued study of topics in advanced mathematics (e.g., Thompson & Carlson, 2017). Thompson and Carlson (2017) note that it would benefit students learning calculus to have a more developed, conceptual understanding of function; and technology can be an effective way for students to make connections between different ways of thinking about function (Dick & Hollebrands, 2011). Students' definition of function is varied, with many being misaligned with the mathematical definition (Vinner & Dreyfus, 1989). Often students rely on the use of continuous functions or think of functions only in terms of a graph or algebraic formula (e.g., Vinner & Dreyfus, 1989). Thus, it is worthwhile to give students an opportunity to reexamine their definition of function using technology, especially in a manner which does not involve graphs, or equations.

We designed an applet to challenge Calculus II students' understanding of function. Our applet (https://ggbm.at/J3mJaU6H) featured a vending machine design, as this allowed us to put the concept of function in a context that did not make use of numbers or other traditional algebraic language. We specifically built the machines to problematize students' understanding of function. Thus we analyzed the students' pre and post definitions to answer the following question: How do students change their definition of function after engaging with the applet?

Pre- and post-definitions were collected from 87 Calculus II students from three different universities. Definitions were coded for many characteristics including accounting for correspondence with elements of the range. Our results indicated that 33 of the 64 students (52%) who did not account for correspondence in their pre-definition did so in their post. Our poster will share full details of our analysis and associated results.

CONSTRUCTING MICROWORLDS, CONSTRUCTING KNOWLEDGE, CONSTRUCTING COMMUNITIES: MATHEMATICAL MICROWORLDS AND CONSTRUCTIVIST THEORY

James Sheldon
University of Arizona
jsheldon@email.arizona.edu

Kai Rands
National Coalition of Independent Scholars
kai.rands@ncis.org

Mathematical microworlds are computer-based exploratory environments with a restricted set of operations but which have no fixed goals. Theories of learning take on a particular importance, as the way in which these environments are used in the classroom depends on how a particular instructor believes that students learn. This literature review surveys nine key articles on learning theory and microworlds, with a particular focus on how social constructivist theories can be used to explain the interactions between the student and the computer.

Keywords: Technology, Learning Theory

The purpose of this literature review is to examine theoretical research on mathematical microworlds and constructivism to determine the contribution that the study of mathematical microworlds (computer environments with restricted sets of possibilities but no fixed goals) has to offer to the ongoing discourse in the area of developmental and social constructivism.
For this literature review, we searched Google Scholar and ERIC for various combinations of the following phrases: math, mathematical, microworlds, constructivism, sociocultural theory, situated cognition, Piaget, and/or Vygotsky. We also used a snowball methodology to look at who cited the articles we found and who those articles were cited by. From this, we created a database of 27 articles. We excluded articles that were empirical and did not have a significant theoretical contribution to offer, narrowing the list down to n=9 articles.

Microworld theorists coming from a developmental constructivist perspective argue for microworlds that are open-ended and focus on studying individual student's explorations and processes. (e.g. Biddlecomb, 1994). Social constructivists raise concerns about the fixed nature of the tools (Cerulli & Mariotti, 2003) but are also intrigued by how the microworlds embed accumulated cultural knowledge (Chiappini, Pedemonte, and Robotti, 2003). Furthermore, they focus on the ways in which students interact with each other when working with these tools in a social context (Chiappini, 2003; Hackenberg & Sinclair, 2007).

Where we choose to focus our attention, on the individual (as the radical constructivists do) or on the social (as the social constructionists do), affects what sort of tools we will create.

ORIENTATION OF PEDAGOGY WHEN EXPLOITING CAS TECHNOLOGY IN THE DEVELOPMENT OF MATHEMATICAL KNOWLEDGE

Candace Terry
Middle Tennessee State University
Candace.terry@mtsu.edu

Keywords: Technology, Instructional Activities and Practice, Algebra and Algebraic Thinking

The purpose of this study was to understand (a) what pedagogical opportunities mathematics teachers exploited with the presence of CAS and (b) how teachers aligned lessons to develop mathematical understandings. The following research question guided the study: How do secondary mathematics teachers orient their instructional practices to exploit computer algebra systems (CAS) in the development of mathematical knowledge? This case study considered two secondary teachers pedagogy as they administered CAS technology. Data included lesson observations, interviews, and reflective writings. Pierce and Stacey's (2010) pedagogical framework (P-Map) illuminated the opportunities that teachers situate their utilization of CAS as a pedagogical tool. The data was matched to the P-Map and analyzed for emergent themes.

Background

The NCTM *Principles to Action* technology standard stated that "an excellent mathematics program integrates the use of mathematical tools and technology as essential resources to help students learn and make sense of mathematical ideas, reason mathematically, and communicate their mathematical thinking" (NCTM, 2014, p. 5). CAS tools have continued to advance in their simplicity, functionality, and availability, but are still not a part of standard educational practice (Heid et al., 2013). The mathematics education community is ripe for technological infusion with the teacher at the heart of implementation (NCTM, 2014; Heid & Blume, 2008). Teachers are the agent of change for technology use in classrooms (Ertmer & Ottenbreit-Leftwich, 2010). It is logical to first consider teacher instructional practice that utilized CAS to develop MK.

Results & Discussion

Teacher pedagogy was adjusted at these levels: subject, classroom, or task. The taxonomy presented by Pierce and Stacey (2010) formed the basis for the analysis. Findings indicate that these two teachers were creative in their methodological approaches. Teachers oriented lessons through outsourcing procedures, providing guidance, verifying answers, regulating access, investigating with multiple representations, and viewing CAS as a mathematical consultant. Motivations were grounded in the CAS' functional capabilities of accuracy and efficiency.

Keywords: Geometry, Spatial Thinking, Reasoning, Proof

We explore whether *directed actions*—body movements that learners are instructed to formulate—enhance mathematical reasoning during proof production. Evidence is mounting that sensorimotor activity can activate neural systems, which can in turn alter and induce cognitive states (Nathan, 2014). New interventions are using motion-sensing technology to track actions that support geometric reasoning (e.g., Smith, King, & Hoyte, 2014). We directed learners to perform mathematically-relevant (vs. irrelevant) motions through motion-capture video game play and hypothesized (H1) that directed actions will facilitate production of dynamic gestures, which will, in turn, (H2) improve students' nonverbal mathematical insights and the production of multimodal transformational proofs. Moreover, we hypothesized (H3) that adding pedagogical hints explicitly connecting directed actions to the conjectures enhances proof performance.

Thirty-five middle and high school students played the *Hidden Village* game for the Kinect. Students played through 6 conjectures, with 2 to 4 conjectures (with relevant motions) revisited where the interviewer revealed to students how the motions related to the conjectures. Students' responses were scored along 4 dimensions: (1) making spontaneous *depictive* gestures, (2) making spontaneous *dynamic* depictive gestures, (3) recognizing key mathematical *insights*, (4) formulation of a *valid* transformational proofs (Harel & Sowder, 1998).

Participants were more likely to make depictive gestures when performing mathematically relevant (vs. irrelevant) directed actions (Odds=4.2, d=0.8, p=.008). Participants who performed relevant directed actions were *not* more likely to make dynamic gestures (H1), demonstrate the mathematical insight, or provide a valid proof (H2; $p > 0.1$). However, after receiving the pedagogical hint (H3), participants were more likely to make depictive gestures (Odds=5.4, d=0.9, p<.001), dynamic gestures (Odds=4.0, d=0.8, p=.001), more likely to express the correct insight (Odds=3.1, d=0.6, p<.001), and more likely to formulate a valid proof (Odds=4.7, d=0.9, p<.001). Producing depictive gestures predicted mathematical insight (Odds=3.0, d=0.6, p=.007), but not formulating a transformational proof. However, making *dynamic* depictive gestures (H2) predicted both insight (Odds=8.1, d=1.2, p<.001) and proof (Odds=11.5, d=1.3, p<.001).

Results suggest that dynamic gestures may be associated with reasoning deductively about generalizable properties of space and shape and that pedagogical hints related to the directed actions are beneficial for insight and learning geometric proof.

Although flipped instruction is often viewed as a unified instructional model, many variations of flipped implementations exist in mathematics (de Araujo, Otten, & Birisci, 2017). Some teachers assign videos for homework and follow that with individual activities in class, whereas others assign videos with embedded questions followed by group projects in class. Extant observation protocols do not adequately capture the nuances between different variations of flipped lessons. Thus, we developed a classroom observation protocol robust enough to capture variations in flipped and non-flipped lessons.

Our Flipped Mathematics Instruction Observation Protocol (FMIOP) draws upon existing frameworks (e.g., Stein, Grover, & Henningsen, 1996), observation instruments (e.g., MQI), and advice from experts in educational technology and mathematics education. We then iteratively revised the protocol based upon teacher interviews and observations of flipped lessons. FMIOP consists of two components: in-class and at-home. The in-class component captures two aspects of the lesson: instructional quality and interactivity. Each aspect has sub-characteristics (e.g., mathematics development, video involvement). The protocol also distinguishes the whole-class and non-whole-class formats. In a departure from prior protocols, aspects such as the nature of authority are not combined into the instructional quality score but instead held separately as descriptive features of the lesson since evidence from different disciplines is contradictory about which authority pattern will be predictive of student learning. The at-home components are examined along three aspects: instructional quality, multimedia design, and interactivity. In addition to lecture videos, FMIOP captures the use of set-up videos, which are those that establish a non-mathematical context to intrigue students about what will happen in class.

Looking back, we see that instruments for lesson observations have progressed as new instructional models took hold. Looking ahead, the use of technology will continue to grow, so our observational tools must advance to account for key features of instructional videos and how videos are used in lessons so that we might distinguish implementations of flipped instruction and draw meaningful conclusions about how the instruction relates to student learning.

In this paper we discuss our development and use of a conjecture map for a large research project on the design and implementation of an online professional development model. Following Sandoval's (2014) model, we built the conjecture map to reflect our high-level conjectures (overarching goals of the project), the embodiment of the learning design, the mediating processes, and the outcomes. After roughly half a dozen iterations to ensure that we accurately and fully captured the features of the learning environment and the mediating processes, we used the conjecture map as an anchor for a number of our data analysis activities, particularly of our online course modules, and for initiating theory-building processes. We also found that it was an expedient way to communicate internally and externally the core assumptions and learning principles of our multifaceted online professional development model.

The project described in this paper involves a three-part model whose primary goal is to transition multi-faceted face-to-face professional development experiences to online environments in order to provide rural teachers access to high-quality professional development experiences. For example, the Teaching Lab lessons (similar to Lesson Study) have traditionally been conducted entirely face-to-face; we subsequently redesigned these experiences so teachers from disparate rural environments can participate without having to travel great distances. Moving face-to-face experiences to online environments is not straightforward and requires an iterative process to understand and respond to the logistic, technological, and theoretical challenges that arise. Consequently, we conceptualized our project as design research in that we planned to use lessons gained from our initial attempts to inform subsequent revisions to the original designs and sequencing of the components of the model. We turned to Sandoval's (2014) description of *conjecture maps* to guide our efforts to unpack the assumptions and theories on which we operated as we designed and redesigned the components.

In this conceptual paper, we discuss the development and use of a conjecture map (Sandoval, 2014) to help us reflect on and better understand our own assumptions regarding the overall conjectures for the project, the design of the learning environment, and the processes that mediate between the learning environment and the outcomes related to our high-level conjectures. Wozniak (2015) used a conjecture map for a project involving online learning and noted that the refinements made through design research due to the conjecture map enhanced their "theoretical understanding about transitioning to online distance learning" (p. 608). In considering the relevance of this model to our own context, we asked ourselves the following questions:

1. To what extent do the conjecture maps have face validity to the actual processes engaged by our participants?

2. How have the conjecture maps informed both the revisions of the professional development model and the data analysis?

Frameworks

Design Research

We follow a design-based research model (Barab & Squire, 2004; Cobb, Confrey, diSessa, Lehrer, & Schauble, 2003; Edelson, 2002; The Design-Based Research Collective, 2003) to guide our research. Design research is intended to engineer learning environments, study the impact of that learning environment on desired outcomes, and revise the learning environment as needed, with the goal of testing and building theory. The goal of design research is to be able to explain learning that occurs and what supports that learning by systematically and iteratively studying the design and the impact of the design (Cobb et al.).

Design research departs from naturalistic research in that it purposefully engineers features in the learning environment, though it retains some of the messy complexity found in naturalistic settings. This type of research departs from experimental design and other research done in highly controlled, even contrived, settings in that it seeks to understand the role of context and the situated nature of activity to explain learning. Design research operates at an intermediate level of theory, to produce useful explanations that extend beyond the context in which the study is situated, but not to pose universal theories of learning (Cobb et al., 2003). Additionally, the design research process purposefully facilitates (engineers) particular interactions in order to produce useful explanations (Barab & Squire, 2004).

In this paper, we describe a model of online mathematics professional development for teachers in rural contexts, the hypothesis and conjectures we developed and are testing, and the way in which we articulated and operationalized features of the design experiment we are conducting. Our goal is to not only understand how our model works with our participants, but how it may inform broader efforts to conduct high-quality professional development online, how to engage rural mathematics teachers in such experiences, and how it leads to theory-building.

Conjecture Maps

We follow Sandoval (2014) in developing and using conjecture maps to articulate our model, guide our research, and build theory. According to Sandoval, "*Conjecture mapping* is a means of specifying theoretically salient features of a learning environment design and mapping out how they are predicted to work together to produce desired outcomes" (p. 19) and is intended to reify the conjectures regarding the learning environment and how they interact to promote learning. There are four main elements to a conjecture map. The first element involves *high-level conjectures* about the learning context and it supports learning. Those conjectures are then operationalized in the *embodiment* of the learning design, which is the second element. In the third element, this embodiment in turn is intended to generate *mediating processes* that produce desired *outcomes*. The desired outcomes constitute the fourth and final element of the conjecture map. The conjectures about how the designed learning environment (the embodiment) results in the mediating processes—or the process from the second to third element—are called *design conjectures*, which take the form "if learners engage in this activity (task + participant) structure with these tools, through this discursive practice, then this mediating process will emerge" (p. 24). The conjectures about how those mediating processes produce desired outcomes—or the process from the third to final element—are *theoretical conjectures*, which take the form "if this mediating process occurs it will lead to this outcome" (p. 24).

High-level conjectures are the abstracted ideas about the learning principles evident in the design of the learning environment and are produced by an analysis of the needs evident in a certain context with respect to the desired outcomes. The embodiment of the learning design involves four elements, according to Sandoval (2014): tools and materials, task structures, participant structures, and discursive practices, described in further detail below. Mediating processes involve the kinds of observable interactions between participants and the design of the environment, though artifacts created through learning activities can be used as well. Observable interactions can show how the learning environment facilitates or mediates participants' interactions, particularly those conjectured as leading to desired outcomes. Analysis of artifacts can show how participants interpret designed activity structures and tools to explain their interactions and engagement. Mediating processes are intended to produce desired *outcomes*. Sandoval notes that different design research projects can utilize "a wide variety of outcomes and could take a wide variety of approaches to gathering evidence of those outcomes" (p. 23).

Online Learning Model

We designed a three part online professional development model with the goal of providing rural mathematics teachers access to high quality professional development. We chose to pursue an online model due to the difficulties for rural teachers to attend face to face professional development. The three components had been originally designed and implemented in face to face formats and were moved to fully online versions for the purposes of this project. Our project utilizes a series of synchronous online experiences, which departs from the typical asynchronous nature of much of the current online professional development, educational coursework, and virtual teacher communities. The three parts of the model include online course modules, Teaching Labs (akin to a lesson study approach), and online coaching. We based our model on research on teacher learning, described in more detail below, which informed our conjectures.

The online course modules were based on discourse practices that orient teachers toward high-leverage discourse practices that facilitate mathematically productive classroom discussions (Smith & Stein, 2011). These discourse practices are facilitated by five practices emphasized in the course, entitled *Orchestrating Mathematical Discussions (OMD)*, anticipating, monitoring, selecting, sequencing, and connecting. The modules also emphasize key aspects of lesson planning, such as goal-setting, in addition to having teachers solve and discuss high-cognitive demand tasks. The modules are designed to develop awareness of specific teacher and student discourse moves that facilitate productive mathematical discussions, to understand the role of high cognitive demand tasks in eliciting a variety of approaches worthy of group discussions, and to further develop participants' mathematical knowledge, particularly the rich connections around big mathematical ideas that are helpful to teach with understanding (Ball, 1991; Ma, 1999). The modules involve a combination of synchronous and asynchronous work, in order to minimize the amount of time teachers must virtually meet together (Robinson, Kilgore, & Warren, 2017). This minimizes logistical challenges and maintains a high degree of teacher effort and attention due to the shortened synchronous time. Hrastinski (2008) found that the combination of synchronous and asynchronous complement each other by offering opportunities for cognitive participation (asynchronous) and personal participation (synchronous). Cognitive participation allows for reflection on complex instruction, while personal participation involves collaborative opportunities for immediate feedback, community building, and collaborative learning.

The Teaching Labs follow a lesson study design, modified to decrease time commitments and, in our case, with the need to be physically present in the classroom of the target lesson. Research on lesson study (e.g., Amador & Carter, 2018; Stigler & Hiebert, 1999) has led to an emphasis on demonstration lessons where teams of teachers collectively plan, enact, and reflect on lessons in ways that make public the features of the lessons and teachers' instructional practices (Saphier & West, 2009). The benefits of lesson study are to help teachers incrementally expand their knowledge base, promote collective professional discussions, and to improve instructional practices (Choskshi & Fernandez, 2005; Stigler & Hiebert, 1999). Our work takes this traditionally in-person model and translates it into a synchronous and asynchronous online professional development opportunity.

Coaching has a relatively short history in education, and online coaching is just now emerging as something that is beyond experimental. Coaching, as characterized by the interactions between coaches and practitioners, facilitates *deliberative practice* in that there are repeated opportunities to reflect on practice in principled and formative ways (Ericsson, Krampe, & Tesch-Romer, 2003). Over the last two decades, there has been an increasing focus on coaches to provide teachers with personalized and content focused professional development (Campbell & Malkus, 2011; Cobb & Jackson, 2011; Hartman, 2013), which is highly valued by the teacher (Chval et al., 2010). Common aspects of coaching include working with teachers to model instructional practices, reflect on observed instruction, study student work, and plan lessons (Batt, 2010; Matsumura, Garnier, & Spybrook, 2012). Research on the impact of coaching has found positive effects of content-focused coaching on teachers' instructional practices and student achievement in the area of literacy (Matsumura et al., 2012). Other research has shown that literacy coaches, when they collaborate closely with teachers around core instructional practices, can have positive impacts, though this impact was mediated by the roles of the coaches and the access of teachers to coaches with expertise in the instructional intervention (Coburn & Russell, 2008; Penuel, Riel, Krause, & Frank, 2009). Again, our work focuses on moving in-person coaching to an online context.

Methods

Development of the Conjecture Map

To develop the conjecture map, we first articulated the high-level conjecture and *desired* outcomes (Edelson, 2002), the bookends of the conjecture map. Our high-level conjecture was that *teachers transform their instructional practices by engaging in collegial interactions related to core instructional practices across multiple online contexts*. This conjecture captured aspects of the goal of transforming practice, the ways in which we were engineering opportunities for that to occur, the kinds of interactions we envisioned, the context in which the designed learning environment was going to be situated, and the theories we hoped to test and build. This conjecture reflected the core hypotheses of our online professional model.

We then articulated four desired outcomes related to our model. These outcomes were that teachers would become more adept at: (1) attending to student thinking in productive ways; (2) noticing key aspects of instructional practices; (3) engaging in high-leverage discursive practices with the goal of eliciting and refining student thinking; and (4) reflecting on one's own practices, using evidence from the classroom, leading to instructional change. The outcomes reflected our understanding of the kinds of instructional practices that result in vibrant and productive classroom learning environments (e.g. Jacobs, Lamb, & Philipp, 2010; Smith & Stein, 2011).

The next step was to describe the embodiment of our conjectures, the designed learning environment or what Cobb et al., (2003) term the *learning ecology*, which they describe as "a complex, interacting system involving multiple elements of different types and levels" (p. 9). Following Sandoval (2014) and Cobb et al., we focused on four features of the learning environment as: (1) tools and materials, (2) task structures, (3) participant structure, and (4) discursive practices. The tools and materials included the online platforms we used, the tools available within those platforms, and the protocols for structuring interactions, such as planning templates and the Noticings and Wonderings prompts for reflecting on mathematical tasks and episodes of instructional practice. The task structures included engaging with and reflecting on mathematical tasks, fictional and real accounts of instructional practices, and planning and reflecting on lessons. The participant structures included a range of whole group, small group, and one-on-one settings. Discursive practices included the type and tenor of interactions we intended to facilitate, such as collegial collective discussions and critical reflection on one's own practices. We identified these four features for each of the three components of the model. For example, for the Orchestrating Mathematical Discussion online model, we listed the Zoom environment (online based video conferencing software) and protocols for interaction as the Tools and Materials, the mathematical tasks and cases of classroom instruction as Task Structures, collective work in small and whole groups in an online space as the Participant Structures, and collegial discussions in which participants share their reflections on the learning activities as the Discursive Practices we were trying to engineer.

Our design conjecture was that the designed learning environment would facilitate the development of four mediating processes. These four mediating processes were: (1) reflection on one's own engagement in mathematical processes, discursive processes, and task characteristics; (2) discussion of core instructional practices in relation to attention to student thinking; (3) collective observation and non-evaluative reflection on concrete instances of practice; and (4) supported observation and reflection on one's own practices. These mediating processes constituted a progression of a sort, in that we felt that participants needed to discuss instructional practices in the abstract initially, discuss how those practices helped to lead to increased attention on student thinking, reflect on instances of actual practice collectively observed, and then reflect on their own practice. We saw these as requiring increased capacity as well as development of non-evaluative norms for noticing and discussing practice.

These mediating processes were the practices in which we hoped to productively engage the participants and which we viewed as essential if we were to realize the outcomes we had identified. While we imagined that we would need to revise the design of the learning environment to better facilitate these mediating processes, we saw the mediating processes as stable features of the overall design and conjectures, and which would be revised only after considerable discussion of the design and systematic analysis of data. We indicate the conjectured contribution of each component of the learning environment to the development of the mediating processes by the arrows shown in the conjecture map (See Figure 1). The width of the arrow indicates the strength of contribution for a particular component to the development of a mediating process. Our theoretical conjecture was that these mediating processes collectively would lead to the desired outcomes noted above.

Results

Below, we first present the conjecture map we constructed and then describe how we use the map to guide our analytic and design processes. The conjecture map is seen in Figure 1.

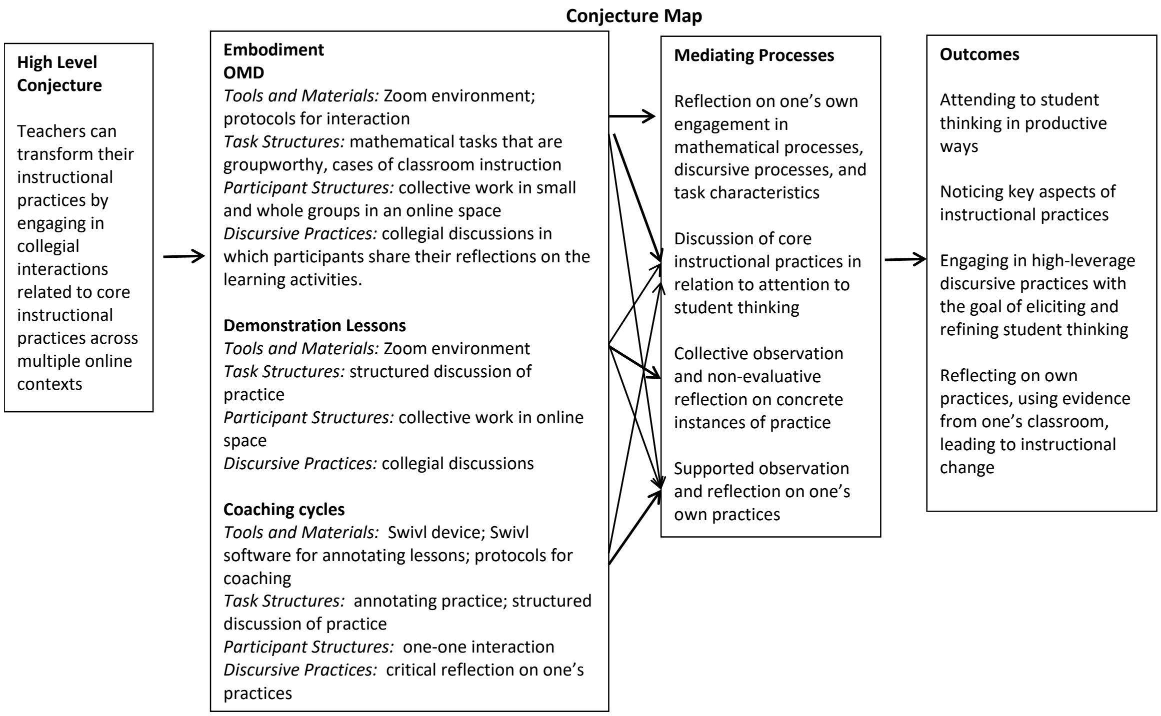

Figure 1. Conjecture Map for the Project

Conjecture Map as Reification of Our Model

Developing the conjecture map helped to reify our core conjectures about the design of the learning environment and the relationship between the design of the model, the intermediate processes we needed to develop, and our desired outcomes. Constructing the model engendered clarifying discussion about the learning environment and what each component was intended to accomplish. In our group, there is a distinction between the design and research teams, with several people dedicated entirely to the design and implementation of the learning environment, and several people dedicated to research, though there is some overlap between the groups. The researchers have focused primarily on the design conjecture at this point in the project: they have focused on how the learning environment facilitates the development of the mediating processes. Developing the map was one way for the design and research teams to come into greater contact with each other. The map provides an explicit articulation of the design and intended impact of the model as well as the conjectures and hypotheses on which we are basing our work.

Conjecture Map Guides Research Activities

The conjecture map has served as an anchor artifact in the discussions around data analysis activities. The map has focused the research team discussions on the design conjectures: we make sure we are documenting the design and we explore the affordances and constraints in the online learning environment; and we explore the impact of the learning environment on the development of the mediating processes. When we find a feature of the learning environment missing from the map, we revise the map to more accurately reflect our observations, and we check back in with the design team to verify the revised map. We develop our data analysis activities keeping in mind that they must speak directly to the nature of the learning environment, the relation between the learning environment and mediating processes, and the nature of the mediating processes in terms of our observations of the participants.

Conjecture Map Guides Documentation and Revision of Model

We use the conjecture map to anchor discussions about whether our designed learning environment facilitates the desire mediating processes and, if not, what needs to be revised within the learning environment. We recognized that it was crucial to fully document the enacted design at key intervals, to note the changes made to the learning environment, and to ensure that those changes are reflected in any revision of the conjecture map. This process has also identified unanticipated processes that have influenced the design of the project. For example, working in rural environments requires much more flexibility on our part in terms of the timing of classes and meetings, and the lack of internet infrastructure in some cases has led to complications. As a result, our design team has made changes on the fly without the benefit of using analysis derived from the research team, who have typically lagged six months behind in terms of processing and analyzing data. Thus, in documenting our design processes, we have audio-recorded and transcribed the design team meetings to understand the motivations behind the changes in the learning environment. Ultimately, however, the design and research teams are accountable to the conjecture map, and thus the teams will collectively revise the map to account for realizations and evidence gleaned through the practical contingencies of implementing a complex online model in rural environments and through systematic data analysis.

Role of Conjecture Map in Theory Building

The work in the project thus far has focused on our design conjectures (the link between the learning environment and mediating processes). However, as we wrap up the initial cohort at the end of the current project year, we will begin testing and revising the theoretical conjectures (the relationship between the mediating processes and outcomes). Ultimately, we will refine our high-level conjecture as we seek to generalize our findings beyond the context of the project, to address broader claims of learning, and, in particular, professional learning in online contexts.

Discussion and Implications

In this conceptual paper, we describe an ongoing design experiment that demonstrates the dynamic nature of the development and use of conjecture maps. Similar to Wozniak (2015), we found that our ongoing use of the conjecture map is strengthening the iterative nature of our design research project. As we regularly revisit the conjecture map and make modifications to our professional development design, we use the map as a framework for planning and evaluating the actual processes engaged by our professional development participants and the theoretical implications of the design. Through this process, the conjecture map is a key artifact for researchers engaging in design experiments (Sandoval, 2014; Wozniak, 2015). Developing and using a conjecture map holds us accountable to the assumptions of design experiments and to our own conjectures and hypotheses about improving classroom instruction of mathematics teachers in rural environments via an online professional development model. The map has anchored discussions about the design of the learning environment and how we research the design conjecture, specifically the data collected and the analysis process. Developing and using the map has helped us to identify misunderstandings between the design and research teams, to understand our lived processes with respect to revising the design of the learning environment, and to be more explicit about the specific mediating processes in which we seek to engage our participants. It has also helped us to be aware of key features of the design process, especially around the intended consequences of our work and the messiness of conducting research in naturalistic, if designed, environments. Ultimately, it will focus our theory-building discussions, especially as we explore the theoretical conjectures.

To better understand how to support high school students' engagement, advancements in research methods that provide greater understandings of malleable factors of engagement and conditions that affect students' engagement are needed. In this conceptual paper, we introduce four dilemmas that researchers need to navigate to study secondary students' engagement with mathematics: How can we concurrently capture engagement in-the-moment and at scale? What counts as a moment or experience? What sorts of experiences could be engaging? Whose perspectives on the experience should be privileged? We propose approaches for navigating these dilemmas in the context of a current research project.

Keywords: Research Methods; Affect, Emotions, Beliefs, and Attitudes; High School Education

The decline of students' motivation and engagement in mathematics as they move through levels of education is a persistent problem. Students' self-efficacy, their enjoyment, and their sense of the utility of mathematics tends to decrease as they move from elementary school into junior high and this trend continues through high school (Chouinard & Roy, 2008; Wigfield, Eccles, Mac Iver, Reuman, & Midgley, 1991). To develop insights about how to create learning environments that engage more students, more deeply, researchers must develop approaches that allow for a greater understanding of students' engagement.

Historically, research on engagement and its associated constructs has been conducted either at a small, descriptive scale, *or* at a larger, probabilistic scale. This issue of scale ranges on two dimensions: idiographic → nomothetic and momentary → longitudinal. Ideally, learning environments would be designed to promote positive experiences at all levels. From the learner's perspective, which is primarily idiographic and momentary, we want to find ways to "catch and hold" their engagement. From the perspective of the education system, which is primarily nomothetic and longitudinal, we want to increase the chance that learners will identify with mathematics-related disciplines and choose to continue learning mathematics far into the future. In particular, greater insights are needed about how to foster engagement with mathematics among high school students. Prior research suggests that instructional practices such as teachers' demonstrations of warmth and focus on understanding over performance engage students (Stipek, Salmon, Givvin, Kazemi, Saxe, & MacGyvers, 1998), but this research was conducted in classrooms with elementary school students. Alternative approaches that address nuanced differences, are likely needed to engage high school students; they are in a different developmental stage both cognitively and socially, and are learning more abstract or otherwise different mathematics. What *is* known is that high school students are more engaged with mathematics when they experience authentic work such as being asked interesting questions, solving novel problems, digging deeply into understanding a single topic, applying the subject to problems and situations in life outside of school, and discussing ideas about the subject with the teacher or students, along with pedagogical strategies that support students socially (Marks, 2000). However, what counts as authentic (i.e., *interesting, novel, applicable*) for some students may not be so for others, and means of social support have numerous facets that are worth understanding more deeply in high schools.

The purpose of this paper is to provide a critical analysis of concepts and methods for studying engagement with mathematics in the moment in high school classrooms. We propose an approach, which we are currently undertaking, that goes beyond fine-grained analyses of a few students to seek out larger trends in a manner that is still situated in the context of classroom opportunities to engage in mathematics. This approach also delineates variability within and between classrooms that might explain some of the reasons students both turn on and turn off from mathematics during the high school years. Below, we describe our approach to investigating students' engagement in relation to four dilemmas, but before we do so, we share our orientation on engagement.

What Is Engagement?

Previous work has considered engagement as both an anthropological and a psychological construct. Anthropologically, engagement can be understood as students' opportunities to participate in a particular activity. Psychologically, engagement is often conceptualized as a personal endeavor, emphasizing how psychologically present a person is during a moment in which they are actively involved (including, but not limited to, a pedagogically relevant experience in a math class) (e.g., Shernoff, Csikszentmihalyi, Schneider, & Steele, & Shernoff, 2003). Engagement can also combine the two approaches, emphasizing sustained behavioral involvement (i.e., making use of opportunities to engage) combined with some emotional tone, either positive or negative, in context. By this view, all students are engaged in some fashion and to some degree, though not all engagement is positive. For example, when engagement occurs by the demands of the educator rather than the will of the student, it may instead manifest as anti-engagement, sometimes termed as *disaffection* (e.g., Skinner & Belmont, 1993).

A useful conceptualization of engagement in mathematics classrooms is a person's investment in a pedagogically relevant object of engagement, such a mathematics task or lesson, as situated in the relationship between the self, the object of engagement, and others in the environment (Middleton, Jansen, & Goldin, 2017). Engagement is dynamic and multi-dimensional. It manifests itself in affect, cognition, behavior (Fredricks, Blumenfeld, & Paris, 2004), and under some definitions, social interactions (e.g., Rimm-Kaufman, Baroody, Larsen Curby, & Abry, 2015; Wang, Fredricks, Ye, Hofkens & Lin, 2016).

Although these four components of engagement (affective, cognitive, behavioral, and social) interact dynamically, they are often defined separately. For instance, the affective dimension of engagement involves both more immediate positive and negative affective reactions to stimuli such as math activities, teachers, or classmates, (Fredricks, Blumenfeld, & Paris, 2004), and higher-order evaluation of those reactions (e.g., Goldin, 2002; Goldin, 2014); for example, perceiving the struggle involved in solving a math problem as enjoyable. By contrast, the cognitive dimension of engagement involves effortful cognitive coordination between prior knowledge and current information (Middleton, Jansen, & Goldin, 2017). Exemplars of cognitive engagement include concentration, and memorization. The behavioral dimension of engagement, then, includes the positive *behaviors* associated with a student's productivity in the math classroom (Rimm-Kaufman, Baroody, Larsen Curby, & Abry, 2015). This entails the actions students employ working on math problems and collaborating with peers. Finally, the social dimension of engagement relates to the quality and investment in social relationships and nature of interactions, such as those with peers and teachers (Wang, Fredricks, Ye, Hofkens & Lin, 2016). We now turn to a critical analysis of four essential dilemmas researchers must face when studying engagement from this perspective.

Dilemma 1: How Can We Concurrently Capture Engagement In The Moment And At Scale?

Engagement is highly dynamic, particularly on a moment-by-moment basis. An uplifting mood, a novel mathematics problem, and an open and welcoming classroom environment might each increase engagement in the moment. However, over time, these dynamics may become less extreme as they become habituated (e.g., a mathematics problem becomes less novel the longer one works on it). It is important, therefore, to consider whether the goal is to capture students' *tendencies to engage* (which may stabilize over time) or to understand conditions that impact the more *malleable* aspects of students' engagement to foster change in engagement patterns. When researchers investigate students' tendencies to engage, they learn about variations between individual students, understanding how different students experience mathematics learning. Alternatively, when researching engagement in the moment, researchers can understand factors that can impact why and how engagement becomes more and less productive for different people at different times. Moreover, sometimes researchers are interested in both the stable and malleable aspects of engagement, trying to piece out what aspects are productive, and what features of classroom practice support productive engagement patterns.

Different pursuits require somewhat different methodological approaches. Researchers interested in students' more stable tendencies to engage have relied on the use of long-term surveys and proxies for successful outcomes, such as grades (Pinxten, Marsh, De Fraine, Van Den Noortgate, & Van Damme, 2014). In contrast, research on engagement in the moment has relied on qualitative data collection techniques such as observations (focused on individuals, small groups, or classrooms), videos, and observer field notes followed up by interviews involving video viewing sessions (e.g., Esmonde, 2009; Gresalfi, Martin, Hand, & Greeno, 2009; Webel, 2013) to capture students' rich experiences in the moment. Although work in this qualitative tradition has contributed considerably to knowledge about student engagement, the intensive nature of such qualitative data collection has typically necessitated the use of small samples, which does not enable seeking wider trends. Efforts to understand students' experiences in the moment have been scaled up using the Experience-Sampling Method (ESM) (e.g. Shernoff, Csikszentmihalyi, Schneider, & Shernoff, 2003), in which respondents are signaled at random intervals or around pre-determined experiences, and complete a series of (closed-ended and/or open-ended) questions about their experience in the moment (Shernoff, 2013). This method has the added benefit of capturing students' impressions in real time relative to later retrospective measures (such as after-the fact interviews) (Shiffman, Stone, & Hufford, 2008). Researchers interested in both the stable and malleable, in-the-moment, aspects of student engagement benefit from triangulating methods. For example, we are currently combining methods ideal for measuring changes in stable traits, such as longer-term surveys, with more in-the-moment methods, such as ESMs, interviews, and observation, as in Figure 1. In Figure 1, our data collection begins with the administration of a long-term survey assessing students' more stable perceptions and traits. This initial survey serves two purposes. First, it can be used to establish a baseline measurement of initial perceptions. These baseline measurements are then repeated at critical times, most notably at the end of data collection, with a post-test version to examine change over time. This provides a check on the validity of the processes going on between the two points of study as well as a means of assessing the effect size of the impact of the processes occurring between long-term survey measurements. Second, responses to the long-term survey can be analyzed using cluster analysis to select focal students to follow up with using qualitative methods, such as observation and interviews (e.g., Patrick & Middleton, 2002).

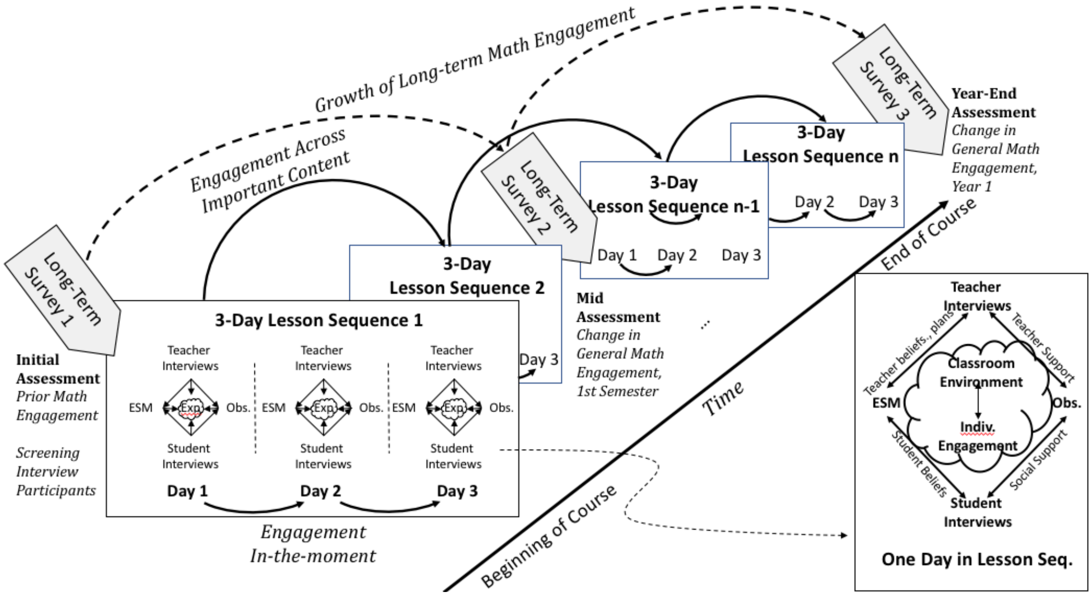

Figure 1. Mixed methods model for studying student engagement over time in one classroom.

Note: In our current project, some classes use a block schedule, completing a course in one semester. Others follow the traditional year-long course model. The number of lesson sequences and long-term survey administrations vary accordingly, with fewer administrations in the block scheduled model.

Data collection then focuses in on a series of pedagogically relevant experiences during a given class period, often identified in advance by the teacher and researcher (a dilemma described further below). During each of these experiences, a series of measurements—ESM surveys, observation, student interviews, and teacher interviews—are taken in parallel in a convergent design (e.g., Creswell & Clark, 2018), characterizing the student's engagement in all of its nuances. By this view, engagement in the moment in Ms. Smith's freshman algebra class is determined by triangulating the teacher's thoughts on the observed session with researcher observations and videos of each experience, with students' in-the-moment ESM reports of their affect and behavior, and finally, with retrospective interviews asking the students about their impressions of each experience. Each of these data points measures and helps describe a given experience and students' engagement in it. Over time, this can uncover the potential factors of classroom practice that *cause* change in engagement, or that *support* engaged behavior over a relatively long period of time, such as a course or academic year. Such mixed methods can characterize the moments of mathematics engagement, provide an explanatory narrative of their development, and estimate their effect size.

Dilemma 2: What Counts As A Moment Or Experience?

When investigating students' engagement, grain size matters. Doing mathematics in school can be viewed as a set of experiences strung together by time, topic, practices, and roles. Thus, an experience could be an entire school year or semester, a single class period, an activity during a class period, or a mathematics problem within an activity. Many studies at a larger scale focus on the longer-term, such as a course, semester, or year (e.g., Skinner & Belmont, 1993). Smaller scale studies focus on the class period, activity, or task-level (e.g., Gresalfi, 2009). The more fine-grained the timescale, the more detailed insights can be gained about engagement. But to understand how to impact students' engagement, whether long-term or short-term, researchers must record the conditions giving rise to engagement patterns, the engagement patterns themselves, and finally, the ways in which students conceptualize their engagement and use it to direct future mathematics-related activity.

By experience, then, we mean an interactive situation (with mathematics content and with others in the classroom) structured by some mathematical task, *cued* by the teacher or students. A *cue* is a social act proffered by a person that indicates an *intended shift in the group interactive behavior* in the mathematics task. Experiences could be operationalized in the context of a teacher cueing, such as launching or introducing a task with various forms of participation, such as having students work on a task (in groups or alone), or discuss a task in small groups, with partners, or as a whole class. Experiences can could also be cued by a student's query about a mathematics concept or procedure.

Yet, this raises another question: is the experience bounded by an activity or by a mathematics problem? We could consider students' engagement during an entire activity, such as the timeframe when students are working together in a small group, as an "experience." Alternatively, we could monitor students' engagement problem-by-problem when working in small groups, considering each problem to be an "experience" in itself.

Ultimately, our definition of experience fundamentally shapes our research methods. For instance, we can take a problem-centered approach by using an ESM to ask participating students to reflect upon the same experience at the same grain size. We can ask for such input either at the end of a given problem, or an entire group task—reflecting either a problem-centric or more holistic approach to the "experience." Such methods could support comparison of students' perceptions across particular experiences, as well as researchers' attempts to track the coincidence of behaviors and reported feelings across particular experiences.

We can also have students or teachers participate in a video viewing session to reflect back on students' engagement, using criteria to select a particular moment in the video record to reflect upon that participants will recognize as an experience, with some beginning, end, and flow of activity. The selection of a clip for a video viewing session can be based on a range of criteria. A focal experience could be one that the teacher conjectured would be productive for students' learning and engagement. Alternatively, researchers could choose a moment that they conjecture could be engaging (or not) for students based on students' displayed affect, and ask the teacher and students to reflect back on that moment.

Each of these potential selection criteria reveal different information regarding what the engagement patterns of the experience are, and what the causal impact of teacher behaviors, mathematics curriculum, and the social setting might be. Defining criteria for selection of experiences that matter, then, must be done carefully, with clear theoretical guidance to generate coherent epistemological claims.

Dilemma 3: What Sorts of Experiences are Engaging?

Following Shernoff et al. (2016), we conjecture that engaging experiences are situated in a learning environment that includes both academic and social support. It is worth investigating the degree to which mathematics learning environments provide students with (a) opportunities to engage in sense-making and reasoning and (b) opportunities to experience positive social interactions. Figure 2 presents hypotheses of classrooms that are likely to result in very different patterns of engagement among students.

A. High sense-making & reasoning Negative social interactions	B. High sense-making & reasoning Positive social interactions
C. Low sense-making & reasoning Negative social interactions	D. Low sense-making & reasoning Positive social interactions

Figure 2. Four patterns of academic and social support

One hypothesis is that when classrooms provide students with academic support through opportunities to engage in sense-making and reasoning (as in A. and B. in Figure 2), students will be more engaged with learning mathematics. For example, prior work has suggested that learning environments that promote making sense of challenging mathematics and opportunities to reason mathematically engage learners in developing mathematical understandings, and, in turn, raise students' self-efficacy, interest, and mastery goals (Stipek et al, 1998).

Another hypothesis is that when classrooms provide students with social support through relatedness (as in B. and D. in Figure 2), students will be more engaged with learning mathematics. Learning environments that are warm and welcoming such that they promote positive social relationships between the teacher and students, and among the students, allow students to feel safe to take intellectual risks and to develop positive emotional well-being (Stipek et al, 1998). Students will then exert more effort spent toward learning mathematics.

Realistically, most classrooms fall in the in-between space of academic and social support, such that sense making is pretty good at some times for some students, and pretty poor at others times for others. Social support may vary likewise at some times and for some students. This makes investigating the dynamics of the pedagogical and social situating of mathematics classrooms so critical for the study of engagement.

To investigate the degree to which such learning environments are engaging, a number of questions could be pursued, such as: How prevalent are learning environments that are high in sense-making and reasoning in these schools; how prevalent are learning environments that focus on positive social interactions in these schools; and how does this relate to engagement? Although learning environments that are high in sense-making and reasoning as well as positive interactions should lead to greater engagement, and learning environments that are low in sense-making & reasoning and have negative social interactions should lead to lower engagement, what does students' motivation and engagement look like in learning environments that are high in sense-making & reasoning and negative in social interaction OR in learning environments that are low in sense-making and reasoning and positive in social interaction?

Dilemma 4: Whose Perspective On The Experience Should Be Privileged?

Multiple perspectives on a school mathematics experience are likely to provide broader insights not only about how or why an experience is engaging, *but for whom*. Nevertheless, consulting different viewpoints also offers the opportunity for discord. When different viewpoints depict differing accounts of who is engaged in the classroom, whose account should be given precedence: our own observations as researchers or students' self-reports?

One answer is to focus on students' own perspectives (in contrast to researchers' perspectives). This seems defensible; even though engagement has dynamic components and is influenced by classmates and teachers in the classroom, engagement is fundamentally a personal, psychological phenomenon. However, the different levels of analysis we prioritize (whole class, a small group, individual student, interactions between these), have implications for the content of interview questions and on the conclusions we are able to draw. For example, in his high school case study of goal development, Webel (2013) found that although engagement behaviors were relatively stable at the group level, they varied considerably at the individual level. Each student's goal-seeking behaviors were expressed differently based on the extent to which they perceived a match between their own goals and that of the group. Had perceived goal match not been a measure in Webel's work, this relationship would have been obfuscated. This suggests a need to capture a broad array of student perceptions, both at the group and individual levels.

Another dilemma that comes with prioritizing students' impressions of engagement is which temporal student account to prioritize. In the mixed methods approach we advocate above, for example, researchers can choose to prioritize in-the-moment assessments, such as the ESM, or retrospective reports, such as student interviews. Each of these methods have been used in meaningful ways across different studies. For example, research using ESMs has suggested that high school students experience more concentration, but less interest and enjoyment when they are in class compared to other places (Shernoff 2013), while research using semi-structured interviews has suggested that seventh-grade students' beliefs about participation (e.g., beliefs constraining or supporting it) influenced the goals they had during participation (e.g., to help classmates and behave appropriately, or to demonstrate competence and complete tasks, respectively) (Jansen, 2006).

Moreover, within the context of a single study, it is possible that a student's in-the-moment impression of an experience may be different than her after-the-fact account. A quiz that seemed difficult in the moment may seem easy retrospectively once the student learns that she had earned an A. What then? Prior research from other domains has suggested that in some cases, willingness to re-engage in an activity (such as an invasive medical procedure) is better predicted by a person's after-the fact impressions than in-the-moment impressions (Shiffman, Stone, & Hufford, 2008). Such discoveries require the measurement of both in-the-moment and later impressions to determine how such memories are consolidated. This suggests yet another utility of using mixed methods, as well as interesting possibilities that may arise from comparing the results of different measurements on educational and persistence-related outcomes of interest, such as grades, and desire to continue in math or pursue a STEM career.

Conclusions

Through this essay, we explored a range of considerations for researchers who are interested in the study of secondary students' engagement in school mathematics classrooms. We reflect upon a current project that attempts to address these considerations. A premise guiding this work is that students' voices should be solicited through multiple methods: long-term surveys of tendencies, ESM surveys, and interviews. We urge for the study of engagement to go beyond observational methods so that students can share the degree to which they experienced the observed incident as engaging. The dilemmas we explore support research that examines engagement in the moment but in ways that also explore trends over time and allows for uncovering variations within individual students as well as between them.

Conventional coordinate systems are often considered representational tools for reasoning about mathematical concepts. However, researchers have shown that students experience persistent difficulties as they engage in graphing activity. Using examples from research and textbooks, we present a framework based on a conceptual analysis of the use of coordinate systems. We discuss the implications of the framework for student learning, curriculum design, and teaching.

Keywords: Cognition, Curriculum Analysis, Modeling

Conventional coordinate systems, such as the Cartesian and polar coordinate systems, are often considered representational tools for reasoning about mathematical concepts such as number systems, geometric figures, ratios and proportional relationships, and equations and functions (e.g., Common Core State Standards for Mathematics). Not only are coordinate systems used in the learning, teaching, and doing of mathematics, they are also commonly used in other fields like science, technology, and engineering as a means to communicate information (Paoletti et al., 2016; Roth, Bowen, & McGinn, 1999; Rybarczyk, 2011).

Despite a widespread use of coordinate systems, researchers have shown that students experience persistent difficulties as they engage in graphing activity—constructing and interpreting graphs—in their mathematics (e.g., Leinhardt, Zaslavsky, & Stein, 1990) and science courses (Potgieter, Harding, & Engelbrecht, 2008). For instance, when constructing graphs, students struggle with establishing axes and scales and transitioning from discrete graphs to continuous graphs (Herscovics, 1989), connect points without considering what happens between points (Yavuz, 2010), and adhere to familiar forms of regularity like linearity (Leinhardt et al., 1990). When interpreting graphs, students show common difficulties such as treating graphs as literal representations of a situation (e.g., interpreting a graph of a biker's speed vs. time as the biker's traveled path) (Clement, 1989; Oehrtman et al., 2008), and focusing on one quantity while tacitly overlooking the other quantity when prompted to interpret relationships between two quantities (Leinhardt et al., 1990; Oehrtman et al., 2008).

A frequently overlooked aspect accounting for students' persistent difficulties in graphing activity is students' understanding of underlying coordinate systems. Researchers and curriculum developers often take coordinate systems for granted as a primitive structure. Little focus is given to students' construction of coordinate systems or their understanding of what is being represented within coordinate systems. For example, most prior research on students' understandings of graphs presumes the Cartesian plane as a given structure in students' reasoning without exploring what meanings students hold for the underlying coordinate system (e.g., Levenberg, 2015). In this report, we outline a framework distinguishing two uses of coordinate systems: situational coordination and quantitative coordination. This explicit distinction has received little, if any, attention in extant mathematics education research and curricula. By bringing attention to the underlying coordinate systems on which students are asked to reason, we intend to provide an explanatory construct as to why students may have difficulty constructing or interpreting graphs represented on coordinate systems. We discuss implications our framework could have and pose future research directions.

Conceptual Analysis

The framework we propose is based on our conceptual analysis (Thompson, 2008) of students' potential uses of coordinate systems as representational tools. Our conceptual analysis is informed by research on spatial cognition (e.g., Levinson, 2003; Tversky, 2003), Thompson's (2011) theory of quantitative reasoning, research examining students' construction and use of coordinate systems (e.g., Lee, 2016; Lee & Hardison, 2016; Lee, 2017), research examining students' graphing understandings (e.g., Moore, Paoletti, & Musgrave, 2014; Joshua, Hatfield, Musgrave, & Thompson, 2015), and our experiences working with students.

Two Contrasting Examples

To illustrate our distinction between two kinds of coordinate systems, we present two tasks from textbooks (Figures 1 and 2). Both tasks involve a Ferris Wheel context and, from our perspective, both tasks involve establishing a coordinate system. Task A (Figure 1) prompts students to find the coordinates of the car located at the loading platform and in other positions, with the axle of the Ferris Wheel defined to be at the origin. In this case, students are asked to coordinate the location of each car within the space in which the Ferris Wheel is *situated*. In other words, the coordinate system in this task is used for spatially organizing the location of each car in reference to the position of the axle of the wheel.

31. **Entertainment** The Ferris Wheel first appeared at the 1893 Chicago Exposition. Its axle was 45 feet long. Spokes radiated from it that supported 36 wooden cars, which could hold 60 people each. The diameter of the wheel itself was 250 feet. Suppose the axle was located at the origin. Find the coordinates of the car located at the loading platform. Then find the location of the car at the 90° counterclockwise, 180°, and 270° counterclockwise rotation positions.

Figure 1. Task A (Holliday, Cuevas, McClure, Carter, & Marks, 2006, p. 95).

1. *Ferris Wheel Problem:* When you ride a Ferris wheel, your distance, $y(t)$, in feet from the ground, varies sinusoidally with time t, in seconds since the wheel started rotating. Suppose that the Ferris wheel has a diameter of 40 ft and that its axle is 25 ft above the ground (see Figure 3-8j). Three seconds after it starts, your seat is at its high point. The wheel makes 3 rev/min.
   a. Sketch the graph of function y. Figure out the particular equation for $y(t)$.
   b. Write an equation for $y'(t)$.
   c. When $t = 15$, is $y(t)$ increasing or decreasing? How fast?
   d. What is the fastest $y(t)$ changes? Where is the seat when $y(t)$ is changing the fastest?

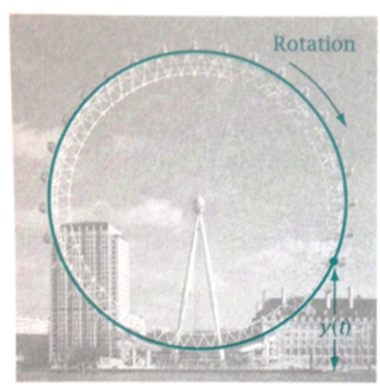

Figure 3-8j

Figure 2. Task B (Foerster, 2005, p. 112).

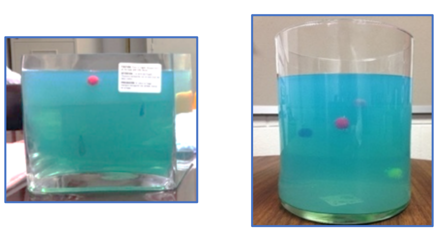
Now consider Task B (Figure 2). Rather than asking students to use a coordinate system to spatially represent the situation, Task B prompts students to graph the relationship between the time elapsed since the wheel started rotating and a rider's distance from the ground. To solve this task, students must extract two quantities (Thompson, 2011), time and distance, from the Ferris Wheel situation and coordinate them in a new space in order to produce a graph. This new space does not entail the spatial situation from which the quantities were extracted. In other words, the Ferris Wheel situation is *not* contained in the graph students are asked to produce or in the coordinate system containing this graph.

Two Uses of Coordinate Systems

As demonstrated through the contrasting examples above, coordinate systems can serve different purposes, which potentially lead to different graphing activities. We propose a framework to distinguish between two uses of coordinate systems, *situational coordination* and *quantitative coordination*. We emphasize we are distinguishing uses of *coordinate systems*, which are different from distinctions others have made about students' *graphing* activities (e.g., Moore & Thompson, 2015); coordinate systems can, but need not, contain graphs. We describe each use of coordinate systems with examples from our research and from textbooks; textbook examples are used to illustrate our interpretations of the textbook author's intended use of coordinate systems, which do not necessarily coincide with how students might perceive of the coordinate system. Through hypothetical examples, we also illustrate how a student might engage in graphing activity in each case.

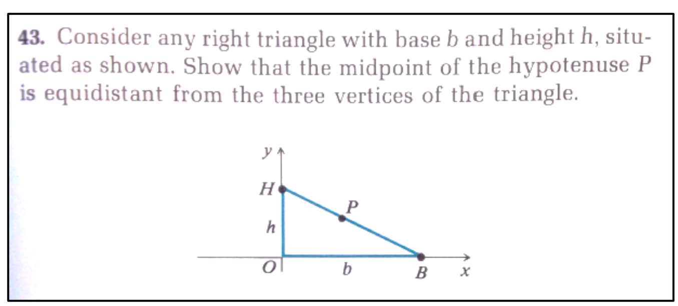
Situational Coordination

Situational coordination refers to an individual using a coordinate system to represent or mathematize a space or physical phenomena, as in Task A (Figure 1). Constructing a coordinate system for situational coordination (i.e., constructing a *situational coordinate system*), involves establishing frames of reference (e.g., Levinson, 2003) to gauge extents of various attributes of objects (e.g., relative location or orientation of an object) within the space or phenomena. When constructing a situational coordinate system, an individual can produce quantities by measuring attributes of the space/situation using their frames of reference and coordinate such measurements to represent attributes of objects *in the space or situation*. An everyday example of a situational coordinate system is used is a map. Graphs constructed on situational coordinate systems can be viewed as projections or traces of physical objects or phenomena onto the *same space* containing the original objects or phenomena (e.g., the movement of a car shown on a GPS).



Locate the four fish in the fish tank models.

Task C: Fish Tank Task (Lee, 2017)



43. Consider any right triangle with base b and height h, situated as shown. Show that the midpoint of the hypotenuse P is equidistant from the three vertices of the triangle.

Task D: (Keedy & Bittinger, 1981, p. 159)

Figure 3. Two Examples of Coordinate Systems Used for Situational Coordination.

As an example of a task designed for students to construct a situational coordinate system, consider Task C (Figure 3) from the first author's research involving students' organization of space. In this task, the researcher asked students to locate four fish figures in three-dimensional tanks. The students' responses to this task (see Lee, 2017) provide an example of how a student might construct a coordinate system to represent objects in space by establishing a frame of reference and locating points within the space using coordinated measurements. As a second example, consider Task D from a college algebra text (Keedy & Bittinger, 1981, p. 159), which asks students to reason about a geometric figure and its characteristics situated in a coordinate system. Here, the x-axis, y-axis, and origin suggest a frame of reference used to locate the points or line segments within the geometrical figure (i.e., triangle). Tasks C and D exemplify situational coordinate systems as the coordinate system is (or can be) used to locate or mathematize objects (e.g., the fish in Task C or right triangle in Task D) in a given space.

The examples above highlight how situational coordinate systems can be used to mathematize a single moment in time (i.e., a snapshot). Situational coordinate systems can be used when representing dynamic situations as well. In other words, a student may think of overlaying a frame of reference on an imagined movie. For example, in Task A, one can observe or imagine a rider's position on the Ferris Wheel changing over time within a situational coordinate system (e.g., Williams, 2018). Similarly, in Task C, one can observe or imagine a fish's position in the fish tank changing over time within a situational coordinate system.

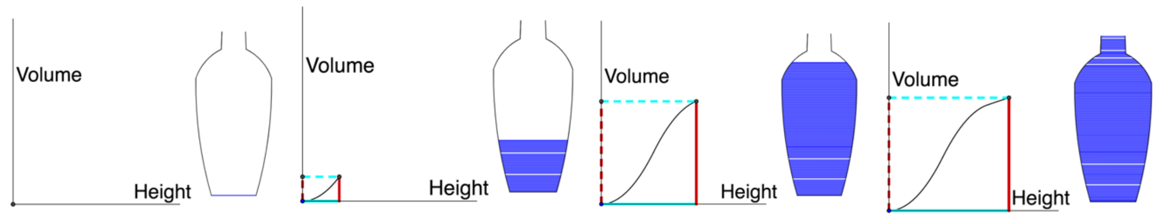
When constructing a situational coordinate system, one can establish and insert a multitude of quantities onto the situation. We have found it helpful to imagine a situational coordinate system as mentally tagging an object with an n-tuple and imagining the values within the n-tuple changing over different situational instances. For example, for a Ferris Wheel car's location in Task A, one can mentally tag a *4*-tuple such as (θ, h, a, t), where θ represents the angle through which a car on the Ferris wheel has rotated, h represents the height of the car, a represents the arc length the car has traveled, and t represents the time the car has been in motion. The quantities one inserts onto the situation need not be purely geometric or temporal in nature, as in Tasks A, C, and D. For example, an individual might also consider inserting the blood pressure of the rider in the car into the situation and therefore the tuple. The critical distinguishing feature of a situational coordinate system is that frames of reference are established and used to construct and tag quantities *onto* the situational space or physical phenomena.

Quantitative Coordination

Quantitative coordination refers to an individual using a coordinate system to coordinate sets of quantities by obtaining a geometrical representation of the product of measure spaces, such as in Task B above. To establish a quantitative coordinate system, an individual must establish quantities within the given space/situation, disembed (Steffe & Olive, 2010) these quantities (i.e., extract them from the situation while maintaining an awareness of the quantities within the situation), and project them onto some new space, which is different from the space in which the quantities were originally conceived. Graphs as emergent traces (Moore & Thompson, 2015) representing relationships between disembedded quantities can be constructed within a quantitative coordinate system. These graphs are not projections of physical objects or phenomena from the same space containing the original objects or phenomena.

Consider Task E (Paoletti & Moore, 2017), a variation of Swan's (1985) bottle problem, which has been used to examine students' graphing activity (e.g., Carlson, Jacobs, Coe, Larsen, & Hsu, 2002). In this problem, students are asked to imagine a bottle being filled with liquid and sketch a graph relating the volume of liquid in the bottle and height of liquid in the bottle. To solve this task, a student must first conceive of two quantities, liquid volume and liquid height. The student may then consider how the two quantities vary as liquid is poured into the bottle.

Next, the student may conceive of two number lines, one for liquid height and one for liquid volume, and use these number lines to represent the varying magnitudes or values of each quantity. The student can then construct a Cartesian plane with the two number lines—the horizontal axis representing liquid height and the vertical axis representing liquid volume—and imagine a point in this space as simultaneously representing the liquid height and liquid volume as water is poured into the bottle (Figure 4a-d). The two-dimensional space that is made by the product of the two axes form a new space (a {height×volume} plane), which is different from, but related to, the space containing the bottle itself. The infinitude of traced points (height, volume) in the graph (Figure 4d) do not depict the physical bottle being filled but represents the covarying quantities.



(a) (b) (c) (d)

Figure 4. Task E: Representing the height and volume of liquid in a bottle.

For an individual to construct a quantitative coordinate system she must first establish a situational coordinate system in terms of the relevant quantities in the imagined situation before disembedding these quantities to create a quantitative coordinate system (Lee & Hardison, 2016). For example, in Task B, in order for a student to coordinate the time traveled and vertical distance of car from the ground, she will first need to establish a situational coordinate system on the Ferris Wheel situation (as in Task A) through which she could gauge the time traveled and vertical distance from the ground before disembedding those quantities into a new space. Similarly, in Task E, a student will first need to establish a situational coordinate system on the bottle situation through which she could gauge the liquid height and liquid volume as the water fills the bottle.

Implications of the Framework and Future Research Directions

We encourage researchers to focus their attention on the two uses of coordinate systems when studying students' construction of coordinate systems and also to use this framework as an analytical tool in future studies examining students' graphing activity. Findings from such studies can support curriculum development and classroom instruction related to coordinate systems and students' graphing activities, which we further discuss in the sections below.

Using the Framework to Better Understand Students' Graphing Activities

The proposed framework may help explain some of the students' challenges in constructing or interpreting graphs represented on coordinate systems as reported in the literature. That is, identifying whether a student is aware of the purpose of the coordinate system he has constructed and/or is reasoning upon can provide insight for his graphing activity. For example, when a student constructs axes, examining whether he is (a) attempting to quantitatively organize a particular situation, (b) representing magnitudes of quantities abstracted from an outside situation, or (c) attempting to reproduce an image from their prior classroom instruction can be informing. Similarly, for a student who draws graphs by connecting points without considering what happens between points (Yavuz, 2010), it could be insightful to investigate whether the student understands points as representing the coupling of two quantities (Saldanha & Thompson, 1998) disembedded from the situation.

The lack of explicit attention to the two uses of coordinate systems can become problematic when a student interprets what a teacher or researcher intends to be a quantitative coordinate system as a situational coordinate system. In such a case, the student will be constrained, at best, to reasoning about points and lengths in graphs as opposed to reasoning about the contextualized quantities outside of the perceptually available graph. Such an interpretation may explain why researchers report students treating graphs as literal representations of a situation (e.g., interpreting a time-speed graph of a biker as the biker's traveled path) (Clement, 1989) or why some students have difficulty "distinguishing between visual attributes of a physical situation and similar perceptual attributes of the graph of a function that models the situation" (Oehrtman et al., 2008, pp. 153).

Looking forward, we intend for our conceptual analysis to be a tool for empirical research examining students' construction of coordinate systems and graphing activities. Furthermore, because a quantitative coordinate system presupposes some situational coordinate system, we hypothesize that many of students' difficulties interpreting and constructing graphs within quantitative coordinate systems can be explained by students' challenges in constructing situational coordinate systems. Even if an individual is capable of constructing a situational coordinate system, transitioning to a quantitative coordinate system is nontrivial. If an individual has constructed a situational coordinate system in the bottle problem, for example, establishing a quantitative coordinate system requires transforming a volume in the situational coordinate system to a directed length on a number line; this transformation cannot be taken for granted when teaching and researching students' graphing activity. As such, we argue students need experiences constructing situational coordinate systems prior to constructing quantitative coordinate systems and we echo others' calls (e.g., Thompson & Carlson, 2017) for more research on how students map quantities onto number lines.

Using the Framework to Reflect on Curriculum and Teaching

Our framework can be used to analyze mathematical tasks. For example, students' thinking of a graph as a picture of a physical situation may be unsurprising when students are, at times, presented with graphs that seem to conflate the two uses of coordinate systems. In Task F (Figure 5), we see a quantitative coordinate system used for relating time and distance. Yet, the use of arrows and labels in the text is problematic from our perspective. The stoplight, school, and school zone are *not* represented physically on this graph as the arrows seem to indicate. These objects exist in a space different from the coordinate plane established by the quantities time and distance. We hypothesize that conflations between quantitative and situational coordinate systems in mathematical tasks can lead to students' difficulties in graphing activity. In analyzing tasks, we also noticed that many graphing exercises in textbooks did not explicitly include quantitative referents for axes, which is consistent with the analysis of pre-calculus and calculus textbooks reported by Paoletti et al. (2016). They found that popular pre-calculus and calculus textbooks almost exclusively used graphs to represent decontextualized functions of x and y. Absent of any quantitative referents, students are likely left with little choice but to interpret these decontextualized graphing tasks in terms of situational coordinate systems. This is problematic as a common way STEM fields communicate information is through graphical representations of two (or more) covarying contextualized quantities.

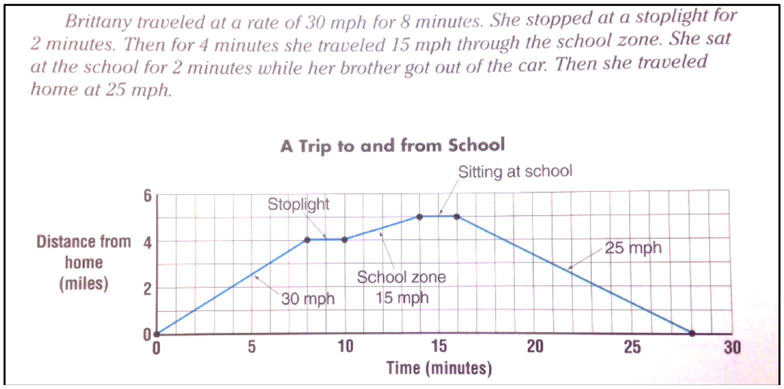


Figure 5. Task F: (Holliday, Cuevas, McClure, Carter, & Marks, 2006, p. 95)

Also relevant to our distinction, Paoletti et al. (2016) found that although many STEM fields (e.g., Biology, Chemistry, medicine) often use quantitative coordinate systems to represent two or more covarying quantities in their practitioner journals and textbooks, other fields (e.g., engineering, physics) commonly employ situational coordinate systems to mathematize a situation or phenomena. This difference between the use of coordinate systems in pre-calculus and calculus textbooks and other STEM fields may help explain why students often do not see connections between the mathematics they learn in mathematics classes and the mathematics they use in STEM courses (Britton et al, 2005). We encourage mathematics educators to provide students with opportunities to develop a balanced understanding of both uses of coordinate systems because it is important for their mathematical development as well as potential future STEM courses and careers.

The body of research examining students' graphing understandings across STEM fields indicates students are not developing productive meanings for graphs. We conjecture such failings may, in part, be explainable by features of students' use of coordinate systems and graphing activity that are under examined. In this theoretical report, we present a conceptual analysis of different ways students may reason about graphs and coordinate systems. Specifically, we describe two different uses of coordinate systems—spatial and quantitative—students might leverage and two ways of reasoning—static and emergent—students might engage in as they construct or interpret graphs. We characterize how a student may engage in each kind of reasoning in each use of coordinate system. We intend this paper to serve as a theoretical lens for future empirical studies examining students' developing graphing understandings.

Keywords: Cognition, Learning Theory, Spatial Thinking

There is a need for U.S. students to enter STEM fields, with mathematics often serving as a "gatekeeper" for student success in these fields (Crisp, Nora, & Taggart, 2009). As such, it is important for students to have experiences in their K–12 schooling that are attentive to the needs of potential STEM coursework and careers. A common way STEM fields communicate information is through graphical representations. Paoletti, Rahman, Vishnubhotla, Seventko, and Basu (2016) analyzed the graphs depicted in commonly used STEM textbooks and practitioner journals, finding the most common uses of graphs were to mathematize a spatial situation or phenomena (e.g., Figure 1, left) or to represent two covarying quantities (e.g., Figure 1, center). In contrast, the researchers noted most graphs in popular precalculus and calculus textbooks were used to represent two decontextualized quantities (e.g., Figure 1, right). Hence, there are discrepancies between the graphs students experience in their math classes and are expected to interpret in other STEM fields.

Researchers have identified persistent difficulties students experience as they engage in constructing and interpreting graphs in their mathematics (e.g., Leinhardt, Zaslavsky, & Stein, 1990) and science courses (e.g., Potgieter, Harding, & Engelbrecht, 2008). For instance, researchers have identified a range of difficulties including (a) drawing graphs by connecting points without considering what happens between points (Yavuz, 2010); (b) treating graphs as literal representations of a situation (e.g., interpreting a time-speed graph of a biker as the biker's traveled path) (Clement, 1989); and (c) attending to one quantity while ignoring other quantities (i.e. reasoning variationally) (Leinhardt et al., 1990). Collectively, this research indicates instructional approaches have not provided students sustained opportunities to develop meaningful ways of understanding and interpreting graphs.

Dewey (1910) stated, "vagueness disguises the unconscious mixing together of different meanings, and facilitates the substitution of one meaning for another, and covers up the failure to have any precise meaning" (p. 130). In this report, we attempt to clarify a vagueness, in Dewey's terms, regarding how students may think about graphs and coordinate systems. We hypothesize supporting students becoming explicitly aware of the subsequent distinctions may alleviate some difficulties students experience as they engage in graphing activity. In this theoretical report, we present a conceptual analysis of different ways students may reason about coordinate systems and graphs. Specifically, we describe two different uses of coordinate systems—spatial and quantitative (Lee & Hardison, 2016)—and two ways students might reason as they construct or interpret graphs within these coordinate systems—static and emergent thinking (Moore & Thompson, 2015). For each use of coordinate system, we characterize how a student may engage in each kind of graphical reasoning, creating a framework that will be useful for future studies.

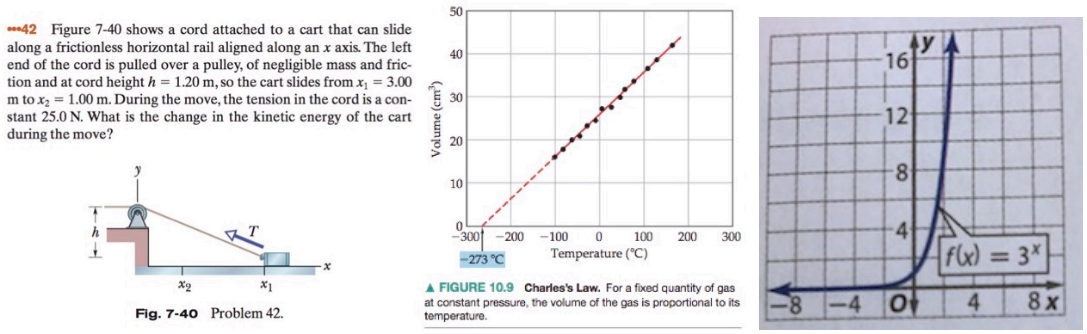

Figure 1. Examples of using coordinate systems to (left) mathematize space (Halliday, Resnick, & Walker, 2011), (center) represent two covarying quantities (Brown et al., 2012), and (right) represent two decontextualized quantities (Glencoe, 2014).

Conceptual Analysis

In this theoretical report, we present a conceptual analysis of ways students may reason about graphs and coordinate systems; we intend for this conceptual analysis to inform future empirical research. Thompson (2008) characterized several uses of conceptual analyses; we leverage two of these uses, namely "describing ways of knowing that might be propitious for students' mathematical learning," and "describing ways of knowing that might be deleterious to students' understanding of important ideas and in describing ways of knowing that might be problematic in specific situations" (p. 46). We present our first-order models (Steffe & Olive, 2010) of how students may reason about graphs and underlying coordinate systems. These models are based on research examining students' graphing understandings (e.g., Moore & Thompson, 2015), research examining students' construction and use of coordinate systems (e.g., Lee, 2017), principles of quantitative reasoning (Thompson, 2011), and our experiences working with students. We point the reader to examples from extant literature in which we infer students are engaging in reasoning compatible with our conceptual analysis.

Bridging Two Theoretical Frameworks

In this report, we examine how a distinction between two uses of coordinate systems and a distinction between two ways of thinking about graphs (i.e., traces within coordinate systems) can create four different ways students may construct or reason about graphical representations within coordinate systems. Below, we describe two frameworks: one for students' understandings of coordinate systems and one for students' thinking about graphs.

Two Uses of Coordinate Systems

Lee and Hardison (2016) found curricular materials often give students rules for "generating" a Cartesian plane and plotting points within it, and these materials rarely address students' conceptions of coordinate systems. They (Lee, 2016; Lee & Hardison, 2016; 2017) have distinguished between two uses of coordinate systems in students' thinking: spatial coordination and quantitative coordination.

Spatial coordination refers to an individual using a coordinate system to represent or mathematize a space or physical phenomena. This involves establishing spatial frames of reference (Levinson, 2003; Rock, 1992), such as a reference point or orienting vectors, to locate objects within the space or physical phenomena (e.g., Figure 1, left). In this case, an individual can produce quantities by measuring attributes of the space/situation using the established frames of reference and thus coordinate such measurements to locate objects in the space or situation (e.g., a map).

Quantitative coordination refers to an individual coordinating sets of quantities by obtaining a geometrical representation of the product of measure spaces. In this case, the quantities being coordinated are already established and abstracted from the space/situation and superimposed onto some new space. This use of coordinate system, as a result of coordinating quantitative frames of reference (Joshua, Musgrave, Hatfield & Thompson, 2015), allows the individuals to coordinate quantities and construct graphs representing relationships between these quantities (e.g., Figure 1, middle). These graphs are not projections of physical objects or phenomena onto the same space containing the original objects or phenomena.

Static and Emergent Shape Thinking

Moore and Thompson (2015, under review) differentiated between students' static and emergent shape thinking. A student's *static shape thinking* entails his thinking of a displayed graph as a shape (i.e. graph-as-wire) that can possibly be manipulated (e.g., translated, rotated). In such a case, properties of the perceptual shape and the shape itself are the focus of the student's thinking. For instance, a student emphasizing the properties of a shape may argue that a straight line moving up from left-to-right unquestionably represents a linear function with a positive slope even if positive *x*-values are represented to the left of the *y*-axis in the Cartesian coordinate system or if the line is represented in the polar coordinate system.

Moore and Thompson also noted static shape thinking can take the form of students' making iconic or thematic associations (e.g., Clement, 1989; Leinhardt et al., 1990). A student reasons iconically when he incorporates visual features of an event in a graph (e.g., drawing a graph resembling a hill because a biker is traversing a hill). A student reasons thematically when he incorporates aspects of a phenomena in his graph that are unnecessary from the researcher's perspective (e.g., an object traveling at a varying speed necessarily implying a curved graph).

In contrast to static shape thinking, Moore and Thompson characterized *emergent thinking* as conceiving a displayed graph simultaneously in terms of "what is made (a trace) and how it is made (covariation)" (2015, p. 785). Critical to such a conception is a student's construction of a point on a graph as a multiplicative object; when using the term multiplicative object, Thompson and colleagues draw on Piaget's notion of "and" as a multiplicative operator. Specifically, Thompson, Hatfield, Yoon, Joshua, and Byerley (2017) noted, "A person forms a multiplicative object from two quantities when she mentally unites their attributes to make a new attribute that is, simultaneously, one and the other" (p. 98). Hence, when reasoning emergently, a student understands a point as simultaneously representing two quantities and imagines a graph being created by the trace of the point as the quantities vary.

A student with sophisticated emergent thinking may, at times, appear to treat a graph as a static shape (e.g., 'shifting' the graph in a direction) for various reasons whilst being able to unpack the static thinking in terms of the graph's emergence. Although such 'shifting' activity could indicate static thinking, if the student is able to unpack his new graph in terms of representing an emergent trace constituted by the new distances, such reasoning would constitute emergent, rather than static, thinking in the quantitative coordinate system.

Static or Emergent Thinking in Spatial or Quantitative Coordinate Systems

In combining the frameworks elaborated above, we differentiate between static and emergent thinking, which characterizes a student's reasoning when producing or interpreting a graph (i.e., a trace within a coordinate system), and quantitative and spatial coordinate systems, which characterizes a student's understanding of the coordinate system potentially containing a graph. We provide an example of each kind of reasoning using a billiard context at the Infinity Pool Hall. Additionally, we provide a description of student reasoning for each case. We reiterate these are first-order models of how students may reason; we point the reader to empirical examples where appropriate.

Table 1: Four ways of reasoning about graphs within coordinate systems.

		Ways of Reasoning About a Graph (Moore & Thompson, 2015)	
		Emergent Reasoning	Static Reasoning
Uses of Coordinate Systems (Lee & Hardison, 2016)	Spatial Coordination	Case A: Emergent thinking within a spatial coordinate system	Case B: Static thinking within a spatial coordinate system
	Quantitative Coordination	Case C: Emergent thinking within a quantitative coordinate system.	Case D: Static thinking within a quantitative coordinate system

Case A: Emergent thinking in a spatial coordinate system (Emergent, Spatial)

To imagine a student reasoning emergently in a spatial coordinate system, consider a student seeing the red 3-ball moving from the left wall to the top middle pocket in a straight line (Figure 2, top). If asked to describe the location of the red ball throughout its journey toward the middle pocket, the student may establish a spatial frame of reference consisting of a horizontal axis and a vertical axis through which the student can gauge the horizontal and vertical locations of the ball. Using this spatial frame of reference, the student can describe the ball's movement in terms of varying horizontal and vertical distances within a spatial coordinate system. By conceiving of the ball's location as simultaneously composed of vertical and horizontal components, the student conceives of the ball's location as a multiplicative object and therefore can reason emergently about the ball's path in terms of its horizontal and vertical components. Figure 2 (bottom) depicts instances of a student's potential emergent imagery when coordinating the ball's trajectory in relation to its horizontal and vertical components.

There are several features critical to a student reasoning emergently in a spatial coordinate system. First the student must conceive of an object or phenomena happening in a spatial system and imagine the object or phenomena as producing a trace in this space. The student then overlays a coordinate system onto the spatial system in order to explicitly coordinate and/or represent how the object or phenomena is producing the imagined trace in terms of the quantities represented in the coordinate system. Hence, the student must conceive of the object or phenomena as representable by a multiplicative object, which she can decompose as simultaneously representing the orienting quantities in the spatial coordinate system. The student can then explicitly coordinate how the orienting quantities are changing as the object moves or phenomena occurs to mathematize the situation. For an empirical example of a student reasoning emergently in a spatial coordinate system, see Lee (2016).

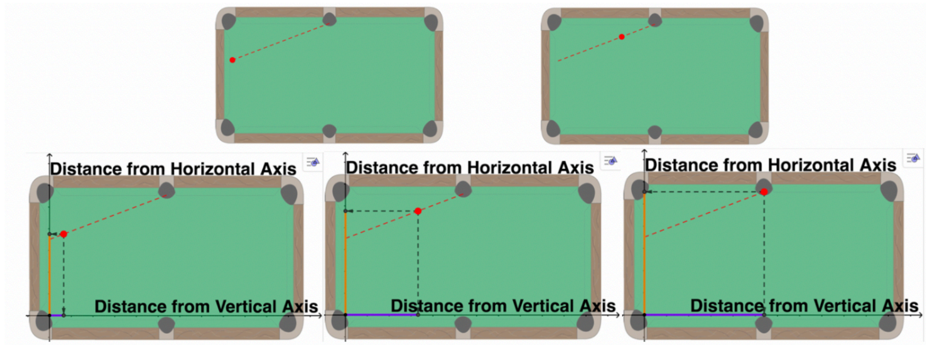

Figure 2. (top) Two instantiations of the red 3-ball traveling from the wall of the table to the pocket and (bottom) three instantiations of how a student may reason about the ball's path as an emergent trace by coordinating its vertical and horizontal components.

Case B: Static thinking in a spatial coordinate system (Static, Spatial)

To imagine a student reasoning statically in a spatial coordinate system, consider the logo on an Infinity Pool Hall table (Figure 3, left). A student sees the logo, which he interprets as composed of two circles tangent at a point (i.e., shapes), and is tasked with describing the shape of this logo mathematically. To do this, the student defines a coordinate system by establishing a spatial frame of reference through which he could describe the location and shape of the logo. This includes choosing a reference point and defining orienting quantities. After constructing the spatial coordinate system, the student may mathematically describe the shapes in the logo within the coordinate system using known equations. For example, in Figure 3 (middle) a student decides to use Cartesian coordinates with the origin at the intersection of the circles, and describes each circle using memorized rules related to the general form of a circle, $(x - h)^2 + (y - k)^2 = r^2$. Alternatively (Figure 3, right), a student might define a polar coordinate system as in Figure 3c, with the pole at the intersection of the circles and use the recalled formula $r = a\cos\theta$.

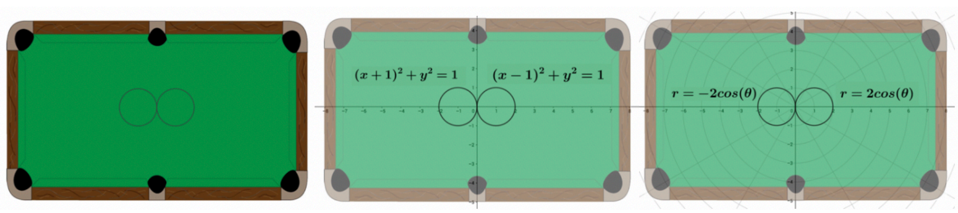

Figure 3. (left) A pool table with logo, and two possible ways to spatially orient the pool table and mathematize the circles in the logo in (middle) Cartesian and (right) polar coordinates.

As exemplified in the above examples, static thinking in a spatial coordinate system entails (a) conceiving of a static shape or object to be located or described mathematically in a situation and (b) establishing a spatial frame of reference through which one can situate, coordinatize, and mathematize the shape. For an example of a teacher using coordinate systems in ways compatible with this description in their classrooms, see Disher (1995).

In this example, we emphasize a student using memorized rules to mathematize the conceived shape, rather than reasoning about an emergent trace. We note that a student *could* demonstrate an understanding of analytic rules as representing an emergent trace of covarying quantities; in such a case, the student would not necessarily be reasoning statically when representing the 'shape' via an analytic rule if the shape's emergence is implicit in his understanding.

Case C: Emergent thinking in a quantitative coordinate system (Emergent, Quantitative)

To imagine a student thinking emergently in a quantitative coordinate system, consider a student seeing the red 3-ball's path, now with the yellow 1-ball and blue 2-ball on the table (Figure 4, we positioned the balls and trajectory to mimic the cities and path of the car in Saldanha and Thompson's (1998) Car Problem). The student may be asked to create a graph representing the red 3-ball's distance from the yellow 1-ball and blue 2-ball as it moves to the pocket. After conceiving the quantities and how they vary, the student may construct a Cartesian coordinate system with the horizontal and vertical axes representing the red 3-ball's distances from the blue 2-ball and yellow 1-ball, respectively. Having constructed a quantitative coordinate system, the student may construct an emergent trace within this coordinate system to represent the relationship between the 3-ball's distance from the other balls (e.g., Figure 4a–d).

We highlight several critical features in this example. First a student needs to conceive of two quantities covarying and intend to represent the relationship between the quantities. The student must then disembed (Steffe & Olive, 2010) the two quantities from the context and insert them onto two number lines to construct a quantitative coordinate system with the intention of simultaneously representing the two quantities in a product space. Each quantity would then be represented by one of the orienting quantities in the coordinate system (see Moore, Paoletti, and Musgrave (2013) for examples in Cartesian and polar coordinate systems). The student understands a point on the emergent trace in this quantitative coordinate system as a multiplicative object simultaneously representing the two quantities.

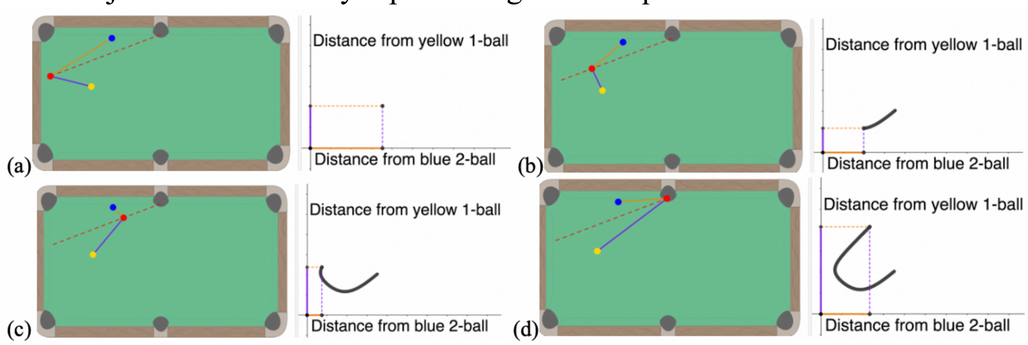

Figure 4. Four instantiations of how an individual may reason about and represent the red 3-ball's distance from the blue 1-ball and yellow 2-ball as an emergent trace.

Case D: Static thinking in a quantitative coordinate system (Static, Quantitative)

We modify the same situation described in Case C to characterize how a student may reason statically while using a quantitative coordinate system. Recall, static thinking may entail graphically representing features of the situation. For instance, Figure 5 (center) shows a student duplicating the 3-ball's path as a representation of the ball's distance from the other two balls, and Figure 5 (right) shows a student using the balls' and pocket's relative locations as points on his graph. In both cases, we highlight that although the coordinate system is meant to represent (from the researcher's perspective) the 3-ball's distance from the 1-ball and 2-ball, the student may not explicitly use the coordinate system in this way. One indication that a student is interpreting the coordinate system quantitatively is if the student interprets her constructed graph by describing the 3-ball's relative distance from the other two balls. For instance, in Figure 5 (center), the student may describe that the 3-ball's distance from the 1-ball increases at a constant rate with respect to its distance from the 2-ball (see Paoletti, 2015 for an empirical example).

Reasoning statically in a quantitative coordinate system can be unproductive in several ways: (a) treating a graph in a quantitative coordinate system as a shape which can be moved around the coordinate system without considering how the translation relates the underlying relationship between quantities, (b) engaging in an iconic translation while interpreting or creating a graph in a quantitative coordinate system, or (c) engaging in a thematic association while interpreting or creating a graph in a quantitative coordinate system. In each case, in order for the system to be a quantitative coordinate system *from the student's perspective*, the student needs to make some indication that he is representing the quantities defined on the coordinate axes.

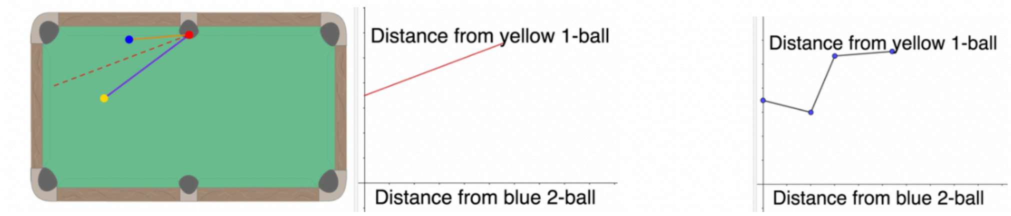

Figure 5. Two examples of static thinking in a quantitative coordinate system.

Concluding Remarks and Areas for Future Research

In this report, we have presented a conceptual analysis that distinguishes meanings students may hold as they engage in graphing activity within coordinate systems. These distinctions can provide insights into some difficulties students experience as reported in extant literature. For instance, students representing the path of a biker (Clement, 1989) may be indicative, not of a misconception, but of the students leveraging a spatial coordinate system to mathematize a situation. In this case, and others, misconceptions identified in the literature may be partially explainable by students' reasoning about coordinate systems and graphs in ways inconsistent with what the researcher (or teacher) intended.

If we intend for curriculum designers, teachers, and students to maintain and convey particular meanings for graphs within coordinate systems, mathematics education researchers must be explicit about these meanings. We intend for the hypothetical models we elaborated, which explicitly address students' meanings for both coordinate systems and graphs, to serve as a resource for future research into how students may develop understandings of spatial and quantitative coordinate systems, as well as graphs in these systems. Further, the similarity between the two uses of coordinate systems discussed here and the uses of coordinate systems observed by Paoletti et al. (2016) in STEM resources (e.g., Figure 1, left, middle) underscores the importance of students explicitly understanding and using coordinate systems for each purpose. Hence, there is a need to develop and test curricular materials that support students in explicitly understanding the differences between spatial and quantitative coordinate systems, as such differences are relevant for their potential future STEM studies and careers.

aconner@uga.edu

Teachers' questioning is a pivotal contributing factor to support students' engagement in productive mathematical collective argumentation. Following Habermas'(1998) construct of rational behavior, we attempted to demonstrate how teachers' questioning can be framed based on this construct. Adapting Habermas' construct with Toulmin's (1958/2003) model for argumentation, we conducted a case study to analyze how a prospective secondary teacher used questions to support collective argumentation in one of her student teaching classrooms. We also explored how the prospective teacher's interpretations of argumentation related to her use of rational questioning. The results suggested that this theoretical integration can be a useful tool to frame teacher questioning based on teachers' intentions and organizations of argumentation. Some educational implications for teacher professional development are provided.

Keywords: Classroom Discourse, Reasoning and Proof, Research Methods, Teacher Education-Preservice

Introduction

Purpose Statement

Developing mathematical reasoning is central to mathematics education. Considerable evidence suggests the beneficial effects of students articulating their mathematical reasoning and challenging others when engaged in collective mathematical argumentation (e.g., Krummheuer, 1995). *Collective mathematical argumentation* can be defined broadly as "any instance where students and teachers make a mathematical claim and provide evidence to support it" (Conner, Singletary, Smith, Wagner, & Francisco, 2014, p.44). Collective mathematical argumentation occurs in a mathematics class when the teacher and students (or a small group of students working independently) work together to construct or reject mathematical arguments.

Facilitating productive mathematical argumentation is challenging for many new teachers. As stated in *Principles to Actions: Ensuring Mathematics Success for All* (National Council of Teacher of Mathematics, 2014), effective mathematics teachers are expected to use purposeful questions to access students' conceptual understanding and to advance students' reasoning and sense making about important mathematical ideas and relationships. Teachers' questioning has the potential to bring students into a conversation and promote participation, and the type and quality of questions can have significant impact on students' engagement in productive argumentation. By examining teachers' actions in support of student participation in mathematical argumentation, Conner et al. (2014) found that posing questions to elicit parts of arguments is a useful strategy that supports collective argumentation. Therefore, it is necessary to understand what factors influence teachers' questioning and how teachers use different types of questioning to support collective argumentation in mathematics classrooms.

Boero (2006) proposed that Habermas' (1998) construct of *rational behavior* can become a frame to deal with the complexity of discursive practices in the intersection of three kinds of rationality: epistemic (inherent in the control of validation of statements), teleological (inherent in the strategic choice of tools to achieve the goal of the activity), and communicative (inherent in the conscious choice of suitable means to communicate understandably within a given community). Researchers have highlighted the importance of Habermas' (1998) construct as a tool to analyze didactical obstacles inherent in proving and argumentative activities (e.g., Boero, 2011; Boero & Planas, 2014). Under the vygotskian didactical perspective, Douek suggested using *rational questioning* as a method to "organize the mathematical discussion according to the three components of rationality" (Douek in Boero & Planas, 2014, p. 210). The teacher plays an essential role in creating a suitable context to promote the vygotskian dialectics and develop argumentation.

An interesting aspect of this construct is that Boero, Douek, Morselli, and Pedemonte (2010) illustrated the possible adaptation of combining Habermas' (1998) construct and Toulmin's (1958/2003) model for argumentation to study discursive practices related to proving and argumentative activities; they claimed that the combination of these two theoretical frameworks might provide a comprehensive frame that would allow one to better analyze students' proving and argumentative activities in mathematics classrooms and support teachers as they plan and carry out rational classroom interventions.

Research Questions

The goal of this study is to build on Habermas'(1998) construct of rational behavior, and to integrate Toulmin's (1958/2003) model for argumentation to ascertain the potential to use this tool to analyze teacher questioning through the lens of supporting mathematical collective argumentation. In addition, we are interested in how teachers' interpretations of argumentation relates to their pedagogical choices for rational questioning. The following research questions guided this study:

1. How does a prospective secondary teacher use rational questioning when guiding collective mathematical argumentation?
    - Which component of rationality is privileged in class?
    - What does rational questioning tell us about a teacher's support for argumentation in class?
    - What combinations of components of rational questioning support students' contribution of argument components?
2. How does a teacher's interpretations of argumentation align with his or her use of rational questioning?

Theoretical Framework

In order to make sense of classroom experiences, we need to broaden our interpretative stance by developing a sociological perspective on mathematical activity. For this purpose, in this study we employed the emergent perspective which emphasizes the idea that knowledge is created through actions and interactions, and that the development of an individual's reasoning and sense-making processes cannot be separate from his or her participation in the social interaction of taken-as-shared mathematical meanings (Cobb, Yackel & Wood, 1992).

According to Habermas'(1998) construct of rational behavior, we developed a Teacher Questioning Framework (see Table 1) by inferring the teacher's intentions and consciousness in asking the question. The framework consisting of three components of rationality and we defined *rational questioning* as a question that contains at least one component of rationality. At times, for clarity, we call a question epistemic rational questioning if it contains an epistemic rationality component.

Table 1: Teacher Questioning Framework

Component of Habermas' Rationality	Description of Questions	Examples
Epistemic Rationality	The questions used not only allow students to provide and evaluate arguments or ideas but also intend to challenge students by asking them to reason and make sense of their arguments and ideas.	Can you tell me why?
Teleological Rationality	The questions used allow students to show or reflect on the strategic choices that they used to achieve their arguments or ideas.	What do we need to do to the cards in the hat to make sure that every single family member has an equally likely chance of being drawn?
Communicative Rationality	The questions used allow students to communicate or reflect on the steps involved in their reasoning and arguments to ensure that their ideas can be understandable in the given community.	So will somebody raise their hand and tell me in their own words what they think it means to be equally likely?

In education literature, Toulmin's (1958/2003) model has been widely used to identify argument components (*claims, data, warrants, rebuttals and backing*) and analyze argumentative activities in classes (see Krummheuer, 1995 for more details on Toulmin's model). Our adaptation of Toulmin's diagrams (see Figure 1) includes the use of color and line style to record the contributor(s) of a component for a given argument and uses "Teacher Support" to denote teachers' contributions and actions (for this specific study, we focused only on teachers' questioning) that prompt or respond to parts of arguments (see Conner et al., 2014 for more details on the development of the framework).

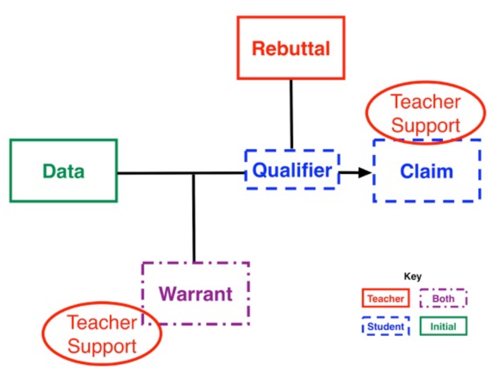

Figure 1. Adaptation of Toulmin's (1958/2003) Diagram for an Argument

In this study, we adapted Habermas'(1998) construct of rational behavior to analyze the rationality of teachers' questioning and employed Toulmin's (1958/2003) model to examine how a teacher used these rational questioning to teaching.

Context and Methods

Context

This study is part of a larger project in which we are examining how teachers learn to support collective mathematical argumentation. The participant, Cathy (a pseudonym) was purposefully selected in this study based on her good understanding of argumentation as she participated in a unit on argumentation during her course work and be willing to support student engagement in argumentation during her student teaching. We observed Cathy's classroom teaching during a statistics and probability unit which focused on chance processes and probability models. The main data sources in this study included (1) video recordings and transcriptions of one representative day of Cathy's classroom teaching, (2) Cathy's interactions during a unit of instruction on collective argumentation (the argumentation unit) at the beginning of her pedagogy course in the mathematics teacher education program, and (3) a reflection that Cathy wrote about argumentation based on her observations in secondary classrooms.

Methods

We used Teacher Questioning Framework (see Table 1) to establish our starting codes to examine teachers' questioning in Cathy's class. A simple enumerative approach was also used to quantify verbal data in order to explicate the patterns that emerged from the open-coding process. Because we want to see how Cathy used her rational questioning to organize arguments, we used Toulmin's (1958/2003) model to diagram every episode of argumentation in Cathy's class, and we noted the parts of an argument that each question prompted. Finally, we used thematic analysis to understand Cathy's priorities and thoughts about argumentation based on her classroom discussions in the argumentation unit at the pedagogy course and her written reflection about argumentation a few weeks into the course.

Results

Use of Rational Questioning

According to our Teacher Questioning Framework (see Table 1), 66% (80/122) of Cathy's questions involved rational questioning. Among these rational questions, the largest component was communicative rationality (83%), followed by teleological rationality (81%); and the portion that involved epistemic rationality was smallest (40%). Although Douek's rational questioning seems to presuppose all three components of rationality, it is apparent that communicative rationality occupied a dominant position in Cathy's class. According to our analysis, only 34% (27/80) of the rational questioning contained all three components of rationality. Moreover, we found that Cathy used a variety of combined forms of rational questioning: some questions included two or three components of rationality and others only involved one.

Our diagrams of argumentation indicated that 59% (72/122) of Cathy's questions were asked during argumentative activities. Among these questions, most of them (81%) contained at least one component of rationality, which showed that Cathy had the intention to use rational questioning to support collective argumentation. Additionally, for these rational questions that were involved in argumentation, most of them had a communicative rationality component (85%) and a teleological rationality component (75%), but only 33% (19/58) had an epistemic rationality component. An interesting aspect of this result is that compared to the percentage of each rationality component Cathy used in her whole class, as reported previously, we found that little difference existed for Cathy in her use of rational questioning during argumentative activities and non-argumentative activities.

According to the above results, Cathy showed a strong emphasis on developing her students' communicative rationality. Some of her communicative rational questioning asked students to explain their reasoning steps (e.g., Can you explain a little bit?). Some of them asked students to communicate ideas more clearly (e.g., And which numbers are they?) or to rephrase a mathematical definition to ensure that their explanations were understandable in the given community (e.g., What does it mean for a coin to be fair?). Cathy also used communicative rational questioning to encourage more students to engage in collective argumentation; this process was evidenced by Cathy often waiting a couple of minutes to see more students' raise their hands before she asked a student to answer her question. In addition, Cathy also pushed her students to evaluate and make sense of the claims and warrants that were provided by other students (e.g., Does it make sense why these two are counted separately?). According to our diagrams of argumentation, for rational questioning containing a communicative component, 24 (out of 44) prompted claims and data/claims while only 13 (out of 44) prompted warrants, which means that Cathy mainly used communicative rational questioning to promote student participation in the construction of arguments.

Within the rational questioning that contained a teleological component in Cathy's class, we found that most all of these questions were strategically goal-oriented reasoning: Cathy first let the students find the possible results of an event, and she next asked them to conjecture whether these events had equally likely chances of happening. Sometimes she asked students to justify their answers by using the classical approach to probability. On a few occasions, Cathy wanted to highlight the importance of the strategic choice of using examples, and she asked her students to provide different examples of what it meant to be "equally likely": "Is any, can anybody think of a different example? That might give you [an] equally likely [chance]?"

Cathy used most of her epistemic rational questioning to push her students to justify why their arguments hold. For example, she asked, "Would you mind sharing your reasoning with the class?" However, only 33% of the rational questioning that contained epistemic components. Cathy's goal for students was apparently less focused on epistemic rationality than on teleological and communicative rationality. This difference was also evidenced by our diagrams of argumentation, within which only 17 (out of 72) questions prompted warrants while 45 (out of 72) prompted claims and data/claims.

As mentioned above, some rational questions involved all three components of rationality (e.g., Can you explain to me why it's going to be fifty fifty?), and we found that more than half (56%) of these questions helped students contribute warrants, which means these questions provided students opportunities to reason about and make sense of their arguments — one of the most important aspects of argumentation for students. Some of Cathy's rational questions contained only teleological and communicative components (e.g., Can somebody remind me how I find the volume of any prism? I will wait until I see a few more hands.), and among these questions, 11 (out of 19) prompted students' claims and data/claims. Cathy used this kind of rational questioning to ask students to communicate their arguments and to focus on the strategic tools that they used to solve the problem.

Interpretations of Argumentation

By examining portions of classroom discussions during the argumentation unit that Cathy participated in and her written reflections about argumentation, we discovered two clear themes.

First, Cathy regarded the role of teachers as asking questions and calling on students to participate. For example, during an in-class discussion in the argumentation unit, Cathy stated, "The role of the teacher is to facilitate, asking questions, and choosing students to participate…" Another theme that emerged concerned Cathy's desire that students be the main contributors to the arguments. In her written reflection, she explained that an effective argument should involve multiple students, and she labeled as an ineffective argument as one that involved only one student.

Our analysis suggests that Cathy's interpretations of argumentation align with her use of rational questioning to support collective argumentation during her student teaching classroom practice. Most of the rational questioning that Cathy asked contained a communicative rationality component, which aimed to bring students' voices into the discussion and encouraged more students to participate in collective argumentation. Data from Cathy's student teaching showed that she used communicative rational questioning not only to encourage students to communicate their ideas more clearly but also to provide opportunities for her students to lead the classroom discussion. For example, she would ask questions such as the following: "Can I have a volunteer go to the board and help us find the unit rate?" Several times after a student gave a claim and warrant, Cathy used communicative rational questioning — "Does anybody have any questions for Ashley?" — to intentionally slow down the presentation to make sure it made sense to others and to inspire students to critique one another's arguments. The large number of communicative rational questions and the way Cathy used them throughout her student teaching seemed consistent with her belief that the teacher was responsibility for promoting student engagement. Cathy also used teleological and epistemic rationality questioning to support of her idea of the teacher as a facilitator and used teleological rationality in her questions to strategically develop goal-oriented reasoning, and then followed up with epistemic rational questioning to request further explanations from her students.

In addition, we noticed that 34% (42/122) of the questions were non-rational, which could be categorized into two types of questions. One type of non-rational questions was either/or questions that were situated in argumentative activities, which prompted claims and asked students to construct results for the final step of argumentation. An example of this type of question would be as follows: Is it equally likely or not equally likely? Another type of non-rational questions was used to present information. For example, Cathy often asked students to read the task. She also asked several factual questions in order to create a probability problem context. We labeled these types of questions as contextual questioning, which may be specific to teaching probability. The way in which Cathy used non-rational questioning showed that instead of giving all the information herself, she asked students to provide data and final claims in the arguments, which aligned with her goal of promoting participation among the students.

Discussion

Many researchers have used Habermas'(1998) construct to conduct studies that centered on *students* (e.g., Morselli & Boero, 2011), and our study showed that this theoretical framework can also be used to investigate *teachers'* intentions when they ask specific kinds of questions. Some researchers have categorized types of teachers' questioning within classroom discourse (e.g., Wood, 1998). The integration of Habermas' construct with Toulmin's (1958/2003) model as a tool to analyze teachers' questioning provides us with a more comprehensive perspective for understanding the roles of teacher questioning within collective argumentation. The two models complement each other in the following sense: Habermas' lens help us to identify fine grained rationality components of teachers' questioning and also how teachers' questioning is constrained in relation to the three components of rational behavior; the teacher then using rational questioning to control the fundamental steps of argumentation is seen through Toulmin's lens. We see the function of rational questioning as fully implementing an approach that pushes students to make sense of arguments, to strategically choose effective tools or methods in problem-solving, and to communicate understandably in a given community, which are essential goals of collective argumentation. This study provides empirical evidence to support Boero et al.'s (2010) idea about the value of integrating Habermas' elaboration of rational behavior with Toulmin's model for argumentation to deal with the complexity of learning and teaching activities, particularly with respect to proving and argumentative activities.

Douek, in Boero and Planas (2014) suggested that teacher's rational questioning can support students' "rationalization" of discourse and develop mathematical discussions along the three components of rationality. Based on our analysis, most of the questions that were posed by Cathy to support collective argumentation were connected to the three components of rationality. Moreover, in this study we found that Cathy used different combinations of rational questioning in her class, and most of them involved only one or two rationality component. According to our analysis, these kinds of rational questioning can also support collective argumentation, and the function of different kinds of rational questioning may vary across different classroom activities. More research is needed to explore whether any other forms of combinations can support argumentation and when are the best times and contexts for teachers to use them.

Although the study showed that Cathy's rational questioning included all three components of rationality, we found that the epistemic component made up a relatively small portion. This result raises an important question: Why do some components of rationality occur less frequently than others? One reasonable explanation from our study is that teachers attempt to use different kinds of rational questioning based on their interpretations of argumentation during course work. We also considered that a teacher's use of different kinds of rational questioning may depend on different mathematical domains, content, and various contexts in the classroom (e.g. whole class discussions or small group discussions). In this study, we only analyzed one of Cathy's probability classes, and more studies are needed to explore what factors influence a teacher's intentional choices of different kinds of rational questioning.

Implications

Our results indicated that Cathy was primarily concerned about her students' participation and thought that the role of teacher was a facilitator; these themes remained consistent with the way she adopted rational questioning during her student teaching. Cathy seemed to take her interpretations of argumentation into her student teaching placement, and it is reasonable to infer that the argumentation unit in her pedagogy course may have influenced her use of questioning for instruction. Our results also suggest that teacher education programs should demonstrate the power of collective argumentation and promote teachers' understanding of the roles of a teacher in questioning.

As mentioned above, Cathy used almost the same proportion of different kinds of rational questioning when she led argumentative activities and non-argumentative activities, which showed that Cathy's intention to strategically use rational questioning as a tool to support collective argumentation spilled over into her regular instruction. More research is necessary to examine how to use the three components of rationality in questions at the moment when argumentation does not develop or when argumentation is begun but breaks off. We hypothesize that understanding specific components of rational questioning could help teachers to integrate multiple questioning strategies to support collective argumentation in a specific content and in a specific context. Future studies should continue to analyze the benefits of rational questioning and how can it be incorporated into teacher education program to make it more approachable to prospective teachers.

THEORY, ETHICS, AND EQUITY IN INTRA-ACTION IN MATHEMATICS EDUCATION: LOOKING BACK, LOOKING FORWARD

Susan Ophelia Cannon
Georgia State University
Scannon5@gsu.edu

This paper considers the intra-actions between poststructural theories and mathematics education over the last 40 years and considers how these theories have resulted in different ways to think students, teachers, and knowledge production. I argue that thinking in intra-action with various and different theories can allow us to ask different questions and radically rethink school mathematics.

Keywords: Research Methods, Equity and Diversity

At the opening plenary of PME-NA Rochelle Gutiérrez (2017) proposed to the mathematics education research community that "interaction between different knowledges, different ways of knowing and different knowers" (p. 2) could serve to respond to and perhaps address the precarious state of our planet and our relationship with it. Gutiérrez is not the first leader in the field of mathematics education research to call on the community to consider not only the what of mathematics education but also the how. William Tate (1995) called on the community to consider policy in relation to equity in mathematics education. He commented that he found the "paradigmatic boundaries of mathematics education somewhat narrow," and he intentionally modeled his work after scholars who "crossed the epistemological boundaries of their fields to provide a more cogent analysis of important issues facing African Americans" (pp. 425-426). In this paper, I will consider research in mathematics education that has already crossed epistemological boundaries to open up spaces for mathematics educators, teachers, and students to think themselves, mathematics, and schools differently. I will then explore Barad's (2007) construct of intra-action and the potential possibilities it offers for qualitative methodology, specifically in mathematics education. Finally, I will come back to calls by Gutiérrez (2017), de Freitas and Sinclair (2014), and Martin (2015) to consider how possibilities for ethical action are structured by the ways we do and think research.

Theory and Qualitative Research in Mathematics Education

de Freitas and Walshaw (2016) describe their approach to theory as impacting their thinking and meaning-making, explaining that "the act of defining or creating new concepts is precisely what theory has the potential to do. Thus, theory is a creative tool, an inventive approach to making meaning, as well as being an intervention into current cultural practices" (p. 4). In this frame, theory becomes not just something that you think about prior to research or something that you apply to research, but something that inevitably impacts the meaning that is made through research.

Stinson and Walshaw's (2017) chapter on theoretical frontiers in mathematics education research explains that theory has not always been considered a foundational aspect of mathematics education research. As theory gains space and attention in the field of mathematics education, the question of which theory to use will continue to surface. Rather than thinking about which theory is best, perhaps mathematics educators can consider how theories have functioned to allow us to "move toward the unthought" (St. Pierre, 1997, p. 185) and ask, what other important thoughts have we yet to think or unthink that matter in mathematics education?

Poststructuralism has intersected with mathematics education for decades, and mathematics educators use of poststructural theories have made it possible to consider how meaning and knowledge get made and whose "interests are privileged, marginalized, or silenced" (Stinson & Walshaw, 2017, p. 139). Poststructural theories have also been taken up to allow a different view of teachers and students as subjects that are constituted through interactions with the powerful discourses of school mathematics, education, and gender.

Walkerdine (1994) drew on poststructural theory to consider the production of the "appropriate" mathematical subject, arguing that "theories of the development of reasoning when incorporated into education become 'truths' which actually serve to produce the desired kinds of subjects as normal and pathologizes differences" (p. 65). Walkerdine was particularly interested in the effects of gender and class on subject formation in mathematics classrooms. She pointed to the ways in which girls were positioned as compared to boys. Her work pointed to the need to recognize the meaning in the practices that mathematics educators carry out and the limitations they, sometimes inadvertently, put forward in how students can live. Similarly, Mendick (2005) questioned why and how particular girls seemed to freely choose paths that reified their oppression. She found that girls were less likely to enroll in accelerated mathematics classes despite equal or higher achievement on math assessments. She used poststructuralism to question the assumptions that math is legitimately powerful and that gender is a natural binary.
Margret Walshaw (2004) describes the "postmodern analytical edge … invites a less certain space for research, pedagogy and practice" (p. 4) that has allowed mathematics educators to recognize and disrupt taken for granted assumptions.

Though poststructuralism has taken on the humanistic stable subject and the power of discursive formations, it has been critiqued for its focus on the linguistic and lack of attention to the material. In the materialistic turn, where the question of what matter matters has been raised, new understandings and theorizations of quantum mechanics and environmental concerns have come together to produce theories that undo the nature culture divide and decenter the human as privileged caretaker or dominator of the earth. van der Tuin and Dolphijn (2010) explain that new materialism is fascinated by affect, force and movement as it travels in all directions. It searches not for the objectivity of things in themselves but for an objectivity of actualisation and realisation... It is interested in speeds and slownesses, in how the event unfolds according to the in-between. (p. 169)

Like poststructuralism, the key tenants of these new materialisms function to trouble binaries and distinctive boundaries. In addition, new materialist theories take seriously what matter matters and how it comes to matter.

Barad—a feminist, philosopher and quantum physicist—introduced many useful and important figurations in the last two decades as she imagined her agential materialism into being. Through her concept of intra-action, Barad (2007) denies the existence of individual separate beings and objects through the exploration and study of Niels Bohr's "philosophy-physics" (p. 24). Intra-action is born out of the recognition that things are not discrete but are always already entangled. Interaction implies separate entities that take individual action towards or away from each other. Instead, Barad considers intra-action that is always taking place between "two mutually entailed folds of the same realm" (de Freitas and Sinclair, 2014, p. 46).

In Barad's view, matter and meaning are co-constituted and inseparable. Just as matter and meaning cannot be separated, so too epistemology, ontology, and ethics cannot be thought apart. We are "part of that nature that we wish to understand" (Barad, 2007, p. 26). Since, things are not thought of as separate and discrete, neither can they have individual agency, "rather what is understood as 'agency' in the relational materialist approach is a quality that emerges in-between different bodies involved in mutual engagements and relations" (Hultman & Lenz Taguchi, 2010, p. 530). In a research setting then, we can no longer think the researcher as an objective separate observer, who studies from afar to know a subject. Instead, researcher, students, teachers, materials are mutually entangled and constituted and come to know "from a direct material engagement with the world" (Barad, 2007, p. 49).

New materialisms and in particular Barad's agential realism are beginning to be taken up by mathematics educators and are effecting/affecting the types of knowledge that are being produced through research. de Freitas and Sinclair (2014) bridge the fields of philosophy, mathematics and feminism, pulling the threads of various (and differing) theories to put forward a new form of materialism that they term *inclusive materialism*, which troubles traditional humanist and rationalist notions and takes up the aesthetic, affective, and material as mattering. Inclusive materialism functions in their work to allow them to conceive of school mathematics as reconfigurable into what they imagine as a minor mathematics that is "not the state-sanctioned discourse of school mathematics but that might be full of surprises, non-sense and paradox" (de Freitas & Sinclair, 2014, p. 226). This is an ethical move for them, though they recognize that this mathematics will be "at odds with current institutional demands. However, a minor mathematics is likely to engage students and teachers in more expansive ways, and our hope is that it would engage more students in mathematics" (de Freitas & Sinclair, 2014, p. 226).
As in the review of poststructural theories, in thinking with Barad and inclusive materialism a new conception of methodology was necessary. de Freitas and Sinclair (2014) show how inclusive materialism might alter the way we think about embodiment of mathematical concepts, offering alternate ways of studying how students learn concepts and of how we might choose and order concepts as part of a curriculum sequence. When concepts are animated differently, learning is similarly altered. Inventive acts in classrooms become part of a growing material assemblage, a process of embodiment in which the potentiality of the body is emphasized.

Implications for Enactment of Qualitative Methodology in Mathematics Education

Though Barad's conception of onto-epistemology and the collapsing of knowing and being are important and productive in how we think mathematics education, given Gutiérrez's (2017) and Martin's (2015) demands, it is Barad's inclusion of ethics and her view on responsibility that could really matter for students and researchers in mathematics education. Her concept of intra-action demands a relational ethics, as being and knowing are entangled, so, too, is living well and in respons-ability to all others. Barad (2007) proposes, ethico-onto-epistem-ology—an appreciation of the intertwining of ethics, knowing, and being— since each intra-action matters, since the possibilities for what the world may call out in the pause that precedes each breath before a moment comes into being and the world is remade again, because the becoming of the world is a deeply ethical matter. (p. 185)

Our ontologies, epistemologies, and ethics cannot be separated out. They are entangled in the production of our worlds and our lives. As we make choices in how we live and research we are, according to Barad's (2007) agential realism, making cuts. We are engaged in boundary-making practices that categorize and classify: "Cuts are enacted not by willful individuals but by the larger material arrangements of which 'we' are a 'part'" (p. 178). These cuts have material effects. For example, in Gutiérrez's (2008) work around the achievement gap, she points to cuts that are made around black and brown bodies that produce them as deficient and lacking. Cathy O'Neil (2016) argues convincingly that mathematics has material effects on people's lives and discriminatively negative effects on the poor. Far from being an abstract and static discipline that it is sometimes assumed to be, mathematics is intimately entangled in our lives as it continues to serve as a proxy for truth and privilege. The way that we do and use mathematics and the way that we do qualitative research matters. The models that we set up, in Barad's (2007) terms—the apparatus within which we are entangled—determine reality (O' Neil, 2016). In each intra-action, we determine reality and reconfigure our worlds. These determinations cannot be made ahead of time and cannot be rule-bound or universalized. This brings us again to calls by Gutiérrez (2017), Martin (2015), and de Freitas and Sinclair (2014), especially as educational researchers. How do we work to continually pose questions to ourselves/each other that take into consideration how we might all live differently? I propose that we as mathematics educators be open and uncertain about what possibilities thinking/being differently in ethical relation with mathematics education might open up. Research over the last forty years has shown that reconfiguration is possible, and we may have to unlearn some of what we know to achieve the needed radical reconfigurations in the next forty.

Productive disciplinary engagement (PDE; Engle & Conant, 2002) describes classroom situations where students publicly engage in disciplinary practices. Researchers have argued that PDE is fostered when students engage in problematizing, where they grapple with genuine uncertainty about mathematical objects, among other characteristics. Building on work by Zaslavsky, this paper advances a framework to capture the nature of uncertainty in mathematics classrooms.

Keywords: Problem Solving, Research Methods, Curriculum, Middle School Education

Introduction

Problematizing is a core principle of classrooms that embody *productive disciplinary engagement* (PDE) (Engle & Conant, 2002). Engle (2011) articulates problematizing as situations involving "uncertainties...related to the discipline...to be taken up by students." Although some existing work has operationalized other principles of PDE, such as authority and accountability, measuring the extent to which students are engaging in problematizing is less well-defined in existing literature. While existing research has modeled uncertainty when students participate in group work (Wood & Kalinec, 2012) and the linguistic basis for verbal expressions of uncertainty (Martin & Rose, 2003; Rowland, 1995), uncertainties that arise during problematizing are tied to the mathematical work students are engaged in. Engle (2011) suggests that uncertainties which arise in situations of PDE include (1) competing claims; (2) unknown path; (3) questionable conclusion; (4) non-readily verifiable outcome; and (5) other. Our work seeks to extend these initial categories to generate a comprehensive framework of situations of uncertainty when students grapple with open mathematical problems.

Methods

To generate the framework, we used an iterative process to code video recordings of classroom episodes where students were engaged in solving open problems. Our video data came from one lesson taught across two class periods in an 8th grade mathematics classroom in a rural school setting, collected in the late spring. The lesson was based on an investigation in the Connected Mathematics (CMP) curriculum (Lappan, Fey, Fitzgerald, Friel & Phillips, 2006), a curriculum used in this school from 6th to 8th grades. The teacher had taught from CMP in prior years. The specific lesson features students engaged in finding and generalizing patterns to find an algebraic expression for the number of tiles around a square pool, given any side length. The video shows the teacher's launch of the problem, small group work as students explore the problem, and a summary discussion of different groups' solutions and strategies.

We used iterative processes (Shaffer, 2017) to generate categories in our framework. The process began with individual open coding by each member of the research team to describe the uncertainties observed through students' spoken words, gestures, postures, and silences. Next, we engaged in several iterative cycles of axial coding (Strauss & Corbin, 1998) to collectively compare codes against the data and existing codes in order to restructure and refine the framework to account for students' processes. In the final iterative cycles, we looked for overlap in our descriptions of types of uncertainty and worked to eliminate any redundancies. We then compiled the framework and individually re-coded the video data to determine that all uncertainties could be coded with the refined framework.

The Framework

The process described in the Methods section yielded the framework shown in Figure 1. Building from work by Engle (2011) and Zaslavsky (2005), our modified categories include uncertainty about: (1) What action to take - students have uncertainty about what to do, where they may feel unable to begin or continue working; (2) Justifying actions or outcomes - students don't know how to verify, check, or justify what they are doing or some outcome of mathematical work; (3) Meaning of conclusion - students have or are presented with a final result, but are uncertain about what it means or how to apply it more broadly; and (4) Competing alternatives - two or more mathematical ideas arise that cause hesitation or uncertainty. Competing alternatives may occur during any stage of problem solving and is not necessarily independent of other types of uncertainty. Further, uncertainties do not necessarily arise in a linear fashion, and the resolution of one uncertainty might give rise to others.

Categories of Uncertainty	
Code	**Definition**
A. What Action to Take	
1. What a mathematical object represents	Students have hesitation/questioning about the possible meaning conveyed by a mathematical object (i.e. a diagram, shape, expression/equation, graph, table)
2. What does [part of problem context] mean?	Students are unsure about what is meant by some detail of the problem statement or part of the problem context.
3. How to create or use something	Students are uncertain about how to use the tools they have to achieve their desired goal.
4. What is the goal? What is to be created?	Students are unsure about what the problem is asking them to do or what they are trying to accomplish.
B. Justifying Actions or Outcomes	
5. Connecting to prior work	Students are uncertain on which prior knowledge they can draw.
6. Whether strategy is productive	Students are pursuing one method or strategy but are unsure if it will help them achieve their desired mathematical goal or solve the problem.
7. Representing thinking	Students have a partially developed idea or conjecture but are not sure how to represent it physically or verbally.
8. Justifying strategy	Students are uncertain of how to justify that the mathematical actions they have taken are correct.
9. Has solution been reached?	Students are unsure if the solution has been reached or if there is more to do.

C. Meaning of Conclusion	
10. What to conclude	Students are uncertain of their solution's broader meaning or why it works.
11. Whether solution makes sense	Students are unsure if their solution makes sense or is reasonable, or how to determine this or explain it to someone else.
12. Strategy works for other cases	Students have an idea or conjecture, but are unsure what it means more generally or in other contexts
D. Competing Alternatives	
13. Relating one mathematical object to another	Students are uncertain if two mathematical objects are related or how they might be related.
14. Finding another way to represent idea/work	Students are uncertain if there is another way to represent their existing mathematical idea/work, or how they would go about doing that.
15. Revising work	Students are uncertain of how to revise or change their work or strategy, once they recognize it needs to be revised.
16. Finding another way to solve problem	Students are uncertain if there is another way to solve the problem, or how they would go about doing that.
17. Seeing commonality among strategies	Students are uncertain if two mathematical strategies are related or how they might be related.

Figure 1. The framework and definitions

Using the Framework: Capturing Uncertainty when Problematizing the Pool Problem

We present some of the uncertainties that arose in one pair of students' efforts on the Pool Problem (Lappan et al., 2006a, p. 6), where they are asked to find an algebraic expression for the number of tiles around a square pool given any side length. This focal pair of students initially created an algebraic expression to determine the correct answer for a 2x2 pool, but when asked if it would work for a larger pool, one student said "I'm thinking… but probably not." They struggled to calculate appropriate examples with the expression s^2+4s+s, unsure which sizes of the pool it might work for. This illustrates the uncertainty Whether a Strategy is Productive (B-6). With the teacher's assistance, the pair tried their expression with a larger pool and determined it was incorrect. One of the students attempted to explain where the structure of their expression came from, saying "I don't know, I tried to take the… what's it called… not the expanded form…", and the teacher asks, "The factored form?" The student agreed, but that they were not sure if it would apply. This illustrates the uncertainty Connecting to Prior Work (B-5). The teacher then directed the pair's attention to the initial problem statement and the use of the variable s, and one student quickly gestured to a diagram in the textbook and asked, "Is it the outside side or just the inside one?" This uncertainty about the labeling of a diagram illustrates What a Mathematical Object Represents (A-1). Moreover, this example shows how addressing one uncertainty may involve one or more additional uncertainties arising.

After resolving this uncertainty about the initial diagram, the teacher asked the pair about an equation they wrote down earlier. One of the students confirmed that they used 4s to represent the sides, and the teacher asked, "Now what do you need?" The student responded, "The… corners." The teacher asked, "So how could you write that into the equation?" and the student answered, "Um… maybe you could, like, put it as a second power?" The student had a mental representation of the problem relating to sides and corners but struggled to represent it as an equation, illustrating the uncertainty Representing Thinking (B-7). The pair knew that they needed to include 4s in their expression, but they were not sure how to modify this expression to account for the corners. One of the students began to try various other multipliers in their calculator and realized that multiplying by a different number for each pool size produced the correct number of tiles. However, the pair tentatively proceeded to produce what they considered as an appropriate equation. This illustrates the uncertainty Revising Work (D-15).

In many cases, not all uncertainties were resolved quickly. Uncertainty about revising work, for example, extended through the rest of the small group work time. To further understand the nature of problematizing, we acknowledge several key categories of meta-data important to correlate with codes for uncertainty, such as *source* (others, technology teacher, self), *indicator* (gesture, statement, question), *phase* (launch, explore, summary), *part of problem* (initial challenge, explore, check, verify), and *number of students* (whole group, small group, individual).

Discussion

An essential part of achieving the goal of increasing students' opportunities to engage in PDE is understanding the mechanisms that allow PDE to emerge in classroom settings. In this paper, we advance a framework that may help the field get closer to identifying situations of problematizing that are essential for PDE by articulating kinds of uncertainty that are empirically grounded from a video-recorded sample of classrooms engaging in rich, open problem solving. This framework provides a starting point for further research, including investigating problematizing as it arises in classrooms with enhanced technology supports for collaborative problem solving as well investigating the relationship between authority and accountability and the emergence or scarcity of particular kinds of uncertainty.

CHALLENGING THE STIGMA OF A SMALL N: EXPERIENCES OF STUDENTS OF COLOR IN CALCULUS I

Because students of color are underrepresented in undergraduate mathematics classes, their experiences are often ignored in studies drawing on large data sets or are inferred based on the experiences of other populations, specifically women. This exclusion and misrepresentation of students of color is often attributed to methodological limitations. We reexamine the data studied for a previous analysis attending to student race and ethnicity rather than to gender. Due to the smaller numbers of non-white students, we utilize different analytic tools, and draw on students' open-ended responses to a survey question asking about their experiences in Calculus I. In addition to adding to the literature on students from marginalized populations in undergraduate mathematics, this paper argues for a reframing of how we value papers with a small n, and what this value indicates about our value of the students making up the small samples.

Keywords: Equity and Diversity, Research Methods, Gender, Post-Secondary Education

A number of recent studies have been published that draw on a large data set to make strong claims about students' gendered experiences in undergraduate mathematics (see e.g., Ellis, Fosdick, & Rasmussen, 2016; Laursen et al., 2011). In each of these studies, the researchers had access to the students' race and ethnicity, but were unable to conduct the same statistical analyses differentiating by race and ethnicity as they did by gender because of the small sample of students from non-white populations. For instance, in discussing learning gains between the active learning courses (specifically Inquiry Based Learning; IBL) and non-active learning courses, Laursen and her colleagues (2011) state: "We could only compare [the learning gains of] white and Asian students, because the number of other students of color in our sample was very low (see Appendix A3)" (p. 55). Similarly, in a recent publication investigating factors related to students' and instructors' experiences in calculus: Hagman, Johnson, and Fosdick (2017) state: "We do not investigate the association between race or ethnicity and [opportunities to learn] due to the small proportion of non-white students and instructors in our study" (p. 5).

Because of the underrepresentation of students of color in undergraduate mathematics courses, their experiences in these courses are made invisible in studies that draw on large data sets, or are inferred based on the experiences of other underpenetrated populations, specifically women. For instance, researchers use Laursen and her colleagues' (2011) paper as evidence that active learning benefits students from "underrepresented" groups. As a prototypical example of this, Webb (2016) states: "Research has shown that undergraduate students who are involved in active learning techniques can learn more effectively in their classes, resulting in increased achievement and dispositions… particularly so for underrepresented groups (Laursen et al., 2011)" (pp. 1-2). While Laursen et al. (2011) are able to make substantive claims about the benefits of IBL for women and typically low-achieving students, which are both underrepresented groups in STEM, these findings are being generalized to make claims about underrepresented students in general, which is often taken to specifically include students from underrepresented racial and ethnic minorities.

While there are some studies about such students' actual experiences in undergraduate mathematics (see Adiredja & Andrews Larson, 2017 for a review of this literature), such studies are limited and, due to the underrepresentation of such students in undergraduate mathematics, draw on a smaller data set and often employ qualitative methods. For instance, McGee and Martin (2011) studied the experiences of 23 Black mathematics and engineering college students, Levya (2016) studied the experiences of five Latinx engineering college students, and Adiredja and Zandieh (2017) studied the experiences of 8 Latina's in a Linear Algebra course. In comparison, Laursen et al. (2011) drew on survey data from 1,100 students and Ellis, Fosdick, and Rasmussen (2016) analyzed data from 2,266 students, with about 50% identifying as female in each study.

Because students of color are underrepresented and their numbers are small, their experiences are often ignored or are inferred based on the experiences of other underrepresented populations, specifically women. This "exclusion and misrepresentation of [students of color] in education research" is often attributed to methodological limitations (Teranishi, 2007, p. 38). In this study, we reexamine the data studied for a previous analysis (Ellis, Fosdick, & Rasmussen, 2016) attending to student race and ethnicity rather than to gender. Due to the smaller numbers of students of color, we utilize different analytic tools, and draw on students' open-ended responses to a survey question asking about their experiences in Calculus I. In addition to adding to the literature on students from marginalized populations in undergraduate mathematics, this paper seeks to argue for a reframing of how we value papers with a small n, and what this value indicates about our value of the students making up the small samples.

Students of color continue to face systemic racism and racialized negative narratives in mathematics classrooms (Spencer & Hand, 2015). Despite the large and still-growing academic research and literature unveiling these disparities and systems of oppression, dominant mathematics education narratives continue to defend the "objectivity" of mathematics as a color-blind discipline (Martin, 2013). While this color-blind narrative put forth in defense of the continued practice of marginalization of students of color has been challenged for many years, the issue remains of low concern and priority in higher education, perhaps largely due to the continued low numbers of students of color in college mathematics courses. This underrepresentation, while itself an area of high concern, has set up those students of color who do gain access to college mathematics to have their experiences and even their entire presence often completely erased in research surrounding college/university mathematics education research. One significant contributor to this phenomenon is the practice of removing would-be outliers and/or subgroups within large data sets that have small sample sizes.

Methods

Background and Data Collection

The data used for these analyses draws on a national data set made available by the Mathematical Association of America. This data was collected by surveys sent to Calculus I students at the beginning and the end of the course. We draw on the larger data set containing survey responses (n=9793) and a smaller data set containing students' free responses on the survey (n=520). Students were grouped into three race/ethnicity groups. We understand and acknowledge the problems in these groupings based on a number of issues. Based on students' responses to race/ethnicity questions, students were categorized as White (68% of large data set, 67% of smaller), Asian (14%, 12%), and Underrepresented Students of Color (17%, 19%), comprised of students who identify as Black, Pacific Islander, Native American or Alaska Native, Hispanic/Latinx, multiple race/ethnicity identities, and race/ethnicities not listed on the survey.

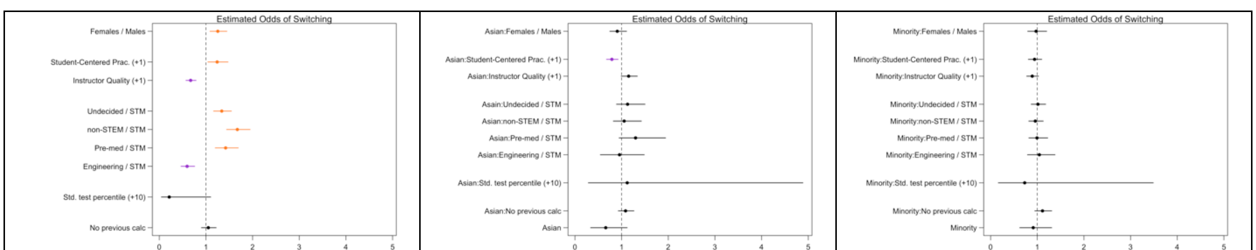
Sample Data Analysis

The first analysis is the coarsest, and attempts to mimic the analysis of the Ellis, Fosdick, & Rasmussen (2016) analysis as much as possible by grouping students into three race and ethnic categories. In this analysis, we run a regression with the outcome of persistence in calculus, and use the same predictors as those used in the initial gender comparison. i.e. previous calculus experience, math standardized test percentile (ACT/SAT), major, scores of teaching quality and student centered instruction in their course, and gender. Additionally, we added interaction terms with each of the predictor variables for Asian students and underrepresented Students of Color; we explain the significance of these interaction terms below. The second analysis investigates students' reasons for switching, and we display student responses grouped by gender and the three race/ethnicity groups identified in the first analysis

Sample Results

The output variable used for the gender-comparison study was student persistence through the calculus sequence. In that study, we looked at the relationship between gender and student persistence, controlling for a number of factors that may be related, such as career intentions and previous calculus experience. Through that analysis, we found that female students were 50% more likely to be identified as Switchers compared to male students, after controlling for a number of factors. This result was very statistically significant, which we were able to test for because of the large number of students and, more specifically, the large number of students who identified as male (n=1,236) or female (n=1,030).

For the first analysis in this paper, we attempt to mimic the gender-comparison analysis as much as possible by identifying students as either White (n=6,674), Asian (n=2,921), or underrepresented Students of Color (n=1,699). Due to the large majority of White students in our sample, we wondered if the results found in Ellis, Fosdick, & Rasmussen (2016) really represented the experiences of only White students. To test this, we rerun the analysis for Asian students and unrepresented Students of Color and compare this to the original analyses of all students.



1a. All students	1b. Asian	1c. UR SOC

Figure 1a-1c. Odds ratios of switching for all students, Asian students, and underrepresented Students of Color (URSOC).

Figure 1 displays the estimated odds ratios of switching out the calculus sequence for each of the predictor categories, for each of the three populations. An estimated odds ratio bigger than 1 (highlighted in orange) indicates a student with this quality has a higher chance of switching out of calculus and if the odds ratio is smaller than 1 (highlighted in purple), then the student has a lower chance of switching.

In our second analysis, we investigate Switchers' reasons for switching, disaggregated their gender and race/ethnicity group. On the end of term survey, all students who said that they either did not intend to take Calculus II, or weren't sure, we given a list of possible reasons for why, and were asked to select all that apply for them. While the numbers of responses are small for some items, we can compare relative frequency and see that, for example, a larger ratio of URSOC women (17/53) attribute a lack of understanding to their decision compared to Asian women (1/53) and White women (40/176, which would be equivalent to approximately 12/53). This second analysis compliments the first by showing that, while the regression analysis did not indicate significant differences related to persistence based on the factors we investigated, students from different populations attribute their decision for leaving to very different aspects of their experience. While this analysis allows us to identify trends between the different racial and ethnic groups of students, we cannot identify the strength of these trends due to the small n's. Our third analysis analyzes students' free responses to the question "Is there anything else you want to tell us about your experience in Calculus I?"

Brief Discussion

The goal of this paper is to bring attention to the normative practice in our community of ignoring the experiences of students of color in our quantitative studies. While our qualitative colleagues work to richly understand and document the experiences of students of color in our undergraduate classes, and while work to increase the representation of students of color in our classes and in our data sets, we must challenge and overcome the stigma of a small n. This paper indicates that the experiences of students of color are (a) different from the experiences of women, (b) not all the same, and (c) are more complex than statistics alone indicate.

Networking theories of different grain sizes, we designed a fully online assessment of students' covariational reasoning. With this assessment, we intend to produce a viable means of measuring students' mathematical reasoning using methods other than clinical, task-based interviews. The assessment is fully online, and readily accessible across different types of devices. We outline design aspects across and within the assessment items and provide three theoretically based design principles underlying the design of the assessment. Through this research, we contribute to the development of new theoretical approaches to investigate and assess complexities of students' mathematical reasoning.

Keywords: Assessment and Evaluation, Research Methods, Reasoning and Proof, Technology

We address the problem: How can a fully online assessment be developed, in place of clinical interviews, to make inferences into students' covariational reasoning? Building from the work of Norton, Tzur, and colleagues (Hodkowski, Hornbein, Gardner, Johnson, Jorgensen, & Tzur, 2016; Johnson, Tzur, Hodkowski, Jorgensen, Wei, Wang, & Davis, in press; Norton & Wilkins, 2009), we designed an assessment to measure undergraduate college algebra students' covariational reasoning. We extend existing research in two ways. First, we developed a fully online assessment, rather than a paper and pencil tool. Second, we designed our assessment to measure covariational reasoning, rather than multiplicative or fractional reasoning.

We aimed to not only assess students' covariational reasoning, but also to distinguish *gradations* in students' covariational reasoning (see also Johnson et al., in press). Building from the work of Johnson and colleagues (Johnson, McClintock, Hornbein, Gardner, & Greiser, 2017), we networked, or interweaved, theories to design assessment items. Interweaving Thompson's theory of quantitative reasoning (Thompson, 1994; Thompson & Carlson, 2017) and Marton's variation theory (Kullberg, Kempe, & Marton, 2017; Marton, 2015), we designed within and across assessment items. To distinguish gradations in students' covariational reasoning, we drew on Tzur's method of fine grain assessment (Tzur, 2007). Using the fine grain assessment method, we designed our assessment with the intent to investigate how students' opportunities to conceive of variation in individual attributes might foster their covariational reasoning. We outline design aspects within and across assessment items and provide three theoretically based design principles underlying the design of the assessment.

Theoretical and Conceptual Framework

Networking Theories to Design Within and Across Assessment Items

To design within and across assessment items, we networked Thompson's theory of quantitative reasoning (e.g., Thompson, 1994; Thompson & Carlson, 2017) and Marton's variation theory (e.g., Kullberg et al., 2017; Marton, 2015). Marton and colleagues (Kullberg et al., 2017; Marton, 2015) identify two key aspects of variation theory: Discernment and variation. For students to discern critical aspects of an object of learning, they need to experience variation (difference). Specifically, learners should experience variation in critical aspects across a background of invariance. Then learners should repeat experiences across different backgrounds. In our set of assessment items, we designed for variation (difference) within assessment items (a background of invariance), then across assessment items (different backgrounds).

To explain the object of learning—covariational reasoning—we appeal to Thompson's theory of quantitative reasoning (e.g., Thompson, 1994; Thompson & Carlson, 2017). In this theory, Thompson draws on students' conceptions of attributes to explain students' mathematical reasoning. In particular, some attribute is a quantity if an individual conceives of that attribute as possible to measure. By covariational reasoning, we mean students' conceptions of relationships between attributes that are capable of varying and possible to measure. For example, consider a toy car moving around a square track. A student engaging in covariational reasoning could conceive of a relationship between the toy car's total distance traveled and the toy car's distance from a center point on the track.

Across our assessment items, we included situations incorporating attributes having different kinds of variation (change). To clarify, we distinguish this use of variation (change) from Marton's use of variation (difference). Across the items, we varied not only the direction of change in attributes (e.g., increases or decreases); we also incorporated variation in unidirectional change in attributes (e.g., "increasing" increases or "decreasing" decreases).

The Fine Grain Assessment Method

To distinguish gradations in students' covariational reasoning, we adapted Tzur's (2007) method of fine grain assessment. When using fine grain assessment methods, designers begin with items that include no supports, then move to subsequent items including increasing amounts of supports. Because items including no supports appear before items with supports, assessment designers have the potential to investigate different levels, or gradations of students' reasoning (see also Hodkowski et al., 2016; Johnson et al., in press). In particular, we intend to use this assessment to investigate how opportunities to conceive of variation in individual attributes might foster students' covariational reasoning.

The Covariational Reasoning Assessment

Table 1 provides a map of the covariation items. The covariational reasoning assessment contains four assessment items. Each assessment item contains four question groups.

Assessment Items and Question Groups

Assessment items. Each assessment item incorporates a situation involving changing attributes. We incorporated variation (difference) across the collection of assessment items. The collection incorporates different kinds of attributes (e.g., height from the ground, total distance traveled, diameter of the water surface of a fishbowl, and distance of a car from a center point). Furthermore, the collection incorporates different kinds of variation (change): Variation in the direction of change and variation in unidirectional change (e.g., an "increasing" increase).

Question groups. Each assessment item contains four question groups. Question group 1 serves as a member check, to assess if students comprehend the situation. Question group 2 serves as the first assessment of covariational reasoning: Reasoning without support. Question group 3 provides support for students' covariational reasoning. Question group 4 serves as a second assessment of covariational reasoning: Reasoning with support. We designed our question groups based on Tzur's (2007) method of fine grain assessment. If students respond correctly to Question group 2, they will move to a new assessment item. If students respond incorrectly to Question group 2, they will move to Question groups 3 and 4.

Table 1: Map of the covariation items in the covariational reasoning assessment

Assessment Item	Question Group 1: Member Check	Question Group 2: Reasoning without support	Question Group 3: Supports for Reasoning	Question Group 4: Reasoning with Support
Ferris Wheel  Nat, Path, Tree  Fish bowl  Toy Car 	Play Video Statement of Attributes Do you understand the situation? •Yes •No •If No, explain what makes this situation difficult to understand •If Yes, move to Q2	Play Video Select a graph that represents a relationship between the attributes •A •B •C •D Explain why you chose the graph you did •If Incorrect, move to Q3 •If Correct, move to next assessment item	Video of dynamic points moving along axes Describe how attribute 1 is changing Video of dynamic points moving along axes Describe how attribute 2 is changing	Play Video Select a graph that represents a relationship between the attributes •A •B •C •D Explain why you chose the graph you did

Design Principles

Assess for a Spectrum, Rather than a Switch

We use the analogy of a spectrum versus a switch to communicate our work to move beyond binaries in assessing students' covariational reasoning. Applying Tzur's (2007) method of fine grain assessment, we designed to distinguish gradations in students' covariational reasoning. We anticipate our gradations to be compatible with, yet perhaps not identical to, levels of covariational reasoning put forward in the framework of Thompson and Carlson (2017).

"Practically" Apply Theories to Design Assessment Items

We aim to interweave and apply theories to do practical work of assessment design. With Thompson's theory of quantitative reasoning, we designed assessment items in which students could have opportunities to conceive of attributes as possible to measure and capable of varying. Therefore, we interrogated the types of attributes and variation (change) included in the assessment. With Marton's variation theory, we designed for variation (difference) within and across assessment items. Within assessment items, we incorporated different types of graphs (e.g., linear/nonlinear). Across assessment items, we incorporated different backgrounds (e.g., a Ferris wheel, a toy car, etc.) and different types of variation (change) in attributes (e.g., variation in direction of change and variation in unidirectional change).

Leverage Technology to Promote Access and Opportunity

We leverage multiple technological affordances to promote greater student access and opportunity. Students can access the covariation assessment via a computer, a tablet, or a mobile phone. We created the animations following design factors for effective educational multimedia, including multiple representation types, pacing, cueing, and user manipulation (Plass, Homer, & Hayward, 2009). The assessment incorporates various multimedia, such as original video animations, which provided multimodal representations of dynamic graph attributes.

Concluding Remarks

Networking theories, we interweave variation (change) and variation (difference) in assessment design. We leverage technology to apply Tzur's method of fine grain assessment. Overall, we are working "practically" to network and apply theories to design accessible tools to investigate and assess gradations in undergraduate students' covariational reasoning.

INTERPRETIVE FRAMEWORK FOR ANALYZING COLLECTIVE LEARNING IN A MATHEMATICS CLASSROOM

Teruni Lamberg

An interpretive framework for organizing and reducing data from a whole class teaching experiment for further analysis is described. Design research typically generates extensive data and can become potentially unmanageable for analysis. The framework described in this paper uses a situated cognitive perspective: Meaning making arises out of activity within the context of the classroom. Each layer affords and constrains each other. Data from a whole class teaching experiment illustrates how the framework was used to reduce and catalog the data for further analysis. The framework can be adapted by anyone who is engaging in design research.

Keywords: Design Experiments, Research Methods

Educational researchers are continually engaging in design research through whole class teaching experiments as a way to study and observe learning. Collective classroom learning is the normative understandings that emerge in a classroom community (Cobb & Yackel, 1996). Most whole class teaching experiments aim to analyze student learning by repeating the process of developing and testing instructional activities. The process of collecting and analyzing data in a design research project is messy as it embraces the complexity of the settings in which the learning occurs (Cobb, Zhao, & Dean, 2009). In order to study learning, researchers must have a variety of data sources to analyze and any source that relates to the broader phenomena being studied in the experiment should be collected (Cobb, Confrey, diSessa, Lehrer, & Schauble, 2003). Data sources include notes from the field, video recordings, and documentation of anything that occurs in the classroom such as students' work, class discussions, and the teacher's reflections. Theories, forming from analysis, inform the design decisions that must be made throughout the teaching experiment. These ongoing interpretations of the activity in the classroom profoundly shape the process of experimenting to support learning (Cobb & Gravemeijer, 2008).

In teaching experiments using design research, the focus is on the whole class' mathematical learning as they practice classroom communal processes (e.g. Cobb, et al., 2009; Confrey & Smith, 1995; Lehrer & Schauble, 2004; Stephan, Bowers, & Cobb, 2003) and participate in learning as a whole group. Learning in this way is a social phenomenon in which mathematical ideas are established in a classroom community through patterns of interaction (Rasmussen & Stephan, 2008). Mathematical learning is both a process of constructing meaning as an individual and a process of acculturation of meanings in society (Eisenhart, 1988). This implies that learners of mathematics learn individually, but also through interaction, eventually constructing new knowledge.

Design researchers document the process of analysis and design in a form intended for public reflection and discussion (Edelson, 2002). We used a framework to make ongoing interpretations and conjectures about the collective learning that took place to guide our thinking process through the design. The framework relates to the conference theme of "Looking Back, and Looking Ahead" because it allows researchers to look back at what happened in a whole class teaching experiment and look ahead with a deeper understanding of student learning. Our purpose in this article is to describe the interpretive framework that we employed to analyze collective classroom learning and make design decisions. Practical applications of the layers of the framework contribute to the field of design research methodology in a whole class teaching experiment and empower teaching experiences.

The Interpretive Framework

The situated cognitive perspective provides a useful lens to study collective classroom learning. According to this perspective, all knowledge is considered situated and is regarded as a product of the activity, context, and culture in which it is produced and used (Brown, Collins, & Duguid, 1986). The situated cognitive perspective has made significant contributions over recent years as presenting knowledge not as a stable individual characteristic, but something that is distributed across activities, systems, and environments (Lave & Wenger, 1991). A challenge of studying the activity in a classroom from a situated perspective is to ensure that what is observed in the classroom is not reduced to single acts or products. Rather, the goal of developing such a framework is to make sense of classroom interactions as continuous, mutually constitutive, and evolving practices where students are engaged in making mathematical meaning. To frame collective learning, we adopt Davis' and Simmt's (2003) view that a classroom is a complex system, "not just the sum of its parts, but the product of the parts and their interactions" (p. 138). Our intention in this paper is to connect the conceptual and methodological theory of collective learning in a classroom to the pedagogical.

The interpretive framework used in this study (see Figure 1) was adapted from (de Silva, 2001) and accounts for individual and collective learning by considering the micro-culture of the classroom (Cobb, Gravemeijer, Yackel, McClain, & Whitenack, 1997). The students' mathematical understandings emerge as they engage in activity within the context of the classroom through social interaction and tools (Cobb, Stephan, McClain, & Gravemeijer, 2001). The interpretive framework reflects that sense making takes place through activity within the context of the classroom as illustrated in Figure 1. The arrows represent affordances and constraints influenced by each nested layer.

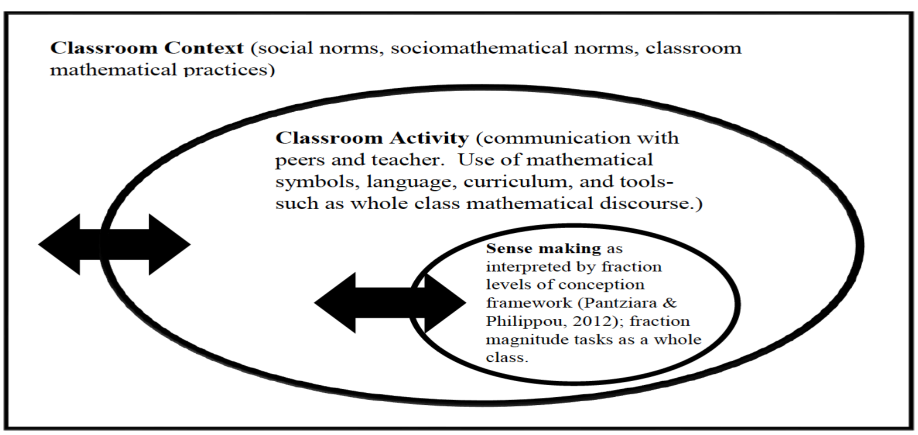

Figure 1. The Interpretive Framework used to analyze collective learning in a classroom (Bertolone-Smith, 2016).

Collective learning contains *sense making* at its core nested within activity that is nested in the context of a classroom. This model of collective learning specifies how sense making of mathematics is situated in a whole class setting. The core of the interpretive framework is the nested layer of sense making. This approach to sense making takes into account both the social perspective (the meanings the class is making as a whole) and the psychological perspective (the meanings and interpretations of individual students as they participate in the classroom community). This layer is critical when conducting a classroom design experiment with students because the purpose of the research is to study learning. The current study needed to address students' learning of fractions in the instructional unit to understand how they were making sense of the tasks and, subsequently, learning. These classroom mathematical practices, "taken-as-shared ways of reasoning, arguing, and symbolizing established while discussing particular mathematical ideas" (Cobb et al., 2001), provide a reference for sense making.

The second layer of the interpretive framework is *activity.* The role of activity in a social setting is to arrive at a common understanding. In the current study, activity accounted for the practices in the classroom and the assumption that students had their own way of communicating and interacting with each other, the teacher, and the content. The *Common Core State Standards for Mathematics* (NGA/CCSSO, 2010) and the *Principles and Standards for School Mathematics* (2000) emphasize communication as essential for how students learn mathematics. Activity occurs through student-student interactions, student-teacher interactions, and student-content interactions. Mathematical learning is both a process of constructing meaning as an individual as well as a process of acculturation of mathematical meanings in society (Eisenhart, 1988). Students learn mathematics individually but also through interaction with each other, as a process that occurs during social interactions, a circular sequence of events (Cobb, Yackel, & Wood, 1992). The theory of social constructivism (Vygotsky, 1978) reflects this perspective where the central tenet is that learners construct their own understanding by participating in meaningful shared discourse. Activity also includes the students' interactions with curriculum and representational tools.

The third layer of the interpretive framework is *context*. Student learning of mathematics is affected by experiences in the classrooms and these experiences are created by and depend on the context of the environment, including the teacher and other students. A context conducive to learning considers the physical environment and also the social environment that includes the interactions that occur among teachers, students, and content (Cohen & Ball, 1999).

In the overall framework, sense making is afforded and constrained by activity that in turn is afforded and constrained by the context. Hence, the framework can be thought of as three layers of nested concentric ovals that can be expanded and collapsed; *sense making* nested within *activity* further nested within *context*. Sense making is interpreted by how students think about and make meaning of the tasks that occur within the activity in light of the context of the classroom.

Using the Framework to Organize Data for Further Analysis

The following section illustrates how the framework was used to analyze and organize data from a whole class teaching experiment (Bertolone-Smith, 2016). We describe a methodological approach to organize and reduce data for further analysis. The data presented in this section represents a sample from a whole class teaching experiment conducted for illustrative purposes. The data collected as part of the whole class teaching experiment in this illustration included video of the teaching sessions, video of student discussions and comments, video and field notes of student interviews and discussions, video and field notes of teacher and researcher debriefing interview sessions, lesson plans, and student work. Analysis of the data occurred every day after each teaching episode. All lessons were transcribed and then analyzed through the interpretive framework. The raw transcript was organized to indicate classroom context, activity and sense making. Since mathematical discourse was a focus of the study, conversations were preserved to better understand how they impacted or represented the shifts in understanding.

Table 2: Emerging Categories through Context, Activity, and Sense Making

	Classroom Context	Classroom Activity	Sense Making
Emerging Categories	Teacher addressing student interruption. Practice expected behaviors. Prime class for "hard work".	Student generated justification of labeling includes distinguishing whole, gesturing to indicate distance by drawing hand along number line. Independence and accuracy celebrated	Student noticing that the whole "unit" and number of parts in whole generates fraction. Student counting by fractional pieces, gesturing across number line to indicate accuracy to justify to class
	Floating dialogue throughout lessons. *Adjusting mindset* of class when lesson increased cognitive demand	*Gesturing* by teacher adapted by students to *reinforce fraction distance from 0.*	Shift from *relying solely on part-whole construct* of fractions to *distance from 0.*

Implications and Discussion

The interpretive framework (Figure 1) is helpful for reducing and organizing data when conducting design research (Cobb et al., 2003) by illuminating aspects of the learning ecology to make design decisions during the experiment and retrospectively study the conditions that contributed to the sense making that took place.

THEORIZING A TRANSLANGUAGING STANCE: ENVISIONING AN EMPOWERING PARTICIPATORY MATHEMATICS EDUCATION *JUNTOS CON* EMERGENT BILINGUAL STUDENTS

Luz A. Maldonado
Texas State University
l.maldonado@txstate.edu

Gladys Rueda Krause
College of William and Mary
gladyshrueda@utexas.edu

Melissa Adams
The Ohio State University
adams.2143@osu.edu

We propose a translanguaging stance in the bilingual mathematics classroom defined by four elements: (1) Con respeto for other people's ideas, leading to positive intellectual relations, (2) Con cariño, a commitment to the learning of others, (3) Como familia, working for the good of the classroom collective and for the benefit of individuals, and (4) Con acompañamiento, where teachers actively do math with their students. We propose a focus for the bilingual mathematics classroom and emergent bilingual students that emphasizes the importance of rehumanizing mathematics classrooms for all students and valuing their full linguistic repertoires.

Keywords: Culturally Relevant Pedagogy, Teacher Affect, Beliefs, Identity

Mathematics education research advocates for practices that celebrate all students' mathematical reasoning and ways of knowing (Turner & Drake, 2016.) There remains a need to study what this means for emergent bilingual (EB) students, especially given the deficit-oriented historical context of U.S. education policy around language with an overemphasis on English mastery (Gandara, et al., 2010). We see an urgent connection between envisioning a different mathematics education for EB students and PMENA's enduring conference challenge of both preparing teachers of EB students and continuing to support *all* students through equitable teaching. Translanguaging, an evolving understanding of language practices (García & Wei, 2014), provides a different lens through which to view multilingual mathematics classrooms.

We briefly describe a translanguaging stance and make relevant connections to mathematics education research moving the field forward as we propose this new lens. We base our arguments on mathematical lessons observed in a 2nd grade dual language class and make an argument for how all EB students could participate in mathematics teaching and learning through ways that are rehumanizing to all people in the classroom space and to mathematics itself.

Theoretical framework

García and Kleifgen (2010) encourage moving past traditional language separation practices (i.e, English day and Spanish day) and instead consider the "dynamic bilingual practices" which emergent bilinguals enact and are context and person specific. García, Ibarra Johnson & Seltzer (2017) define a translanguaging classroom as a "space built collaboratively" with their own language practices, and teaching and learning in "deeply creative and critical ways" (pg.2). Due to a lack of translanguaging studies in elementary mathematics classrooms, we further argue that it is necessary for mathematics educators to cultivate a *translanguaging stance* and build classrooms in which teachers and students *juntos* (together).

We conceptualize a translanguaging stance in the mathematics classroom as the deliberate choice by teachers to use children's thinking while engaging in mathematics instruction that develops knowledge, dispositions and practices that not only support the development of children's mathematical thinking, but also build on students' cultural, linguistic and community-based knowledge (Turner et al., 2012). We posit that students can not only expand their sense of what they can do mathematically, but also develop a sense of what mathematics can be, and develop mathematical identities characterized by power and possibility (Adams, 2018). Building on an active anti-racist stance that first acknowledges EB student's racialized schooling and mathematics learning experiences in US schools (Martin, 2009), we theorize classroom practices in a translanguaging mathematics classroom. García, Ibarra Johnson & Seltzer (2017) identified four translanguaging classroom elements that support and value EB students: *con respeto, con cariño, como familia, and con acompañamiento*. We briefly present each of these elements and supporting mathematics education research.

Four Elements of a Mathematics Translanguaging Classroom

***Con respeto* (with respect)**. Two second grade EB students, Rubén and Hernán, shared their strategies, one in English and one in Spanish, for a subtraction problem, while the teacher, Ms. Amaris used mathematical notation to represent their mathematical thinking. Ms. Amaris elicited mathematical ideas in both languages and did not provide translation, but let the notation and sharing of the strategies remain the focus of the conversation. When teaching with respect, we observe how our EB students expand the entire class' ways of knowing both by honoring the languages in which students express themselves and the ideas and reasoning that they share. At the same time, by bringing students' knowledge and ideas to bear in discussions of mathematics, we are also showing other ways to *mathematize*, much like translanguaging expands notions of what it means to *language* (García, Ibarra Johnson & Seltzer 2017).

We also observed how the teacher understood children's multidigit subtraction strategies and selected powerful mathematical strategies to be shared with the entire class (Carpenter, et al., 2000). *Con respeto* is enacted when teachers make instructional decisions based on how their students understand mathematics (Franke, et al., 2001). Knowledge of children's mathematical thinking is an important component of how teachers can view their EB students' mathematical thinking in an empowering way, by positioning the students as mathematical thinkers and creating a shift in who "does" mathematics (Turner, Domínguez, Maldonado & Empson, 2013).

***Con cariño* (with fondness).** *Cariño* denotes the love that can bring together all members of a classroom community, along with their languages (García, Ibarra Johnson, & Seltzer, 2017). This includes the ways of doing math that students bring with them and how their mathematical reasoning intertwines with their languages and their experiences to weave ideas.

Ms. Amaris posed a Join Change Unknown problem, part of a unit in which the class explored how children were affected by the Flint water crisis. Her students proposed raising money for Flint children, providing a meaningful context for problems (Dominguez, 2011). The class shared strategies and Hernán shared his incorrect answer in Spanish. Ms. Amaris then explored a common computational error to promote Hernán's powerful subtraction base ten strategy. This was a common practice in Ms. Amaris' classroom: Hernán used his linguistic repertoire by sharing in Spanish, which provided a space where language was a resource for mathematical understanding. In this classroom, encouraging students to express their thinking in the language in which their minds happen to express the idea at that moment, shifted the focus from *form* (English vs. Spanish) to *content* (the mathematical idea being learned).

This corroborates with Moschkovich's (2015) definition of academic literacy in mathematics for English language learners which posits that academic mathematical literacy is not just about the cognitive aspects of mathematics, but also situated in experiences such as discussion and being able to express one's ideas in a known language. It is thus the participation in mathematical practices, in this case discussion of one's strategies, that leads to mathematical proficiency for EB students. In this interaction, Ms. Amaris makes a purposeful decision, *con* *cariño*, because of her knowledge of the student's academic literacy in mathematics, to use Spanish as the means through which to encourage a powerful strategy into the classroom space.

***Como familia* (like a family).** *Familia* as a translanguaging stance in the mathematics classroom takes the form of a group that collectively works to support and promote both the whole group and each individual member. García (2017) describes how, when a classroom is like a *familia*, classroom discussions address content and language along with "inner truths", with the goal of fostering meaningful learning and strong connections. The previous observed lesson showcased how Ms. Amaris' classroom behaves as a *familia* and shows mathematics being learned through a student-centered discussion and connected to the original ideas that students produced. Ms. Amaris often put the responsibility of making sense on students, and through this sense making the original idea shared shifted.

This element connects to vast research on discussion in mathematics education. Highlighted in Moschkovich's (2015) work as an important component of academic literacy in mathematics, other research has iterated how important discussion is for developing conceptual and procedural mathematics understanding (Stein, Engle, Smith & Hughes, 2008). Past studies of how teachers should include EB students in mathematical discussions (Maldonado, Turner, Dominguez & Empson, 2009) have not been viewed through a translanguaging lens, but the element of *como familia* aptly fits the type of classroom that this research advocates for.

***Con acompañamiento* (truly together).** This element goes beyond being together and empathizing for one another and involves actively doing mathematics with one another--in the classroom this means that instruction is planned so that teacher and students engage in learning, *languaging* (García, 2017) and *math-ing* together. Ms. Amaris' classroom shares a deep and profound understanding of *why* mathematics matters and are engaging in mathematics together. In learning mathematics *con acompañamiento* we see how the focus on the ways students learn to treat each other, and the respect they learn for people from circumstances different from their own, produce equitable relations that are encouraged and developed in the classroom. This supports the importance of using TEACH MATH modules, which encourage teachers to view the students and community as sources of mathematics learning (Aguirre, et al., 2012).

Conclusions

We have focused on the importance of a translanguaging stance for teaching mathematics to EB students, but feel that these elements serve the possibility of rehumanizing mathematics classrooms for *all* students who are seen from a deficit perspective. Moving forward, we also need to reconsider how we prepare future bilingual education teachers for this kind of mathematics teaching which shifts the focus from language use to mathematical reasoning. Given the tensions that bilingual teachers face in classrooms, we need to view this education as not only liberatory for the students, but for the teachers as well.

ADDRESSING TENSIONS IN MATHEMATICS EDUCATION THROUGH FORMATIVE INTERVENTION RESEARCH PARTNERSHIPS

This paper describes an approach to cultivating formative intervention research partnerships in mathematics with school districts in the U.S. state of Missouri by researching the diagnosis and specification of problems as framed and experienced by those grappling daily with challenges related to learning and teaching mathematics. Through a mixed methods approach, we engage various stakeholders in identifying and describing important problems of practice, work to specify the inherent tensions that often exist in those challenges, and, by confronting those tensions, initiate a process of innovation rooted in the contexts in which students, teachers, leaders, and parents learn and work.

Keywords: researcher-practitioner partnership, formative intervention research

Changing the nature of mathematics teaching in the U.S. at any significant scale has proven to be extremely difficult (Hiebert, 2013). The predominant approach continues to be some variant of what Freire (1970/2000) criticized as the "banking" method, with teachers narrating largely procedurally-focused demonstrations and asking students to repeat it themselves. A common story in research in mathematics education has been the introduction of some conjectured driver of change (e.g., a professional development program, a new curriculum, different approaches to assessment, etc.), for which researchers work to find schools or districts willing to provide test-sites and subjects for their research, with the idea that an "effective" idea will eventually get "scaled up" (Institute of Education Sciences, 2016). While innovations in education are certainly needed (and worthy of support), and while there are potential benefits for the students, teachers, parents, principals, and district leaders who act as research participants, the problems and designs for solutions are typically identified at the outset by researchers, rarely originating in the communities with whom those researchers briefly partner. Consequently, the innovations that are put in place are often not sustained after the research effort has concluded (Resnick & Hall, 1998), and typically fail to change the "instructional core" of what happens between teachers and students around disciplinary ideas (Elmore, 2004; Hiebert, 2013).

Innovation Through Partnership

To address this shortcoming, different "improvement science" (Lewis, 2015) models for collaborating and conducting research in/with school districts have emerged in recent years, all of which share a commitment to taking up "problems of practice." For example, one of the more prominent models—and one that has been well received in mathematics education—has been *design-based implementation research* (DBIR). As described by Penuel, Fishman, Cheng, and Sabelli (2011), DBIR focuses on persistent problems of practice from multiple stakeholders' perspectives through iterative, collaborative design work. Consistent with the tradition of design research in education (Cobb, Confrey, DiSessa, Lehrer, & Schauble, 2003), the aim of DBIR is to develop theory related to both classroom learning and implementation through systematic inquiry, but it is also concerned with developing capacity for sustaining change in systems. Still, improvement science approaches such as DBIR implicitly require something to be implemented. But what if potential collaborators wish to begin at a less prescribed place, focusing first on understanding and defining the problem(s) and only then co-designing and pursuing potential solutions? As Lewis (2015) noted, "there is relatively little education research in the improvement science tradition, which emphasizes building organization members' understanding of the problem and its causes" (p. 2015).

One approach that holds promise for treating such problem specification as an object of interest (and not merely prerequisite work) is the cultural-historical activity theory tradition of *formative intervention research*. Drawing on Engeström (2011), Penuel (2014) suggested that the methodology includes three key commitments: (a) *focusing on a problem of practice*—a contradiction encountered by participants in their life or work activities (the "germ cell"); (b) *stimulating participants to produce innovations*—by first calling attention to a challenging situation or set of obstacles, and then triggering a process for overcoming those obstacles through design work; and (c) taking as the primary goal the *expansion of participants' agency*—to "enable new forms of collective activity to emerge through direct engagement with the contradictions embedded in practice" (p. 100). These contradictions are, at first, abstract. Through attempts to understand and model their relationship, they are made concrete, through which "learners learn something that is not yet there" (Engeström & Sannino, 2010, p. 2).

As an example in mathematics education, for teachers who strive to provide students with culturally relevant opportunities to engage in mathematical practice and to become proficient in standard ideas and skills, a contradiction in practice might be the inherent challenge of affording learning opportunities that are *emergent* in order to achieve learning goals that are largely *prescribed* (Gutiérrez, 2009; Munter, Stein, & Smith, 2015). Neither emergent nor prescribed learning goals can be eliminated; the transcendence of the contradiction is fundamental to the work (and agency expansion) of teachers and students. But, as the first commitment of formative intervention research above suggests, such "germ cells" cannot be identified a priori, but only as the result of investigating a problem of practice. Instead of pursuing a predetermined agenda or implementing a particular program, "the researcher aims at provoking and sustaining an expansive transformation process led and owned by the practitioners" (Engeström, 2011, p. 606). It is exactly there that our project is attempting to initiate partnerships with school districts—in the investigatory work of understanding problems that students, teachers, principals, parents, and leaders face, and identifying tensions for expansion through partnership. Ultimately, our aim is to change the learning and teaching of mathematics in the state of Missouri. Our starting point, however, is to enlist practitioner partners in co-investigating their current problems of practice.

Methods

Our work is guided conceptually by the three commitments of formative intervention research listed above. Our first step—and the focus of this paper—is to diagnose the problem(s) of practice that Missouri school districts are facing, and how leaders and other stakeholders frame those problems. To accomplish this, we employ a mixed methods approach—primarily through interviews, and supported by quantitative analyses of district data where applicable.

Setting and Sample

To date, our collaboration includes 9 K-12 school districts across the state of Missouri, ranging in size from large urban districts to very small rural districts. Our sample includes 32 district leaders, principals, teachers, and parents/community stakeholders.

Data Sources

Beginning with an initial, relevant contact in each district (e.g., curriculum director), we conducted semi-structured interviews, snowballing out to others from there (Spillane, 2000; Talbert & McLaughlin, 1999), including district leaders, principals, teachers, and other partners (e.g., parents). In each case, we wrote a summary of the interview, shared it with the participant and invited their feedback with respect to the summary's accuracy. Additionally, we made use of publicly available quantitative data for each participating district.

Analysis

After interviewing additional individuals suggested by interviewees and summarizing those interviews, we analyzed the summaries using qualitative analysis software (NVIVO) to identify the (a) problems, (b) underlying causes of those problems, and (c) responses to those problems described across all interviews in the district. In general, our interest was in understanding how individuals frame the problems that they identify, for which the three framing tasks described by Benford and Snow (2000) are applicable. The first, *diagnostic framing*, concerns the underlying cause(s) of a problem. The second, *prognostic framing*, pertains to the proposed solutions for (or responses to) a problem. The third, *motivational framing*, which "provides a 'call to arms' or rationale for engaging in ameliorative collective action" (Benford & Snow, 2000; p. 617) represents one task that we hope to work toward in collaboration with participating districts. We also conducted quantitative analyses of publically available data for the district that are relevant to the problems described by interviewees. We then wrote a synthesis report for participants to review and to initiate a follow-up discussion, in which we called attention to similarities and differences between participants with respect to not only what problems, causes, and responses were identified but also how those problems, etc. were framed—with the intention of sparking subsequent investigations of those problems and possible responses, which, in some cases, we might take up in continued partnership.

Results

Thus far, a number of patterns have emerged across multiple districts. For example, a key concern in a number of districts has been students' number sense in the early grades. However, the underlying causes of that problem that participants identify—both among and within school districts—vary widely. For example, some suggest the problem is a matter of teachers' mathematical knowledge (e.g., Hill, Schilling, & Ball, 2004) or views of students (Jackson, Gibbons, & Sharpe, 2017), while others view the cause as curricular in nature (e.g., an ineffective program, the lack of a program, or the lack of "vertical alignment" across years). A second finding concerns broader considerations of curriculum. By looking across multiple districts, we have pieced together a model of a "curriculum cycle," in which districts repeatedly gather and then relinquish control for determining curriculum. In such a cycle, districts often adopt a new program as a means for improvement. Initially, teachers are expected to strive for fidelity of implementation (i.e., using the program "as intended" by developers). However, this expectation can lead to over-scriptedness, which can limit teachers' professional autonomy and ability to respond to student needs and interests. In reaction, districts relax expectations, inviting teachers to adapt materials as they see fit. But, over time, this leads to the program being phased out, until the district has returned to a state of teachers drawing on different sources to develop their own instructional materials, with little coordination (or vertical alignment) across grades.

Discussion and Conclusion

Our efforts are dual in nature. First, by investing in understanding the problems of practice that district leaders face, including how individuals within the same community might frame those problems differently, we hope to initiate partnerships at the ground level—a co-investigation of problems before anything is "implemented." Second, through such a process, we hope to find inherent tensions on which we can focus sustained attention as a means for inducing innovation. For example, in initial presentations of our findings to potential partnering school districts, we have used a representation of the curriculum cycle to invite participants' reflection on whether a tension exists between teacher autonomy and centralized curricular efforts—which, as we view it, is a potential germ cell that could manifest at multiple levels.

As noted above, these are the very initial stages of what we hope will be prolonged partnerships. By starting a few "steps back" from where work typically has begun, we hope to make progress in confronting the stubborn challenge of changing mathematics teaching.

PSYCHOMETRIC ASSESSMENT OF THE MATH ANXIETY SCALE WITH THE RASCH MEASUREMENT MODEL

İbrahim Burak Ölmez
University of Georgia
i.burakolmez@hotmail.com

Safiye Bahar Ölmez
Augusta University
safiyebaharolmez@gmail.com

The purpose of this study was to investigate the psychometric characteristics of the Math Anxiety Scale (MANX; Erol, 1989) with data collected from 952 middle school students in Turkey. The Rasch Rating Scale model was used to examine the MANX at the item level. The results reveal that although the MANX is sensitive to detect students with moderate levels of math anxiety and it is not targeted to identify those with very high and low math anxiety levels, it has high reliability and validity. Moreover, the majority of the MANX items are of good quality. The results provide strong evidence for the validation of the MANX despite the need for deletion of eight misfit items, and three redundant items.

Keywords: Affect, Emotion, Beliefs, and Attitudes, Middle School Education, Research Methods

Math anxiety can be defined as "feelings of tension and anxiety that interfere with the manipulation of numbers and the solving of mathematical problems in a wide variety of ordinary life and academic situations" (Richardson & Suinn, 1972, p. 551). Math anxiety has been consistently linked to several negative outcomes such as low academic performance (Ashcraft, 2002), and reduced working memory functioning (Young, Wu, & Menon, 2012). This, in turn, can cause many students to pursue career paths that do not involve mathematics.

In response to the need to identify math anxiety levels, researchers have developed self-report scales including the Mathematics Anxiety Rating Scale (MARS) by Richardson and Suinn (1972), and the Mathematics Anxiety Questionnaire (MAQ) by Wigfield and Meece (1988). In addition to these scales' Turkish translations, there also exist a few scales originally developed in Turkish such as the Math Anxiety Scale (MANX; Erol, 1989), which has been used to measure math anxiety levels of middle grades students (e.g., Erden & Akgül, 2010), and of high school students (e.g., Ader & Erktin, 2010). The only study, however, that examined the psychometric characteristics of the MANX was the one conducted by Erktin, Dönmez, and Özel (2006), which used factor analysis to determine the underlying factors of the scale. Erktin et al. identified four factors: (a) *test and evaluation anxiety*, which captures anxiety about exams and evaluation; (b) *apprehension of math lessons*, which captures anxiety related to mathematics lessons; (c) *use of mathematics in daily life*, which captures anxiety in daily situations involving mathematics; and (d) *self-efficacy for mathematics*, which captures self-perceptions on mathematics.

Regarding the negative long-term impacts of math anxiety, it is important to have scales that fully measure math anxiety levels of students for the sake of identifying those students and providing specific interventions based on the needs of each student. To achieve this aim, examination of the psychometric characteristics of the math anxiety scales is critical at the item level. To our knowledge, however, the studies which have examined the math anxiety scales predominantly rely on factor analysis for validation, which is at the total score level (e.g., Baloğlu & Zelhart, 2007; Beasley, Long, & Natali, 2001). Therefore, the purpose of this study was to examine the psychometric characteristics of the MANX for measuring 8th grade students' math anxiety at the item level. The following research questions were addressed:

1. Does the internal structure of the MANX represent gradations of item difficulty?

2. Do the MANX items demonstrate acceptable model-data fit supporting the validity of inferences in terms of students' math anxiety levels?

The present study is one of the few studies (e.g., Prieto & Delgado, 2007) that examine the validation of a math anxiety scale with the Rasch measurement model. Specifically, this study is the first effort to evaluate the item-level quality of the MANX using the Rasch Rating Scale model. Moreover, this study focuses on 8th grade students because this grade is a critical transition period from middle school to high school with potential high math anxiety levels.

Theoretical Framework

The theoretical framework is based on the Rasch Rating Scale model due to its advantages over other approaches such as factor analysis. First, if the data fit the Rasch model well, then person trait and item difficulty estimates can be obtained as independent from the sample (Engelhard, 2013). Second, the Rasch model transforms the ordinal raw data into interval measures as opposed to approaches such as factor analysis relying on correlations of sample dependent ordinal data (Bond & Fox, 2015). Third, the Rasch model provides a variable map that locates persons and items simultaneously on the latent trait.

Methods

The sample consists of 952 Turkish 8th grade students from nine schools located in different regions of Turkey. Students' range of age was between 14 and 16 years.
The *Math Anxiety Scale* (MANX), developed by Erol (1989), with 45 items, has four response categories for each item including "never," "sometimes," "usually" and "always." Coefficient alpha (i.e., α) was .91 in Erol (1989) and .92 in Erktin, Dönmez, and Özel (2006). By following the factors in Erktin et al., coefficient alpha in the present study is .95 for the MANX. Before performing the analyses, the 9 positively worded items of the MANX were reverse-coded so that higher scores demonstrate higher levels of math anxiety, and vice versa. Students completed the MANX during approximately 30 minutes of a class period.

To evaluate the psychometric characteristics of the MANX, we, first, evaluated the unidimensionality of the MANX by exploratory factor analysis as implemented in the SPSS 16.0 software (SPSS Inc., 2007). Second, we obtained reliability of person separation and reliability of item separation values. Third, the variable map was evaluated based on the appropriateness of the sample for the MANX. Fourth, we examined item quality of the MANX based on individual mean square (MS) error statistic. In this study, MS error statistic between 0.60 and 1.40 was considered reasonable fit for the MANX items (Linacre & Wright, 1994). All analyses except the analysis of unidimensionality were performed using the Facets program (Linacre, 20013).

Results

The unidimensionality of the MANX was confirmed with an exploratory factor analysis that reports eigenvalues of the first three factors as 14.3, 2.6, and 1.9. The total variance explained by the first factor was 31.7%, indicating that the MANX is essentially unidimensional (Reckase, 1979). Regarding the reliability values for person and item separation, the MANX has a high reliability of person separation with Rel = .93, χ^2 (951) = 11066.3, and $p < .01$, and of item separation with Rel = .99, χ^2 (44) = 6462.4, $p < .01$. Furthermore, Figure 1 displays a variable map showing item and person locations. In column 3, item locations are displayed with four sub-columns showing the underlying factors ranging from *test and evaluation anxiety* (i.e., sub-column 1) to *self-efficacy for mathematics* (i.e., sub-column 4) as left to right.

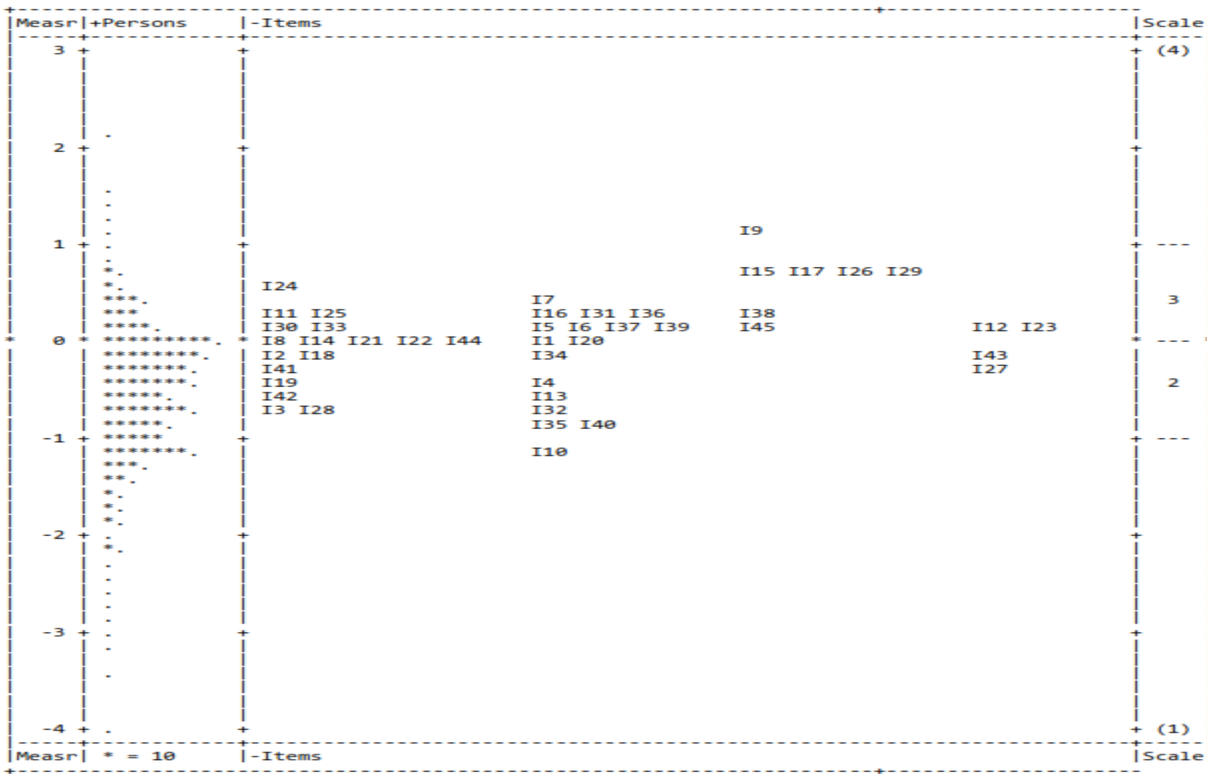

Figure 1. Variable map of students' math anxiety levels and item locations.

According to the variable map, there exists a good overlap between the person trait and item difficulty due to the match between means of the person trait (*M* = -0.58) and item difficulty (M = 0.00). Thus, the majority of the items were appropriate for the sample. While person trait measures range from 2.13 to -5.41 logits, the item difficulties range from 1.14 to -1.08 logits.

Regarding the variable map, the MANX appears to have few limitations. First, the MANX has lack of items that provide information about students who are located at the very high and low ends of the continuum (i.e., above 1.14 logits and below -0.85 logits). Second, regarding distributions of items with respect to their underlying factors (see Figure 1), most of the items are spread enough except those which belong to *use of mathematics in daily life* (i.e., items 9, 15, 17, 26, 29, 38, and 45). Five of these seven items' (i.e., items 9, 15, 17, 26, and 29) being located at the high end of the continuum indicates that these items do not provide adequate information to discriminate between students with very high levels of math anxiety related to the *use of mathematics in daily life*. Third, in terms of redundancy of the items, Item 17 and Item 26, represented by the *use of mathematics in daily life*; Item 6 and Item 37, represented by *apprehension of math lessons*; and Item 21 and Item 44, represented by *test and evaluation anxiety*, have same mean ratings, item difficulties and standard errors as within pairs. Therefore, Item 17, Item 37, and Item 21, which has slightly worse fit statistic (Infit and Outfit), can be eliminated from the scale.

Finally, according to item quality indices for each item, most of the items (i.e., 37 of the 45 items) have a good fit (Linacre & Wright, 1994). Eight of the 45 items, however, demonstrate misfit including items 5, 9, 10, 13, 20, 34, 35, and 43. Item 34 is the only item that exhibits less variation than expected (Infit = 0.59 and Outfit = 0.58). The remaining seven misfit items had more variation than expected due to unpredictability of students' responses in these items. Five of these items (i.e., items 10, 13, 20, 35, and 43) were positively worded (reverse-coded).

Discussion

The purpose of this study was to assess the psychometric characteristics of the MANX at the item level using the Rasch Rating Scale model. The results revealed that the MANX is essentially unidimensional and highly reliable for persons and items. Furthermore, the variable map indicated that the MANX, overall, captures a range of item difficulties reflecting order structure of math anxiety. However, we also found that items related to the *use of mathematics in daily life* are quite difficult to agree with for students, and there is shortage of items at the very high and low ends of the continuum, indicating that the MANX is not sensitive enough to discriminate among students with very high and low levels of math anxiety. Hence, researchers and teachers using the MANX in its current form should be cautious when interpreting their results for students who have very high and low math anxiety levels. Regarding item quality, 37 of the 45 items exhibited good psychometric quality, indicating that the items provide adequate information to measure moderate levels of math anxiety. Among the eight misfit items, five of them were reverse-coded. This might have confused the students and contributed to bias toward response styles. In addition, three redundant items can be removed from the scale to reduce the length of the administration. In conclusion, the results of this study provide strong evidence for the validation of the MANX despite the need for considering deletion of eight items that show misfit and of three items that are redundant. Future studies should consider including only the 34 items that have good item qualities and prioritize using the Rasch model for scale development and validation studies over other approaches.

Keywords: Equity, Policy

In 2017, a National Council of Teachers of Mathematics research committee identified *inequity* as "a long-standing, thoroughly documented, and seemingly intractable problem in mathematics education," and called for more (and more *responsible*) research to help "solve this problem with all its facets" (Aguirre et al., 2017, p. 125). This multi-facetedness likely plays into how equity is defined and pursued. Gutiérrez (2012) defined it as access, achievement, identity, and power, all of which "are necessary if we are to have true equity" (p. 21).

But in practice, as schools and districts take up equity-focused policies and initiatives, to what extent do they attend to all of these dimensions? How are problems of inequity framed—in terms of both their sources ("diagnostic framing") and appropriate responses ("prognostic framing") (Benford & Snow, 2000), and are those framings well aligned? In short, *where* do educational leaders identify inequity and pursue equity?

With this poster, we describe an approach to answering such questions based on our work with one urban district. Our study originated in a multi-year, multi-institution partnership with an urban school district in the northeast U.S. focused on racial equity in secondary (grades 6-12) mathematics. In the course of that project we conducted annual interviews with district leaders as a way to understand the broader district policy context in which the partnership's primary efforts were situated. All interviews were audio-recorded and transcribed. We also collected relevant policy documents. In our analysis of both transcripts and artifacts, we characterized sources of inequity and each policy or initiative aimed at addressing those inequities.

Our analyses revealed that district leaders, at times, framed sources of inequity and corresponding pursuits of equity at different levels (individual, institutional, etc.) and according to different equity dimensions. As a consequence of such misalignments in frames, attempts to address inequities were sometimes misdirected and often undermined by disproportionate focus on achievement. With our poster we will discuss implications for research and policy.

Acknowledgments

This material is based upon work supported by the National Science Foundation under Grant No. 1321216. Thanks to the district leaders who allowed us to collaborate with them.

Keywords: Policy Matters; Teacher Beliefs; Teacher Education-Preservice; Teacher Knowledge

A longstanding challenge in U.S. mathematics education is that, despite research evidence supporting new approaches, conventional teacher-centered forms of instruction still predominate (Hiebert, 2013). Despite this problem's persistence, it has been difficult to achieve consensus education on the role novice teachers should play in effecting cultural change. This poster provides a theory-based distinction between two approaches to teacher preparation and different views on how preparation might carry forward into teachers' early career classrooms.

The *agent-of-change approach* is based on the notion that without a clear vision of a very different kind of mathematics education and the kind of political disposition necessary to pursue it, teachers will not look for or be prepared to act on opportunities for challenging and disrupting the status quo (Gutiérrez, 2013). It supports prospective teachers (PTs) in attempting to dismantle conventional practices by introducing a series of critical lenses—from access and opportunity to status and power, and then learning to enact more equitable and dialogic forms of teaching. The goal is that, upon graduation, PTs will have developed sufficiently robust visions and commitments to recognize and reject unproductive institutional routines and to find and create opportunities for pursuing a better mathematics education.

In contrast, the *incremental approach* starts in close proximity to conventional practices. It involves identifying aspects of conventional teaching that can be positive (e.g., conceptually-rich lectures) while also raising specific, small-scale critiques (e.g., lack of student involvement in particular lessons). In response to the critiques, PTs learn about and practice explicit, tangible recommendations for instruction. These recommendations should be small in number but developed deeply in conjunction with specific mathematical content, which is the type of preparation that has been found to carry forward (Jansen, Burk, & Meikle, 2017). Moreover, because PTs view this incremental preparation as realistic and relevant, they will gain trust in the preparation institutions and thus be amenable to additional incremental changes in the future.

The poster will review further literature and also propose research questions and potential study designs for assessing the effectiveness of the two approaches. This work will inform those who are revising teacher preparation programs and promote collaborations to make evidence-based decisions as our field moves to meet the longstanding challenge of instructional change.

Keywords: Design Experiments, Learning Progression, Geometry, Middle School Education

In the competitive world, America's' future scientists, technologists, engineers, and mathematicians must be prepared to remain effective and efficient through re-energized attention to Science, Technology, Engineering and Mathematics (STEM) education (Wang, Moore, Roehrig, & Park, 2011). A biggest challenge in K-12 STEM education is that few general guidelines or models exist for teachers to follow for how to teach using STEM (Kimmel, Carpnelli, & Rockland, 2007). The purpose of this study is to contribute to the ongoing dialogue regarding the efficacy of genuine STEM integration. Specifically, this study explores the process of design and implementation of a learning trajectory that attempts to integrate mathematics and engineering in an authentic manner to evoke STEM practices more generally. Our goal is to explore the feasibility of using engineering contexts to teach mathematics and develop a conceptual framework for genuine STEM integration.

The rationale behind choosing design based research approach is the ability to contribute to development of theory and means of that are designed to support that learning that is the educational practice (Plomp & Nieveen, 2007). The research aims to capture the emergence of STEM practices, which is the normative way of using STEM practices to interact with others in the classroom. The research was conducted in a 7th grade mathematics classroom of a STEM middle school in a sub-urban school district in the Southeast region of United States. The classroom teacher was part of the design team along with faculty specializing in mathematics education, chemistry, and engineering of a large urban university. The engineering context involved designing blueprints of a new housing development and building 3D houses. The instructional activities were designed to develop students' understanding of parallel lines as the same distance apart and measuring angles as the degree of turn.

From our preliminary analysis, a separate emphasis was intentionally placed on mathematics and engineering instructional sequences because, the goal of mathematician and engineer are different and hence the learning outcomes of mathematics and engineering are going to be different as well. The design constraints of the engineering problem was used to purposefully guide the exploration of mathematics context. For instance, students played the role of architect to design the layout of the phase II of a residential community and a design criteria was to create a new parallel road to an existing road in the phase I of the residential community. In the process, students' understanding of parallel lines moved to more sophisticated notions. The instructional sequences were designed to encourage students to switch back and forth between the engineering context and the mathematics embedded within that context.

Concept and Research Questions

STEM education provides opportunities for mathematics educators to participate in research teams. However, research groups face challenges with communication and methodology (e.g., Lyall & Meagher, 2012). This poster examines the following questions: (a) What is the nature of STEM research collaborations? (b) What challenges exist for mathematics educators in research collaborations? and (c) What strategies enrich interactions in STEM research groups?

Methodology and Findings

Data consisted of research articles that explored STEM research collaborations published in one of the first ten mathematics education journals listed in Williams and Leatham (2017, p. 377). Search terms used to identify articles for the data were (a) interdisciplinary, transdisciplinary, multidisciplinary, monodisciplinary coupled with the term research and (b) STEM education. Based on the search, eight articles were identified as data for this study. A constant comparative analysis (Strauss & Corbin, 1994) was used to classify the articles based on their alignment with categories of integration (monodisciplinary, multidisciplinary, or interdisciplinary) as defined by Williams et al. (2016), articulated frameworks, reported challenges, and strategies for enriching research.

We found that the nature of the research teams described in the articles was multidisciplinary or interdisciplinary. In addition, six of the eight articles described a framework used by the research team. The frameworks in the research articles varied and included cognitive neuroscience, situated learning, and learning as a conceptual network. Challenges for the research groups included: (a) interacting and conducting research in two or more disciplines, (b) translating integrated findings into viable applications, and (c) having institutional/community support for research involving multiple disciplines. Strategies for enriching interdisciplinary research included: (a) focusing on communication and collaboration, (b) developing reconceptualized or more efficient models, (c) identifying shared research questions, and (d) understanding the role mathematics plays with other disciplines. Future studies should explore the role of mathematics education researchers in the context of STEM research collaboration.

ADDRESSING EQUITY AND DIVERSITY ISSUES IN MATHEMATICS EDUCATION: LOOKING BACK AND LOOKING AHEAD

Joel Amidon	Jennifer M. Langer-Osuna	Gregory V. Larnell
University of Mississippi	Stanford University	University of Illinois at Chicago
jcamidon@olemiss.edu	jmlo@stanford.edu	glarnell@uic.edu

Embracing the theme of this year's meeting, we seek as a community to embrace the history of mathematics education, the history of PMENA, and the promise of the future of mathematics education. Following on the topics discussed at the Working Group between 2009-2017, this year the focus is continuing on the reestablished purpose of this group and supporting the development of new directions for equity-oriented research working groups. The sessions will focus on regrouping attendees interested in equity, generating and brainstorming new subtopics and potential projects, and working to establish standalone working groups dedicated to furthering research on equity. The purpose of this resetting is to encourage a move away from "big-tent" equity thinking and toward more productive working collectives.

Keywords: Equity and Diversity

Brief History

This Working Group originates from the Diversity in Mathematics Education (DiME) Group, one of the Centers for Learning and Teaching (CLT) funded by the National Science Foundation (NSF). DiME scholars graduated from one of three major universities (University of Wisconsin-Madison, University of California-Berkeley, and UCLA) that comprised the DiME Center. The Center was dedicated to creating a community of scholars poised to address critical problems facing mathematics education, specifically with respect to issues of equity (or, more accurately, issues of inequity).The DiME Group (as well as subsets of that group) has engaged in important scholarly activities, including the publication of a chapter in the *Handbook of Research on Mathematics Teaching and Learning* which examined issues of culture, race, and power in mathematics education (DiME Group, 2007), a one-day AERA Professional Development session examining equity and diversity issues in mathematics education (2008), a book on research of professional development that attends to both equity and mathematics issues with chapters by many DiME members and other scholars (Foote, 2010), and a book on teaching mathematics for social justice (Wager & Stinson, 2012) that also included contributions from several DiME members. In addition, several DiME members have published manuscripts in a myriad of leading mathematics education journals on equity in mathematics education. This working group provides a space for continued collaboration among DiME members and other colleagues interested in addressing the critical problems facing mathematics education.

It is important to acknowledge some of the people whose work in the field of diversity and equity in mathematics education has been important to our work. Over time, the Working Group has encouraged building on and featuring senior scholars' work, including Marta Civil (Civil, 2007; Civil & Bernier, 2006; González, Andrade, Civil, & Moll, 2001), Eric Gutstein (Gutstein, 2003, 2006; Gutstein & Peterson, 2013), Jacqueline Leonard (Leonard, 2007; Leonard & Martin, 2013), Danny Martin (Martin, 2000, 2009, 2013), Judit Moschkovitch (Moschkovich, 2002), Rochelle Gutiérrez (2002, 2003, 2008, 2012, 2013) and Na'ilah Nasir (Nasir, 2002, 2011, 2013; Nasir, Hand & Taylor, 2008; Nasir & Shah, 2011). We have as well been building on the work of our advisors, Tom Carpenter (Carpenter, Fennema, & Franke, 1996), Geoff Saxe (Saxe, 2002), Alan Schoenfeld (Schoenfeld, 2002), and Megan Franke (Kazemi & Franke, 2004), as well as many others outside of the field of mathematics education.

Previous iterations of this Working Group at PMENA 2009 – 2013, and 2015-2016 have provided opportunities for participants to continue working together as well as to expand the group to include other interested scholars with similar research interests. Experience has shown that collaboration is a critical component to this work. These efforts to expand participation and collaboration were well received; more than 40 scholars from a wide variety of universities and other educational organizations took part in the Working Group each of the past five years. Starting in 2017, an effort was made to "reset" the group toward providing opportunities for a new generation of scholars whose work intersects with issues of equity/inequity, diversity/inclusion, privilege/oppression, and justice in mathematics education research, practice, and development.

Focal Issues

Under the umbrella of attending to equity and diversity issues in mathematics education, researchers are currently focusing on such issues as teaching and classroom interactions, professional development, prospective teacher education (primarily in mathematics methods classes), factors impacting student learning (including the learning of particular sub-groups of students such as African American students or English learners), and parent perspectives. Much of the work attempts to contextualize the teaching and learning of mathematics within the local contexts in which it happens, as well as to examine the structures within which this teaching and learning occurs (e.g. large urban, suburban, or rural districts; under-resourced or well-resourced schools; and high-stakes testing environments). How the greater contexts and policies at the national, state, and district level impact the teaching and learning of mathematics at specific local sites is an important issue, as is how issues of culture, race, and power intersect with issues of student achievement and learning in mathematics. There continues to be too great a divide between research on mathematics teaching and learning and concerns for equity.

The Working Group has begun and will continue to focus on analyzing what counts as mathematics learning, in whose eyes (and for whose benefit), and how these culturally bound distinctions afford and constrain opportunities for traditionally marginalized students to have access to mathematical trajectories in school and beyond. Further, asking questions about systematic inequities leads to methodologies that allow the researcher to look at multiple levels simultaneously. This research begins to take a multifaceted approach, aimed at multiple levels from the classroom to broader social structures, within a variety of contexts both in and out of school, and at a broad span of relationships including researcher to study participants, teachers to schools, schools to districts, and districts to national policy.

Some of the research questions the Working Group will continue to consider are:

- What are the characteristics, dispositions, etc. of successful mathematics teachers for *all* students across a variety of local contexts and schools? How do they convey a sense of purpose for learning mathematical content through their instruction?
- How do beginning mathematics teachers perceive and negotiate the multiple challenges of the school context? How do they talk about the challenges and supports for their work in achieving equitable mathematics pedagogy?
- What impediments do teachers face in teaching mathematics for understanding?
- How can mathematics teachers learn to teach mathematics with a culturally relevant approach?

- What does teaching mathematics for social justice look like in a variety of local contexts?
- What are the complexities inherent in teacher learning about equity pedagogy when students come from a variety of cultural and/or linguistic backgrounds all of which may differ from the teacher's background?
- What are dominant discourses of mathematics teachers?
- What ways do we have (or can we develop) of measuring equitable mathematics instruction?
- How do students' out-of-school experiences influence their learning of school mathematics?
- What is the role of perceived/historical opportunity on student participation in mathematics?

Specific to the intent of this year's Working Group, we will organize around questions like the ones above in order to create specific, targeted working groups that are charged to address and act around such questions.

Plan for Working Group

Based on feedback from the previous year and the emergence of new working groups related broadly to "equity," this working group has shifted toward a renewed focus on facilitating "collaboration within the growing community of scholars and practitioners concerned with understanding and addressing the challenges of attending to issues of equity and diversity in mathematics education." We have reconfigured the working group toward being a catalyst for new spaces instead of a "destination" for the inclusion of equity discourse within the PME-NA organization. To put it differently, our vision for the working group is to bring together attendees toward developing their own agendas and specific working groups related to equity-oriented themes--or toward themes that push the field beyond traditional equity discourses yet adhere to the needs and challenges of inequity within mathematics education.

Our plans for PMENA 2018 will proceed as follows. Each session will build on previous sessions, beginning with a facilitated conversation around the previously stated purpose of the working group. The format for the sessions will include:

- DAY 1: Presenting the Vision, Norm-setting, and Brainstorming: On the first day, we will lead attendees through introductory activities, collective norm-setting, and a series of small- and whole-group brainstorming activities that will generate new ideas and directions for the working group more broadly.
- DAY 2: Agenda-setting: On the second day, the major focus will be the development and support of new smaller sub-specializing groups based on the reported interests of attendees. We will work with and encourage these subgroups to establish possible common topics of interests, potential products, and planning for the next year to support the growth of their group and topic.
- DAY 3: Working groups: On the third day, the newly established subgroups will "take flight" and initiate their yearly plan to support their chosen topics.

Previous Work of the Group

The Working Group met for productive sections since 2009. In 2009, participants identified areas of interest within the broad area of equity and diversity issues in mathematics education. Much fruitful discussion was had as areas were identified and examined. Over the past five years subgroups met to consider potential collaborative efforts and provide support. Within these subgroups, rich conversations ensued regarding theoretical and practical considerations of the topics. In addition, graduate students had the opportunity to share research plans and get feedback. The following were topics covered in the subgroups:

- Teacher Education that Frames Mathematics Education as a Social and Political Activity
- Culturally Relevant and Responsive Mathematics Education
- Creating Observation Protocols around Instructional Practices
- Language and Discourse Group: Issues around Supporting Mathematical Discourse in Linguistically Diverse Classrooms
- A Critical Examination of Student Experiences

As part of the work of these subgroups, scholars have been able to develop networks of colleagues with whom they have been able to collaborate on research, manuscripts and conference presentations.

As a result of the growing understanding of the interests of participants (with regard both to the time spent in the working group and to intersections with their research), we began to include focus topics for whole group discussion and consideration and continued to provide space for people to share their own questions, concerns, and struggles. With respect to the latter, participants have continually expressed their need for a space to talk about these issues with others facing similar dilemmas, often because they do not have colleagues at their institutions doing such work or, worse yet, because they are oppressed or marginalized for the work they are doing. These concerns, in part, informed the focus topics for whole group discussion and consideration. For example, in 2009 research protocols (e.g., protocols for classroom observation, video analysis and interviewing) were shared to foster discussions of possible cross-site collaboration. In 2012, the Working Group explicitly took up marginalization in the field of mathematics education with a discussion about the negotiation of equity language often necessary for getting published; this was done in the context of the 'Where's the mathematics in mathematics education' debate (see Heid, 2010; Martin, Gholson, & Leonard, 2010). Dr. Amy Parks was invited to join Working Group organizers to share reflections on their experiences. In 2013 the Working Group hosted its first panel in which scholars (Dr. Beatriz D'Ambrosio, Dr. Corey Drake, Dr. Danny Martin) shared their perspectives on the state of and new directions for mathematics education research with an equity focus. In 2017, we had collections around topics that have resulted in several proposals for sessions and working groups for this years convening of PMENA.

Pre-Conference and Follow-up Activities

In order to best plan for working group facilitation and prepare attendees for working group participation, we plan to send out pre-conference communication, including a survey, to former and potential participants in order to gauge the topics and kinds of work being done or sought, as well as the resources and forms of support desired by participants.

The Models and Modeling Working Group at PME-NA has provided a forum for discussing and collaborating on research projects fundamental to this area since the first PME-NA conference in 1978. We propose to convene this Working Group at PME-NA 40 with a dual purpose: (1) to build on discussions at PME-NA 37-39, extending collaborative research directions formulated at the Indianapolis meeting, and (2) to continue to invite newcomers to the Models and Modeling Perspective (MMP), giving them an introduction to this design research tradition.

Keywords: Modeling, Problem Solving, Design-Based Research, Design Experiments

The Models and Modeling Working Group has been a significant presence in the PME-NA community since the inaugural year of the conference in 1978. Over the 40 years of its existence, working-group format has supported substantial research efforts, and also has helped to foster collaboration and mentoring relationships between researchers interested in what has come to be known as the "Models and Modeling Perspective" (MMP). Since its inception, the MMP has pursued fundamental pragmatic questions of effective knowledge, such as "What ... beyond having a mathematical idea ... enables students to use it in everyday problem-solving situations?" (Lesh, Landau, & Hamilton, 1983, qtd. in Lesh & Doerr, 2003, p. i.). An important historical purpose of the Working Group has been to pursue innovations in design-based research (cf, Kelly, Lesh, & Baek, 2008) – to discuss and extend the ways in which a focus on models and modeling can be used both to support learning in STEM, and to study such learning processes in action. Indeed, calls for STEM integration (English, 2016; English & King, 2015) and for attending to Engineering perspectives (Diefes-Dux, Moore, Zawojewski, Imbrie, & Follman, 2008; Roehrig, Moore, Wang, & Park, 2014) have only increased the potential of this long-standing tradition to contribute to efforts to innovate in teaching and research.

Early in its history, the Group focused heavily on the design and analysis of particular activities that enabled groups of learners to engage in a deep form of modeling and that produced an auditable trail of thinking, exposing their thought processes to teacher and researcher observers. In this phase of the field's development, a primary effort involved elaborating design principles for these activities as learning environments and documenting the idea development they promoted. Gradually over time, however, researchers associated with the Group have expanded their perspective to consider implementations and curricular sequences that have longer time-duration, and that integrate models and modeling into the experience of learning mathematics in more extensive ways. Several broad patterns in this more extensive and disseminated approach to modeling in the curriculum have emerged, and there is no sense that we have yet exhausted the space of possibilities. These broader perspectives open both exciting opportunities and significant challenges. On the one hand, new questions can be researched, opening the way for new forms of contact and interaction with classroom practice; on the other, the approach raises new challenges at the level of methodology, data analysis, and forms of evidence that are convincing backings for claims about learner activity.

We propose convening the Group at PME-NA 40 to continue a style of work that has characterized the Group's collaborations over the past several years. In particular, based on our experiences in 2015-2017, we propose a work-session structure that can serve two dual purposes: (a) making substantive progress in concrete projects of collaborative research – planning and framing shared implementation, analysis, and writing work; while also (b) integrating newcomers to Models and Modeling as a research area.

For this Working Group, these two goals are ***both*** essential: we do not propose to gather as a closed expert group. (Broadening exposure to this kind of learning design is important to the individuals of the Group as well as to the group as a collective whole.) And we also do not aim only at providing an initial introduction to the approaches characteristic of the MMP and the activity designs the tradition has developed. (There are urgent opportunities and problems of research and practice that the Working Group aims to address.)

In the following sections, we provide a very brief overview of the field of research represented by the Models and Modeling Perspective; we outline patterns in research efforts that have extended modeling activities over longer timescales; and we describe our plan of work in detail, illustrating how these goals are addressed as well as how we plan to productively integrate newcomers to the Group over the three working sessions offered in the Conference.

The Models and Modeling Perspective (MMP)

Since the 1970s, MMP researchers and educators have engaged in design research directed at understanding the development of mathematical ideas among groups of learners. A key principle behind this work has been that learners' ideas develop through, and in relation to conceptual entities called *models*. The core construct of a "model" and the activity of "modeling" are both central to the MMP; and they are also multidimensional, playing multiple roles in the MMP theory.

Models & Modeling Working Group founder Dick Lesh and Helen Doerr provide the following working definition of *models*:

> conceptual systems (consisting of elements, relations, operations, and rules governing interactions) that are expressed using external notation systems, and that are used to construct, describe, or explain the behaviors of other system(s)—perhaps so that the other system can be manipulated or predicted intelligently (Lesh & Doerr, 2003, p. 10)

In this spirit, "being a good modeler is in large part a matter of having a number of fruitful models in one's 'hip pocket.'" (Lesh, 1995, personal communication, qtd in Lehrer & Schauble, 2000).

But the term "model" not only applies to features of "target knowledge" that are built through learning: the interpretive systems that people *bring* to problems are also "models." When explicitly expressed through representational media, such models—personal interpretive systems—can provide illumination into how students, teachers, and researchers adapt, formulate, and apply relevant mathematical concepts in particular situations or contexts (Lesh, Doerr, Carmona, & Hjalmarson, 2003). In fact, "models" are the shape and vestment of most all knowledge--whether this knowledge appears as the patterns of perspectives and pre-conceptions that learners bring with them "in the door"; the shared ways of thinking that a group of learners build in solving a problem; or the systematic accounts of phenomena that represent the normative views of a scientific discipline at a given moment in its history.

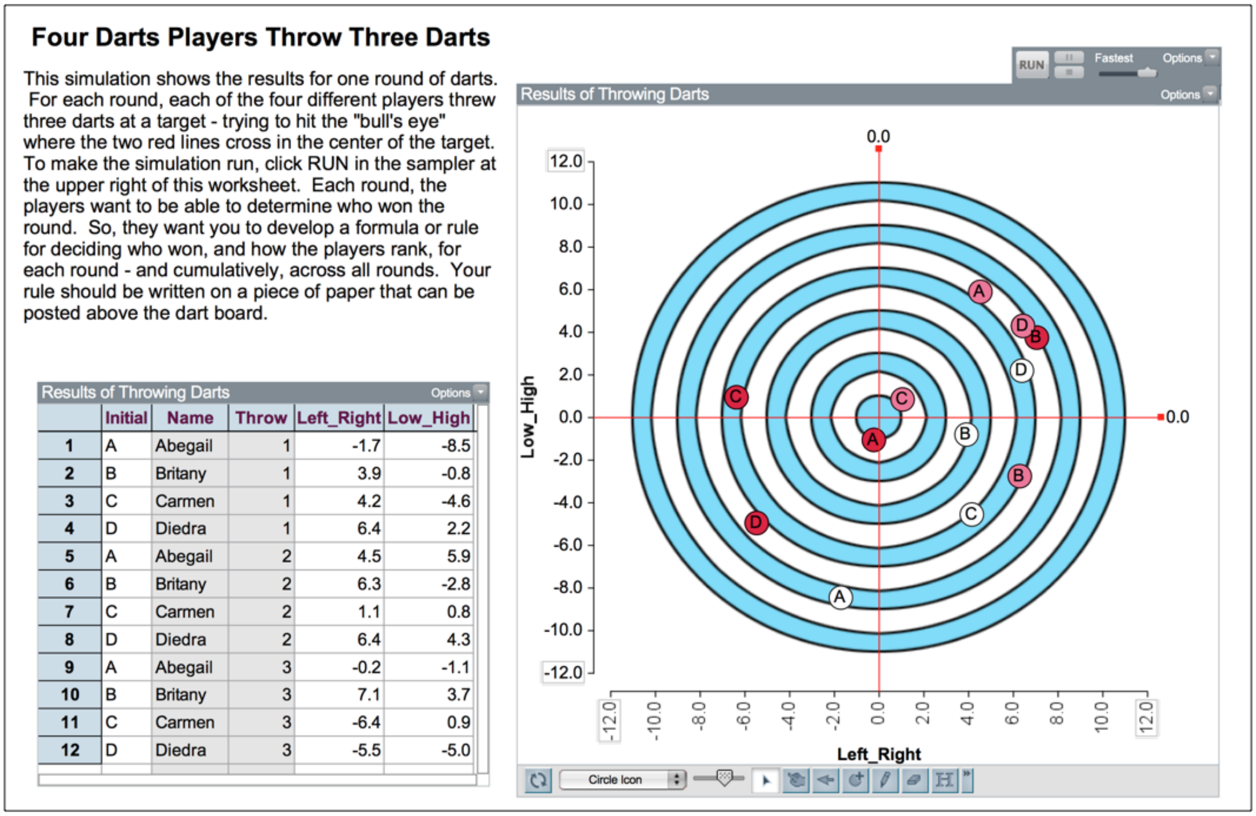
An early finding of research in the Models and Modeling Perspective (MMP) was that, under appropriate conditions, groups of learners can be supported in producing external representations of the models they bring to a situation, and that when these groups put their initial models into conversation with one another, they can be supported to revise, and refine them in rapid and iterative cycles, building toward a more robust model that reflects their achievement of a shared way of thinking. In particular, when individuals and groups encounter problem situations with specifications that demand a model-rich response, their models can be observed to grow through such relatively rapid cycles of development toward solutions that satisfy these specifications.

While the elicitation of initial ways of thinking is valuable, MMP researchers' interest quickly turned to this process of model refinement—that is, to the dynamics of model***ing*** (as opposed to the statics of mod***els***), and to the features of activity environments that foster modeling and make it visible for teachers and researchers. The dynamics of modeling represent, for the MMP, an account of *idea development*, as observed in the discourse and other representations produced by groups of learners as they iteratively work to mathematize and formulate a solution that meets the needs of a concrete *client* in a realistic setting.

Thus, the MMP tradition became focused squarely on local conceptual development (Lesh & Harel, 2003): that is, on investigating the micro-evolution of ideas in groups of students (and teachers). The resources and tools its researchers produced were first and foremost designed to study idea development and the range of possibility for this mode of learning activity. The results of this work include a body of *Model-Eliciting Activities* (MEAs), in which students are presented with authentic, real-world situations where they repeatedly express, test, and refine or revise their current ways of thinking as they endeavor to generate a structurally significant product—that is, again, a *model*, comprising conceptual structures for solving the given problem. These activities differ markedly from some other environments dedicated to applications of specific mathematical concepts and procedures. In contrast, MEAs give students the opportunity to create and adapt mathematical models in order to interpret, explain, and/or predict the behavior of real-world systems (Zawojewski, 2013). An extensive body of MMP research has produced accounts of learning in these MEA environments (Lesh, Hoover, Hole, Kelly, & Post 2000; Lesh & Doerr, 2003), design principles to guide MEA development (Hjalmarson & Lesh, 2007; Doerr & English, 2006; Lesh, et. al., 2000; Lesh, Hoover, & Kelly, 1992) and accounts and reflections on the design process of MEAs (Zawojewski, Hjalmarson, Bowman, & Lesh, 2008).

As an example of the activity-type of Model-Eliciting Activities (MEAs), consider the Darts problem (**Figure 1**). This problem provokes students to grapple with notions of centrality, spread, and distance. Students are often introduced to Darts problem after having engaged with several other MEAs that challenge them to develop operational definitions for intuitive but difficult-to-quantify constructs such as "worker productivity" or "volleyball-playing ability," and to use data to produce measures of such constructs. The Darts problem pushes them to extend this line of thinking, creating operational definitions both to evaluate *performances* (the darts games) and assess *performers* (the darts players).

Above is the statement of the Darts problem as presented to students. In this realization of the Darts problem, the printed sheet is accompanied by a TinkerPlots document, which allows learners to create simulated rounds of darts games by pressing the **Run** button shown in the diagram.



Results of Throwing Darts

	Initial	Name	Throw	Left_Right	Low_High
1	A	Abegail	1	-1.7	-8.5
2	B	Britany	1	3.9	-0.8
3	C	Carmen	1	4.2	-4.6
4	D	Diedra	1	6.4	2.2
5	A	Abegail	2	4.5	5.9
6	B	Britany	2	6.3	-2.8
7	C	Carmen	2	1.1	0.8
8	D	Diedra	2	6.4	4.3
9	A	Abegail	3	-0.2	-1.1
10	B	Britany	3	7.1	3.7
11	C	Carmen	3	-6.4	0.9
12	D	Diedra	3	-5.5	-5.0

Figure 1. Example MEA: The Darts problem

The second "phase" of the Darts problem asks students to evaluate *players* (**Figure 2**):

Darts, Part Two: *Going for the Championship*
The local pub is now preparing for a season of competitive darts, and you need to provide useful information to the captain, Laura, to help her field a team. Beyond the four players from Part One, a group of "regulars" at the pub will be trying out. Describe how results from several rounds of darts can be used to create a rating or description of players' darts throwing skills. Your procedure should help Laura to choose a team based on the tryouts.

Figure 2. The second phase of the Darts problem

Student groups iteratively develop solutions to this problem in the time allotted—usually 50-60 minutes for this MEA. Afterwards, the teacher may organize a "poster session" for the groups to share and learn from each others' solutions. In one version of this activity structure, one member of each group hosts a presentation of the poster showing their results. The other students circulate to learn about other groups' solutions, using a Quality Assurance Guide to assess the results produced by others in the class. These instruments are submitted to the teacher and contribute to assessment in various ways, providing evidence for the achievements of both individuals and groups.

MEAs like the Darts problem present learners with situations where familiar procedures, ways-of-operating, and constructs may be *applicable,* but where they are also *insufficient*. In this sense, they support a learning environment that has a "low threshold" but a "high ceiling" (cf

Papert, 1980). That is, on the one hand they are accessible to learners from a wide range of levels of ability, experiences, or knowledge (from upper elementary school through graduate school). On the other hand, learners encountering these problems find that they have no ready-made solution they can apply to address the client's needs. As a result, groups learners must engage in sense-making and solution-construction processes that position them as mathematical creators and also put them off balance in comparison to typical school-mathematics tasks. Indeed, this uncertainty is part of the design of MEAs, illuminating fundamental conceptual issues associated with the core mathematical structures involved.

MEA Design Principles

As individual MEAs emerged, an intense period of design research ensued to understand them as a genre of learning tasks that could (a) stimulate mathematical thinking representative of that which occurs in contexts outside of artificial school settings (Lesh, Caylor, & Gupta, 2007; Lesh & Caylor, 2007); (b) enable the growth of productive solutions through rapid modeling cycles; and (c) leave behind "auditable trails" - researchable traces of learners' ways of thinking during the process (Kelly & Lesh, 2000; English et al., 2008; Kelly, Lesh & Baek, 2008). The success of MEAs as an activity genre and as research tools was both enabled by and illustrated by the MMP's articulation of a set of six design principles (Lesh & Harel, 2003; Lesh et al., 2000; Hjalmarson & Lesh, 2007). These principles indicate essential elements of MEAs and their classroom implementations, enabling them to serve as rich contexts for student problem solving. Table 1, below, also indicates "touchstone" tests for whether each of these six principles has been realized in a given implementation setting.

Table 1: Six Design Principles for MEAs and Touchstones (see also Brady et al, 2017)

Principle	Touchstone Test for its Presence
Reality Principle	Students are able to make sense of the task and perceive it as meaningful, based on their own real-life experiences.
Model Construction Principle	To solve the problem, students must articulate an explicit and definite conceptual system (model).
Self-Evaluation Principle	Students are able to judge the adequacy of their in-process solution on their own, without recourse to the teacher or other "authority figure".
Model Generalizability Principle	Students' solutions are applicable to a whole range of problems, similar to the particular situation faced by the "client" in the MEA.
Model-Documentation Principle	Students generate external representations of their thinking during the problem-solving process.
Simplest Prototype Principle	The problem serves as a memorable representative of a kind of mathematical structure, which can be invoked by groups and by individuals in future problem solving.

Nested Levels of Modeling: Multi-Tiered Design Research

In parallel with learner-focused research using MEAs, researchers also have observed that *teachers'* efforts to understand their students' thinking involve yet another process of modeling: In this case, teachers engage in building models of student understanding. Although these teacher-level models are of a different category from student-level models, students' work while engaged in MEAs does provide a particularly rich context for teachers' modeling processes. Following this line of inquiry, the MMP community has also produced tools and frameworks that can be useful to teachers in making full use of MEAs in classroom settings, while also providing *researchers* with insights into *teachers'* thinking.

Finally, at a third level of inquiry, researchers' own understandings of the actions and interactions in *curricular activity systems* (Roschelle, Knudsen, & Hegedus, 2010) involving students, teachers, and other participants in the educational process can also be studied through the lens of model development. Multi-tier design experiments in the MMP tradition have done precisely this, involving researcher teams in self-reflection and iterative development as well (Lesh, 2002). Therefore, the MMP version of multi-tier design research can involve at least three levels of investigators— students, teachers, and researchers—all of whom are engaged in developing models that can be used to describe, explain, and evaluate their own situations, including real-life contexts, students' modeling activities, and teachers' and students' modeling behaviors, respectively. The situation can be further enriched by considering other educational stakeholders and learning settings, such as interactions between academic coaches and teachers (Baker & Galanti, 2017), and between schools and community organizations, and between students and parents.

Constructing Curricular Materials to Support Modeling at Larger Timescales

Over the past 15 years, MMP researchers have continued this direction of work in their own teaching and in partnerships with K-12 classroom teachers. Within the domain of statistical thinking in particular, this effort has produced resources and tools sufficient to support *entire courses* in several versions and including accompanying materials related to learning and assessment aimed at both student and teacher levels.

In their work on MEAs, students have rich but idiosyncratic mathematical experiences that need to be *unpacked* and placed into relationship with each other and with more canonical concepts, practices, and procedures from the discipline. To investigate such matters, MMP researchers attend to learner activity beyond the scope of single MEAs, formulating tools and designs for Model Development Sequences, or MDSs (Arleback, Doerr, and O'Neil, 2013; Doerr and English, 2003; Hjalmarson, Diefes-Dux, and Moore 2008; Lesh, Cramer, Doerr, Post, & Zawojewski, 2003). Work here includes approaches for extending the modeling dynamics that MEAs foster and for unpacking and making explicit learners' ways of thinking, so that they are available to be reflected upon by the classroom group as a whole and systematized in relation to big ideas in the discipline (see also Brady, Eames, & Lesh, 2015 for tentative MDS design principles).

Because the courses supported by these materials were designed explicitly to be used as research settings, for investigating the interacting development of students' and teachers' ways of thinking, the materials were modularized so that important components could be easily modified or rearranged for a variety of purposes in different implementations. In particular, by selecting from and adapting *the same core collection of MEAs*, and surrounding them with MDS activities tailored to the learning goals and emergent ideas of different classrooms, parallel versions of the course have been developed for: (a) middle- or high-school students, (b) college-level elementary or secondary education students, and (c) workshops for in-service teachers. Existence-proof versions of these courses have produced impressive gains (see, e.g., Lesh, Carmona, & Moore, 2009).

As a result of the breadth of the MMP, other models for engaging with MEA-style modeling at larger timescales have also emerged. These larger structures reflect other professional and theoretical interests and concerns, such as a commitment to iterative design-based inquiry (Eames, et al, in press); a focus on socio-mathematical norms (Yackel & Cobb, 1996), or the dynamics of coaching (Baker & Galanti, 2017).

Research and Discussion Themes to Guide the Working Group

In all, our previous PME-NA working group meetings in East Lansing, Tucson, and Indianapolis have brought together over 30 participants from the US, Canada, and Mexico. Participants have described ongoing implementation and research across a wide range of grade levels and educational settings. In their work, attendees reported that they apply a variety of interpretive lenses and frameworks to modeling, and they situate their work in a variety of ways with respect to other current trends in mathematics education research. Moreover, in pursuing their practice, they developed definitions of core MMP constructs that were both broadly compatible (enabling productive discussion) and differently specialized and exemplified (enabling illuminating debate).

We have thus found Working Group meetings to offer unique opportunities to connect research voices and viewpoints, spurring conversations between research groups that have common inspiration and compatible interests, but very diverse local experiences and perspectives. The Working Group meetings have also consistently been a vehicle for connecting "old timers" with "newcomers." Some of the giants in the PME-NA community (e.g., Dick Lesh, Lyn English, Helen Doerr, Margret Hjalmarson, Jim Middleton, Tamara Moore, Eric Hamilton, and others) have also been leaders in the MMP, and in each of our sessions, we have invited participation from one or more of these leaders to offer perspectives on our thinking and on the field as a whole. We see these interactions as an important aspect of newcomers' (and old-timers') experience of the conference as a site for the exchange of wisdom, perspective, and enthusiasm among participants.

As one artifact of the meeting in Indianapolis, we identified several areas of prospective collaborative work. While we have pursued some of these ideas in the intervening five months, several of these remain to be done and can serve as indicators of the work that we will strategize and pursue in Greenville:

- Categorizing and classifying MEAs and other activities that make up MDS sequences. Providing a taxonomy and rationale. (This was a request by Lyn English, who described this as a gap in the literature and current discussion of modeling).
- Pursuing an idea of studying a particular MMP analytical perspective across multiple implementations of multiple MEAs (orchestrating multiple implementations of different MEAs in different settings, where a shared analytical frame was foregrounded and exercised).
- An article digging into the researcher level of the multi-tiered modeling research process, and investigating (as one does at teacher and student levels) what conceptual strategies and observation tools are needed to make these processes visible for reflection and analysis.
- An exercise in developing new MEA activities that are specifically designed to highlight themes in research on *learning dynamics* (as well as, or as opposed to only themes and big ideas in the discipline).
- A discussion and investigation of technology supports for MEAs and activities in Model Development Sequences.
- A concerted effort to bring the MMP to Latin America, with a focus on one or more Spanish-language journal articles that present the theory, differentiate it from other forms of activity, and present empirical results from implementations.
- A series of translations of canonical works in the MMP tradition into Spanish, with a space for commentary and relation to current work by researchers in Latin America.

(That is, moving far beyond "translation" to support a renaissance of inquiry into foundational MMP issues in the Latin American context.)

Session Outline: Advancing the Research Agenda while Building Community and Capacity

The working group will meet in three sessions over the course of the conference. As the organizers and facilitators do the preparatory work for the conference, these plans will be refined, but the broad outlines here reflect our current thinking.

As mentioned above, our experience of the working group over the past three PME-NA conferences has highlighted the value of these meetings for both (a) establishing and "hashing out" plans for innovative new research collaborations, and (b) inviting interested newcomers to the MMP and providing them opportunities to engage with its principles and practices, and interact with some of its founding members. Although it imposes an intense challenge for organizing and facilitating the working group, we aim to continue to support these two strands of activity. In part, we are committed to both because we recognize the importance to the MMP both to advance its agenda and rejuvenate its participant group. But in addition, we recognize that these two threads are in fact inseparable. Some of our most interesting theoretical discussions have come out of the friendly challenges from newcomers/outsiders, and we aim to cultivate and integrate rather than cordon off these voices and perspectives.

Session One. Accordingly, there are two tracks for the first day of the conference (one for newcomers, one for relatively experienced researchers who know the MMP). The rationale for initial separation is based on the need to produce sharable artifacts representing each group's interests and perspectives, so that we can integrate the participant group productively in Sessions Two and Three. We have tested and refined this broad structure in recent years, where it has enabled all attendees to participate meaningfully without producing a permanent separation between the Newcomer and Experienced groups.

The initial day's activity for the MMP Newcomer research group is oriented to introducing the MMP by directly experiencing the kinds of learning environment that it is committed to designing and studying. Participants will start by engaging with an MEA as though they were learners. We find that this "learning by doing" approach is as important for researchers as it is for teachers and students, and it creates a shared experience that can ground theoretical discussions that follow. Although Newcomer participants engage as learners, they also are encouraged to reflect on how they would want to study the kind of learning and group dynamics that they see and feel themselves enacting. This group ends the first day with a facilitated discussion of their "student" experience, reflecting on teacher and researcher perspectives of this kind of learning, and framing how they might formulate a research study around this kind of classroom activity. The group also prepares questions that they might want to ask the Experienced group participants in the General discussion that will start Session Two.

The Experienced MMP research group's initial activity will be oriented to tackling challenges for cross-institutional research in the MMP. This opening session is structured as a "research design charrette" in which we will identify, structure, and sketch a plan to tackle a shared problem of design research that the group could address after the conference. Participants will start by breaking into smaller groups to tackle one of the study topics generated in the Indianapolis meeting (see listing above). The small groups' goal for Session 1 is to frame an "elevator pitch" for a study or article, framing their pitch as a provocation for others in the group to identify relevant resources (data, un-identified connections in the literature, analytical frames, etc) as well as to critique and refine the pitch into a proposal. At the end of Session 1, one or two projects (depending on the participant group size) will be chosen as the focus of work for

Sessions 2 and 3. The particular shape of work for Sessions 2 and 3 will thus be somewhat dependent on the nature of the projects that emerge.

Sessions Two and Three. The collective goal of these sessions is to unify the group toward collective research action, identifying connection points between the Newcomer and Experienced groups and finding opportunities for all participants to contribute during the Conference and afterwards, as they wish. At the beginning of Session 2, Newcomer groups will present their solutions to the MEA to the larger group, and they will raise the questions they have generated in Session One. They will also have some opportunity to share their perspectives and impressions with the larger group, though moving to focused projects by the mid-point of Session 2 is critical for success of these projects.

The Experienced track will then present their "elevator pitches" for study projects, and the large group will have a brief discussion of the intrinsic interest of these projects and their significance for the MMP agenda.

Session Two will continue with options for members in the Newcomer track to join a project team based on the 'elevator pitches' of the Experienced track. The facilitator group is also considering an alternative option, in which newcomers engage in MDS activities with an eye to implementation at this scale. (If pursued, this activity would involve both engaging with and adapting/extending MDS activities.) Because a substantial number of PME-NA attendees depart before the final working group session, the end of Session Two must reach a clear “waypoint” in inquiry, and logistical issues must be addressed, such as establishing a group email list and collaboration tools.

Session Three takes the project (and possible MDS) tracks forward toward collaboration after the conference. The facilitator group typically also meets after the last session, to debrief and establish plans and to-do lists for follow up with the broader participant group.

As mathematics education researchers and practitioners, we are poised to look ahead and to forge new narratives by challenging work traditionally relegated to special education. Our working group, which formed in 2016, is composed of researchers and educators who draw upon critical theories such as Disability Studies in Education, Critical Race Theory, and DisCrit, in order to offer an alternative vision of mathematics education based around a different conceptualization of disability and learning differences. Research on mathematics and disabilities traditionally has been conducted within a special education paradigm, which often implicitly or explicitly adopts a deficit model of the learner. The deficit model locates the "problem" within the individual student rather than in the social, discursive, political, or structural context. Instruction for these students tend to focus primarily on rote algorithms and calculation skills rather than the solving of rigorous, high cognitive demand problems. We consider both the framing of these students as well as how to reframe classroom practice utilizing models like Multiple Mathematics Knowledge Bases and Culturally Responsive and Sustaining Practices to create classrooms in which all students are able to access curriculum and have it represented in meaningful and rigorous ways.

Keywords: Equity and Diversity, Instructional activities and practices, Classroom Discourse, Learning Theories

Overview of the Working Group

As we think through how mathematics education has evolved over the last 40 years, this working group brings to light a challenge that has persisted with relation to issues of mathematics education and disability: How do we support the learning of all students, particularly those students with disabilities? The purpose of this working group is to create a community of scholars and educators who have share a critical lens to issues of mathematics education and disability. Historically, the consideration of disability in mathematics education has been examined from a special education lens, which focuses on identifying student deficits with the goal of "fixing" or remediation of these perceived deficits. While well-known epistemological differences exist between special education and mathematics education, we seek to explore new scholarly paths. As mathematics educators we believe a critical perspective on disability, drawing upon Disability Studies, Critical Race Theory, and DisCrit, can address these differences and offer an alternative vision of mathematics education and disability. Our working group is designed to create sustainable opportunities for researchers, teacher educators, and practitioners interested in bringing a critical lens to understanding disability, differences, and how we respond to differences in mathematics education and how these lenses can address persistent challenges in the education of each and every student. In this proposal we briefly present the history of this working group, the theoretical perspectives that this group draws upon, and our plans for collaboration.

History of the Working Group

Our PME-NA working group met for the first time in 2016. Fifteen researchers (faculty and graduate students) and two classroom teachers met during PME-NA 2016 in Tucson, Arizona. In our initial set of working group meetings, participating group members shared theoretical perspectives of disability they employed within their work in mathematics education, current projects they were engaged in related to disability and mathematics education, and critical issues members often found themselves confronting in taking up this complex work. Conversations that took place during this time were exciting. Many common interests were uncovered and shared among group members. At the conclusion of our time together at the conference, many of the group members were hopeful that the working group in subsequent years could serve as a foundation for continued work and conversation. The impact and work of this group continued through the year. We established an email list-serv which members have used regularly to share and solicit feedback on work and to organize our collective efforts. From this 2016 meeting we were able to garner a special issue in the journal Investigations in Mathematical Learning called Critical Approaches for Mathematics Learning of Students with Disabilities.

The second time the working group met was at PME-NA 2017 in Indianapolis, Indiana. During this time, we continued conversations of our identity as a working group, the goals we wanted to accomplish for the upcoming year, potential future collaborative work, and the extent to which we ought to seek partnership with a similar working group meeting at PME-NA that year. The group was made up of several returning members as well as new scholars interested in our work. One major goal we discussed for the upcoming year was a book project on critical mathematics education for practitioners. We identified NCTM as a potential venue to put forth our proposal and were thrilled to learn during the spring of 2018 that NCTM accepted our book proposal. In turn, this book project will be a major focus of this working group for the 2018 working group. During this meeting we also decided to open dialogue with the Special Education and Mathematics working group, yet scheduling conflicts during the conference prevented this from taking place. After this year’s meeting, we continued to communicate and to organize our collective efforts via our email list-serv. We also forged new partnerships between members including with doctoral student attendees who expressed interest in supporting and enacting this type of scholarship.

In this coming year we plan to continue and expand collaborations between members of this working group with the intention of looking ahead to how this working group will structure research through a critical lens to address the enduring challenge of reframing disability in mathematics education. This working group will create a space in which all involved can learn with and from each other with a purpose of establishing the foundation for collaborative work throughout the year. Members of the working group have submitted a conference proposal through the AERA conference grants. Even though we are actively pursuing opportunities to bring this working group together for a more extended period of time maintaining our PME-NA working group is essential. The space at PME-NA provides opportunities to connect with others, engage in ongoing projects, the possibilities of growing our community, especially in regards to bringing special education and mathematics education together. Each year brings this working group can come together, there is the potential to bring new members. This provides a synergistic place for an ever-growing number of scholars to pursue collaborations around these enduring challenges and hope this working group can provide a space for scholars who are taking a critical lens to explore disability related to mathematics education and create a conversation around the enduring challenge of supporting all students, with a specific focus on disability studies. This year, our group will also focus on strengthening connections with international scholars who are similarly interested in mathematics education and students with disabilities. Our efforts to connect with others who may have a similar interest have been ongoing since our first meeting.

Paradigm Shifts for Disabilities in Mathematics

Gathering together a group of researchers, teacher educators, graduate students, undergraduate students, and classroom teachers interested in developing an alternate paradigm around disability, we have begun to explore the different theoretical frameworks that we can use to analyze and change the status quo within mathematics education. This working group draws from a number of critical theories that have a common intersection around problematizing normativity. Our working group draws upon critical theories such as disability studies, critical race theory, and other poststructural theories (including queer studies and trans studies) in this analysis. In the following sections, we describe a sampling of these perspectives in order to frame the work of the group.

Critical Theories

Critical theory seeks to reshape reality, not just explain things as they are as evidenced by Karl Marx (1845) saying "The philosophers have only interpreted the world, in various ways; the point is to change it." Critical theory encompasses any theory that seeks to transform rather than explain society. The three main criteria for a critical theory as written by the Stanford Encyclopedia of Philosophy, are as follows, "it must explain what is wrong with current social reality, identify the actors to change it, and provide both clear norms for criticism and achievable practical goals for social transformation." As such, the theoretical perspectives that our working group draws upon are each in their own way "critical theories."

Disability Studies and Disability Studies in Education

Disability studies (DS) and disability studies in education (DSE) are modes of inquiry that question the taken-for-granted assumptions and practices in education and the intervention paradigm. Both DS and DSE provide frameworks for exploring questions such as: who is labeling, who is being labeled, whose voices we value, and how do we advance more equitable practices for all students. DS specifically questions the medical model of disability in which disability is seen as a deficit within an individual that requires intervention.

Many DS scholars and activists have adopted a social model of disability, which locates disability in an inaccessible environment and make a distinction between impairment, as any physical or mental limitation, and disability, as the "social exclusions based on, and social meanings attributed to, that impairment" (Kafer, 2013, p. 7). This distinction between impairment and disability is unhelpful because it "fails to recognize that both impairment and disability are social" (Kafer, 2013, p. 7). In the book Feminist Queer Crip, Kafer suggests the term "political/relational model" to refer to perspectives recognizing that both impairment and disability are socially constructed.

By framing disability as social, researchers acknowledge individuals with disabilities should be included within the research process itself. Traditionally researchers determine the questions asked, the methods of data collection, and the meaning made of the data, with no input from the individuals with disabilities, which is oppressive to individuals with disabilities (Oliver, 1992). By adopting a social model of disability, researchers acknowledge individuals with disabilities have unique insights into their lived experiences and empower them to engage directly in the research process (Barnes, 2003). Members of the working group recently published an emancipatory research study (Lewis & Lynn, 2018) where Lewis was positioned as the inquirer (the researcher) and Lynn as the expert (the participant). These research collaborations create powerful studies that illuminate students with disabilities lived experiences with mathematics and ensures the research is in service of those being studied.

In educational settings, this construction of disability manifests in the double education system that splits general education and special education. There is a divide in how students with disabilities are framed within special education research and mathematics education. One line of research pursued by working group members involves developing understanding and theorizing the research divide between special education and mathematics. Institutional practices such as writing Individual Education Plans (IEPs) construct certain students as having disabilities; however, from a disability studies perspective, "the label of students with IEPs [can be viewed] not as an inherent and static determinant of individual ability, but as a school-based designation which reflects and recreates differential ability within the classroom" (Foote & Lambert, 2011, p. 250; also see Dudley-Marling, 2004; McDermott, Goldman & Varenne, 2006; Skrtic, 2005). Particular students are chosen for this assessment and intervention, however the selection process is not objective and often singles out those students who are not from a dominant cultural background.

A DS perspective problematizes the taken-for-granted assumption that what is "wrong" with the situation requiring intervention is a pathology or deficit within students. Instead, the problem is located around the lack of access in the environment. The environment needs to be changed to allow access for students who differ from one another. As Reid and Valle (2004) assert, "the responsibility for 'fitting in' has more to do with changing public attitudes and the development of welcoming classroom communities and with compensatory and differentiated instructional approaches than with individual learners.

The focus of this group is on redesigning the context, not on remediating of individual's impairments. Different working group members address this in different ways. One scholar, draws upon a Vygotskian framing of disability and identifies the ways in which standard mediational tools (e.g., mathematical representations or symbols) are inaccessible to some learners. This scholar reframes the word "remediation" as "re-mediation" to move away from the deficit framing and toward a framing of disability in terms of access to mediational tools (Lewis, 2017).

A second scholar looks at interventions as increasing participation rather than specific skills and thinks through what types of interventions might create more equitable participation and deeper engagement across students in mathematics classrooms (Lambert & Sugita, 2016). This has been explored through empirical research focused on equitable participation in a Cognitively Guided Instruction algebra routine (Foote & Lambert, 2011). A political/relational model suggests inaccessibility is embedded in the context of power relations and in finding interventions to create a more accessible environment requires analyzing the power relations involved in maintaining inaccessibility.

A third scholar is exploring children's knowing and learning as cognitive diversity in the "Small Environment" (Hunt, 2018) of one-on-one and small group instruction. Specifically, the author studies children's learning trajectories - not as a means of "fixing" children but as a way to uncover the knowledge children DO have and leverage the diversity in conceptual understanding and strategic competence in instruction (Hunt, Westenskow, Silva, & Welch-Ptak, 2016; Robertson & Ne'eman, 2008). In this way, Hunt proposes research and instruction in Small Environments should begin by engaging in the mathematics of children and paying attention to their reasoning. Ultimately, teaching is leveraged to support children to explore, revise, and adapt both their own reasoning and the learning environment through a negotiation of meaning (Hunt & Tzur, 2017; Siebers, 2008).

Critical Race Theory and DisCrit

According to Critical Race Theory (CRT), racism is 'normal' rather than an anomaly in U.S. society (Delgado, 1995). CRT theorists claim the U.S. was founded on property rights, specifically that enslaved African Americans were considered property, rather than civil rights (Ladson-Billings & Tate, 1995). CRT reveals how race and racism continue to structure U.S. society and education. CRT theorists have addressed the issue of over-representation of students of color in special education. These analyses leave ableist assumptions in place and DS perspectives often fail to adequately consider race. DisCrit acknowledges that racism and ableism are both normalizing processes that are interconnected and collusive. Racism and ableism work in unspoken ways, yet, racism validates and reinforces ableism, and ableism validates and reinforces racism (Connor, Ferri, & Annamma, 2016). Studies of both administrators' and teachers' perceptions related to overrepresentation of students of color in special education reveal their perceptions tend to be rooted in "deficit thinking and infused with racial and cultural factors" (Connor, et al., 2016, ch. 1; also see Skiba et al, 2006). DisCrit perspectives identify the individual problematic attitudes of educators as one "accessible entry point for intervention" (Connor, et al., 2016, ch. 1).

Extending Previous Work

As a working group, we identify DisCrit as a crucial area of growth and for future scholarship. Several of our working group members have close connections with Dr. Subini Annamma, thus we are primed to integrate DisCrit into our work. Likewise, the charge of Waitoller and King Thorius (2016) to cross-pollinate Culturally Sustaining Pedagogies and Universal Design for Learning frameworks will be an important area to extend on our previous work. Indeed, transdisciplinary research work related to disability studies and mathematics education (Tan & Kastberg, 2017) is an emerging focus of our working group to extend our work.

Our working group's special issue in the journal *Investigations in Mathematics Learning* represents another area that we have extended on previous work. This special issue, which is scheduled to be published in the Fall of 2018, centers reframing disability in mathematics education and features papers addressing disability with a critical lens. One of the papers is from members of this working group who share their insider perspectives on experiences with a mathematics learning disability (Lewis & Lane, 2018). Lewis and Lane explore the compensation strategies used by Lane, who has been identified as having a mathematics learning disability (MLD), and how these compensation strategies could help other students with MLD gain access into mathematics.

A second paper explores middle grades d/Deaf and hard of hearing (DHH) students' perceptions of their identities of competence in mathematics classrooms (Goldstein, 2018). This paper is significant to the field and to our working group because this disability category is one that has been historically under-served and under-researched. Goldstein (2018) offers insight into two DHH students their experiences in learning mathematics in a DHH self-contained classroom. The students in the classroom experienced mathematics as only procedural in nature and viewed competence in mathematics as being able to complete problems. One student, Vivian, did not view herself as competent in mathematics, due to a variety of negative experiences in mathematics classes, including being moved from a mainstream classroom into a self-contained classroom. While in the mainstream classroom, she had a teacher who did not provide accommodations for Vivian, including not using an FM system, even though the classroom was equipped with one, or providing Vivian with someone who could sign for her. This illustrates issues of access for DHH students in mathematics classes and how these issues of access can result in students' lack of identities in competence in mathematics.

Another paper in this special issue highlights a conversation between the two authors, a special educator and a mathematics educator which was sparked by the question "How can I know what's possible in terms of engaging students with disabilities in mathematical thinking and reasoning?" (Greenstein & Baglieri, 2018). This piece is significant and extends our work because it offers ways in which synergistic activities across disciplinary fields can take happen. The conversation between Greenstien and Baglieri explores how mathematics educators and disability studies scholars could come together to support thinking about mathematics in ways yet to be imagined. This speaks to the work of this working group, as we come together to address critical issues in DS and mathematics education and continue to advance our work in new areas.

Summary of the Problem

This working group will examine issues related to disability in mathematics education and push for new understandings. Using multiple theoretical frameworks, the working group participants will analyze current practices in mathematics interventions, including the power relations involved, and develop and elaborate on alternatives in order to address enduring challenges in disability studies. The working group participants will also plan ways to evaluate these alternatives in various educational settings and contexts.

Plan for Active Engagement of Working Group Participants

Session 1

In the first session, the organizers will introduce the rationale for the working group and its two-year history. We will spend time hearing how each of the members is theoretically addressing disability from a critical perspective and collaboratively:

- Establish the groups' vision and mission for this coming year and beyond.
- Identify and refine the long- and short-term goals of the working group.
- Develop a strategic plan to meet our goals.

Session 2

In the second session, (based on input from Session 1) participants will either:

- Brainstorm potential collaborative endeavors.
- Brainstorm how to position this critical work to address enduring challenges in disability studies.
- Break up into subgroups to make progress on collective projects (e.g., NSF Conference grant, NCTM book project, collaborative work)
- Discuss how to develop projects around member's PMENA presentations or

- Discuss a shared reading (distributed to the list-serv before the conference and handed out during session 1) to push our thinking and shared understanding of critical perspectives.

Session 3

Session 3 will be devoted to planning our ongoing collaboration and distributing responsibilities for the group's shared endeavors (e.g., conference/book proposals, developing a shared online repository of research and teaching resources).

Plan for Sustainability: Anticipated Follow-up Activities

The working group sessions during the conference are designed to enable the participants to develop concrete plans for collaborative work beyond the end of the conference timeframe. We plan on continuing to communicate between working groups through our email list-serv. Specifically, the third session is allotted for developing specific plans for future collaborative work. Partnering with doctoral students will continue to be crucial to this group's sustainability as over the working group's history; they have expressed a great appreciation for this type of scholarship in pursuing their own work. In turn, members will continue to share information about this working group with others during professional meetings and in informal spaces. For example, several of us will also be attending the AERA conference in the spring 2019 and are members of the Disability Studies in Education and Research in Mathematics Education SIG. This will be an opportune time to both sustain our work and to expand in areas such as DisCrit. Lastly, we will continue to purse and apply for funding opportunities to meet as a group outside of PME-NA. This will allow us to meet for follow-up activities, sustain and advance our work, strengthen existing partnerships and forge new ones, and to produce collaborative scholarly works.

In this working group, we continue with previous efforts to consider design and research methodologies related to teacher learning in online professional development contexts. We describe the extant literature on online professional development, including a review of digital technologies and the applicability of this practice to teacher learning in education. We then describe an innovative project designed to support the development of middle school mathematics teachers in rural contexts, with a focus on three distinct forms of online learning: digitally communicated teaching lab lessons, an online course, and online video coaching. Given recent technological advances and demands to support teachers in various contexts, we contend that researching and understanding these online models, as well as other online models is important for the broader field of mathematics education. As a result, Year Two of this proposed discussion group will combine whole-group and subgroup time to converse about: (a) the challenges of online professional learning experiences, (b) research tools, methods, and analyses, (c) the connections among different projects and studies, and (d) future collaborations and research.

Keywords: Teacher Education-Inservice/Professional, Research Methods, Learning Theory

All teachers need access to high quality professional development in order to meet the needs of students and to teach rigorous mathematics as outlined in college and career-ready standards (Marrongelle, Sztajn, & Smith, 2013). In order to accommodate the limited resources in some areas, including rural and urban school districts, online professional development has the potential to provide access to a wider range of teachers than what is possible face to face. Furthermore, given the propensity of millennials to seek online learning experiences, we feel that more attention needs to be given to the design, dissemination, and research of online professional development. Given the emerging importance and availability of online professional development, we propose the continuation of a working group that met at PMENA 2017 to continue focus on the design, dissemination, and research on online professional development. The working group participants will analyze current practices in online professional development, including the technology affordances and limitations. Major themes that will be addressed are:

- affordances of online platforms,
- affordances and constraints of synchronous vs. asynchronous experiences,
- challenges related to scaling up high-quality online professional development,
- methodologies used to research professional learning in online contexts.

As schools turn to digital learning contexts, it is inevitable that professional development will follow a similar trend. It is imperative to have research-based models that demonstrate how the features of high quality face-to-face professional development can be matched or augmented in online contexts. As an example of necessity, teachers in rural areas face constraints in terms of accessing the expertise and resources required for high-quality professional learning experiences, often because of lack of proximity to such resources as institutions of higher education and critical masses of teachers required to collectively reflect on problems of practice (Howley & Howley, 2005). Rural contexts are thus ideal sites for online professional development, which can be offered at a distance and can involve geographically dispersed participants (Francis & Jacobsen, 2013). At the same time, teachers in urban and suburban areas may have more regular access to professional development, but online formats afford conveniences and customized learning opportunities that may not be available in face-to-face settings. Digital learning contexts provide opportunities for connections and visual supports that may otherwise not be accessible in face to face professional development. As a result, we consider it necessary to research online professional development and to engage with other mathematics educators and researchers about online professional learning. This working group is intended to advance the practices of designing and researching online professional learning experiences by investigating the challenges of balancing high quality learning experiences and accessibility for teachers. The focus is also on reconnecting with those in attendance during the 2017 conference for updates on discussions about current happenings and experiences with online learning.

Below we provide an overview of the literature related to professional learning in online contexts. Then we revisit the NSF-funded model of online professional development discussed last year, describing what we have learned in the last year in terms of the learning environment and our efforts to research its impact. We will devote part of the first session providing updates on the project as a means of introducing possible models and methodologies to study online professional development, leaving opportunities over the next working sessions to incorporate discussion of other models and methodologies. We then conclude with aims for the 2019 working group.

Literature Related to Online Professional Learning

Digital Technologies

Online professional learning experiences combine longstanding and emerging digital technologies to provide high-quality, interactive, content-focused professional development. Longstanding digital technologies (e.g., electronic learning management systems) have been used to implement online courses to design and implement professional development for the past couple of decades. Emerging digital technologies involve an internet-based platform to implement online video coaching, or other online communications, in ways that augment the interactivity of face-to-face coaching. Online video coaching emerges from the content-focused face-to-face coaching that the project personnel have engaged in over the last ten years.

Research shows that while online communication lacks some of the modalities (e.g., gestures, facial expressions) and spontaneity of face-to-face communication (Tiene, 2000), there are also affordances unique to its asynchronous and text-based nature. In online discussions, communication tends to be more exact and organized (Garrison, Anderson, & Archer, 2001; McCreary, 1990), involve more formal and complex sentences (Sotillo, 2000; Warschauer, 1995) and incorporate critical thinking, reflection, and complex ideas (Davidson-Shivers, Muilenburg, & Tanner, 2001; Marra, Moore, & Klimczak, 2004). Research on synchronous online communication – which can include text chat windows and shared space in learning management systems – shows that it is experienced as more social than asynchronous spaces (Chou, 2002). Synchronous sessions induce *personal participation*, which Hrastinski (2008) compared to *cognitive participation* in that personal communication in synchronous spaces "involves more intense interaction … while cognitive participation is a more reflective type of participation supported by asynchronous communication" (p. 499). Furthermore, synchronous communication fosters multiple communication channels based on emerging networks within the larger group, including the use of chat boxes and personal email during synchronous sessions (Haythornthwaite, 2000, 2001). Researchers have reported positive outcomes from professional development involving synchronous exchanges via typing (e.g. Chen, Chen, & Tsai, 2009). However, synchronous verbal online discussions and group activities have not been a focus of research.

Online Professional Development in Education

Despite the growing popularity of online professional development, there is a continued need for empirical research regarding its quality and effectiveness (Dede, Ketelhut, Whitehouse, Breit, & McCloskey, 2009). Prior research has not demonstrated advantages for online professional development in terms of teacher outcomes (cf. Fishman et al., 2013), in part due to the lack of online professional development contexts that involve teachers in sustained, intensive reflection on their practices. Furthermore, teacher learning in online spaces can be challenging, especially related to complex forms of learning. Sing and Khine (2006) found that a number of factors make it difficult for teachers to engage in complex or difficult forms of learning in an online context, such as teachers' roles as implementers rather than producers, cultural norms where disagreement is seen as confrontational, and the cognitive demands relative to the available teacher time. Teacher learning in online contexts is discussed in more detail below.

In order to illustrate professional learning in an online context, we present a model that the authors are currently using in a project situated in rural contexts. We present the model in order to continue the discussion of this model and other potential models, as well as the learning platforms and other features, such as the synchronous or asynchronous nature of learning in online environments.

A Model of Online Professional Development

The innovative online professional learning experiences in the author's project focus on the development of teacher capacity to enact ambitious, responsive instruction aligned with the rigorous content and practice elements of the Common Core State Standards for Mathematics (CCSSM). We use the term *professional learning experiences* to denote that the professional development we employ differs from traditional workshop or other models that are too short or fragmented to be effective (Garet, Porter, Desimone, Birman, & Yoon, 2001).

In the project, we identified three primary research goals. To study and understand: (a) the ways online-based professional development can help teachers improve their instructional practices and their ability to notice and respond to student thinking; (b) the characteristics of the feedback cycles in the online coaching, the role of video feedback, and the asynchronous components of feedback cycle; and (c) the features of the professional development model that would inform efforts to scale up the model, including the resource commitments, the requisite capacity of the course instructors and coaches, and the logistical requirements of the courses and coaching. We are currently in year two of four years of the project. The following describes the three online components of our project. In the working group, we envision these and other components used by other researchers serving as the catalysts for dialogue around online professional learning and will engage particpatns with conversation around our learning in the past year while encouraging them to share their recent experiences.

Teaching Labs

In order to address the challenges of engaging teachers in learning complex practices in an online context, we include a component aimed at initiating and reinforcing relationships between participants and project personnel and at helping participants to understand the types of learning experiences and design and feedback cycles that will be the core of the project. Research on lesson study (e.g., Amador & Weiland, 2016; Stigler & Hiebert, 1999) has led to an emphasis on demonstration lessons where teams of teachers collectively plan, enact, and reflect on lessons in ways that make public the features of the lessons and teachers' instructional practices (Saphier & West, 2009). Consequently, one component of our project is a collaborative classroom activity, a Teaching Lab, that builds from the *studio classroom* model developed by the Teachers Development Group (2010), with features consistent with content-focused coaching (West & Staub, 2003). For each lesson, a group led by project personnel plans a lesson around a cognitively demanding task. On the day of the lesson, project participants review the lesson plan and explore the task, the mathematics embedded in the task and anticipated student approaches to solving the task, and the related CCSSM practice and content standards, making necessary revisions to facilitate the lesson. The project personnel then enact the lesson while the rest of the group observes and collects evidence of student thinking and learning. The group then collectively reflects on the experience, with a focus on describing evidence for student understanding using the data gathered by the teachers and observers. This process is repeated regularly with participants.

In the beginning of the project all demonstration lesson activities were face-to-face. However, at this point in our project, this component has moved to an online format of synchronous and asynchronous activities. The planning and debriefing portions are held via a video conferencing platform, Zoom, allowing for synchronous engagement in both whole group and small group discussions of the lessons. Asynchronous activities include watching and reflecting on the video recording of the demonstration lesson between the planning and debriefing sessions. Discussion in the working group will center on the affordances and constraints of the online model and possible modifications to ensure the intended professional development goals are met.

Online course - Orchestrating Mathematical Discussions

The second component of our project is the two online course modules, *Orchestrating Mathematical Discussions Parts One and Two*, aimed at orienting the participants toward high-leverage discourse practices that facilitate mathematically productive classroom discussions (Smith & Stein, 2011). In this course, the participants solve and discuss a series of high cognitive demand tasks, activities that will be accompanied by synchronous and asynchronous discussions around the *5 Practices for Orchestrating Productive Mathematics Discussions* (i.e. anticipating, monitoring, selecting, sequencing, connecting; Smith & Stein, 2011). The courses are designed to develop awareness of specific teacher and student discourse moves that facilitate productive mathematical discussions, to understand the role of high cognitive demand tasks in eliciting a variety of approaches worthy of group discussions, and to further develop participants' mathematical knowledge, particularly the rich connections around big mathematical ideas that are helpful to teach with understanding (Ball, 1991; Boaler & Staples, 2008; Chapin, O'Connor, & Anderson, 2003; Choppin, 2007a; 2007b; 2014; Herbel-Eisenmann, Steele, & Cirillo, 2013; Ma, 1999; O'Connor & Michaels, 1993).

In order to take advantage of the affordances of both asynchronous and synchronous characteristics of online communication, the course is embedded in a learning management system (LMS) that: allows for synchronous whole class and small group interaction; the sharing of artifacts, including those collectively developed in the LMS; and asynchronous discussion threads. In the online course modules in the LMS, the facilitator verbally presents a challenging task to the participants, which is viewed in the shared work space. The course instructor then assigns participants to virtual breakout rooms, in which the participants work synchronously in a common workspace, creating virtual white boards to share with the other groups. They can talk to each other, work simultaneously in the virtual space, and use the chat window to communicate. The course instructor can listen to and participate in these group discussions to determine when the groups are ready to present their solutions. The course instructor then closes the virtual breakout rooms, which automatically returns all participants to the main room to conduct a summary discussion of the different strategies, in effect modeling the practices in the *5 Practices* book. Asynchronously, the group can continue to go back and reflect and comment on the task and related solutions, as well as on the readings from the *5 Practices* book using discussions threads in the LMS. Participants are also encouraged to share resources, lesson plans, and student work as appropriate. The working group will discuss this format for online professional learning as well as other formats and tools that have proven beneficial for users.

Online Video Coaching

The third – and most innovative – component of our project's professional development program is the online video coaching that builds from models of content-focused coaching (West & Staub, 2003). More recently, thanks to the advent of improved internet-based software aimed at increasing collaboration around video data, the project personnel have begun conducting online video coaching with teachers. The coaching cycles are focused on identifying and unpacking the mathematics with the teacher, while anticipating likely student strategies, conceptions, and misconceptions. The coach helps the teacher identify evidence for demonstrating how students are thinking (from the video as well as from student artifacts) and make connections between different student approaches in order to help the teacher structure the summary discussion of the lesson.

The online coaching experiences involve synchronous and asynchronous components, with the goal of engaging participants in reflective or deliberative practice. The online coaching has features similar to face-to-face coaching, such as video conferencing conversations via Zoom, in which the coach and participant collaborate to plan lessons and reflect on the qualities of lessons. However, the online coaching includes an innovative component that involves asynchronous collaboration and feedback that structures the post-lesson collaborative reflection, features that augment or surpass the kind of feedback that can be given face-to-face. Teachers video-record themselves using Swivl, which allows them to place a camera (iPhone or other device) on a robot that tracks them around the room, allowing for teacher-focused video without the necessity of someone operating the camera. The video is automatically uploaded into a password-protected site and processed, and is immediately accessible to view and notate. The notation feature in Swivl allows the coach and the candidate to separately view and annotate the video. For example, a teacher can stop the video by hitting the pause button and type in a comment or question that is synced with the video, so that when the coach watches the video, she can read the comment during the point in the video referenced by the comment. The coach can do the same. The video can be viewed repeatedly, which allows for more thorough reflection and analysis. The notation provides for more in-depth and substantive feedback, pointing to specific instances of practice. The discussion group will focus on this model for professional coaching as well as other models or avenues for supporting individual teachers in online professional learning.

Researching Online Professional Learning Experiences

There is a dearth of research on online professional development, especially online professional development that is sustained and intensive. Similarly, while there have been 16 years of intensive efforts to implement coaching in schools, much of the research have revolved around the role and impact of coaches (Coburn & Russell, 2008; Penuel, Riel, Krause, & Frank, 2009), and less around the impact on reflective or deliberative practice. Although coaching has now been around for over ten years, there is limited research on the effectiveness of coaching in terms of improving teacher quality (Matsumura, Garnier & Spybrook, 2012). The greatest dearth of research involves online video coaching in education, as opposed to face-to-face video coaching, which has no peer-reviewed research yet associated with it.

Structure of the Working Group Sessions

Within this working group we propose to explore the following questions related to researching online professional learning experiences:

1. What are various platforms and models for online professional development?
2. What theoretical framework and methodologies are salient for researching online digital technologies and online professional learning experiences?
3. What data analysis methods are suited to the data captured in online environments?
4. In what ways can online professional learning experiences help teachers improve their instructional practices and their ability to notice and respond to student thinking?
5. In what ways can the characteristics of the feedback cycles in online coaching, the role of video feedback, and the asynchronous components of feedback cycle inform the design on online professional learning experiences to maximize teacher learning?
6. What features of the professional development model would inform efforts to scale up the model, including the resource commitments, the requisite capacity of the course instructors and coaches, and the logistical requirements of the courses and coaching?

Plan for Working Group:

In Session 1, the organizers will present brief update reports on the Author's project and research design, as well as a recap of the 2017 working group discussions. Subgroups will be formed to continue conversations around design and implementation efforts with online professional learning experiences from their own research and current efforts in the field; attendees from this working group at PMENA 2017 will provide updates on their respective projects in the small-group setting.

During Sessions 2 and 3 we will provide the subgroups time to continue collaborating on themes identified in the PMENA 2017 working group: a) identifying the challenges of online professional learning experiences that are the most challenging and why—this will include a specific look across the projects presented and with a focus on activities on the last year, b) refining research tools, methods, and analyses, c) exploring connections among different projects and studies for former and new attendees, and d) discussing future collaborations and research. We will close Session 3 with time to review group progress and discuss next steps for our work as shown in Table 1. Meeting notes, work, and documents will continue to be shared and distributed via our Google Folder (set up for this Working Group). The use of Google documents allows members to create an institutional memory of activities during the working group that we will continue to use and add to following the 2017 and 2018 working groups. This shared folder will also provide a shared space for future collaborations and writing projects related to online professional learning experiences within the 2017 and 2018 working group members.

	Overview of Proposed Working Subgroup Sessions	
Session 1	**Activities:** 1. Introductions and Agenda 2. Brief Presentations of Authors' Project and Research Questions 3. Brief Presentations of former Attendees' and New Attendees' Projects and Research Questions 4. Subgroup formation and initial work time - designing Online PD experiences	**Guiding Questions:** 1. What are the different forms of online professional development? 2. What research is being done related to online professional development? 3. Which aspects of online professional learning experiences are the most challenging to implement or research? 4. What are new questions that have arisen within the last year?
Session 2	1. Overview of subgroup's work from previous day 2. Subgroup work time - engagement in online professional learning experiences 3. Brief sharing of work in subgroups	1. How can online learning support teacher learning? 2. What are the affordances and constraints of various platforms? 3. What are the affordances and constraints of synchronous and asynchronous experiences?
Session 3	1. Overview of subgroup's work from previous day 2. Subgroup work time - researching online professional learning experiences 3. Brief sharing of work in subgroups 4. Final reflections – future collaborations and research	1. What theories and theoretical frameworks have informed the design of your research project(s)? 2. How might your work inform theory in researching online professional learning experiences? 3. What issues and challenges have you faced in designing studies in this area? 4. What challenges may exist for scaling up high-quality online professional development?

Argumentation, justification, and proof are conceptualized in many ways in extant mathematics education literature. At times, the descriptions of these objects and processes are compatible or complementary; at other times, they are inconsistent and even contradictory. The inconsistencies in definitions and usages of the terms argumentation, justification, and proof highlight the need for scholarly conversations addressing these (and other related) constructs. Collaboration is needed to move toward, not one-size-fits-all definitions, but rather a framework that highlights connections among them and exploits ways in which they may be used in tandem to address overarching research questions. Working group leaders aim to facilitate discussions and collaborations among researchers to advance our collective understanding and conveyed use of argumentation, justification and proof, particularly the relationships among these important mathematical constructs. The 2018 working group sessions will extend previous conversations into issues of teacher preparation with respect to argumentation, justification, and proof. The group will also discuss how issues of equity, social justice, and marginalized populations intersect with the teaching and learning of argumentation, justification, and proof.

Brief History of the Working Group

The *Conceptions and Consequences of What We Call Argumentation, Justification, and Proof* Working Group (AJP-WG) has met for three consecutive years, beginning in 2015. The working group's primary focus is on the field's conceptualization of the interrelated objects and processes of argumentation, justification, and proof. Previous working groups at PME and PME-NA had focused on either proof or argumentation, but the present working group is the first to attend specifically to the connections among these three constructs.

During the working group's initial meeting (2015), attendees made progress on considering the interrelationships among argumentation, justification and proof, and we deepened our understandings of our own perspectives and the range of perspectives held by others in the group. The goal during this meeting was not consensus or deciding a best approach. Rather, we sought to better understand the complexity and diversity of individuals' perspectives with respect to their research agendas and professional practice. We were encouraged that our efforts were well received, with 46 scholars, including at least 10 graduate students, participating in the working group the first year.

The second gathering of the AJP-WG was held in 2016 at the annual meeting for PME-NA in Tuscon, AZ. Thirty-six scholars attended the sessions, which continued the group's focus on the interrelationship between and among the concepts and terms related to argumentation, justification, and proof. Specifically, participants considered their definitions for these concepts and how such definitions may change given different contexts and foci.

The AJP-WG met for the third time in 2017 in Indianapolis at the 39th Annual Meeting of PME-NA. This meeting, attended by 28 scholars, involved examining a set of middle grades student artifacts from different perspectives on argumentation, justification, and proof. Analyses were presented by members of the working group, and these analyses were critiqued and compared by the working group during our meetings. Additional information about these meetings of the AJP-WG is included later in the proposal.

Summary of Focal Issues

Engagement in disciplinary practices of constructing viable arguments, justifying conclusions, critiquing the reasoning of others, and constructing proofs for mathematical assertions appear in educational policy documents of K-12 students. (National Council of Teachers of Mathematics [NCTM], 2000; National Governors Association Center for Best Practices [NGA] & Council of Chief State School Officers [CCSSO], 2010). Most recently policy documents have begun to focus on the teaching practices and the preparation and development of teachers in facilitating argumentation, justification, and proof. For example, according to *Principles to Actions: Ensuring Mathematical Success for All* (NCTM, 2014): "Effective teaching of mathematics facilitates discourse among students to build shared understanding of mathematical ideas by analyzing and comparing student approaches and arguments" (p. 29). An example of teacher preparation and development is the *Standards for Preparing Teachers of Mathematics* from the Association of Mathematics Teacher Educators (AMTE, 2017) "Well-prepared beginners encourage students to communicate their reasoning, critique the reasoning of others, and develop arguments through discourse and mathematical writing" (p. 77). Due to these recent calls, the 2018 AJP-WG will engage participants in sessions to extend previous conversations of argumentation, justification, and proof into issues of teacher education.

There is a growing body of research in mathematics education focused on teachers' argumentation, justification, and proof. The research on proof, for example, have included studies on teachers' conceptions (Knuth, 2002) and perceptions (Boyle, Bleiler, Yee, & Ko, 2015) of proof, how teachers enact proof-related tasks (Bieda, 2010; Bostic, 2016), how teachers engage with students in proving (Herbst, 2002; Martin, McCrone, Bower, & Dindyal, 2005), teachers' evaluation of student-generated proofs (Tsamir, Tirosh, Dreyfus, Barkai, & Tabach, 2009), and how coursework impacts teachers' reasoning and proving (Karunakaran, Freeburn, Konuk, & Arbaugh, 2014). While proof has received more attention, argumentation, as a concept, is garnering new prominence with increasing attention in the mathematics education research. Research on argumentation has included examining new methodologies to understand teachers' argumentation (Metaxas, Potari, & Zachariades, 2016), teachers' contextualization of argumentation in the classroom (Staples & Newton, 2016), and teachers' discursive actions during argumentation (Conner, Singletary, Smith, Francisco, & Wagner, 2014; Kim & Hand, 2015). In regards to justification, researchers have investigated justification in mathematics courses for prospective elementary teachers (Simon & Blume, 1996), teachers' perceptions of justification (Staples, Bartlo, & Thanheiser, 2012), and professional development to support justification (Lesseig, 2016).

Highlights from the Year 1 Working Group Discussions

A focal activity during the initial working group sessions in 2015 was the development of Diagrams/Concept Maps in which each participant generated a representation of the relationships among argumentation, justification, and proof from his or her perspective. Discussion surrounding the relationships between constructs was supported by an initial presentation by Keith Weber on Day 1, followed by a panel presentation, moderated by Samuel Otten, with Kristen Bieda, AnnaMarie Conner, and Pablo Mejía-Ramos serving as expert panelists (i.e., Bieda – justification; Conner – argumentation; and Mejía-Ramos – proof). The panelists shared how they conceptualized the interrelationships among argumentation, justification and proof; they explicated how they came to use the central construct they use in their research and why they felt that choice was productive for their work; and they offered their thoughts on the current state of the field and what we might need to tackle next in relation to these constructs. The final day of the 2015 working group sessions offered the opportunity to revisit participants' Diagrams/Concept Maps, though now potentially informed by additional perspectives and questions gained from the prior two sessions.

Three products were generated from the 2015 meeting. First, a pair of podcasts generated by Samuel Otten are available worldwide: The first podcast is of Weber's talk (http://mathed.podomatic.com/entry/2015-11-16T07_01_19-08_00), and the second podcast is the moderated panel discussion (http://mathed.podomatic.com/entry/2015-11-19T07_19_37-08_00). The second product was a white paper that was developed by the working group organizers, the panelists, and several other participants from the working group who volunteered to participate in the online publication (Cirillo et al., 2016). The white paper summarized the working group activities and discussions and also includes the set of 44 Diagrams/Concept Maps that were generated as well as annotations and analyses. The final product was a poster presentation for PME-NA 2016 that was based on the analyses of the Diagrams/Concept Maps (Strachota et al., 2016).

Weber's presentation highlighted different traditions and points of disagreement, for example, citing Reid's (2001) observation that research simultaneously suggests that secondary students struggle to construct proofs, while at the same time suggesting that primary children are capable of engaging in proof. Weber prompted the group to consider how different traditions may inform each other in order to advance the field collectively. In particular, he outlined three broad traditions in proving: *proving as problem solving, proving as convincing,* and *proving as socially embedded activity.* Each corresponds to a different focus for research and/or instruction. Weber offered two thought-provoking suggestions, both of which may help us understand the lack of convergence in results and definitions. One suggestion was that proof may not be a singular, easily defined concept, but rather a *cluster concept,* as used by Lakoff (1987). In this sense, there is no list or decision procedure to identify a proof, but rather there is a set of features associated with the concept, and many - but not all - apply in any one instance.

The second suggestion was that the features or properties associated with proof may be closely interrelated for mathematicians, but not for students. In particular, for mathematicians, a convincing argument and socially sanctioned argument are often one-in-the-same. For students, however, those are not tightly connected and may describe very different types of arguments. He suggested, "Perhaps much of the disagreement amongst mathematics educators is that they are using proof as a shorthand to denote things that are different to students but similar for mathematicians" (Cirillo et al., 2016, p. 7).

The panel discussion on our second day further raised awareness of how crucial it is to not only define one's terms, but also to specify the context of one's work. For example, Bieda and Conner both work closely with students and teachers in secondary settings, and in that context, they have found proof and proving to be terms that distance or invoke conceptions of end product and formality. Consequently in their work, they have chosen different focal constructs. Both Bieda and Conner articulated an explicit link of their work to students' proof-producing capacities at the tertiary levels, but they do not centralize that term in their research in school mathematics.

Our discussions and subsequent analyses of the Concept Diagrams/Maps offered additional information about the variety of ways these three important constructs are understood in relation to one another. During the gallery walk and subsequent analyses across the Concept Diagrams/Maps, we could discern little to no agreement about the relationship between justification and argumentation. It seemed that participants held these two constructs (justification and argumentation) either fully distinct from the set of things we call proof, or that proof was a very specific version of each of these. Some considered justification a subset of arguments; others positioned arguments as a subset of justifications; and still others had them as overlapping, but not concurrent, sets.

Proof (and proving) seemed to be of a different nature than argumentation and justification for our participants, and proof participants either positioned it at the far end of a continuum of the constructs, a plane above, or as a separate entity. Others considered proof to be a specific subset of arguments and justifications. Additional details can be found in the White Paper (Cirillo et al., 2016). A question raised in the discussion on Day 3 was whether proof was so valorized that we position it as the "desired end product" for all arguments, even when that might not be a productive or educative goal. This lack of not only convergence but general clarity provides an important opportunity for further exploration and raises questions about the consequences of these different concepts. It implores us to continue to work to develop a framework to connect these constructs and clarify not only our commitments and definitions but the interrelationships among these important ideas.

Highlights from the Year 2 Working Group Discussions

During the first session of the second meeting of the AJP-WG, Samuel Otten moderated panel presentations on differing applications of definitions provided by Eric Knuth, David Yopp, and Orit Zaslavsky. On the second day, participants examined data artifacts from different grade levels and were asked to consider whether and in what ways they would define features in the data with respect to argumentation, justification, and proof. All participants were provided two common artifacts (a transcript of a high school math class discussion & five samples of grades K-3 writing samples) as well as one additional artifact of choice (middle school, high school, or tertiary level artifact). Discussion surrounding the artifacts provided an opportunity for participants to consider how their definitions were affected by application to the differing data. It provided an arena in which to see how each definition served as a lens for viewing the artifacts and how these different lenses might lead one to position a work sample in different ways, depending on the type of mathematical activity represent in the work sample based on the definition. This discussion continued through to the final session. Further, the discussion surrounding the artifacts facilitated initial organization of three networking groups–one focused on reading and sharing journal articles and two focused on producing written products. One product available from this second AJP-WG meeting is a podcast of the panel discussion produced by Samuel Otten (https://www.podomatic.com/podcasts/mathed/episodes/2016-11-

14T07_10_36-08_00). A second product is a white paper (available at https://www.researchgate.net/publication/317267228) summarizing the working group activities and discussions of the artifacts from year two (Staples et al., 2017). The final product is the organization of networking groups for continued collaboration related to, but independent from, the working group. Thus, activity across both years of the working group has facilitated the continued development of a community of mathematics education researchers who we anticipate will continue these discussions over several years.

During the panel discussion, our panelists shared how they used and defined justification, argumentation, and proof and how their definitions and applications of these constructs influenced, and were influenced by, their research questions or contexts. A key point arose from David Yopp's juxtaposition of his definition of proof with Stylianides' (2007) definition of proof in relation to a particular 8th-grade work sample. Yopp argued that by Stylianides' definition, the student's work was not a proof (violating two of three conditions). By Yopp's definition, however, the student's work was a proof. Yopp stated that a proof eliminates the possibility of counterexamples. Thus, from the student's perspective—and perhaps class's perspective—he had eliminated the possibility of counterexamples, thus providing proof of the claim (see Figure 1).

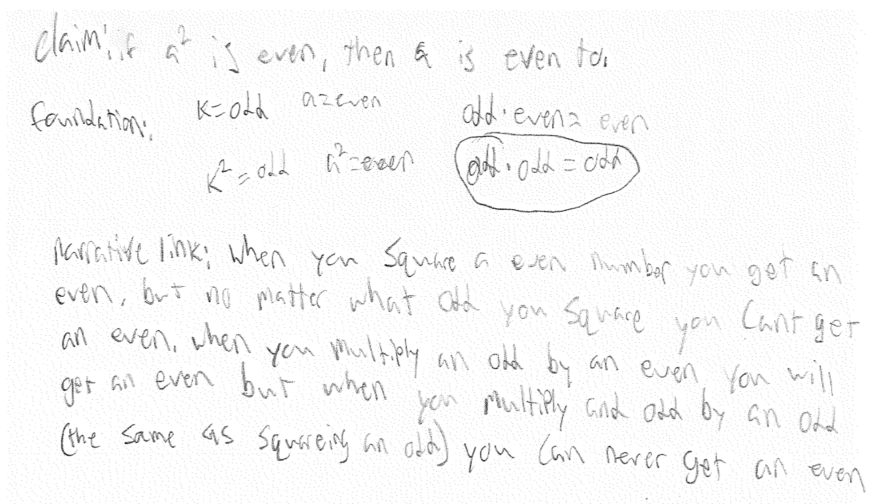

Figure 1. Student work samples shared by David Yopp.

We then turned our attention to reviewing artifacts of K-16 classrooms, to provide a concrete opportunity to see how definitions might interact with context. Participants were offered two artifacts in common, from elementary grades work samples and a high school transcript, and then could choose a third artefact to review, from middle school, high school or tertiary level. Although it became apparent was that we offered too much in too short a time frame, our discussion was productive, and we recap a few of the key ideas offered here.

One question raised was how much context we needed to know in order to engage the question, is this a proof? Or is this an argument? This question was posed based on recognizing that both Yopp and Stylianides offered definitions of proof that dependent to a degree on a child's/class's conceptual sphere. In Stylianides' definition, this context element comes through with the criteria that all must be "known by" or "within the conceptual reach" of the community. In Yopp's, this context element comes through with the idea that one must eliminate all possible counterexamples, so if a student is not aware of, say, complex numbers, s/he does not have to offer a proof that accounts for all complex numbers. The student can only attend to and eliminate the possibility of counterexamples (actively) from his or her realm of possibility. Continuing with the general idea of context, questions were raised about how grade-level dependent a proof was, and whether one needed to know more about what was taken-as-shared in a class to evaluate whether an argument did or did not comprise a proof. One of the final points raised was that a proof is not a stand-alone entity; we need to know what the norms and assumptions are in order to understand if something is operating as a proof in that context.

In our final session, we sought to continue the discussion from the previous session and also organize toward "networking groups" for those interested in sustaining or advancing conversations with respect to argumentation, justification and proof during the year. Participants each wrote brief questions they were interested in pursuing and indicated a level of commitment they might have for the pursuit (e.g., discussion groups, reading groups, research group). Our time then was devoted to participants having conversations to connect with one another around shared areas of interest and similar levels of desired future commitment.

Highlights from the Year 3 Working Group Discussions

In Year 3, the working group explored the consequences of examining data from differing perspectives on the definitions of and relationships among argumentation, justification, and proof (see Cirillo et al., 2015; Staples at al., 2016; Conner et al., 2017). During the first session, working group participants examined a set of data that included both a transcript and students' written artifacts from a middle grades classroom (shared by Megan Staples from the JAGUAR project), using perspectives negotiated among themselves. Conversations revealed working group participants used a wide range of perspectives as they looked at the data. Working group participants raised a number of questions as they looked at the data, including the importance of knowing the teacher's goals for the lesson; emphasizing how a task was set up would impact the students' productions of argumentation, justification, or proof; and how different definitions of argumentation, justification, and proof might yield different conclusions about the conversation and written work.

During the second session, the working group heard presentations from two researchers who had deliberately taken different perspectives on the data presented in session 1. Kristen Bieda examined the data using Harel and Sowder's (2007) definition of proof, and Megan Staples examined the data using a community-of-practice lens (Lave & Wenger, 1991; Wenger, 1998) involving justification. Harel and Sowder's definition of proof involves the constructs of ascertaining and persuading. Bieda raised the question of collective ascertaining, asking if ascertaining has to be done by one person or if it could be done by or within a group. She also noted that the definition of proving as ascertaining and persuading omits specifying forms of reasoning that are valid. Staples pointed out that her analysis showed different kinds of language use during small-group and whole-class discussion. Significantly, she did not find any teacher use of the word justification, but she found numerous instances of justification within the transcript, particularly in the context of "explain your thinking." Discussion after the presentations included the importance of positioning definitions of argumentation, justification, and proof within a larger perspective. Also discussed were issues of disciplinary norms, including a tendency to examine proof from a disciplinary perspective but justification without assigning a disciplinarily specific definition.

In session 3, Karl Kosko introduced a third perspective on the data, using Pierce's (1903/1998) semiotic view coupled with Toulmin's (1958/2003) diagrams of argumentation to examine how grammar in the mathematics register functioned to convey meaning. He examined how use of warrants influences the co-construction of mathematical argumentation. In the subsequent discussion of the three presentations, working group participants emphasized that definitions and methodology were intertwined and difficult to separate. Essentially, in examining the data, the three researchers were looking at different things: justification as a means of concept development, understanding whether doubt is removed, and what students are doing as they use or omit warrants. All of these perspectives resonated with participants, and the conversation validated the importance of specifying both the perspective and the definition being used in research about argumentation, justification, and proof.

Focus for Year 4

Our focus for Year 4 is how mathematics teacher educators prepare K-16 teachers for enacting argumentation, proof, and justification in their own classrooms. We will engage in discussion on how focusing on argumentation, proof, and justification may result in different outputs from teachers, in teacher preparation programs and professional development. As learned in Year 1 and 2, the members of this community have a variety of definitions and perspectives of argumentation, proof, and justification (see Cirillo et al., 2015; Staples et al., 2016; Conner et al., 2017). The community's perspectives on the relationship between argumentation, justification, and proof also varied. We will explore how these differing perspectives inform the ways prospective and in-service teachers conceptualize argumentation, justification, and proof. Guiding this year's focus are the following questions: How have our group members helped teachers conceptualize argumentation, justification, and proof? What conjectures do our community members have about the consequences of the teachers' conceptualizations of argumentation, justification, and proof in their teaching and learning of mathematics?

In Year 3, the relationship between context and the individual's definitions of argumentation, justification, and proof was further explored. We plan to build on these previous conversations by including how different members have attempted to teach prospective and inservice teachers about argumentation, justification, and proof. We hypothesize one's conceptualization of argumentation, justification, and proof will inform the activities and tasks given to prospective and inservice teachers. Time will be allotted for the participants of the community to work together to discuss, brainstorm, and share different activities they have enacted or could enact with preservice and inservice teachers to highlight important aspects of argumentation, justification, and proof. Moreover, ways in which argumentation, justification, and proof could be emphasized in already enacted activities (e.g. high cognitive demanding tasks) will also be discussed. We will use these opportunities to build collaboration among the members of the working group. Facilitating these conversations on developing potential activities for prospective and inservice teachers, we will construct an online space to share the different activities, tasks, and other interventions the members of the working group develop or have enacted previously. Continued collaboration will be promoted to design and investigate the enactment and learning results of these activities on argumentation, proof, and justification.

Plan for the Working Group

Session 1: Exploring the teaching and learning of AJP with prospective teachers

In Session 1, we will begin with introductions and review our progress from the past three years. Then, we will start a panel discussion. The specific focus of this panel discussion is: How can we, as mathematics teacher educators, support prospective teachers to learn and teach argumentation, proof and justification from elementary to tertiary education?

In past discussions, working group participants shared how they defined and conceptualized the interrelationships among argumentation, proof, and justification. This year, we will follow up to explore how their different perspectives influence their preparation of prospective teachers to teach argumentation, justification, and proof in mathematics classrooms. During the session, we will invite working group participants to share how they prepare prospective teachers to engage in argumentation, justification, and proof in their classrooms.

Session 2: Issues of equity and social justice in classrooms involving AJP

In Session 2, we will have a series of presentations exploring the intersection of equity and social justice and teaching and learning AJP. We will focus on teaching involving AJP in areas with marginalized populations. Researchers will be invited and will share their work, particularly about how they conceptualize and use AJP in their studies and implications for marginalized students. With working group participants, we will discuss what AJP might look like in mathematics classrooms with marginalized students and what the role of equity and social justice is and how they can be incorporated into the learning of AJP in those contexts. We will also discuss what else a teacher should consider in the intersection of conceptualizations of AJP and equitable instruction.

Session 3: Brainstorming recommendations for the preparation of teachers

In Session 3, working group participants will brainstorm recommendations for teacher educators who are preparing prospective and practicing teachers to teach AJP in the context of mathematics classrooms. We will discuss what activities or resources might be helpful for the teachers learning to teach the AJP constructs in classrooms and what the teachers could learn from participating in these activities. Building on session 2, we will also discuss what the teachers should pay attention to when implementing AJP in their classrooms and what relevant researchable questions are important to the field.

Anticipated Follow-up Activities

We anticipate that the products and follow-up activities from Year 4 will build on the activities and products from our three previous years. A major follow-up activity for this year will be a white paper exploring recommendations for exploring argumentation, justification, and proof in teacher education. We will continue to encourage networking groups, which will likely shift and expand. Additional networking groups with other related interests will also be encouraged.

This Working Group builds on the work of Working Groups in 2015 and 2016. We will continue considering multiple aspects of research and practice related to mathematics learning and teaching with English Learners. Our goals for the 2018 Working Group include: (1) sharing current perspectives on extant research related to mathematics and English learners, (2) understanding venues for dissemination of research on ELs, including novel outlets that connect research to practice, and (3) fostering new collaborations and supporting further connections among researchers. In Session 1, the organizers will present brief reports on the work that will be used to catalyze subsequent sessions' work. During Session 2, we will engage in a shared data analysis activity drawing on excerpts of student interview data. The activity will center on comparing and contrasting methods for analyzing the learning and teaching of ELs. In the final session, we will have four breakout groups from which participants can choose to join. Each group will revisit a key aspect of the prior days' work. We will close with time to review group progress and discuss next steps for our work.

Keywords: Equity and Diversity; Teacher Education-Pre-service; Teacher Education-In-service/Professional Development; Research Methods

Focal Issues

English Learners (ELs) are the fastest growing group of U.S. students (Verplaetse & Migliacci, 2008). U.S. schools have seen an increase of 152% in the population of EL students over the past 20 years (National Clearinghouse for English Language Acquisition, 2008). This increase in the population of ELs has created a need for schools and teachers to create inclusive and equitable mathematics classrooms. No longer is supporting ELs a concern for only for educators in states like Arizona, Texas and California with traditionally high numbers of EL students. Instead, with all but 15 states across the country seeing increases in their EL populations between 2004-05 and 2014-15 (National Center for Educational Statistics (NCES), 2017), there is increasing nationwide pressure for support in addressing the needs of these students.

The implementation of the Common Core State Standards for Mathematics (National Governors Association Center for Best Practices, Council of Chief State School Officers, & Officers, 2010) has put additional pressure on mathematics teachers of students who are still gaining proficiency in English. Teaching aligned with the CCSSM's content standards and the standards for mathematical practice must address the language demands required to engage in mathematical discourse. Providing ELs with quality educational experiences is no longer relegated only to language specialists; it is a "mainstream" issue for which all mathematics teachers must be prepared (Bunch, 2013). In light of these demographic and curricular shifts, there is a growing body of research on the teaching and learning of ELs in school mathematics.

In the following we briefly summarize research on mathematics teacher preparation for working with ELs and mathematics curriculum design issues for ELs.

Despite the rise in the number of ELs and changes to school mathematics standards, there has not been an increase in teacher preparation geared toward supporting ELs, and this is especially the case for content-specific preparation (e.g., Kaufman & Stein, 2010). Although the consensus among mathematics educators that teachers need focused, content-specific preparation to teach ELs effectively, most inservice teachers have had few, if any, professional learning experiences around working with ELs in mathematics classrooms (Ballantyne, Sanderman, & Levy, 2008). In fact, many mathematics teachers struggle to understand their role in supporting ELs' mathematics language development (Willey, 2013). In 2008, Ballantyne et al. found that it was "likely that a majority of teachers have at least one English language learner in their classroom," although "only 29.5% of teachers with ELs in their classes have the training to do so effectively" (p. 9). This misalignment of the realities of today's classrooms and teacher preparation has necessitated examination into effective means of supporting current teachers and preparing prospective teachers to meet the needs of linguistically diverse learners and studying such work.

In addition to the need for inservice teacher training to teach mathematics with ELs, preservice teachers are also underprepared to teach mathematics with ELs. Preservice teachers typically have few opportunities to think specifically about how they will work with ELs in their mathematics classrooms. Preparation programs often include coursework on teaching ELs that is not specific to the content areas in which preservice teachers will work. Meanwhile, the content courses for preservice teacher often focus solely on content, devoid of exploring how to support ELs in mathematics classrooms. Recently researchers have shared strategies for engaging preservice teachers in working with ELs in mathematics classrooms. For example, Fernandes (2012) suggested a series of mathematics task-based interviews to engage preservice teachers in the process of noticing the linguistic challenges that ELs face and the resources these students bring to their mathematical communication. In another example of such work, the TEACH MATH research team is using tasks in their content courses to support preservice teachers in drawing on students' funds of knowledge (Turner et al., 2012).

Beyond using tasks in content courses, teachers use tasks in their classrooms in the form of curriculum. Such curriculum plays a key role in the teaching and learning of mathematics and teachers play a pivotal role in selecting and enacting curriculum materials for students. The choice of curriculum materials impacts students' opportunities for learning in the mathematics classroom (Kloosterman & Walcott, 2010). Early work on curriculum and English learners focused specifically on the challenges ELs encounter when completing or interpreting word problems (Téllez, Moschkovich, & Civil, 2011). Since that time, the field has transitioned to focus on curriculum that draws on and connects to students' cultural resources (e.g., Barton, 1996; D'Ambrosio, 2006), the development of curriculum materials specifically for ELs (e.g., Freeman & Crawford, 2008), and the evaluation of a curriculum's appropriateness for ELs (e.g., Khisty & Radosavljevic, 2010). More recently, work related to ELs and curriculum has begun to look at teachers' use of curriculum (e.g., de Araujo, 2017).

This year, our Working Group aims to look backward to synthesize research related to the mathematics education of ELs broadly, and in relation to this Working Group specifically, while also looking forward to consider new research in the field. In looking back at research that the field has completed, the organizers have completed a literature review of research on ELs and mathematics education (de Araujo, Roberts, Willey, & Zahner, under review), and we found 99 empirical articles on this topic since 2000. This represents an increase in attention toward the mathematics education of ELs, with most recent work being framed using sociocultural and sociopolitical frameworks. We note that this research is occurring in concert with the political landscape, acknowledging the sociocultural and political dimensions of mathematics and of school mathematics (Gutiérrez, 2013). There is still much work to be done; some contexts and critical dimensions remain unexamined. Moreover, teachers still need more support, and we still need to acknowledge and build on the resources that ELs bring to classrooms.

In addition to synthesizing the literature, the 2018 Working Group will look forward as we foster new collaborations and help define future directions for research. To do this work, we will bring together researchers from diverse contexts to examine current and past research on ELs in mathematics education while also supporting burgeoning collaborations to establish future, imperative research directions.

Brief History of the Working Group

The facilitators of this Working Group initially came to work together through the NSF-funded Center for the Mathematics Education of Latinas/os (CEMELA). CEMELA brought together researchers from across the country to collaborate on research focused specifically on critical issues related to Latinos/as in mathematics. Prior to CEMELA, researchers interested in such a focus worked mostly in isolation. In considering issues related to Latinos/as in US schools, issues of language and culture were central, which often had direct implications for English Learners (ELs) more broadly. While not all Latinos/as are English Learners, and not all ELs are Latinos/as, these two groups have significant overlap. For example, about 80% of ELs speak Spanish as a first language, and Spanish-speaking ELs appear to struggle on measures of academic achievement (Goldenberg, 2008).

CEMELA expanded the field's knowledge of ELs in mathematics through conducting interdisciplinary studies that helped researchers and practitioners better understand the reality of Latinas/os and mathematics teaching and learning. CEMELA's research focused on teacher education, research with parents, and research on student learning, resulting in over 50 publications and presentations. Again, several of these studies involved the investigation of questions related to the interplay of language, culture, and mathematics education. CEMELA also had the goal of connecting the network of scholars focused on these issues, as a means to build capacity and sustain the work.

Following the conclusion of CEMELA's funding, Zandra de Araujo, Sarah Roberts, Craig Willey, and William Zahner continued to meet regularly. These meetings focused on examining intersections among these early career scholars' work related to the mathematics education of ELs. To date these meetings have resulted in a number of national presentations at the annual meetings of the National Council of Teachers of Mathematics, the American Educational Research Association, and PME-NA. Currently, this group is working on several manuscripts and follow-up studies related to the preparation of teachers to work with ELs. Perhaps most notable is an extensive review of the international literature focused on mathematics and ELs.

The Mathematics Education and ELs Working Group met at PME-NA in 2015 (de Araujo et al., 2015) and 2016 (de Araujo et al., 2016). At those meetings, we brought together a diverse group of about 30 researchers who started working together on several projects related to the mathematics education of ELs (see descriptions of these projects in the section below titled *Previous Work of the Group*). Our aim for the 2018 Working Group is to provide a space for these scholars to continue their work and bring new scholars into the fold.

Previous Work of the Group

The 2015 and 2016 Working Groups (de Araujo et al., 2015, 2016) began with whole group discussions aimed at examining five aspects related to the mathematics education of ELs including: a) Student Learning; b) Family and Community Resources; c) Language Perspectives; d) Teacher Education; and e) Curriculum. In the following sections we briefly summarize our discussions and subsequent work in each of these areas.

Student Learning

Building upon situated and sociocultural perspectives (Moschkovich, 2002), the student learning group started from the premise that ELs, like all students, learn mathematics through a process of appropriating discourse practices, tool use, and perspectives of mathematics. In reviewing the literature on the mathematics learning of ELs, we have identified a need to understand better how research in mathematics education at large is connected with research on the mathematics learning of ELs. Much of the content-focused work in mathematics education is isolated from research on how ELs develop specific mathematical understandings. Previous discussions at this working group have supported ongoing research and development efforts focused on bridging the literature on supporting ELs in mathematics classrooms and the literature on students' mathematics learning through focused instruction.

Family and Community Resources

Families and communities can serve as resources for ELs in their mathematics learning in myriad ways. Families can advocate for their children and provide and support learning experiences both in and out of the classroom. Communities can also provide a wealth of support mechanisms and learning possibilities. Moll et al. (1992) described how students studied candy making and selling within their neighborhood to explore mathematics within this context, such as discussing and analyzing production and consumption. In doing so, the teachers and students acknowledged the value of these community experiences. Additionally, Civil and Bernier (2006) explored the challenges and possibilities of involving parents in facilitating workshops for other parents around key math topics. These studies and others like them illustrate the promise of family and community resources in fostering ELs' mathematics learning. At our 2015 meeting, Civil shared her recent work on how school language policies impact ELs' engagement and how teacher educators can draw on family and cultural resources in support of ELs. We followed up on this work during our 2016 with small group discussions.

Language Perspectives

Teachers' and researchers' conceptions of language, second language acquisition, and bilingualism affect teaching and learning mathematics for ELs. In 2015, Judit Moschkovich shared her work that highlighted how perspectives of language, second language acquisition, and bilingualism appear in both theory and practice. We also discussed, in particular, how work focused on ELs can draw on current work on language and communication in mathematics classrooms, classroom discourse, and linguistics. Looking for these intersections and connections was crucial because it ensures that work in mathematics education is both theoretically and empirically grounded in relevant research, and it will prevent researchers from reinventing wheels.

Teacher Education

Much of the prior work on teacher education related to ELs has focused on more general strategies (e.g., sheltered instruction, as in Echevarria, Vogt, & Short, 2007), such as using visuals, modifying texts or assignments, and using slower speech. We argue there is a need for content-specific support for mathematics teachers of ELs. At our previous meetings, we explored ways to support teachers, both pre-service and in-service, in better understanding the strengths, and meeting the needs, of ELs in the mathematics classroom.

During the 2015 and 2016 Working Groups, the teacher education subgroup focused on the primary issues that arise in the preparation of teachers to teach ELs at the various institutions. As a group we recognized that there were few attempts to include the teaching and learning of mathematics to ELs beyond the states where there was a high population of ELs. Given that some of the group members were meeting for the first time, a significant portion of the allotted time was spent sharing the details of the research we did and our interest in being part of this particular subgroup. One of the members shared a survey about examining preservice teachers' conceptions about teaching mathematics to ELs and the other members agreed to administer the survey at their locations. Together, the responses will provide us with some insight about possible conceptions that need change and the steps we can take to make that happen. The group has stayed in touch online and continue the discussions about potential collaborations.

Curriculum

In 2015, the curriculum subgroup focused on the role of textbooks, specifically teachers' guides and student work pages, in demonstrating how one might approach supporting ELs in building mathematical understanding and developing mathematics language. We inquired about the process publishers undergo to incorporate and offer support to teachers. What assumptions do they make? Who do they consult? What motivates them to invest in serving ELs better? What is/are their end goal(s)? The group decided to conduct an analysis of various middle grades curriculum to ascertain what supports and guidance are offered to teachers. It was suggested that we might build on the work of Pitvorec, Willey, and Khisty (2010), who explored the features of Finding Out/Descubrimiento (FO/D) that proved to be successful with bilingual children of migrant families in the 1980's and partially contributed to the development of complex instruction (Cohen, Lotan, Scarloss, & Arellano, 1999).

At the 2016 meeting, this group continued to examine textbooks to understand better the supports they provide for ELs. Participants considered language issues in mathematics texts for ELs, especially as related to word problems and assessment items. We shared a short literature review of relevant research on linguistic complexity and vocabulary for mathematics word problems. Based on that research, we summarized recommendations for addressing language complexity and vocabulary in designing word problems for instruction, curriculum, or assessment. We then used examples of released sample Smarter Balanced Assessment Consortium items to illustrate how to apply those recommendations to designing word problems and to designing supports for ELs to work with word problems. Several of the participants have continued this work examining curriculum accommodations for ELs and are completing a research study based on the work started at the 2016 Working Group.

Aims for the 2018 Working Group

Previous meetings of this Working Group brought together a large and diverse group of attendees. For example, in 2016 there were approximately 30 attendees including teachers, preservice teachers, researchers, graduate students, and teacher educators from a range of institutions. In light of the variety of contexts from which the attendees came and the attendees' various career stages, we have worked to reconceptualize the Working Group in order to offer substantial benefits to all in attendance. The result is a highly interactive, three-day series of meetings focused on bridging past research findings and looking forward to new avenues for research and practice guided by the following objectives: *(1) Sharing current perspectives on extant research related to mathematics and English learners, (2) Understanding venues for* *dissemination of research on ELs, including novel outlets that connect research to practice, and (3) Fostering new collaborations and supporting further connections among researchers.* In the following section we provide an overview of each of the sessions in relation to these aims.

Plan for the 2018 Working Group Sessions

During the three sessions in 2018, participants will continue the work of the subgroups and bring new members up to date on the group's prior activities. In participating in the three sessions, participants will work to: a) clarify research questions, b) refine research tools, methods, and analyses, c) explore connections among different projects and studies, and d) discuss further collaborations and research on learning and teaching mathematics in classroom with English learners.

Session 1: Introductions and Brief Reports

The goals for the initial session are to allow participants to meet fellow attendees and to share current perspectives on extant research related to mathematics and English learners. The organizers will present brief reports on the work that resulted from the 2015 and 2016 Working Groups. Each of these brief presentations (5-10 minutes) will focus on the conference theme of "Looking Back, Looking Ahead." We will preview the schedule for this year's Working Group sessions.

Activities

- Introduction and overview of the Working Group including introduction to the Google Community.
- Brief presentations by panel members from each of the subgroups providing overviews of research projects with specific examples of how researchers have designed the studies. The purpose is to provide an overview and update of scholarly activities that were initiated at the 2015 and 2016 Working Group.
- Following the presentations, participants will discuss specific questions posed by the subgroups and aims for the subgroups' work at the 2018 meeting.

Guiding Questions

1. What research has been done in relation to the Working Group's prior meetings and avenues exist for future work?
2. Which aspects of studies focusing on English learners do you find most puzzling? Most useful? Most misunderstood?
3. What are the goals for the 2018 Working Group?

Session 2: Interactive Data Analysis

During Session 2 we will engage in a joint exercise focused on data analysis, using data from Zahner's ongoing research in linguistically diverse high schools to motivate a discussion of research methods, tools, and questions.

Activities

- Introduce a focused set of data for discussion (videos, transcript, and written work from two 9th grade ELs' problem-based interviews).
- Consider the interview tasks and discuss potential foci.

- Break into small groups. Immerse selves in data for 45 minutes, discuss guiding questions using the data as touchstone for discussion.
- Share results of small group discussions with larger group.
- Facilitated discussion focused on the following set of questions.

Guiding Questions

1. What theories and theoretical frameworks have informed the design of your research project(s)?
2. How do sociocultural theories of learning mathematics and language allow for a non-deficit view of ELs' mathematics reasoning?
3. How might your work inform theory building in studies of mathematics learning and teaching for ELs? How can work on this student population expand our theoretical lenses?
4. What issues and challenges have you faced in designing studies and analyzing data?

Session 3: Breakout Groups and Next Steps

Given the diverse backgrounds and experiences of attendees of our prior working groups, our final session will allow attendees to engage in small group discussions aligned with their particular interests. The organizers will lead subgroups as described below.

- **Subgroup 1: Diving deeper into the data**. This subgroup will focus on continuing the work from the prior session. Zahner will continue to guide the participants in further analysis and open space for further discussion of the data and avenues for future research.
- **Subgroup 2: Diving into the translation of research for non-researchers**. This subgroup will focus on ways in which to researchers can communicate their findings with the general public. Willey will share his experiences writing policy briefs and open access papers for practitioners, policy makers, and community members.
- **Subgroup 3: Diving into teaching.** In this subgroup, de Araujo will lead discussion on how to take what we have learned from research into the preservice mathematics methods classroom. The group's discussions will focus on studying our teaching practice in relation to ELs and ways of sharing lessons and activities with other teacher educators.
- **Subgroup 4: Diving into dissemination.** Roberts will lead this small group in a discussion of publication venues that are open to scholarship related to the mathematics education of ELs. She will frame the discussion in what was learned from the organizers' review of literature on the mathematics education of ELs. She will also discuss funding opportunities for research related to this work and questions raised by our literature review.

We will close Session 3 with time to review group progress and discuss next steps for our work. Meeting notes, work, and documents will continue to be shared and distributed via our Google Community (https://plus.google.com/communities/104376842129206334879) and corresponding Google Drive folder (https://goo.gl/EXhUVm). The use of Google Community allows members to create an institutional memory of activities during the Working Group that we have continued to use and add to following the 2015 and 2016 Working Groups. In addition to the Google Community and Drive resources, anticipated follow-up activities include planning for a continuation of the Working Group at PME-NA in 2019, an informal group meeting at

TODOS' 2020Conference, and organizing one or more collaborative writing projects on this topic.

Activities

- We will engage in a brief welcome activity focused on the prior session's data analysis activity and to recap session 2 and to ensure attendees have a chance to meet those in attendance.
- The organizers will briefly introduce the four subgroups and invite attendees to select a group to join for continued collaboration.
- The subgroups will work to discuss their given focus and possible directions for continued collaboration.
- The organizers will bring the groups back together to debrief the subgroup discussions.
- We will end with a discussion of next steps for continued collaboration, particularly via the Google Community

Guiding Questions

1. How might we take what we learned from the data analysis activity and apply it to your work researching and teaching the mathematics education of English learners?
2. How will we disseminate our work?
3. What are the next steps in continuing this work?

Follow-up Activities

We anticipate that this Working Group will again attract other researchers interested in issues related to the mathematics education of ELs. Therefore, an important component of this third meeting of the Working Group will be to maintain current relationships while also continuing to establish connections with other interested researchers in order to build opportunities for future collaborations. We will provide space for new researchers to contribute to our collective work, to suggest new directions, and to add to the growing body of research on mathematics and ELs. At the first session of our Working Group, we will share our ongoing online Google Community, which uses Google applications (Hangout, Groups, Drive, etc.). Google's applications are freely available and allow for a number of collaborative opportunities, including video conferencing, group messaging, collaborative document development, and shared web and social media space. Through this collaborative Google Community, we have organized follow up meetings both virtually and at conferences such as TODOS and the NCTM Research Conference. These meetings, both face-to-face and virtual, allow us to set concrete goals in preparation for the creation of a Working Group proposal for PME-NA 2018 to continue our work.

In addition to these short-term goals, we have several longer-term goals for this Working Group, depending on which groups individuals join during their time on days 2 and 3. First, for those who *dive into data* will consider further collaborations will extend with a Google group where individuals can connect with one another as they consider their own data dives around mathematics and ELs and where to go next with this work. Second, those who *dive into translating research* will work together beyond the conference to consider white papers and publications with broader audiences, particularly teachers. This will also be an opportunity to engage in efforts to transform the way mathematics curriculum is developed and enacted with respect to enhancing access and engagement of ELs. Third, those who *dive into teaching* will consider collaborations around enhancing PSTs' work with ELs and the development of actual lessons and activities beyond the conference for doing this work. Finally, those who *dive into research* will consider friendly publication venues, set-up writing groups, and identify future research partnerships.

We propose a working group that will bring mathematics education researchers together to explore how immersive spatial display technologies (e.g., room scale virtual reality) can be used for the teaching and learning of mathematics. The sessions will provide participants with the opportunity to explore a range of virtual worlds that are accessible via the HTC Vive, including mathematics-specifics environments that were designed by session organizers. The working group will provide a venue where participants can work together to plan research studies, discuss instructional activities, and design virtual environments for making and exploring mathematical figures. Our group aims to look ahead to a time in the near future–when immersive spatial displays are as commonplace as mobile phones–and anticipate the research, design, and development that can guide how these technologies will be integrated into schools.

Keywords: Virtual reality, augmented reality, dynamic mathematics, spatial thinking

Motivation

The commercial release of the HTC Vive (April, 2016) marked the beginning of a new era for representing and interacting with information. The Vive is an example of a technology that can host immersive, room-scale virtual reality experiences. The experiences are immersive because one's visual and aural senses are saturated by the sights and sounds of a virtual world. Room scale virtual reality experiences are distinct from stationary experiences, such as those that can be supported by phone-based viewers (e.g., Google cardboard, Gear VR). In room scale virtual reality, one's physical location within a physical room is used to determine one's position in a virtual world. This location tracking allows users to have direct control over where they are in a scene, and local movement in a virtual world is linked to one's movements in the physical world. Room scale virtual reality also affords users more options for interacting with virtual environments than VR viewers, such as the ability to create virtual objects.

Room scale virtual reality is an example of an *immersive spatial display*—a technology that enables *space itself* to be the canvas for making inscriptions (Dimmel & Bock, 2018). We use the term *immersive spatial display* to bring a range of related technologies under the same heading, including augmented reality (e.g., the Hololens), holographic projection, and volumetric video. The capacity for making three-dimensional inscriptions in virtual space will open up new modes for making and exploring mathematical figures. An example of a mathematical activity that is possible with spatial inscriptions that would be infeasible without them is plane-and-sphere constructions (i.e., the three-dimensional analogs of compass and straightedge constructions; Dimmel & Bock, 2018).

The mathematical questions that pertain to generalizations of geometric constructions have been answered (Franklin, 1919). But before the advent of immersive spatial displays, it would have been difficult to engage in the activity of constructing spatial figures from the intersections of planes and spheres, such as the tetrahedron that is shown in Figure 1. The construction is the spatial analog of the compass-and-straightedge construction, from two congruent, intersecting circles, of an equilateral triangle: the three centers of the spheres determine the vertices of the equilateral triangle that forms the base of the tetrahedron, and a point of concurrency for the three spheres determines its apex and other equilateral triangular faces. The image shown in Figure 1 was captured from *HandWaver* (Dimmel & Bock, 2017a), a gesture-based virtual environment for making and exploring mathematical figures. Plane-and-sphere constructions are just one example of new types of mathematical activities that will be possible with immersive spatial displays.

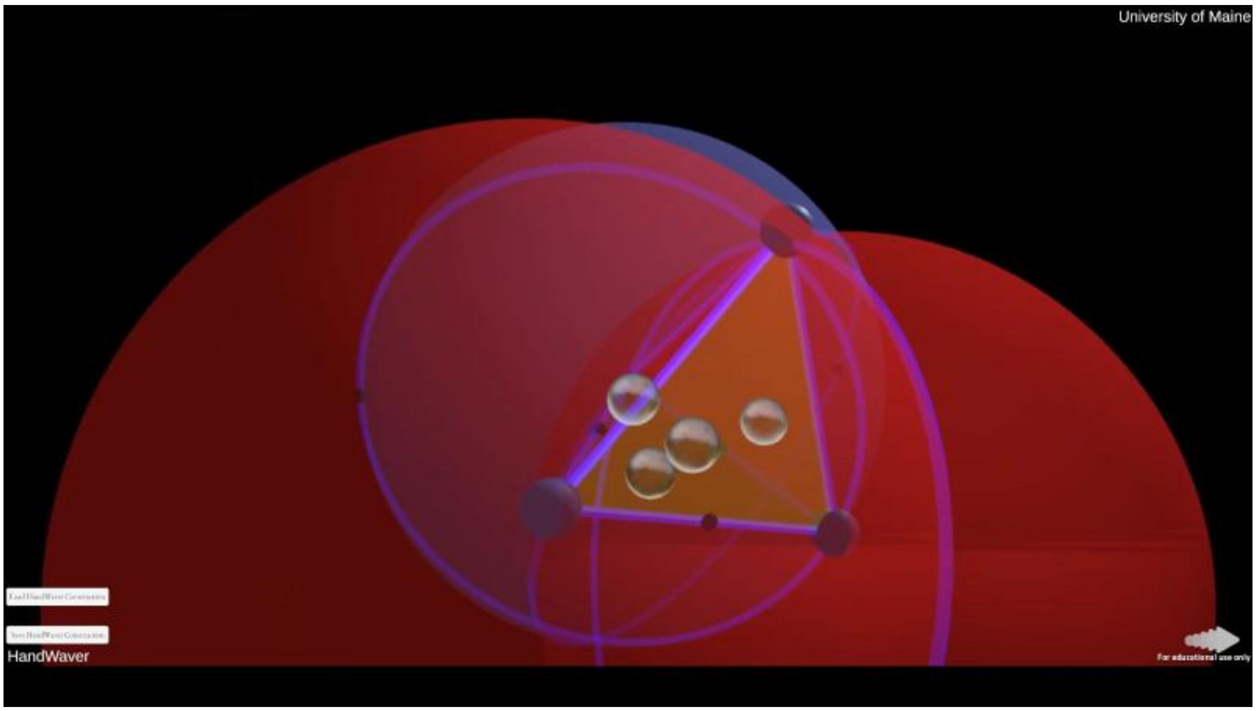

Figure 1. A tetrahedron constructed from three spheres.

That inscriptions have been confined to two-dimensional surfaces has constrained how mathematical concepts are canonically represented and influenced what subjects are taught, especially in the case of geometry (Franklin, 1919; Herbst et al., 2017). The fine-motor skill coordination that is necessary to create two-dimensional inscriptions has also limited who has the ability to inscribe and engage in mathematical representations. Spatial display technologies will make it possible to view and interact with dynamic, virtual, three-dimensional figures and allow learners to share a virtual space with the mathematical objects they are investigating. They have the potential to introduce new subjects of study into the school mathematics curriculum, such as inquiries into the mathematical properties of polyhedrons that go further than calculating the Euler characteristic of the platonic solids or explorations of higher-dimensional polytopes more generally.

Because spatial displays make available an additional dimension for representing mathematical figures, students could explore four-dimensional objects by investigating their three-dimensional projections. Limited versions of such experiences are possible with two-dimensional dynamic diagrams or physical models, but spatial displays make it possible to have the best of both worlds: They combine the graspability of physical things with the variability of dynamic diagrams.

Immersive spatial displays also present the possibility of allowing rich mathematical participation to students who are limited by geography, disease (hospital/homebound), or any other socio-economic or physiological deterrents. Two-dimensional surfaces have prevented some vulnerable populations from meaningful engagement in mathematics, and in some cases (e.g., children with cerebral palsy), the ability to create mathematical inscriptions all together (Nickels, Barrett, & Fralish, 2018). Immersive spatial displays allow users to circumvent or overcome their physical disability and create inscriptions that reveal, for the first time, their mathematical thinking and reasoning. The working group we propose is motivated by a broad question: How can the new modes of representing and interacting with information that are possible in spatial displays transform mathematics education?

Relevance to PME-NA Conference theme: Looking back, looking ahead

Mathematics has always been linked to display technology, from the sand flats used in the ancient world (Davis, 1972), to the chalkboards that are ubiquitous in mathematics departments (Greiffenhagen, 2014), to the digital displays that emerged in the latter part of the 20th century. And historically, new representations of mathematical figures have lead to the generation of new knowledge, such as when 19th century mineralogical collections that featured crystals-within-crystals helped Lhuilier and Hessel broaden the definition of three-dimensional figures that could be considered polyhedral (Lakatos, 1976, p. 15). Already, mathematicians have used the visual immersion possible with virtual reality viewers to model and gain new insights into non-Euclidean geometry (Hart et al., 2017a, 2017b). Whereas mathematicians will be the principals who use immersive spatial displays for generating mathematical knowledge, the mathematics education research community has an essential role to play in describing and researching the opportunities for mathematics education that are possible with these new technologies.

The working group we propose will bring together mathematics education researchers to explore what is currently possible with immersive spatial displays, collaborate to plan research studies and imagine mathematics-specific virtual environments, and consider the opportunities and challenges of using immersive spatial displays in mathematics classrooms. With current technology, it is still impracticable for every student in a class to have access to his or her own immersive spatial display (i.e., they are not yet a one-to-one technology); but as the state of the art for immersive spatial displays improves, the technologies will become smaller, less expensive, and will soon be as ubiquitous as mobile phones. When immersive spatial displays are commonplace, how will they be used for mathematics education? We are thus looking ahead to a time in the near future and attempting to anticipate the research, design, and development that can guide how immersive spatial display technologies will be integrated into schools.

Focal Issues

Research has suggested effective uses of technology in the teaching and learning of mathematics. We should rely on these findings as we consider the affordances and limitations of using immersive spatial displays. We should not use a new technology simply because it is available, rather we should be asking how we can best use this technology and if the benefits outweigh the costs. We note several key suggestions for effective technology use which can guide our initial attempts to integrate immersive spatial displays into mathematics education. We note researchers suggest using technology to engage students in exploring and conjecturing (e.g., Ball & Stacey, 2005, Cuoco & Goldenberg, 1996; Doerr & Zangor, 2002; Laborde, 2007; Wilson, 2008), to present and connect multiple representations (e.g., Cuoco & Goldenberg, 1996;

Doerr & Zangor, 2002; Laborde, 2007; Lee & Hollenbrands, 2008; Wilson, 2008), and to support students as they work with data or reason from cases (e.g., Cuoco & Goldenberg, 1996; Doerr & Zangor, 2002; Lee & Hollenbrands, 2008).

We should point out that we do not see these three uses of technology as mutually exclusive and in fact imagine ways in which there can and should be overlaps or interaction among the three. We do not suggest these three uses of technology as the only possible effective uses, but rather as examples and starting points as we set out to explore the potential role of immersive spatial displays in the teaching and learning of mathematics. This work will be guided by essential questions that pertain to student cognition, instructional design, teacher professional development, and assessment: How do immersive spatial displays affect student mathematical conceptions? What new mathematical learning experiences are possible with immersive spatial displays? How can immersive spatial displays be used as an instructional technology? What supports do mathematics teachers require to meaningfully incorporate immersive spatial displays into their classes? How can we design assessments that will measure what students learn by exploring immersive mathematical worlds?

An additional focal issue concerns the use of theory in research related to immersive spatial displays. Until this point in time, theories in mathematics education have acted as multiple lenses for examining our data. They have answered the question: *How does the theory make meaning for the data?* Immersive spatial displays, however, have the potential to significantly disrupt what is known about mathematical thinking, learning, and teaching. Inherently, they pose textual, lexical, and semantic questions as to what counts as inscriptions—moving beyond analysis of word-based text and 2-d graphical representations. Immersive spatial displays provide, at minimum, data that is not normally or easily accessible—e.g., real-time tracking on the user's head, body, and gestures, and the user's first-person point-of-view of their activities in the environment. Thus, the question, *How does the theory make meaning for the data?* is, on its own, insufficient. We must now ask, *What does an immersive spatial display do to the theory?* To address this focal issue, we will begin to consider: What substantive theories within mathematics education are appropriate to immersive spatial displays regarding students' schemes and reasoning? What effects do immersive spatial displays have on students' progression through hypothetical learning trajectories and other known hierarchical theories of mathematical learning?

Session Organization and Participant Engagement

Session goals

One goal of our proposed working group is to provide a setting where participants can explore the virtual worlds that are possible with immersive spatial displays. While spatial display technologies have been commercially available since April, 2016, they are still relatively novel. We believe there will be value to the PME-NA community if we provide a setting where mathematics education researchers can learn first hand about the kinds of experiences that are now possible in virtual worlds. Our second goal is to provide a venue where participants can work together to plan research studies, discuss instructional activities, and design virtual environments for making and exploring mathematical figures. Throughout each session, participants will be engaged in the working group by exploring virtual environments, working collaboratively to examine the potential of immersive spatial displays for mathematics education practice and research, and discussing how the potential of immersive spatial display technologies can be used by teachers in schools.

Each session will feature some time when participants can work in small groups to explore different virtual environments, followed by small group and whole group discussions. During the discussions, participants will describe what they did in the virtual environments, what they would have liked to do, and how they see spatial display technologies as relevant to mathematics education. The organization of each session will be open and flexible so that participants will have the opportunity to shape the work that we do during the three days of the conference. The session plans that we describe below are intended to give some idea of the different types of activities participants' would be engaged in throughout their participation in the working group. Session organizers will draw on their experience conducting focus group studies of secondary mathematics teachers' encounters with immersive virtual worlds to facilitate small group discussions.

Session 1: Introduction to Immersive Spatial Displays

The session will begin with a presentation (< 10 minutes) that describes the technological state of the art and considers the affordances for representing mathematical concepts that are possible with currently available immersive spatial display technologies. Following the presentation, participants will break out into four groups (6-8 participants per group) and take turns exploring virtual environments (<60 minutes). The environments that will be available to participants will include commercially available products (e.g., *CalcFlow*, *TiltBrush*, *Blocks*) as well as products that are under active development by session organizers (e.g., *HandWaver, LatticeLand*). Each group of participants will have access to a head-mounted display, and each session organizer will work with one group of participants. The goal for the first session will be to ensure that every participant that wants to explore the virtual environments has the opportunity to do so. Each of the session organizers has experience introducing new users to immersive virtual reality, and the session organizers will work with participants to make sure that they are comfortable. Once every participant has explored the virtual environments, we will convene as a large group and participants will discuss their experiences (remainder of session).

Session 2: Research and Design with Immersive Spatial Displays

For the second session, participants will start in their breakout groups. Each group will have access to a head mounted display that participants can use at their discretion to explore virtual environments. The first activity (<30 minutes) will be small group discussions at each table, each of which will be facilitated by one of the session organizers. The purpose of the opening discussion will be to brainstorm ideas about how the virtual environments that were surveyed during the first session could be used for mathematics education research. After the breakout discussions, participants will share their ideas with the whole group (<20 minutes). Session organizers will then present to the whole group about mathematics education research that has been conducted with immersive spatial displays. Nickels and Cullen will present about their work using *TiltBrush* to investigate children's conceptions of units of measure (<10 minutes). Dimmel and Bock will present their work designing and developing mathematics-specific environments for use in room scale virtual reality (<10 minutes). A discussion across both presentations will follow (<10 minutes). For the final activity of the second session, participants will break out in small groups again and work together to design virtual environments that could be supported by the immersive spatial display technologies (remainder of session).

Session 3: Immersive spatial displays as instructional technologies

The third session will focus on how immersive spatial display technologies could be used in mathematics classrooms. The session will begin with a short presentation (<10 minutes) during which session organizers (Dimmel and Bock) will describe their work designing and installing a virtual makerspace in a rural Maine school. Participants will then breakout into small groups and discuss how immersive spatial displays could be used by teachers in schools (<30 minutes). Participants could work together to design instructional activities, discuss strategies for how the technologies could be equipped in schools, and consider the pedagogical challenges of teaching with a technology that, for the near future, will remain impracticable to implement one-to-one. During the breakout session, each group will be able to use an HTC Vive as needed to test ideas or ground their discussion in the specifics of the virtual environments. The remaining time will be used for each group to share their ideas about using spatial displays as instructional technologies (<15 minutes) and a final, whole group discussion that reviews the work we did together across all three sessions (<35 minutes). The final group discussion will also provide an opportunity to plan for further collaboration among participants in the group.

Anticipated Follow Up Activities

The work that we begin at PME-NA 40 will be sustained by several anticipated follow up activities. Each working group session will feature ample time for participants to work together in breakout groups to explore and discuss existing virtual environments or to imagine virtual environments they would like to be developed. Following the conference, the connections participants make through working together during the breakout sessions will create opportunities for participants to plan collaborative projects that are linked to immersive spatial displays. For example, participants could work together to plan collaborative projects, design instructional activities that could be used as the basis for teaching experiments, or propose studies that could be conducted by a network of researchers at different universities.

The session organizers have experience equipping spaces with the hardware that is necessary to conduct research with immersive spatial displays, and we could advise interested participants about how to set up such equipment in their own research labs. For participants that are interested in designing and developing immersive virtual environments, we could point them to open-source projects and to resources for getting started using the Unity development engine. To facilitate these ongoing discussions, we will create an immersive spatial displays *slack* channel, use folders in Google drive to share resources (e.g., literature, proposals, manuscripts in progress), and, if there is sufficient interest from participants, we could create a mathematics in immersive spatial displays website that could serve as an information clearing house. We also anticipate that we would continue to convene the working group at future meetings of PME-NA.

harringtonr@mail.wou.edu

The purpose of this working group is to understand how teachers are implementing digital curricula to teach elementary mathematics, to explore best teaching practices for using digital curricula, and to understand how students are learning from digital curricula. We propose a working group on digital curricula that focuses on the themes of: access, equity, and empowerment; data generation/use; mathematical content; motivation and mindset; and nurturing NCTM Mathematics Teaching Practices and Common Core State Standards for Mathematical Practices. The overarching goals are to:

1. *Understand and develop ways to support teaching and learning with digital curricula,*
2. *Create a community that will continue to grow and learn and initiate long-range projects to improve teaching and learning with digital curricula, and*
3. *Serve as a forum to spark conversation and establish a research agenda on teaching and learning mathematics with digital curricula.*

During our time at the conference, each theme group within the working group will work toward: (a) identification of the issues that surround the theme, (b) recommendations for a research agenda, and (c) initiation of work on potential data collection tools.

Keywords: Curriculum Analysis, Technology, Elementary School Education, Middle School Education

Across the nation, schools are moving toward one-to-one capability with technology in every classroom. As districts seek ways to make best use of newly purchased technology, school spending on digital curricula is rapidly increasing: from $1.8 billion in 2013 to $4.8 billion in 2014 (Cauthen, 2017). Pepin, Choppin, Ruthven, and Sinclair (2017) propose a definition for "digital curriculum materials/resources/programmes" (DCR):

> Curriculum materials that are programmatic in concern: specifically, organised systems of digital resources in electronic formats that articulate a scope and sequence of curricular content. It is the attention to sequencing—of grade- or age-level learning topics, or of content associated with a particular course of study (e.g., algebra)—so as to cover (all or part of) a curriculum specification, which differentiates DCR from other types of digital instructional tools or educational software programmes (p. 657).

Pepin et al. (2017) contends that this definition is "distinct from the broader literature on instructional technology, though clearly there is some overlap" (p. 647). For the purpose of this working group, we plan to adopt this definition under the umbrella of "digital curricula." We contend that a broader definition allows participants to think more openly about digital curricula.

In 2016, spending on digital curricula increased by 25% over 2015, so that spending on digital curricula "now exceeds all K12 spending by $3.5 Billion" (Kafitz, 2017, n.p.). The Bill and Melinda Gates Foundation study (2015) found that 60% of elementary teachers believe digital tools are effective in teaching mathematics. While some educators may view a one-to-one classroom—where each student has access to one technology device (e.g., laptop, tablet, smartphone)—as a means to increase academic outcomes (Sauers & McLeod, 2012), other teachers may view a one-to-one classroom as detrimental to students' creativity, self-concept, or socio-emotional skills (Gardner & Davis, 2013).

With the surge of digital curricula, it is critical that enactment of that curricula enables rich mathematics teaching and learning within the classroom. We believe that such rich mathematics teaching and learning is best understood through the lens of the NCTM (2014) Mathematics Teaching Practices and the Common Core State Standards for Mathematical Practice (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010), and that these practices and standards (see Table 1) are seamless within the context of digital curricula.

Table 1: NCTM Mathematics Teaching Practices and CCSS for Mathematical Practices

NCTM Mathematics Teaching Practices	CCSS for Mathematical Practices
1. Establish mathematics goals to focus learning. 2. Implement tasks that promote reasoning and problem solving. 3. Use and connect mathematical representations. 4. Facilitate meaningful mathematical discourse. 5. Pose purposeful questions. 6. Build procedural fluency from conceptual understanding. 7. Support productive struggle in learning mathematics. 8. Elicit and use evidence of student thinking.	MP1: Make sense of problems and persevere in solving them. MP2: Reason abstractly and quantitatively. MP3: Construct viable arguments and critique the reasoning of others. MP4: Model with mathematics. MP5: Use appropriate tools strategically. MP6: Attend to precision. MP7: Look for and make use of structure. MP8: Look for and express regularity in repeated reasoning.

Given the emerging availability of digital curricula, we believe that more attention must be given to supporting teaching and learning with digital curricula and to creating a research community that will discuss and further establish a research agenda on teaching and learning with digital curricula. Therefore, we propose a working group on digital curricula that focuses on the themes of: access, equity, and empowerment; data generation/use; mathematical content; motivation and mindset; and nurturing NCTM's Mathematics Teaching Practices and the CCSS Standards for Mathematical Practice.

Overview of Literature Related to Teachers' Instructional Choices

Research has reported that the teacher's role in implementing new curriculum is consequential for student outcomes (Remillard, 1999; Sherin & Drake, 2009; Son & Kim, 2015, 2016). Some teachers embrace new curricula to meet the goals of reform, while other teachers consciously or unconsciously make changes and bypass the goals of reform (Sherin & Drake, 2009; Smith, 2000). Thus, the decisions teachers make about curriculum can enhance or hinder students' understanding of mathematics (Nguyen & Kulm, 2005).

Teachers develop curriculum strategy frameworks to implement new curriculum in the classroom. Implemented curricula can take three forms: written, intended, and enacted (Stein, Remillard, & Smith, 2007). The *written curriculum* is sterile in itself. Therefore, teachers receive guidance or "strategy frameworks" from professional development about the *intended curriculum*. Curriculum authors also foreground and highlight particular approaches and mathematical ideas. Curriculum materials mediate teachers' decision making while, at the same time, a teacher's orientation toward such materials reflects that teacher's characteristics, prior experiences, perception of the intended goals, and personal goals that influence instructional decision making and ultimately, the *enacted curriculum*, or what actually takes place. District- and school-level support, professional development, and communicated perspectives can also influence teachers' instructional choices and effectiveness in implementing the curriculum.

Gender can also be a factor in digital curricula implementation, although research is mixed. Some research indicates that female teachers tend to be less confident with technology and integrate it into their instruction less (Markauskaite, 2006; Wozney, Venkatesh, & Abrami, 2006), while other studies indicate the gap has reduced (Yukselturk & Bulut, 2009). Duration of teaching experience has also been found to influence use of technology in classrooms (Hernandez-Ramos, 2005).

The SAMR model can be used to classify teachers' instructional choices in leveraging digital technologies (Puentedura, 2013). In the *Substitution* level, digital technology is simply substituted for analog technology. For example, the elementary teacher substitutes paper worksheets for digitized PDFs, but everything else remains the same. *Augmentation* uses technology in place of a previous task, and the use of technology improves the task. In a third-grade classroom, for instance, instead of a teacher-led, whole-class lesson in which the teacher explains a mathematical task, students use tablets to read or listen to an explanation, while English language learners listen to the explanation in their first language. At the *Modification* level, technology integration requires significant redesign of a task. For example, instead of using worksheets with the same problems for every student, students complete a set of problems using a digital curriculum that adapts to where students are in their thinking. Finally, the *Redefinition* level uses technology to create novel tasks. For example, instead of teaching students a skill and having them practice it and then apply it to solve word problems, the teacher poses a problem, each student decides what skills they need to solve that problem, and then they individually access web-based instruction on those skills. The technology enables students to drive the learning process in a way that was not possible before; thus, students' activity and engagement with mathematics is redefined.

Overview of Literature Related to Digital Curricula

The digital curriculum program iXL found through self-funded research that although use of their program in California ranged from 1 minute to 100 minutes per week in the classroom, there was a strong positive correlation between iXL usage and state test scores (Empirical Education, 2013). A randomized control study of the Odyssey program with fourth-grade students found that use of the program for 60 minutes per week did not significantly increase students' achievement (Wijekumar, Hitchcock, Turner, Lei, & Peck, 2009). Salman Khan, founder and executive director of Khan Academy (KA), recommended using KA to personalize instruction, freeing up class time for engaging, high-yield activities like student discourse and meaningful collaborative projects (Khan, 2012). Khan added, "ironically, the technology makes the classrooms more human for the teachers and students. It has also made the teachers that much more valuable" (Weltner, 2012, n.p.). Contrary to Khan's assertion however, a small study by Cargile and Harkness (2015) found that KA was not used to foster more active learning in the classroom; nor was instruction customized to students' progress and achievement levels.

Other researchers contend that digital curricula have the potential to transform teaching and learning and allow for frequent updating, use of multimedia, increased interactivity, connection to virtual communities, varied socialization, reduced costs in production and distribution, customized instruction, ongoing assessment, and reporting of student progress (Abell, 2006; Fletcher, Scaffhauser, & Levin, 2012; Mayer, 2003; Selwyn, 2007; Zhao, Zhang, & Lai, 2010). Digital curricula designs can cover a wide spectrum; however, Confrey (2016) identifies specific design decisions and design principles that should be the foundation for all digital curricula. When addressed, these principles (e.g., "*A workspace for deploying and using tools separated from lesson flow allows students to become independent and proficient tool users*." (p. 15)) lead to powerful resources that enable the NCTM Mathematics Teaching Practices and the CCSS Standards for Mathematical Practice.

Choppin, Carson, Borys, Cerosaletti, and Gillis (2014) analyzed how six digital curriculum programs leverage student learning experiences; support differentiation/individualization; and support socialization or communication through discussion boards, Google Docs, or other virtual spaces. Through this analysis, they identified two distinct curriculum types. Individualized learning programs (e.g., *ALEKS*, *Dreambox*) were programs "designed for use by individual students . . . with minimal teacher intervention with respect to the design of lessons or assessment" (p. 15). The digitized traditional textbook (i.e., *ConnectED*) included multimedia files, virtual tools, management and assessment systems, and communication features. Choppin (2016) expanded the number of programs to eight and extended to four types of programs: a) individualized learning programs; b) collection of digital lessons (e.g., *LearnZillion*); c) digitized versions of traditional textbooks; and d) a microworld environment (i.e., *Algebra in Action*).

Yerushalmy (2016) provides a more expansive idea of e-textbooks and includes three e-textbook models: interactive, integrative, and evolving. In identifying three models of e-textbooks, he warns that the models "are not distinct but are presented this way for clarity of the discussion, as each marks a key rationale or aspect of functionality" (p. 88). The authors of these e-textbooks can be teachers or other experts, and each of the three types of e-textbooks "can be either used as is or changed by its users (teachers or students)" (p. 88).

Overview of Literature Related to Teachers' Use of Assessment Data

Effective assessment data analysis is one tool to inform instruction, yet schools often lack the capacity to execute what research suggests (Marsh et al., 2005; Petrides & Nodine, 2005). To improve this issue, some school districts have allocated resources toward management information systems and professional development (see, e.g., Borja, 2006). However, research suggests that teachers are not using the resultant data to inform their classroom planning or instruction (Earl & Katz, 2006).

Teachers can use data to determine if students are responding to the digital instructional program, to identify students who are not making adequate progress, and to help in designing effective intervention programs for students who are not profiting from typical instruction (Fuchs & Stecker, 2003). Use of progress monitoring for individualized instruction has shown increases in learning achievement (Stecker, Fuchs, & Fuchs, 2005), yet less is known about progress-monitoring practices in mathematics, as compared to reading (Foegen, Jiban, & Deno, 2007). Research has focused on curriculum-based measurement (CBM) and computer adaptive tests (CATs). Specifically, CBM in mathematics for elementary and middle school consists only of computation and concepts/application measures (Fuchs, Hamlett, & Fuchs, 1999).

CATs are an emerging method for monitoring learning progress. One benefit of CATs is that the administration of items on a computer allows for subsequent items to be generated, based on the accuracy of a student's response. A program such as Dreambox can acquire about 50,000 data points per student per hour, tracking "a student's every click, correct answer, hesitation, and error" (Singer, 2017, n.p.). CATs can also provide a student or class profile of items learned or not learned. As Stecker, Fuchs, and Fuchs (2005) acknowledge, teachers need support in deciphering, and then effectively using progress monitoring results.

SRI Education (2014) conducted a two-year study of KA with 20 elementary, middle, and high schools in California, including more than 70 teachers and 2000 students in grades 5 through 10. Over half of the teachers (56%) reported reviewing student performance data at least once a week. With approximately 40% of teachers reporting that they reviewed student performance data less than once a month or not at all, questions remain about how teachers use real-time data to differentiate instruction and address specific individual, small-group, or whole-class learning needs.

Since formative assessment strategies such as communicating learning expectations, providing descriptive feedback, and adapting instruction based on feedback have positively influenced student learning (Hattie & Jaeger, 1998; Stiggins, 2005), it is imperative to investigate whether this holds true when teachers use digital curriculum assessments. Identifying the presence or absence of these assessment issues will help professional development focus on improved digital curriculum assessment strategies and inform teacher education programs on how to better prepare preservice teachers to use digital curriculum assessment.

Overview of Literature Related to Teachers' and Students' Disposition

The Association of Mathematics Teacher Educators' (2016) *Standards for Preparing Teachers of Mathematics* emphasizes that a positive disposition (i.e., attitudes, beliefs, mindset, motivation) toward mathematics is essential for successful mathematics teaching. Yeşilyurt, Ulaş, and Akan (2016) contend that "academic self-efficacy, teacher self-efficacy, and computer self-efficacy are important predictors of the attitude toward computer-assisted learning" (p. 592). A concern in regard to academic self-efficacy is that many elementary teachers bring their own mathematics anxiety with them into the classroom (Bursal & Paznokas, 2006; Haciomeroglu, 2014). Overall, about one-third of elementary teachers may feel anxiety about mathematics (McAnallen, 2010). On the other hand, teachers with confidence in their mathematics tend to better transform lower-cognitive-demand problems into higher-demand problems (Son & Kim, 2016). Furthermore, curricula, professional development, administrators, etc. can communicate conflicting perspectives about the nature of mathematics. For instance, mathematics can be seen as the development of isolated skills and knowledge, as a vehicle for interacting with one's world, or as the means of fostering citizenship and responsibility (Winter, 2001).

One way to positively influence disposition is to positively influence one's mindset. Dweck (2006) summarized decades of research showing that when students develop a "growth mindset," they believe the brain and intelligence can grow. On the other hand, those with a "fixed mindset" believe that you are born with a certain level of intelligence: either you are smart or you are not smart. Dweck suggests that the type of feedback students receive can influence students' mindsets. When feedback communicates that mistakes are learning opportunities and that learning takes time and effort, students are more likely to develop growth mindsets. Incentives have been shown to increase student motivation (Nguyen, Hsiech, & Allen, 2006), yet research also indicates that generic praise reduces persistence in children (Zentall & Morris, 2010). Digital curriculum includes different types of feedback and motivational strategies for students, such as badges and personalized avatars. When students receive personalized feedback on what they are and are not understanding, they can target their learning more efficiently.

Teachers' dispositions toward mathematics and toward using technology to teach mathematics will affect how they integrate digital curriculum into their instruction—which will, in turn, directly influence student outcomes. Similarly, students' dispositions toward mathematics and toward using technology to learn mathematics will affect their motivation toward mathematics, mindset about mathematics, and how they learn—or fail to learn—through digital curriculum. Learning about teachers' dispositions toward digital curriculum may help in understanding what influences their decisions to adopt, modify, or reject it. Furthermore, research on the types of feedback and motivational strategies digital curriculum provides students, and its effect on their dispositions toward mathematics, is needed.

Structure of the Working Group

To understand how teachers are implementing digital curricula to teach elementary mathematics, to explore best teaching practices for using digital curricula, and to understand how students are learning from digital curricula, the overarching goals of this working group are to:

1. Understand and develop ways to support teaching and learning with digital curricula,
2. Create a community that will continue to grow and learn and initiate long-range projects to improve teaching and learning with digital curricula, and
3. Serve as a forum to spark conversation and establish a research agenda on teaching and learning mathematics with digital curricula.

Theme Groups

The working group will achieve these goals by forming five theme groups:

- Access, Equity, and Empowerment: Digital curricula often enters schools with the promise of handling remedial issues in mathematics. The intention of this working group is to examine issues with the teaching and learning of mathematics involving students with learning disabilities, learning differences, or difficulties in mathematics; talented and gifted students; and concerns about disproportionate access to learning. This group will discuss who benefits from digital curricula use and if using digital curricula is influencing broader participation in STEM.
- Data Generation/Use: Participants in this theme group will discuss how to make sense of the abundance of data that can be generated by digital curricula to maximize student learning, the nature of that data, who should use such data and for what purposes, which data is most valuable for informing learning, and how teachers can be assisted in making data-driven instructional decisions to meet the needs of all learners.
- Mathematical Content: This theme group will discuss how digital curricula can support conceptual understanding, problem solving, procedural fluency, and strategic reasoning of mathematics. Participants will consider how to examine which features of digital curricula are most effective in aiding students' development of deep and flexible mathematics content knowledge.
- Motivation and Mindset: This theme group's focus will be issues and concerns with how digital curricula use influences students' motivation for learning mathematics and affects students' mathematical mindsets toward either "growth" or "fixed". This theme group will also consider how digital curricula use influences K–8 teachers' attitudes about mathematics and the teaching of mathematics.
- Nurturing the Standards for Mathematical Practices: The Mathematical Practices must be a central feature in the teaching and learning of mathematics. Participants in this theme group will discuss the impact of digital curricula on students' development of the Standards for Mathematical Practices through the Mathematics Teaching Practices. Discussion will also emphasize teachers' actions during non-digital curricula activities to enhance students' mathematical practices.

During our time at the conference, each theme group will work toward: a) identification of the issues that surround the theme, b) recommendations for a research agenda, and c) initiation of work on potential data collection tools.

Working Group Outline

The outline of each session is described in Table 2:

Table 2: Outline of Each Session

Session 1: *What do we know already?*		
	Activities	Guiding Questions
Whole Group (30 min)	Discuss proposed working definition of digital curricula. Discuss goals for the working group. Discuss proposed themes.	Examine digital curricula implementation through the five themes named above. Are these the right themes? Are there others?
Theme Groups (45 min)	Describe the nature and importance of the theme. Identify and categorize issues with digital curricula based on the group theme.	How is digital curricula being implemented in K–8 classrooms? What are we seeing in classrooms regarding the identified themes? What are components of the theme? Implications?
Whole Group (15 min)	Briefly report on Theme Group work. Identify next steps.	
Session 2: *What do we need to know and understand?*		
	Activities	Guiding Questions
Whole Group (30 min)	Set goals for the session.	What do we need to know and understand?
Theme Groups (45 min)	Begin writing a research agenda.	What are potential areas of research pertaining to this theme? What might that research look like? What type of data would be useful?
Whole Group (15 min)	Briefly report on Theme Group work. Identify next steps.	
Session 3: *How will we find out what we need to know and understand?*		
	Activities	Guiding Questions
Whole Group (30 min)	Set goals for the session.	How will we find out what we need to know and understand?
Theme Groups (45 min)	Establish a research plan. Initiate identification and design of data collection tools. Write group report.	What potential tools might be used to examine implementation of digital curricula through this theme? Write 5–10 questions you would want to see on a survey, 5–10 situations you would want to observe, and 3–5 interview questions for both teachers and students. What would be the structure and methods of the research?

		Write research plan and timeline.
Whole Group (15 min)	Report on Theme Group work. Identify next steps.	Groups share their action plan for further work. Who is willing to collect this data? Determine organization for the coming year/timeline.

Anticipated Follow-Up Activities

As a result of our working group discussion and research plan development, we anticipate several follow-up activities:

- Ongoing work with Google Docs for collaborative development of data collection tools for observations, surveys, and interviews;
- Online webinar in early January 2019 to finalize data collection tools and initiate data collection for the Spring 2019 semester;
- Online webinar in April 2019 to check in regarding data collection;
- Online webinar in July 2019 to initiate state data analysis; and
- PME-NA 2019 to reunite the working group and to bring together data across states. Analysis of the data across states will be used to initiate discussions on how to improve both professional development for inservice teachers and teacher preparation for preservice teachers.

Students' construction, coordination, and abstraction of units underlie success across multiple mathematics domains. Structures for coordinating units underscore notions of numbers as composite units (e.g., five is a unit of five and five units of one). In this working group, we seek to facilitate collaboration amongst researchers and educators concerned with composite unit formation and units coordination. The aim for this working group is two-fold: (1) to extend our research around units coordination to new grade levels; and (2) to collaborate with researchers who investigate students with learning differences in school settings to determine diverse students' mathematics learning trajectories.

Introduction

The phrase "units coordination" has many connotations. One meaning of the phrase refers to operations related to understanding place value, such as exchanging ten 1s for one 10 when executing arithmetic algorithms (e.g., Thanheiser, 2009). Other meanings involve relationships between measurement units, such as extensive measure equivalencies (e.g., 1 foot = 12 inches) or intensive measure definitions (e.g., speed = distance/time) (Smith & Barrett, 2017). In Steffe and colleagues' research program, the term "units coordination" refers to the mental operations of composing and distributing units involved in a numerical conception (Steffe, 1992). Units coordination is fundamental for distinguishing children's ways of counting - specifically the ways that students unitize, iterate, partition, disembed, and compose units. Researchers have investigated how ways of coordinating units are connected to students' learning within and across mathematics content domains, from additive and multiplicative reasoning to algebra (i.e., Hackenberg & Lee, 2015; Norton & Boyce, 2015; Steffe, 2017; Ulrich, 2015). For instance, Hackenberg and Lee (2015) described similarities and differences between units coordination with whole number units, fractional units, and variable units (e.g., linear algebraic equations); Ulrich (2015) described units coordination with signed integer addition.

In Steffe's 2017 plenary for PME-NA, he substantiated particular needs for investigating how children develop operations when coordinating units. The aim of this working group is to facilitate collaboration amongst researchers and educators concerned with units coordination for all learners. Our main goals are to extend our research around units coordination to new grade levels and to collaborate with researchers who investigate students with learning differences in school settings to determine diverse students' mathematics learning trajectories. Outcomes from these collaborative efforts could inform the development/revision of theoretical frameworks, learning trajectories for diverse populations, and professional development for educators.

Background and Theoretical Perspective: Composite Units – Old and New

We provide a theoretical background for units coordination (Norton & Boyce, 2015) focusing on units coordination in students' number sequences (Steffe, 1992), multiplicative concepts (Hackenberg & Tillema, 2009), and fractions schemes (Steffe & Olive, 2010).

Units Coordination

The construction of mathematical objects forms the basis for units coordination, as students rely on concrete, pictorial, fingers, symbolic numerals, and language to evidence internalized (being able to mentally re-imagine contextual actions) or interiorized (being able to draw on de-contextualized actions) actions. Unitizing, or setting an object or a unit aside for further action or activity (Steffe, 1992), is the basis for units coordination. Consider the construction of additive reasoning as an example. When considering how to add eight and seven, students might not yet see the cardinality of eight, counting a set of objects to create eight, then another set of objects to create seven, and finally combining the two sets, beginning at one to quantify the total. Should students see the cardinality of eight, they might use it as an input for solving the problem. They will count on from eight, using objects (cubes, fingers) to keep track of the addition (e.g., 8…9 [raises a finger], 10 [raises another finger]…). The double counting involved in this activity (e.g., **8**…, 9 (1), 10 (2), 11 (3), 12 (4), 13 (5), 14 (6), **15** (7)) promotes a coordination of the start value and the stop value. That is, eight, seven, and 15 are taking on some meaning as composites (8 and 7) and a unitized whole (15). Evidence of this meaning includes the breaking apart of one or both of the numbers to arrive at the total (e.g., 8 is 5 and 3; 7 is 5 and 2; 8 + 5 is the same as 5 + 5 + 3 + 2, or 15). This type of units coordination can be explained through the type of numerical sequence students produce and rely upon.

Number Sequence Types (INS, TNS, ENS, GNS)

Steffe and Olive (2010) described four counting sequences that children develop and evidence: (1) Initial Number Sequence (INS), (2) Tacitly-Nested Number Sequence (TNS), (3) Explicitly-Nested Number Sequence (ENS), and (4) Generalized Number Sequence (GNS). Each illustrates stages of children's units development and coordination.

Initial Number Sequence. Steffe (1992) explained that children who segment and interiorize number sequences have developed *Initial Number Sequence (INS).* Children who develop an INS are characterized by their counting of single units and then their segmenting of a numerical sequence (evidenced through "counting on" activity). When children segment numerical sequences, they are interiorizing patterned templates for counting, which allows them the ability to count on from a composite unit (e.g., developing one composite unit to use when counting on, 4…5-6-7-8). Thus, through counting actions, numerical patterns are developed and become interiorized (evidenced through less reliance on sensory-motor experiences; e.g., verbalizing counts, using fingers, or tapping) before being segmented into a composite unit.

Tacitly-Nested Number Sequence. Once children have developed composite units through their INS activity, they can begin to *coordinate* these composite units, treating the result of counting activity as <u>both</u> a unit to count on from and one to keep track of when counting. These actions evidence children's development of a *Tacitly-Nested Number Sequence (TNS).* Steffe (1992) explains that when children have a numerical sequence interiorized and segmented they can use their segmented numerical sequence as material for making new composite units within these numerical sequences. The awareness of one number sequence contained inside another, or *double-counting,* is an indication of TNS, as is a skip count (i.e., 4, 8, 16,…) to solve early multiplicative kinds of problems, such as how many 3's are contained in 12.

Explicitly-Nested Number Sequence. Children who are described as having part-whole number reasoning in place are capable of disembedding parts from wholes and developing iterable units of one. These children are described as reasoning with an *Explicitly-Nested Number Sequence* (ENS) (Olive, 1999; Steffe, 1992; Ulrich & Wilkins, 2017). Children capable of multiplicatively understanding a single unit and a composite unit without disrupting the whole are said to be operating with an ENS (Ulrich & Wilkins, 2017). The two given composite units (e.g., parts and whole) provide children material to coordinate while constructing a third composite unit; e.g., a unit of units of units (Steffe, 1992). This part-whole reasoning with abstract units provides children multiplicative number structures.

Generalized Number Sequence. Children capable of developing iterable composite units where units of units of units can be coordinated, are described as operating with a GNS. For example, Olive (1999) explained that when children are asked to find common multiples, they are required to keep track of two series of composite units (e.g., 3, 6, 9, 12; 4, 8, 12; 12. The LCM of 3 and 4 is 12). Children evidencing successful completion of tasks like this are described as using two iterable composite units (e.g., 3 and 4), while keeping track of the common composite unit in each sequence. At the root of much of this number sequence development, units development and coordination explain how and why children are capable of transitioning from additive/subtractive operative structures towards multiplicative/division operative structures towards rational number understanding.

Multiplicative Levels of Units Coordination

A student is said to assimilate with one level of units when she conceives of multiplication situations, such as seven iterations of four, by counting on from the first or second set of four by ones and double-counting the number of fours to reach a stop value (*e.g., **4**, **8**,…9-10-11-**12**; 13-14-15-**16**; 17-18-19-**20**; 21-22-23-**24;** 25-26-27-**28***). Here, the child has to model or carry out the situation by using internal (e.g., subvocal counting) or external (e.g., fingers or objects) representations. This is referred to as coordinating two levels of units *in activity*. Units coordination in activity is ephemeral: in a follow-up task, such as how many ones are in eight iterations of four, the student would likely repeat a similar process rather than count-on.

A student's use of strategic reasoning in such situations may be evidence that she *assimilates* the situation with two levels of units. For example, a student assimilating with two levels of units might conceive of seven iterations of four as five iterations of four plus two iterations of four (e.g., five 4s is **20**; 21-22-23-**24**; 25-26-27-**28**). As opposed to modeling the entire coordination, the child can *anticipate* breaking apart the composite unit of seven into five and two and use each of those parts to solve the problem. For a student assimilating with two levels of units, the result of operating is simultaneously 28 ones and 7 fours; hence a follow-up task of finding the number of 1s in 8 fours would not require building up from 5 fours again.

A student is said to assimilate with three levels of units when she can conceive of a situation such as seven iterations of four as resulting in three distinct yet coordinated units: (a) one unit of 28 that contains (b) seven units of four, each of which contains (c) two units of two. Students assimilating with three levels of units have flexibility to reason strategically with each of the units. For instance, a student assimilating with three levels of units might solve the task, "How many more twos are in 32 than in 28?" by reasoning that 32 is one more 4, which is thus two more 2s. This reasoning involves assimilating three levels of units, multiplicatively.

Norton, Boyce, Ulrich and Phillips (2015) conducted a cross-sectional analysis of 47 sixth-grade students' reasoning in whole number multiplicative settings in clinical interviews. Figure 1 displays descriptors of attributions of students' activities Norton and colleagues identified as corresponding with students' reasoning with one, two, or three levels of units. For instance, they describe students' activity when transitioning from reasoning with one level of units to reasoning with two levels of units with descriptors G-K (Norton et al., 2015, p. 62). Though there are commonalities with descriptions of students' counting schemes (e.g., descriptors C and J), the focus of the descriptors are more generally about how and whether students are able to flexibly reverse and reflect on their multiplicative reasoning.

Descriptors			
A. Iterates units of 1	E. Works with at least one level of units within a figurative three-level structure	I. Works with at least two levels of units within a figurative three-level structure	M. Assimilates three levels of units within a task
B. Builds composite units	F. Indicates a reciprocal relationship between the size and number of parts in a whole	J. Distributes composite units	N. Reflects on all levels within a three-level structure
C. Iterates composite units	G. Reverses multiplicative relationships	K. Immediacy of response	O. Conflates or confuses units
D. Uses multiplicative relationships	H. Builds a three-level structure	L. Flexibly works with a three-level structure	P. References the structure of units

Figure 1. Descriptors of counting schemes.

These stages of units coordination, as delineated in Norton et al.'s (2015) findings, comprehensively explains transitions children make from additive operations to multiplicative operations. These findings also explain fractional unit development, as recursive units coordination in which to act upon and explain how students develop fractions as mental objects.

Fractional Units

Reasoning with fractional units requires unitizing a fractional size, $1/n$th. When children first conceptualize fractional units, Steffe (2001) posited that they would reorganize natural number schemes to develop fractional schemes. Olive (1999) and Steffe (2001) argued that they would have to re-interiorize their units coordination operations, to consider a fractional unit as a result of *equi-partitioning* a unit whole into a size that, when iterated n times, would result in the size of 1. This re-interiorization of schema requires students to recursively develop and coordinate new composite units relationships (Olive, 1999). Thus, children's production of numerical sequences and their associated units coordination provide children necessary operations for their fractional units coordination.

To conceive of a fraction m/n as a number, one must understand m/n as equivalent to m $1/n$ths, n of which are equivalent to 1. In the case of $m > n,$ the meaning of $1/n$ must transform from thinking of $1/n$ as one out of n total pieces (a *parts-out-of-wholes scheme*) to thinking of $1/n$ as an amount that could be iterated more than n times without changing its relationship with the size of 1 (an *iterative fraction scheme*). This measurement conception of fraction (Lamon, 2008) involves coordinating three levels of units of nested units: 8/3 is 8 times (1/3), 1=3/3 is 3 times (1/3), thus an 8/3 unit contains both a unit of 1 and a unit of 1/3 within 1 (Hackenberg, 2010). Students in the intermediate stages of constructing such a measurement conception may reason about the size of proper fractions of form m/n by counting the number of parts of size $1/n$ within a whole of n/n. Such students are not yet iterating the amount of $1/n$, which limits their ability to iterate unit fractions beyond the size of the whole (Tzur, 1999).

Issues Related to the Psychology of Mathematics Education

Steffe's 2017 plenary included both a summary of contributions and important extant problems for mathematics educators pertaining to units coordination. Given these advances in research surrounding K-8 students' units coordination, our mathematics education field is still limited by the context in which students' units coordination develops and how preschool and high school students' units coordination may inform these trajectories. Further, Steffe (2017) proposes that about 40% of first grade students have very different learning trajectories than their peers, suggesting a need to develop alternative means in which units coordination may be developed by children. Finally, Steffe suggests that our field would benefit by investigating children's transitions in scheme development. For instance:

> It is especially crucial to investigate possible changes that indicate *fundamental* transitions between reasoning with two levels of units and three levels of units induced in the construction of quantitative measuring schemes and their use in the construction of multiplicative and additive measuring schemes (Steffe, 2017, p. 46).

One of our intentions for this working group is for researchers from different backgrounds to collaborate to work toward solving such problems. Consider in Smith and Barrett's review of research on quantitative reasoning, the following:

> [We] found it striking how often the same conceptual principles and associated learning challenges appear in the measurement of different quantities… Despite the clear focus in research on equipartitioning, units and their iteration, units and subunits… curricula (and arguably most classroom teaching) focus students' attention on particular quantities and the correct use of tools, as if each was a new topic and challenge. (p. 377).

Consistent with Arbaugh, Herbel-Eisenmann, Ramirez, Knuth, Kranendonk, and Quander's (2010) call to "develop mathematics proficiency in various school, cultural, and societal contexts" (p. 13), we aim is to connect units coordination research with other learning theories.

Unfortunately, many students with mathematics learning difficulties do not transition from two levels of units to three levels of units at the same pace as their more successful peers. In fact, the construction of ENS is one pervasive mathematical impediment for students with mathematics difficulties (Landerl, Bevan, & Butterworth, 2004). Compared to students without mathematics difficulties, students with mathematics difficulties develop less sophisticated strategies for number computation problems over time, suggesting a lack of a conceptual basis for ENS engagement *that actually plays a part in their later disability identification* (Butterworth, Varma, & Laurillard, 2011). Therefore, particular research programs with these foci are desperately needed to nurture multiplicative and rational number conceptions (Boyce & Norton, 2017; Grobecker, 1997; Kosko, 2017) and operations (Grobecker, 1997; Grobecker, 2000; Kosko, 2017; Norton & Boyce, 2015) for students who need our support.

By designing interventions with children's mathematics and their units coordination, the field has grown over the years, yet there is much opportunity for improvement. Relations between cognitive factors and test performance may be important, yet these relationships are only one way to conceptualize "cognition." Instead of focusing on aspects of students' working memory or processing, researchers can revolutionize access for these students by intervening on the *malleable cognitive factors that can be improved upon* through students' own development.

Research Designs and Methodologies

The primary methodology for investigating units coordination has been the radical constructivist teaching experiment (Steffe & Thompson, 2000). A main role of these teaching experiments is to generate (and refine) epistemic models of students' mathematics - models for how students with common underlying conceptual operations learn within a particular mathematics domain (Steffe & Norton, 2014). Such teaching experiments involve close interactions with a teacher-researcher modeling the dynamics of students' ways of operating longitudinally. Teaching experiment methodology is also used as part of design research (Cobb, Confrey, diSessa, Leher, & Schauble, 2003), to inform instructional approaches or interventions that could be "scaled up" to heterogeneous classroom settings.

Results from analyzing teaching experiments have also informed methods for assessing a child's ways of coordinating units at a particular moment. In addition to task-based clinical interviews (Clement, 2000), Norton and Wilkins (2009) created written instruments for assessing middle-grades' fractions schemes and operations associated with units coordination. These instruments have been used to validate conjectured learning trajectories for children's construction of schemes for coordinating fractional units (e.g., Norton & Wilkins, 2012). These instruments currently serve as tools for participant selection in teaching experiments with middle-grades students (e.g., Hackenberg & Lee, 2015). These instruments also serve as valuable opportunities for connecting results to classroom teaching and learning.

Consideration of these methodologies for researching units coordination suggests areas for collaborative work to build our understanding not only of the research programs Steffe (2017) described, but also opportunities and needs regarding related research domains. For instance, Norton and Wilkins' (2009) instruments have been modified to assess prospective teachers' units coordination with fractions (Lovin, Stevens, Siegfied, Wilkins, & Norton, 2016). Thus, research development with these methodologies are better served in collaborative designs to allow more perspectives in the design and analyses when determining students' mathematics.

First Aim: Extending Units Coordination Research

The first aim of this working group proposal is to extend units coordination research to investigations that include both older students and younger students. For instance, questions regarding whether differences in secondary students' units coordination persist beyond eighth-grade, and, if so, how these differences manifest in older students' learning, remain underexplored. In interview and teaching experiment settings, Grabhorn, Boyce, and Byerley (2018) have found that students enrolled in calculus in university do not necessarily coordinate three levels of units. Further expanding understanding of students' units coordination beyond eighth grade would contribute to the development of "coherent frameworks for characterizing the development of student thinking" (Arbaugh et al., 2010, p. 15).

In addition to studies focusing on relationships between units coordination and older students' mathematics, studies of pre-kindergarten children are also warranted. For instance, Wright (1991) found that kindergarten students had a wide variance in their number knowledge, suggesting critical mathematics learning occurs prior to the elementary school. With a significant dearth of research studies in the early childhood years (De Smedt, Noel, Gilmore, & Ansari, 2013), we posit that studies of young children are a critical area of research. Another potential need regards equity and access in mathematics education. Researchers might investigate whether analyses of students' units coordination provides insight to the mathematical reasoning of diverse and underserved populations. We envision collaborations around similar conceptual principles and learning challenges, to investigate units coordination of children enrolled in different grade levels and representing different population groups (i.e., special education, early childhood, secondary education, teacher education), which would allow more coherent mathematical learning theory and practical means in which to link research to mathematics classrooms.

Steffe (2017) estimated that about 40% of first grade students rely solely on perceptual material when counting all items (Counters of Perceptual Unit Items - CPUI) and that 45% of first grade students are capable of counting figurative unit items (CFUI), a particularly necessary step when interiorizing counting actions and developing "counting-on" activity (e.g., INS) (see

Figure 2). These estimates indicate that children entering early elementary school grades have not yet been able to internalize their actions and rely on relatively more abstract representations for number. Steffe further posits that these two distinct groups of children would require different learning trajectories, as they have different operational means and different conceptual material in which to coordinate for TNS and ENS activity.

With more U.S. students attending preschool programs and an increase of 48% in national funding towards preschool programs, it would be advantageous to develop research that could directly inform early childhood mathematics curricula (Diffey, Parker, & Atchison, 2017; Sarama & Clements, 2009). Also, given that these curricula should be coherently aligned with elementary grade mathematics curricula initiatives, it would serve early childhood curriculum designers to bridge research programs around number development in early elementary grades to preschool grade levels. For instance, MacDonald and Wilkins (under review) found in a case study that one preschool student may be using early subitizing activity to promote her composite unit development and units coordination. Investigating how early, perceptual actions may relate to students operations development around units coordination would serve these foci. Thus, our first aim is to extend our research around units coordination to new grade levels.

Grade/N Seq.	CFUI or INS	ENS	GNS
First	≈ 45 Percent	≈ 10 to 15 Percent	≈ 0 to 5 Percent
Second	≈ 30 Percent	≈ 25 to 30 Percent	≈ 0 to 5 Percent
Third	≈ 5 Percent	≈ 45 to 50 Percent	≈ 0 to 10 Percent

Figure 2. Steffe's (2017) estimated percentage of students capable of counting figurative unit items (CFUI), engaging with initial number sequence (INS), engaging with explicitly-nested number sequence (ENS), or engaging with generalized number sequence (GNS) (p. 41).

Second Aim: Widening Units Coordination Research

Our second aim is to widen units coordination research by collaborating with researchers who investigate students with learning differences, from diverse cultures, and from low-socioeconomic households to determine diverse students' mathematics learning trajectories. For instance, Hunt and MacDonald (in press), who work closely with students with learning differences in case study research, uncovered three important challenges students experience as they work toward more sophisticated coordination of units. First, when engaging in tasks that support the construction of composite unit, the use of memorized fact combinations or teacher taught strategies eclipsed the use of one students' natural reasoning (in press) yet supported another's (Hunt, Silva, & Lambert, 2017). All three students evidenced tacit ways of reasoning (e.g., 2 is contained in 3, 3 is contained in 4); two reverted to pseudo-empirical abstractions, tricks, or algorithms that they could not explain to solve the tasks. These ways of engaging in the tasks were counterproductive to one student's reflection on their own actions upon units such that adaptations in their reasoning could occur. Conversely, the second student leveraged his knowledge of number facts and alternative representations to advance his fractional reasoning and compensate for his perceptual motor differences (2017). For both students, teacher encouragement and support to engage in each student's own ways of reasoning was imperative. Second, Hunt & Silva (forthcoming) found evidence that confirms previous research (Geary,

2010) that one of the students sometimes lost track of counting during a count on, possibly due to working memory. We conjecture that this learning difference interferes with the move from counting on to more sophisticated additive reasoning (e.g., breaking apart tens). Yet, in this case, the problem is alleviated through opportunities for within-problem reflection through experiences that the child has to construct addends involved in number problems through counting, sweeping small numbers as lengths, and improving the usability of small composites like 2, 4, 3, 5, and 6 (forthcoming). Lastly, both students evidenced an affinity towards symmetric notions of units coordination across learning situations and across natural and fractional number reasoning. Hunt is currently conducting cross-case analysis to discern whether the symmetry is indicative of unique trajectories in number and/or fractional reasoning.

We argue that equitable instruction for all students begins with increased opportunities to adapt *their own thinking* grounded in a construction within their own mathematical realities. When well-intentioned educators provide children interventions that promote procedures and actions, not only are they not serving their children's mathematics learning needs, they may be preventing them from engaging in learning situations that support the children to adapt their thinking structures and advance their learning.

Specific Goals and Aims

To extend and widen units coordination research this working group intends to accomplish the following: (a) develop a research agenda for the group, (b) brainstorm specific research questions and unpack theoretical frameworks that will address that agenda, (c) explore research methodologies that can answer the potential research questions, (d) discuss the logistics of collaborations to carrying out these studies, and (e) embark upon collaborations leading to publication and funding opportunities.

Plan for Working Group

Session 1: Concept Formation

<u>GOAL: Generation of research questions that are important to the group and/or sub-groups</u>. *Introduce focus for the working group* by asking "what types of problems would members like to explore?", by viewing/discussing short video clips of students working through various mathematical concepts to better understand the students' thinking, and developing potential research foci (e.g., overall purpose/goals of this working group, ties between composite units, coordination of units, and particular mathematics content). Finally, subgroups will be developed to form research questions that can cross-domains and use questions to form collaborations based on each members' area of interest and expertise.

Session 2: Theoretical Frameworks and Methodologies

<u>GOAL: Explore appropriate research methodologies</u>. *Formulate plans for research and collaboration across group members by* examining a variety of methodologies. Means for these examinations would include the following: (a) view videos of work already conducted to highlight possible methodologies for future studies; (b) discuss other potential methodologies not highlighted during the video viewing; (c) discuss how to design robust collaborative studies. *Small group would entail:* (1) work already done; (2) research agenda development; *Large group would entail*: (1) share small group discussions; (2) delineate session 3 goals

Session 3: Planning and Writing

<u>GOAL: Embark on collaborations</u>. *Small group will entail*: (1) work on written product of research agenda; (2) develop shared conceptual framework and the relationship of our framework to what is currently being done; (3) identify target journals and outlets or grants and funding sources. *Large group will entail*: (1) share progress and commitments from small group

discussion; (2) finalize a plan for individual groups to continue updating progress to the larger group; (3) creation of working group website or blog.

Anticipated Follow-up Activities

Throughout the year, the members of this working group will continue working on research problems of common interest. They will contribute to a common website in which they will update other members of the working group about the progress of the various research collaborations. In the future, this working group will propose a special issue to a leading journal in the field and/or construct a grant proposal to a nationally recognized funder.

Embodied cognition is growing in theoretical importance and as a driving set of design principles for curriculum activities and technology innovations for mathematics education. The central aim of the EMIC (Embodied Mathematical Imagination and Cognition) Working Group is to attract engaged and inspired colleagues into a growing community of discourse around theoretical, technological, and methodological developments for advancing the study of embodied cognition for mathematics education. A thriving, informed, and interconnected community of scholars organized around embodied mathematical cognition will broaden the range of activities, practices, and emerging technologies that count as mathematical. EMIC builds upon our prior working groups with a specific focus on how we can leverage emerging technologies to study embodied cognition and mathematics learning. In particular, we aim to develop new theories and extend existing frameworks and perspectives from which EMIC collaboration and activities can emerge.

Keywords: Technology; Cognition; Informal Education; Learning Theory

Motivations for This Working Group

Recent empirical, theoretical and methodological developments in embodied cognition and gesture studies provide a solid and generative foundation for the establishment of **a regularly held Embodied Mathematical Imagination and Cognition (EMIC) Working Group** for PME-NA. The central aim of EMIC is to attract engaged and inspired colleagues into a growing community of discourse around theoretical, technological, and methodological developments for advancing the study of embodied cognition for mathematics education, including, but not limited to, studies of mathematical reasoning, instruction, the design and use of technological innovations, learning in and outside of formal educational settings, and across the lifespan.

The interplay of multiple perspectives and intellectual trajectories is vital for the study of embodied mathematical cognition to flourish. While there is significant convergence of theoretical, technological, and methodological developments in embodied cognition, there is also a trove of technological, methodological, and theoretical questions that must be addressed before we can formulate and implement effective design principles. As a group, we aim to address basic theoretical questions such as, What is grounding? And practical ones such as, How can we reliably engineer the grounding of specific mathematical ideas? We need to understand how variations in actions and perceptions influence mathematical reasoning, including self-initiated vs. prescribed actions, and actions that take place in intrapersonal versus interpersonal interactions; how gestural point-of-view when enacting phenomena from a first- versus third-person perspective, including how gestures move through space, influences reasoning and communication; how actions enacted by oneself, observed in others, or imagined influence cognition; and how gestures connect with external visual representations (Alibali & Nathan, 2012; in press).

A thriving, informed, and interconnected community of scholars organized around embodied mathematical cognition will broaden the range of activities and emerging technologies that count as mathematical, and envision alternative forms of engagement with mathematical ideas and practices (e.g., De Freitas & Sinclair, 2014). This broadening is particularly important at a time when schools and communities in North America face persistent achievement gaps between groups of students from many ethnic backgrounds, geographic regions, and socioeconomic circumstances (Ladson-Billings, 1995; Moses & Cobb, 2001; Rosebery, Warren, Ballenger & Ogonowski, 2005). There also is a need to articulate evidence-based findings and principles of embodied cognition to the research and development communities that are looking to generate and disseminate innovative programs for promoting mathematics learning through movement (e.g., Ottmar & Landy, 2016; Smith, King, & Hoyte, 2014). Generating, evaluating, and curating empirically validated and reliable methods for promoting mathematical development and effective instruction through embodied activities that are engaging and curricularly relevant is an urgent societal goal. As embodied cognition gains prominence in education, so, too, does new ways of using technology to support teaching and learning (Lee, 2015). These new uses of technology, in turn, offer novel opportunities for students and scientists to engage in math visualization, symbolization, intuition, and reasoning. In order for these designs to successfully scale up, they must be informed by research that demonstrates both ecological and internal validity.

Past Meetings and Achievements of the EMIC Working Group

"Mathematics Learning and Embodied Cognition," the first PME-NA meeting of the EMIC working group, took place in East Lansing, MI in 2015. Our group has been growing ever since. In addition to the PME-NA meeting each year, there are a number of ongoing activities that our members engage in. We have built an active website which provides updates on projects, and hosts resources. On this website, we have a list of members with their emails and bios, information about our PME-NA presence, and short personal introduction videos. We've also created a space for members to share information about their research activities – particularly for videos of the complex gesture and action-based interactions that are difficult to express in text format. In addition, we have a common publications repository to share files or links (including to ResearchGate or Academia.edu publication profiles, so members don't have to upload their files in multiple places). Our members collaborate on ongoing projects, and have presented at other pre-conference workshop events such as the Computer Supported Collaborative Learning conference (Williams-Pierce et al., 2017), and the APA Technology, Mind, and Society conference (Harrison et. al, 2018). Several research programs have formed to investigate the embodied nature of mathematics (e.g., Abrahamson 2014; Alibali & Nathan, 2012; Arzarello et al., 2009; De Freitas & Sinclair, 2014; Edwards, Ferrara, & Moore-Russo, 2014; Lakoff & Núñez, 2000; Melcer & Isbister, 2016; Ottmar & Landy, 2016; Radford 2009; Nathan, Walkington, Boncoddo, Pier, Williams, & Alibali, 2014; Soto-Johnson & Troup, 2014; Soto-Johnson, Hancock, & Oehrtman, 2016), demonstrating a "critical mass" of projects, findings, senior and junior investigators, and conceptual frameworks to support an ongoing community of like minded scholars within the mathematics education research community.

Some of **our collaborative accomplishments** since 2015 include:

1. Developing a group website using the Google Sites platform to connect scholars, support ongoing interactions throughout the year, and regularly adding additional resources/activities https://sites.google.com/site/emicpmena/home
2. Joint submission of several NSF grants by members who first met during the 2015 EMIC sessions
3. Some senior members joining junior members' NSF grant proposals as Co-PIs and advisors
4. Submission to the IES CASL program to study the role of action in pre-college proof performance in geometry (Funded 2016-2020 for Nathan & Walkington), as well of the use of perceptual learning on algebra learning (Ottmar & Landy, 2018)
5. Submission of 2 NSF Proposals to host Workshops on Embodied Cognition (one for researchers and one for K-16 math educators)
6. A joint symposium on Embodied Cognition with 6 members at the 2018 APA Technology, Mind & Society Conference
7. Examining the potential for an NSF Research Coordination Network (RCN)
8. Application for a grant from Association for Psychological Science (APS) to develop a better website and offer stipends for contributors
9. Presenting a pre-conference workshop to CSCL 2017 on the embodied tools to promote STEM education (Williams-Pierce et al., 2017)
10. A Conference at Berkeley's Graduate School of Education to examine the relevance of coordination dynamics -- the non-linear perspective on kinesiological development -- to individuals' sensorimotor construction of perceptual structures underlying mathematical concepts. https://edrl.berkeley.edu/cdme2018

Current Working Group Organizers

As the Working Group has matured and expanded, we have a broadening set of organizers that represent a range of institutions and theoretical perspectives (and is beyond the limit of six authors in the submission system). This, we believe, enriches the Working Group experience and the long-term viability of the scholarly community. The current organizers for 2018 are (alphabetical by first name):

- Candace Walkington, Southern Methodist University
- Carmen J. Petrick Smith, University of Vermont
- Caro Williams-Pierce, University at Albany, SUNY
- David Landy, Indiana University
- Dor Abrahamson, University of California, Berkeley
- Edward Melcer, University of California, Santa Cruz
- Emily Fyfe, Indiana University
- Erin Ottmar, Worcester Polytechnic Institute
- Hortensia Soto–Johnson, University of Northern Colorado
- Ivon Arroyo, Worcester Polytechnic Institute
- Martha W. Alibali, University of Wisconsin-Madison
- Mitchell J. Nathan, University of Wisconsin-Madison

Focal Issues in the Psychology of Mathematics Education

Emerging, yet influential, views of thinking and learning as embodied experiences have grown from several major intellectual developments in philosophy, psychology, anthropology, education, and the learning sciences that frame human communication as multimodal interaction, and human thinking as multi-modal simulation of sensory-motor activity (Clark, 2008; Hostetter & Alibali, 2008; Lave, 1988; Nathan, 2014; Varela et al., 1992; Wilson, 2002). As Stevens (2012, p. 346) argues in his introduction to the *JLS* special issue on embodiment of mathematical reasoning, "it will be hard to consign the body to the sidelines of mathematical cognition ever again if our goal is to make sense of how people make sense and take action with mathematical ideas, tools, and forms".

Four major ideas exemplify the plurality of ways that embodied cognition perspectives are relevant for the study of mathematical understanding: (1) *Grounding of abstraction in perceptuo-motor activity as one alternative to representing concepts as purely amodal, abstract, arbitrary, and self-referential symbol systems.* This conception shifts the locus of "thinking" from a central processor to a distributed web of perceptuo-motor activity situated within a physical and social setting. (2) *Cognition emerges from perceptually guided action* (Varela, Thompson, & Rosch, 1991). This tenet implies that things, including mathematical symbols and representations, are understood by the actions and practices we can perform with them, and by mentally simulating and imagining the actions and practices that underlie or constitute them. (3) *Mathematics learning is always affective*: There are no purely procedural or "neutral" forms of reasoning detached from the circulation of bodily-based feelings and interpretations surrounding our encounters with them. (4) *Mathematical ideas are conveyed using rich, multimodal forms of communication, including gestures and tangible objects in the world.*

In addition to theoretical and empirical advances, new technical advances in multi-modal and spatial analysis have allowed scholars to collect new sources of evidence and subject them to powerful analytic procedures, from which they may propose new theories of embodied mathematical cognition and learning. Growth of interest in multi-modal aspects of communication have been enabled by high quality video recording of human activity (e.g., Alibali et al., 2014; Levine & Scollon, 2004), motion capture technology (Hall, Ma, & Nemirovsky, 2014; Sinclair, 2014), developments in brain imaging (e.g., Barsalou, 2008; Gallese & Lakoff, 2005), multimodal learning analytics (Worsley & Blikstein, 2014), and data logs generated from embodied math learning technologies that interacts with touch and mouse-based interfaces (Manzo, Ottmar, & Landy, 2016).

Theme: Looking Back, Looking Ahead: Celebrating 40 Years of PME-NA

Inspired by the PME-NA 2018 theme, we will specifically focus on the ways in which the field of embodied cognition has developed and how new emerging technologies and innovative pedagogies can influence mathematics teaching and learning. This effort will be crafted to align with recent developments in the embodiment literature, and new theoretical frameworks tying various perspectives on embodiment to different forms of physicality in educational technology (Melcer & Isbister, 2016; see Figure 1 below).

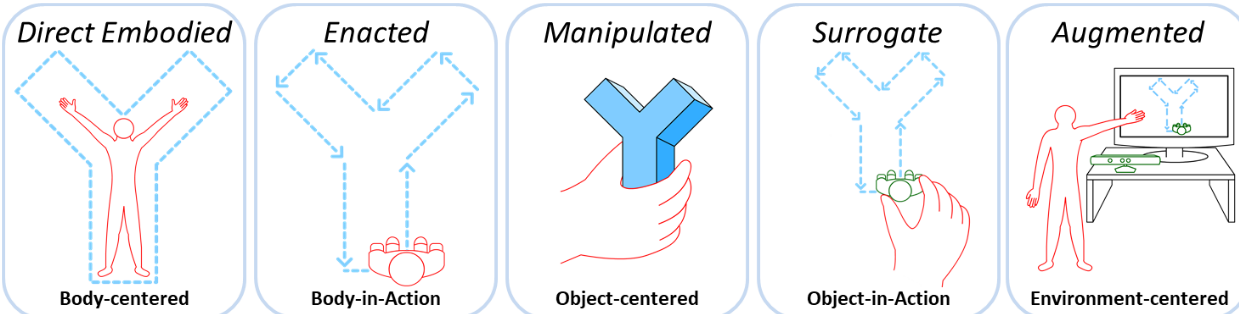

Figure 1. Five distinct approaches to facilitating embodiment through bodily action, objects, and the surrounding environment in educational technology.

Examples include: coding videos of pre-service teachers' distributed gestures to explore a mathematical conjecture (Walkington et al., 2018); exploring mathematical transformations while using a dynamic technology tool (Ottmar & Landy, 2016), having students and teachers play and create embodied technology games to teach mathematics and computational thinking (Arroyo et al., 2017; Melcer & Isbister, 2018); usng dual eye tracking (Shvarts & Abrahamson, 2018), and a teacher guiding the movements of a learner exploring ratios (Abrahamson & Sánchez-García, 2016). Through these examples, we will explore questions such as: what role does technology play on supporting the connections between the mind, body, and action? During the conference, participants in our EMIC workshop will engage in dedicated activities and guided reflections as a basis for exploring the role of technology, action, and embodiment in the emergence of mathematics learning.

Plan for Active Engagement of Participants

Our formula from prior PME-NA working groups proved to be effective: By inviting participants into open ended math activities at the beginning of each session, we were rapidly drawn into those very aspects of mathematics that we find most rewarding. We plan to facilitate collaborative EMIC activities, followed by group discussions (and we now have many activities and members who can trade off in these roles!) that will help us all to "pull back" to the theoretical and methodological issues that are central to advancing math education research. Within this structure of beginning with mathematical activities and facilitated discussions, on **Day 1** we plan to begin with four different group activities that highlight the interplay of mathematics content, cognition, physicality, and action. These activities will serve as the foundation for a broad group discussion about the varied roles of technology in EMIC. See Figure 2 below for examples of collaborative activities from PME-NA 2017.

Figure 2. Collaborative activities. Participants explore geometric rotation and reflection(left); two groups act out and prove mathematical conjectures (middle and right).

The full first session will generally be taken up by introductions and a round of open-ended activities followed by discussion. On **Day 2**, we will begin the session with technology-based collaborative activities, with four stations that pairs of participants rotate through. Examples of three of those stations are in Figure 3. Continuing with the routine established in Day 1, a full group discussion will follow, with a particular focus on designing EMIC digital contexts to support ongoing collaboration.

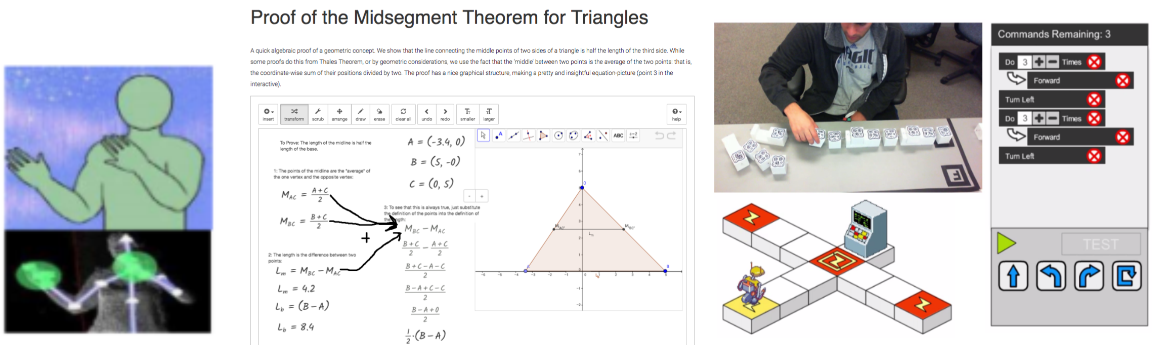

Figure 3. Technology activities. *The Hidden Village* (left); *Graspable Math* (middle); Bots & (Main)Frames (right).

After the discussion, we will discuss different EMIC activity ideas, with the goal of developing additional collaborative activities that can be used in various research and learning contexts. The final activities will be shared on the EMIC website.

Day 3 is agenda-setting day, where we all discuss how we will keep the momentum going, such as developing an NSF Research Coordination Network (RCN) to build the networked community of international scholars from which many fruitful lines of inquiry can emerge. A second group may draft a proposal for a special issue of the *Journal of Research in Mathematics Education* that focuses on creating an integrated theoretical framework or sharing the different theoretical perspectives, research activities, and operationalization of EMIC by the working group members.

In order to find common ground for the RCN submission and the JRME special issue, we will perform a live concept mapping activity that is displayed for all participants to explore the range of EMIC topics and identify common conceptual structure. We will discuss different general foci, such as teacher professional development with EMIC, designing EMIC games or museum exhibits, etc. Building on the four major ideas that we developed earlier, possible topics for organizing this activity will be explored, such as:

1. Grounding Abstractions
    a. Conceptual blending (Tunner & Fauconnier, 1995) & metaphor (Lakoff & Núñez, 2000)
    b. Perceptuo-motor grounding of abstractions (Barsalou, 2008; Glenberg, 1997; Ottmar & Landy, 2016; Landy, Allen, & Zednik, 2014)
    c. Progressive formalization (Nathan, 2012; Romberg, 2001) & concreteness fading (Fyfe, McNeil, Son, & Goldstone, 2014)
    d. Use of manipulatives (Martin & Schwartz, 2005)
2. Cognition emerges from perceptually guided action: Designing interactive learning environments for EMIC

   a. Development of spatial reasoning (Uttal et al., 2009)
   b. Math cognition through action (Abrahamson, 2014; Nathan et al., 2014)
   c. Perceptual boundedness (Bieda & Nathan, 2009)
   d. Perceptuomotor integration (Ottmar, Landy, Goldstone, & Weitnauer, 2015; Nemirovsky, Kelton, & Rhodehamel, 2013)
   e. Attentional anchors and the emergence of mathematical objects (Abrahamson & Bakker, 2016; Abrahamson & Sánchez–García, 2016; Abrahamson et al., 2016; Duijzer et al., 2017)
   f. Mathematical imagination (Nemirovsky, Kelton, & Rhodehamel, 2012)
   g. Students' integer arithmetic learning depends on their actions (Nurnberger-Haag, 2015).
3. Affective Mathematics
   a. Modal engagements (Hall & Nemirovsky, 2012; Nathan et al., 2013)
   b. Sensuous cognition (Radford, 2009)
4. Gesture and Multimodality
   a. Gesture & multimodal instruction (Alibali & Nathan 2012; Cook et al., 2008; Edwards, 2009)
   b. Bodily activity of professional mathematicians (Nemirovsky & Smith, 2013; Soto-Johnson, Hancock, & Oehrtman, 2016)
   c. Simulation of sensory-motor activity (Hostetter & Alibali, 2008; Nemirovsky & Ferrara, 2009)

We will also discuss the implications of this work and the different areas of the concept map for teaching, and discuss ideas for bridging the gap between research and practice.

Follow-up Activities

We envision an emergent process for the specific follow-up activities based on participant input and our multi-day discussions. At a minimum, we will continue to develop a list of interested participants and grant them all access to our common discussion forum and literature compilation. Those that are interested in the NSF RCN plan will work to form the international set of collaborations and articulate the intellectual topics that will knit the network together; and those that are interested in the JRME special issue proposal will outline a specific timeline for progressing. One additional set of activities we hope to explore is to create a series of instructional activities that can be used to introduce educational practitioners at all levels of administration and across the lifespan to the power and utility of the EMIC perspective.

In the past several years, we have seen a great deal of progress. This is perhaps best exemplified by coming together of the EMIC website, the ongoing collaborations between members, and the annual workshops, which each draws across multiple institutions. We thus will strive to explore ways to reach farther outside of our young group to continually make our work relevant, while also seeking to bolster and refine the theoretical underpinnings of an embodied view of mathematical thinking and teaching.

After not having met for a number of years, the Gender and Sexuality in Mathematics Education Working Group will meet again this year with a new name, new members, and a new focus. During this Working Group, we will discuss current research being conducted on these topics and identify themes for discussion and possible research collaborations. We plan to include a discussion about how research assumptions, such as language assuming that gender is binary, can affect research findings. All PME-NA attendees with an interest in gender and sexuality in mathematics education are invited to attend.

Keywords: Gender; Equity and Diversity; Affect, Emotion, Beliefs, and Attitudes

Introduction

The Gender and Sexuality in Mathematics Education Working Group will reconvene this year with a new focus and a new name. After not having met for many years, there is a renewed interest in this topic and new leadership for this Working Group. During last year's PME-NA, in Indianapolis, a group of scholars met to discuss their interests in gender and sexuality in mathematics education. As a result of those October 2017 meetings, we set up a Google Docs shared folder so that we could share relevant research and other resources. At that time, we also agreed that having a formal Working Group at PME-NA in 2018 would allow the work of this group to coalesce and would be a productive way to invite interested others to join us. We have also chosen to rename the Working Group to include the word "sexuality" in order to be more inclusive and to remain current with the expanding themes within this area of research.

In this proposal, we share a brief history of the past work of this group and discuss connections of our work to the psychology of mathematics education and to the theme of this year's conference. We also discuss some relevant research being conducted by current members of the group and discuss initial themes noted within this work. Finally, we describe our plans for the active engagement of participants during the conference and conclude with a discussion of anticipated follow-up activities and future directions for the Working Group.

Brief History of the Working Group

The Gender and Mathematics Working Group (GMWG) began 20 years ago at PME-NA XX in Raleigh, North Carolina. At this conference, mathematics education scholars came together "in order to weave together the findings of various strands in research and understanding of issues in gender and mathematics" (Damarin et al., 1998). This Working Group continued to meet between 1998 and 2007, with the exception of the 2003 joint conference between PME and PME-NA in Honolulu, Hawaii. The group also reconvened for the 2011 PME-NA conference in Reno, Nevada.

The Working Group's past discussions have involved reviewing the scholarship surrounding gender and mathematics, defining research strands, determining gaps in the literature, and establishing directions for future work. Some notable accomplishments of this group have been creating a visual representation of the field of gender and mathematics and the social and psychological complexities of the topic (Erchick, Condron, & Appelbaum, 2000) and publishing a monograph on gender and mathematics research as a joint project with scholars from the International Group for PME (Forgasz, Becker, Lee, & Steinthorsdottir, 2010).

Connections to PME and the Conference Theme

The conference theme this year, "Looking Back, Looking Ahead," nicely ties in with the resurgence of this Working Group. Research on gender and sexuality in mathematics education has drastically shifted focus throughout the past few decades. In the 1970s and 1980s, much of the work on gender and mathematics focused on sex differences in mathematics achievement, often with a focus on biological differences. Through the years, given that sex differences in achievement have been found to be relatively small and have decreased over time (Hyde, Fennema, & Lamon, 1990), gender research has shifted its focus more to participation, with an emphasis on social/cultural influences, as opposed to biological ones. In other words, the research questions tend to center around why girls/women are not pursuing mathematics or mathematical careers at the same rate as boys/men and what can be done to change this imbalance. This work has revolved around many topics, such as agency and voice, self-efficacy and self-concept, stereotypes and stereotype threat, curriculum and pedagogy, and differential treatment and institutionalized discrimination.

In more recent years, the field has also begun discussing the need for more research on queer, transgender, and gender non-conforming students. Recent researchers have noted that work done on gender and mathematics tends to utilize binary wording – dividing participants into males/boys/men and females/girls/women, without clearly defining these categories and without allowing for students who might not identify with one of these categories (Damarin & Erchick, 2010; Glasser & Smith, 2008; Hall, 2014). In looking ahead, it is important for researchers in this field to develop and define appropriate and inclusive terminology and research methodologies that can address issues that arise when conducting gender and sexuality research.

Current Research in Gender and Sexuality in Mathematics Education

To provide more details on the type of work currently being done in the field with respect to gender and sexuality in mathematics education, the following is a short summary of each author's recent work in this area. More detailed discussions and connections across this work will take place during the Working Group sessions.

Laurie Rubel, Brooklyn College of the City University of New York/University of Haifa

Laurie Rubel's current research focuses on the educational experiences of women Palestinian citizens of Israel (Arab Israelis, who represent 25% of the population of Israel). Arab Israelis are a minority group with limited access to opportunity and resources and lower socioeconomic standing in Israel (Bar-Tal & Teichmann, 2005; Zuzovsky, 2010). Arab Israeli girls outperform boys in mathematics (Rapp, 2015) and have been found to have beliefs about success in mathematics different from Western or Westernized peers (Forgasz & Mittelberg, 2008). It has been hypothesized that girls appropriate academic success to overcome the lower status that they hold as a minority in Israel as Palestinians, which is further exacerbated by their role as women in a patriarchal society (Rapp, 2015), and as an unintended consequence of less diversity among course offerings in Arab high schools (Ayalon, 2002).

Rubel's research methodology consists of life-story interviews with Arab Israeli women in undergraduate and graduate programs in mathematics education, from diverse Arab ethnic groups and geographies, in which they are asked how they understand and interpret the effects of local racialized narratives in relation to learning, how they interpret their achievement and others' lack of achievement, and which factors they identify as supporting or inhibiting their success. Analysis will pursue the educational experiences of these women, as told in their own stories and counterstories, with particular attention to how these stories converge or contrast with Western narratives. The commentary will include analysis of researcher positionality (Milner, 2007) and will discuss methodological tensions inherent to research about equity in mathematics in relation to social groups known to espouse conservative, patriarchal, and homophobic ideologies.

Lynda Wiest, University of Nevada, Reno

Lynda Wiest's scholarly interests involve understanding factors that influence gender differences in mathematics, including those that relate to dispositions and beliefs, and strategies and opportunities for supporting and encouraging females in mathematics. Wiest has particularly focused on the role that out-of-school-time (OST) learning can play in this regard because it is an area of rising scholarly interest in education, especially STEM education (e.g., McCombs et al., 2012; Slates, Alexander, Entwisle, & Olson, 2012). Wiest developed and has directed a residential summer math program for middle school girls for 20 years, conducting research in association with the program and recently publishing the first book of its kind on OST STEM programs for females (Wiest, Sanchez, & Crawford-Ferre, 2017).

In researching factors that participants consider most important in a one-week residential summer mathematics and technology program for middle school girls, Wiest and colleagues (2017) have determined that the girls find the academic learning most important, indicating that they can willingly engage in rigorous mathematics even outside of school. Although social opportunities (sometimes embedded in recreational activities) were reported as a distant second among the most important program features, the academic and social opportunities interacted in important ways in the context of a mathematics experience to influence dispositions and beliefs (Lavy & Sand, 2012; Szucs, 2014). In terms of most effective instructional approaches, the girls most prominently listed active engagement (e.g., hands-on, collaborative, and communicative learning) and a high-quality staff (based on individual attention given and perceived effectiveness).

Currently, Wiest is completing a study on the influence of the summer program on motivation (internal and external). She and her co-researchers concur with existing findings that dispositions can influence STEM achievement and participation (Ellis, Fosdick, & Rasmussen, 2016; Goetz, Bieg, Lüdtke, Pekrun, & Hall, 2013). They find the fact that females grapple with less favorable dispositions toward STEM than males, such as weaker self-beliefs and confidence as well as lower interest (Ellis et al., 2016; Lubienski, Robinson, Crane, & Ganley, 2013), problematic and thus investigate ways OST programs might favorably influence females' dispositions in mathematics overall and in relation to race/ethnicity and socioeconomic status.

Rebecca McGraw, University of Arizona

Rebecca McGraw's work related to equity, gender, and mathematics includes co-facilitating a residential summer math camp for middle grades girls (led by another co-author of this proposal), studying teacher classroom practice from an equity perspective (e.g., distribution of images by gender in classroom resources, patterns of participation, course-taking, and achievement), and investigating pre-service secondary teacher preparation (Bay-Williams & McGraw, 2008; Eli, McGraw, Anhalt, & Civil, in press; McGraw & Lubienski, 2007; McGraw, Romero, & Krueger, 2009; Rubinstein-Avila et al., 2014). Currently, McGraw is particularly interested in the development of teacher and student beliefs about mathematics and learning, and the development of middle/high school students' mathematical identities.

Very recently, McGraw began serving as PI on a multi-institutional NSF research project (#1758401) focusing on the development of equitable teacher practices in middle/high school pre-service and beginning teachers. The study is framed by the theories of equity literacy (Gorski, 2014; Gorski & Swalwell, 2015) and culturally relevant teaching (Gay, 2002), and the researchers seek to understand the ways that teacher education programs can productively engage future teachers in identifying and confronting bias and discrimination (as expressed by oneself, others, and institutions), rejecting deficit views and fixed-ability mindsets, and engaging with and building upon the resources that students bring to the classroom. This project will include five teacher education programs from across the U.S. and approximately 100 future/beginning mathematics teachers. The Working Group will provide an important venue for the bidirectional sharing of ideas – from project research to working group members, and from the varied expertise of group members back to the project.

Angela Hodge, Northern Arizona University

Angela Hodge's research interests lie at the intersection of active learning (Ernst, Hodge, & Yoshinobu, 2017) and gender equity in the STEM disciplines. Most recently, Hodge conducted research on a four-week summer camp for underrepresented middle school girls (Hodge, Matthews, & Squires, 2017). The camp was based on empowering the young women by engaging them in hands-on, minds-on activities in STEM. The girls participated in physical activities each day as well as explored various STEM careers. Hodge was one of the co-founders of the camp, which has now been active for six years. During the Working Group, Hodge will offer insights gained by research on starting a summer camp for girls, maintaining the camp, and selecting activities that are both engaging and empowering for young women. Future research ideas for the camp can also be explored during the Working Group.

In addition, Hodge conducted a research study on why some women choose STEM fields and what has made them successful in such majors (Weber & Hodge, 2012). It was found that childhood experiences greatly influenced these women in choosing a STEM major. Support groups and mentors helped influence their choices to stay in the STEM major, even when their coursework became challenging.

One of the current research projects in which Hodge is involved relates to perceptions of women related to their mathematics history. Data were collected in university calculus classes (a course with few women enrolled, but all students enrolled are in STEM disciplines) and in a math for elementary education course (a course mostly populated by women not in STEM). The data first being analyzed come from a pre-course writing assignment called a math autobiography. The students in both classes were asked the same questions/prompts. Women's perceptions of themselves as students of mathematics will be explored with both of these groups of students. This project will be further discussed during the Working Group.

Kathy Stoehr, Santa Clara University

Kathy Stoehr's research focuses on preservice and early-career teachers' experiences with mathematics anxiety. She utilizes different theoretical lenses to add a deeper understanding of how and why mathematics anxiety is so prevalent among women (Penafiel, Stoehr, & Martinez, 2016; Stoehr & Olson, 2015; Stoehr, 2017a, 2017b). Stoehr argues that this gender issue is important to study so that teacher educators may address this issue and be better equipped to prepare competent and confident women to teach elementary mathematics.

Stoehr is also a co-researcher on two large grants. As Co-Principal Investigator on a two-year research project with Dr. Marta Civil from the University of Arizona, she is working with in-service women elementary teachers and mothers from an underserved community to focus on their understanding of each other's roles in supporting children's mathematics education. In addition, she works with the teachers and mothers to develop deeper confidence and competence in mathematics.

For the other grant, Stoehr is a co-researcher on a five-year U.S. Department of Education Grant with Co-Principal Investigators Marco Bravo and Claudia Rodriguez-Mojica. The aim of the grant is to enhance teacher preparation for dual-language environments. Stoehr's responsibilities include co-designing two elementary mathematics courses for bilingual preservice elementary teachers (mainly women) that focus on the role language plays in learning mathematics. She also develops and facilitates workshops for parents (mainly mothers) of bilingual students on ways to promote children's co-development of mathematical knowledge and bilingual language proficiency at home.

Katrina Piatek-Jimenez, Central Michigan University

Katrina Piatek-Jimenez's research interests focus on what motivates women to study mathematics at the undergraduate level and what influences their decisions whether or not to continue in mathematical careers. In order to begin addressing these questions, Piatek-Jimenez has explored many potential factors, such as the development and role of one's mathematics identity (Cribbs, Piatek-Jimenez, & Mantone, 2015; Piatek-Jimenez, 2015), images of mathematicians (Piatek-Jimenez, 2008a), knowledge of mathematical careers (Piatek-Jimenez, 2008b), and equity within mathematics textbooks (Piatek-Jimenez, Madison, & Pzybyla-Kuchek, 2014).

In her more recent work, Piatek-Jimenez has been focusing on the role of stereotypes held by college students. In one study, Piatek-Jimenez explored whether college students believe that society sees particular personality attributes as gendered. Findings suggest that personality attributes often associated with the field of mathematics (such as "thinks logically" and "analytical") were seen as gender neutral by participants, but those associated with caring for others (such as "shows concern for people's well-being" and "puts others' needs above one's own") were ranked as female dominant. Furthermore, women planning on entering STEM careers rated these caring attributes as female dominant even more so than the men in the study or the women who were not planning on STEM careers. Piatek-Jimenez and colleagues (Cribbs, Piatek-Jimenez, & Gill, in press) raise concerns about the influence that these pressures may have on women interested in STEM fields, especially since mathematically-based careers are often viewed as being less people- or service-oriented than many other careers (Morgan, Isaac, & Sansone, 2001).

In another recent study, Piatek-Jimenez explored college students' stereotypes of mathematicians using two different data collection methods. One method was the "Draw a Mathematician Test." The second involved focus groups in which students were asked to consider photos of real people and determine whether or not they thought each was of a mathematician. Initial results suggest that the distinct methods employed allowed the researchers to identify different stereotypes and beliefs of the participants. As such, Piatek-Jimenez cautions how choice of methodology in gender research may affect results.

Jennifer Hall, Monash University

Jennifer Hall's interest in gender research in mathematics education began when she was a master's student. In her master's research, she collected data on the experiences of women who were upper-year undergraduate mathematics majors, investigating the supports and challenges they faced as they selected and persevered in this field of study, which remains dominated by men in Canada, where the research was conducted (Hall, 2010).

During her doctoral studies, Hall's research focused on elementary students' experiences with and views of mathematics and mathematicians, and the ways that their views are impacted by parents' views, teachers' views, and popular media representations. Throughout her doctoral journey, Hall became increasingly aware of how to conduct research in a gender-sensitive manner, and ensured that all aspects of her research, from conception to presentation of findings, were conducted in such a manner (Hall, 2014).

More recently, Hall was part of an international research project led by Helen Forgasz and Gilah Leder. This project involved asking the general public about their views on gender and mathematics, as well as related fields, via street-level interviews. While reporting on her findings from the Canadian dataset (Hall, 2017), she raised concerns about the binary wording ("girls or boys") of the survey questions. As a result, she designed a more recent project that involved replicating the aforementioned project, but with an alteration of the data collection instrument (1) to make all the questions non-binary (e.g., "For which gender…") and (2) to add questions that explicitly queried the participants' views on gender. Data collection took place in Canada and Australia, and initial analyses are currently underway.

Hall has also begun a new project in which she and two colleagues will investigate the supports and challenges faced by undergraduate students in two Australian universities. This project will also have a gendered focus, as the researchers will investigate the ways that gender impacts students' experiences.

Elizabeth Kersey, Purdue University

Elizabeth Kersey also notes concerns about utilizing binary wording in gender research. She expresses concern about dividing participants into males and females without clearly defining those categories and without acknowledging transgender, nonbinary, and intersex identities. Kersey is working to address this oversight by using a narrative methodology to examine how gender affects the experiences of transgender students in mathematics and other STEM fields. She draws from research and theory in (a) feminism, (b) queer theory and intersectionality, (c) general education research on transgender students, (d) science education research on LGBTQ issues or queer theory, and (e) research on gender and equity in mathematics education. Drawing from both feminism and queer theory facilitates a dual focus on gender category privilege/oppression and on gender conformity privilege/gender transgression oppression, as suggested by Rands (2009).

The transgender participants in her recent study were more attuned to differences in gendered treatment both before and after transitioning, from which we can learn about how mathematics and other STEM fields are gendered for all students, not just those who are gender variant. Participants in this study regularly described the culture of their fields as masculine. One exception is mathematics education, which was described as much less masculine than mathematics. Participants also reported being taken less seriously when they transitioned from male to female. For instance, they might make a suggestion that would be ignored, only to have the same suggestion be taken up when suggested by a male colleague. For those participants who were transgender women, however, the improvement in their quality of life when their presentation corresponded with their identity far outweighed any disadvantages they faced when presenting as female. All participants in this study were either transgender women or nonbinary; more research is required that includes transgender men.

One strong pattern that emerged in this study is that all participants waited until during or after college to transition. While this is not true of everyone who is transgender, it is a common phenomenon. Based on this observation, Kersey proposes a model of gender refraction. In this model, gender often appears to be a binary because conservative societal norms enforce that gender binary. However, when one experiences an open and accepting environment where it is safe to explore one's identity, this environment acts as a prism and reveals gender to be a spectrum with a multitude of possible identities. College often acts as this prism, but this is not always the case, and different people experience the same environment in different ways. The most important aspect of this model is that the spectrum of identities was always present, but it was not visible until the conditions were favorable. Kersey argues that our goal as a society and as mathematics educators should be to create more environments that can act as a prism and allow our students to explore their identities in an environment of safety and acceptance.

Initial Themes

The study of gender and sexuality in mathematics education is a complex field and is approached from many angles. During the Working Group sessions, we plan to discuss in depth themes and commonalities found in our work and to identify ways that we can continue to support each other's work and move the field forward.

Based on an initial review of our respective work, some preliminary themes begin to arise. One important theme is language and methodology, which involves not only the choice of language that we as scholars use when conducting research on gender and sexuality in order to be inclusive of all individuals and to reflect a multi-dimensional understanding of gender and sexuality, but also a reflection on how our choice of language and our choice of methods may affect our research results and interpretations. Another theme found in our research is interactions between gender/sexuality and students' perceptions of themselves as mathematical learners. While some of our work focuses on mathematics autobiographies and mathematics identity and other work specifically explores math anxiety, these are all topics that consider the learners' experiences related to gender/sexuality and mathematics. A third theme found in our work is the role of curriculum, pedagogy, and teacher education in the study of gender and sexuality in mathematics education. From the role of classroom materials to that of teacher practices, the experiences and messages to which students are exposed within the mathematics classroom affects their achievement and participation. The final theme involves summer camps for middle school girls intended to engage and empower them in the pursuit of mathematics.

Plans for Active Engagement During the Conference

Session 1:

Because this Working Group has not met for many years, and since the group is composed of mostly new leadership and new participants, it is important for the participants to become familiar with one another's work. Therefore, we will begin this session with introductions and a brief overview of the plan for this Working Group at the conference. Each author of the proposal will then present a short synopsis of their research relevant to the topic of gender and sexuality in mathematics education, each followed by a brief discussion with the group at large. Finally, as time permits, other participants will be invited to introduce their related research to the group, continuing into the next session as needed.

Session 2:

We will begin this session with a discussion of language and methodology in gender and sexuality research. Given that the language used within the field changes so quickly, and that certain fields, such as sociology, have worked at refining this language, we consider it important to discuss and develop some consistent language to be used within the group. During this session, we will also facilitate a broader discussion that focuses on connections identified between one another's work, and directions the participants see the field of gender and sexuality in mathematics education moving. Through these conversations, we anticipate that themes will arise that will naturally allow us to divide into smaller, theme-based groups for the third session.

Session 3:

During the third session, breakout groups organized the previous day will meet and discuss potential collaborations and other ways in which they can support each other's work on gender and sexuality in mathematics education.

Anticipated Follow-up Activities and Future Directions

After last year's PME-NA conference, we created a Google Docs shared folder, which has been used to share related articles and information about conferences and funding opportunities. We plan to add all interested attendees of this year's Working Group to the Google Docs shared folder and intend to continue the discussions and shared resources begun during the Working Group throughout the rest of the year.

Also, given that it has been nearly a decade since a monograph has been published on work in gender and sexuality in mathematics education, and because the field changes so quickly, we will begin thinking about putting together an edited volume with current work being done in the field.

The field of mathematics education is embracing a diversity of research paradigms, which have allowed mathematics teacher educators (MTEs) to research their academic experiences. This has begun to unearth the diversity and complexity of MTEs' work. Yet, there are few spaces for MTEs to explore and reflect on those experiences. In this working group, we introduce narrative inquiry, self-study, and autoethnography as methodologies that focus on the study of the self. Through posing research questions and creation of research texts from existing field texts, participants will explore these methodologies. Field texts used will be videos, personal journals, and transcripts of conversations that the leaders of the working group have constructed in their different research studies. The creation of a nurturing space to conduct and review research using these methodologies will be promoted in this working group.

Keywords: Mathematics Teacher Educators, Research Methods, Narrative Inquiry, Self-study, Autoethnography

Significance and Historical Context of the Working Group

PME-NA has historically created spaces for mathematics teacher educators' (MTEs') professional growth (e.g., Bastable & Shifter, 1997; Kastberg et al., 2012). As the mathematics education field starts refuting closure and embracing a diversity of possibilities for mathematics teaching and learning (Stinson & Walshaw, 2017), MTEs' sharing of their experiences has disclosed the complexity of their academic work (e.g., Chauvot, 2009; Jaworski & Wood, 2008; Tzur, 2001). For example, Chauvot (2009), building on Shulman (1986), documented the nature of knowledge she used in her different roles as MTE. Tzur (2001), building on his personal experiences as a mathematics learner and becoming an MTE, documented the importance of promoting MTEs' appreciation for reflecting about their practice. The first International Handbook of Mathematics Teacher Education (vol. 4) was dedicated to the work of MTEs as professionals (Jaworski & Wood, 2008). In 2013, the Journal for Research in Mathematics Education Equity Special Issue documented a conversation among MTEs where they shared their experiences, struggles, questions, and tensions about how they position themselves in their work (D' Ambrosio et al., 2013). Back in 2009, Gutierrez claimed that politics is always a present aspect of MTEs' work whether issues of power are acknowledged or avoided.

As research is one important part of MTEs' work, we acknowledge that there seems to be a consensus that the main goal of doing research is to develop new knowledge or understand a phenomenon (Lincoln, Lynham, & Guba, 2011). However, the kind of research that is legitimate and what knowledge is valued varies according to external contexts and overarching paradigms held by the researcher. MTEs' personal worldviews or paradigms inform the decisions we make in designing and implementing research. Teppo (1997) defined paradigms as "overarching worldviews that represent particular belief systems about the nature of knowledge and how that knowledge is acquired" (p. 3). Ernest (1997) explained that each research paradigm has its own expectations about the nature of reality (ontology), knowledge and how do we know (epistemology), and the best way to gain that knowledge (methodology). To build perspective on a research paradigm, Ernest (1997) advised researchers to consider their personal mission for knowledge, whether they want "to predict and control the phenomena under study (technical interest), to understand and make sense of them (the practical interest), and to achieve social justice through this understanding (the emancipatory interest)" (p. 33). All of these are valuable missions that will determine the methodology of a study and contribute to making the field of mathematics teacher education rich in diversity of researchers and research approaches (e.g., Stinson & Walshaw, 2017).

At the same time, MTEs' daily work may be influenced by external factors, such as funding and/or peer acceptance, as they try to decide what research questions to pursue and select methods for exploring these questions. Negotiating external factors and internal passions to conduct inquiry may constrain MTEs' work. Historically, political organizations in the education community have privileged the practice of scientific methodologies in research (e.g., National Mathematics Advisory Panel, 2008; National Research Council, 2002). However, recently researchers in general teacher education (e.g., Borko, Liston, & Whitcomb, 2007; Lather, 2004), and particularly in mathematics education (e.g., Gutstein, 2008; Stinson & Walshaw, 2017), have called for more diversity in research. In this present moment there is opportunity for MTEs to develop spaces according to their passions and explorations of their identities as writers and researchers. Such as work would fulfill the emancipatory interests described by Ernest (1997), while develop new insights into MTEs' practices.

Energizing MTEs has been identified as critical to sustaining the field of mathematics teacher education (e.g., Whitcomb, Liston, & Borko, 2009). As Wilson (2006) described, being a "teacher educator-researcher requires understanding the practice of teacher education and the practice of teacher education research" (p. 316). MTEs' experiences working in institutions, teaching courses, providing service, conducting research, and wrestling with the competing demands of stakeholders as well as within their own practice could make them feel that academic life is unsustainable. We argue that MTEs can create spaces to share human experiences of their work, and their work with teachers, by conducting research that explores their lived histories and practices. Currently this is possible because our field is embracing the exploration of identity and power using methodologies "that privilege the self" (Hamilton, Smith, & Worthington, 2008, p. 17). We envision this working group as a space for those who have used or are interested in the methodologies of narrative inquiry (Clandinin & Connelly, 2000), self-study (LaBoskey, 2004), and autoethnography (Ellis & Bochner, 2000). Using these methodologies, MTEs could unearth new research questions and communicate the complexity of their work. These methodologies have allowed the authors to empathetically and respectfully collaborate with students and teachers, while also giving us an opportunity to develop self-awareness of our identity, experiences, and bias.

History of the Working Group

Before becoming part of this group of MTEs, we carried out studies independently using the methodologies of narrative inquiry (Clandinin & Connelly, 2000), self-study (LaBoskey, 2004), and autoethnography (Ellis & Bochner, 2000). As conferences and committee meetings brought us together, we developed a mutual understanding of the potential of these methodologies as tools for MTEs' professional growth. We also came to a greater understanding of that potential only after mingling our work and examining the relationship of one study to another. We came to the understanding that our collective research and practices were not only situated in the context of time and place, but also in the social (Clandinin & Connelly, 2000), and that our work is enriched by the sharing of personal history and experience. Furthermore, as Ellis (2004) described, we came to understand human experiences as being connected to ones' culture, consisting of both the beliefs and values one holds. These understandings help us to be mindful of how difficult it could be to incorporate these methodologies when studying mathematics teacher education, and that a space for sharing experience and ideas is necessary to support MTEs who strive to use them. Our collective experience is the strength we bring to the working group and at the same time drives the need for it.

Signe started using self-study as a methodology in 2009 to identify her core beliefs and explicitly align these with her MTE practice. This collaborative self-study provided a mechanism for aligning Signe's research, teaching, and service. Different happenings in her life as a MTE motivated Signe to see self-study methodology as personally rewarding, but not necessarily integrated her roles as MTE. In 2014, to understand the experiences of teacher-learners, Signe explored the creation of moments of intrigue in her methods courses (Kastberg & D'Ambrosio, 2012). Over the years, Signe started understanding that self-study was not just a methodology that was personally rewarding, but that could be used to improve her practice as MTE. For example, in her current work on written feedback, Signe and her colleagues reported the tensions that make some "problems of practice" unsolvable and accepted the notion of wrestling with tensions as a process of growth (Kastberg, Lischka, & Hillman, 2016a, 2016b). Signe's passion for teaching teacher-learners motivated her to engage with other MTEs to gain insight into the experiences of designing and exploring of mathematics methods courses (Kastberg, Tyminski, Lischka, & Sanchez, 2017).

Dana's research journey shifted in 2014 after working with a group of colleagues on a research paper where they explored their beliefs and practices as teacher educators and education researchers (Cox, D'Ambrosio, Keiser, & Naresh, 2014). This was the first time that Dana used the self-study methodology and wrote the results in the form of a narrative. Becoming aware of contradictions in her practice brought Dana to start understanding how qualitative research can act to subvert teacher voices and identity. Later, she challenged the notion that researchers are distinct from participant in Cox and D'Ambrosio (2015) and called for new methodologies that allowed for a blurring of that distinction in D'Ambrosio and Cox (2015). Empathy is a theme that plays out across these three manuscripts. Empathy for others in that work is supported by the use of narrative inquiry as a methodology. This positions her participants, be they teachers or students, as partners and knowledgeable people from whom she learn, and together construct new understandings of mathematics and its teaching. This is reflected in her recent pieces (Cox & Harper, 2017; Simon & Cox, under review) where she has used narrative inquiry as a methodology to explore and communicate experiences working with her students on problem solving and posing in technological environments, and mathematical design.

Olive, who studied with Michael Connelly, has used narrative inquiry as a research methodology in studies of her teaching and mathematics teachers, a research tool to obtain phenomenological data in studies with mathematics teachers, and an approach to in-service and prospective mathematics teachers' learning. With the goal of understanding mathematics teachers from a holistic context that considers their perspectives, Olive has been communicating mathematics teachers' personal meanings (Chapman, 1994; Chapman, 1997) and teachers' agency on their practice change (Chapman & Heater, 2010; Chapman, 2011; Chapman, 2013).

Olive has also used narratives as a research tool and pedagogical tool. When working with prospective teachers (Chapman, 2008a), Olive has asked them to write and share narratives of teaching mathematics and re-write them later in the course. This pedagogical tool has triggered prospective teachers' reflection of mathematics teaching practices. Olive's research and teaching experience using narrative inquiry and narratives to approach teachers in different stages of their career had brought her to lead one of the PME 2017 plenary session, chapters in handbooks (e.g., Chapman, 2008b; Chapman, 2009), and discussion groups at PMENA and ICME (Beswick, Chapman, Goos, & Zaslavsky, 2012; Beswick & Chapman, 2013) that focused directly or indirectly on the mathematics teacher educator knowledge and learning that included narratives and self-study.

As an early childhood mathematics educator, Jennifer seeks to engage teachers on exploring and validating children's mathematics. She learned about this by being involved in the community that surrounds the school and engaging in conversations with children. In her methods courses, Jennifer has been working on different ways to encourage teacher learners to explore children's mathematics and their cultural backgrounds. Part of her journey creating spaces for teacher learners to explore children' mathematics was described in Ward (2017). In this chapter, Jennifer described her experience adapting an assignment so that it provides entries for teacher learners to explore children's ways of knowing, which includes sociocultural background information. Seeking to add the voice of a mathematics teacher to the existing literature on teaching math for social justice, Jennifer chronicled her journey as a MTE working in an early childhood setting with four and five year old children. During this time, Jennifer was focused on merging mathematics content with social justice goals as described by Gutstein (2008) as she sought to explore her own experience in teaching mathematics for social justice with young children. It was through the use of autoethnographic methods that Jennifer was able to convey her story, seeking to connect with other who had similar experiences with a level of honest and raw narratives about the experience.

As part of her dissertation study, Elizabeth explored the concept of personal practical knowledge ([PPK], Elbaz, 1981, 1983) while working with an eighth-grade mathematics teacher for three years. Dewey's (1938) theory of experience and Schwab's (1969, 1983) conceptualization of curriculum served as theoretical lenses in her study. Different histories and experiences encouraged Elizabeth to understand teachers' ways of knowing through the methodology of narrative inquiry. The teaching of secondary mathematics in Chile; learning about research in education; having a collaborative relationship with a mathematics teacher (Suazo, 2016); and encountering Jean Clandinin at an AERA 2016 satellite seminar are some of them. Following this methodology, Elizabeth documented her experiences planning and implementing a mathematics lesson with the teacher. Once outside of the school, when working on the research text, Elizabeth realized that she learned about the teacher's PPK, but also about herself as MTE. The research text relates both mathematics teachers' PPK before coming together and during the planning and implementation of the mathematics lesson. Insights into their personal experiences, teaching practices, and conceptualization of the concept area are interrelated in her narrative inquiry study.

Through our collaboration writing a proposal for and presenting at the Association of Mathematics Teacher Educators (AMTE) 2018, we realized that our methodologies had commonalities and differences. As Hamilton, Smith, and Worthington (2008) stated, these methodologies have in common the "I" and the goal of understanding participants' ways of being or thinking. Self-study and autoethnography share the goal of understanding the self, but autoethnography pays attention to the cultural surroundings of the participants and self-study has the goal of improving the teacher/researcher's practice. Narrative inquiry focuses on acknowledging research as collaboration where researchers focus on the knowledge that is constructed when interacting with participants. Something that is common to all these methodologies is the rewarding feeling we have experienced. Reflecting on and discussing our research made us conscious of lenses and biases involved in our design and implementation of research. This contributed to our learning. In our representations of our work and methods, we also began to consider ways we might invite other MTEs to engage with us and with one another on the development of researchable questions and the use of these methodologies in mathematics education.

Background Information

To consider what sorts of activities might support the emergence of research questions and understandings of the methodologies, we began by summarizing our views of these methodologies that have nurtured and energized our practices.

Narrative Inquiry. The purpose of this methodology is to study lived experiences (Clandinin & Connelly, 2000) and the way we create meaning in our lives. In narrative inquiry, it is understood that the only way to construct knowledge of participants' experiences is to be involved with them in their environments and move to a place of empathy (i.e., making emotional and cognitive connections). The benefit of using narrative inquiry (Clandinin & Connelly, 2000) is to capture more personal and human dimensions of experience. Records of experiences are taken as they occur, but are then layered with reflection upon those experiences. While the experiences are temporal and situated in a place and social context, their meaning expands through reflection. More than just providing access to the lived experiences of individuals who may or may not be represented in the literature, narrative inquiry is a way to uncover things that we as a field, or as individuals are not even aware that we do not know. As practitioners of narrative inquiry, we can attest to the transformative nature of this work; we, as researchers, cannot remain passive and unchanged. We are active within the study and the study is only possible because of our proximity.

Self-study. This methodology involves studying self as teacher in context (LaBoskey, 2004). MTEs' lived experiences as learners and teachers in relation to learners are sources of insight about knowing and knowledge. As a form of practitioner research (Borko, Liston, & Whitcomb, 2007), self-study is self-initiated and aimed at improving one's practice (LaBoskey, 2004). We view self-study as characterized by openness, collaboration, and reframing (Samaras & Freese, 2009). Self-studies further situate questions in existing research literature and suggest implications for "the larger audience of teacher-educators" (Borko, Liston, & Whitcomb, p. 9). We view MTEs' self-awareness and commitment to self-improvement in the context of working with others as the initial steps in self-study. In addition, we view self-study as a methodology that can be used to improve practice and support sustainable scholarly inquiry.

Autoethnography. Situating the writer as both researcher and participant, autoethnography allows MTEs systematically analyze their experiences to understand a culture or group in which they are members (Ellis & Bochner, 2000). Presenting the story of experience, we aim to connect with other MTEs that have had similar experiences through elements of coherence, verisimilitude, and interest. As such, we see autoethnography as a means to nurture and energize our own practice through critical examination of our own personal beliefs and values. By employing autoethnography as a methodology we have been able to develop a sense of connection with other MTEs engaged in similar work. These connections manifest into feelings of empathy as we share about experiences and constructed beliefs with other MTEs.

Beyond Representations to Developing Research Spaces

Participants in the AMTE session, were curious about and interested in incorporating these methodologies in their work. Many of them were looking for spaces that support research under such methodologies. This encouraged us to think about proposing the construction of a similar space at PMENA 2018. AMTE 2018 was the physical place where we connected for the first time with Olive Chapman and invited her to join our group. Meeting our audience and Olive energized us in continuing creating spaces for MTEs who are interested on, or could use, these methodologies. The construction of such space as AMTE 2018 also brought us to the writing a chapter called Mathematics Teacher Educators Inquiry into Their Practice for the International Handbook of Mathematics Teacher Education. This chapter will be part of a volume that focuses on MTEs as a developing professional. We envision having a working group at PMENA 2018 as another evidence that our field is embracing diversity in research methodologies and exploring new research questions related to MTEs' work.

Outline of Working Group Session

Our first session will include introductions and overviews of the participants, and the leaders', and an exploration of the overviews of the methodologies of narrative inquiry, self-study, and autoethnography described in the background information of this proposal. We anticipate that this will generate questions from the audience about the nuances of these methodologies. To build from participants' interests and experiences, we will provide opportunities to brainstorm research questions that have emerged for participants from their work as MTEs. These questions will be compiled and discussed to gain insight from the group about how to study these questions using the stated methodologies. In the second session, participants will select one methodology to explore the study of a research question that was previously identified as being answered by a certain methodology (i.e., narrative inquiry, self-study, or autoethnography). Part of the second and third day, participants will engage in the creation of research texts from existing field texts in the forms of video, personal journals, and transcripts of conversations using the different methodologies. By having the experience of analyzing existing field texts and creating narratives from them that align with the methodologies, we hope participants will engage in a reflection about the "use" of these methodologies and their interactions with their personal worldviews. We anticipate this activity will generate a discussion about the challenges, tensions, dilemmas, and joys of implementing studies under these methodologies. In the third session, we also plan to discuss ways to continue and extend our spaces for learning and support of the writing and publication of studies begun or fostered through the working group. Some of the activities we plan to implement to generate ideas about follow up activities are the following:

1. Participants grouped according to the methodology they are interested in will share their reflections about their experiences exploring such methodologies during the working group session and plan for scholarly inquiry.
2. Small groups will share ideas with the whole group and together we will develop potential collaborations and plans to write, lead sessions in conferences, or publish manuscripts.
3. Participants will discuss ways (e.g., social media, emails, Google Drive, Skype) to continue communicating throughout the year.

This working group will engage PMENA members to better understanding the nature of mathematical modeling in the early grades while considering the student perspective and recognizing the importance of teachers knowing their students and the contexts that are meaningful to their students. We will investigate how K-6 teachers demonstrate the interdisciplinary nature of mathematical modeling, the diversity of mathematical approaches taken by student modelers, and the multiple pathways the teacher can use to elicit students' mathematical thinking. We will explore how mathematical modeling bridges equity and social community in teaching and learning mathematics for all students. Exemplar tasks that emphasized local contexts and tapped into students' funds of knowledge and student artifacts will be shared to illustrate the child's perspective and the developmental progression. These topics will facilitate group discussions exploring the learning progression for mathematical modeling thinking and habits of mind that can develop for emergent mathematical modelers from an early grade. We will map out productive learning pathways for mathematical modeling and task design for K-6 mathematics education and beyond.. Finally, based on the interests of the participants, we will devote work time to finding synergistic collaborative topics to pursue for future research and practice.

Keywords: Mathematical Modeling, Elementary Education, Teaching Practices, Professional Development, Learning Progressions, Knowledge of Content and Pedagogy

Overview of the Working Group

This working group had its first meeting at the 2017 PMENA in Indianapolis, IN. We wanted to build on PMENA's long tradition of working groups on *Models and Modeling* with a special focus on early mathematical modeling. Our goal continues to focus on broadening the access of mathematical modeling to diverse learners in the elementary grades and advance the field's collective understanding of the interrelated processes of mathematical modeling in the elementary grades and beyond. Although there has been a long history of mathematical modeling at PME and PMENA, the focus has primarily been on middle, high school and university levels. We believe it is critically important to understand the learning progression of mathematical modeling from elementary to secondary grades to ensure coherence and rigor in the mathematics curriculum.

Our goal from last working group leaders was to propose an edited handbook or a special issues journal venue for mathematical modeling where participants interested in submitting manuscripts can work together to provide a comprehensive research trajectory documenting the progression of mathematical modeling from emergent levels to more sophisticated levels of modeling. We are excited to share that this working group was able to secure a contract with Springer to publish an edited handbook on this very topic! We hope to continue this working group so that we can invite more mathematics educators in the important research of mathematical modeling in the early grades. Since our first working group meeting where we had leaders three university collaborating working with school districts, we have now expanded just within our facilitator leadership over six different universities working with diverse populations to understand the nature of mathematical modeling in the elementary grades. In our design-based implementation research, each university site worked with the collaborating district's teacher leaders to co-plan the professional development. Teachers became co-designers of the mathematical modeling curriculum for the elementary classrooms. In our project, we engaged elementary teachers in considering mathematical modeling using real world tasks that contained several of the following attributes: (a) Openness; (b) Problem-posing; (c) Creativity and choices; d) Iteration and revisions.

Implementing mathematical modeling in the elementary grades is not just going "light" with the high school math modeling curriculum. Instead we advocate integrating aspects of mathematical modeling in the early grades effectively to enhance student learning and to help build their competency in real-world problem solving using their current mathematical knowledge. The latter content knowledge is expected to evolve as students continue to learn new mathematics as they progress towards high school and beyond. So what does mathematical modeling look like in the elementary grades? Why focus on early grades? In addition to the direct benefits of modeling, the elementary school environment affords many advantages that complement work in mathematical modeling. Elementary students often rely on using concrete referents such as objects, drawings, diagrams, and actions or pictures to help conceptualize and to construct carefully formulated arguments to solve a problem. Such arguments can make sense and be correct, even though they are not generalized or made formal until later grades (CCSSO 2010). Young students have high potential to become fluent – native speakers, thinkers and dreamers of mathematics. Thinking creatively may come more easily to children first learning and exploring mathematical concepts. Kindergarten students can use manipulatives to independently solve traditional multiplication or division problems they have never seen before, which is evidence that students come with knowledge--we don't have to wait to incorporate modeling activities until we have "shown them how" to do everything. Because early grade teachers are generalists, they can address several subjects simultaneously through modeling activities. Mathematical Modeling is of interest and relevance to the mathematics education community especially because it connects to the need for professional development focused on mathematical modeling in the elementary grades.

Our researchers used Design-Based Implementation Research methodology, DBIR (Fishman, Penuel, Allen, Cheng, & Sabelli, 2013) to examine the design of our professional development and to study and enhance our design through feedback from our iterative implementation cycles. DBIR was a method of choice for our study because it has (1) a focus on problems of practice from multiple stakeholders' perspectives; (2) a commitment to iterative, collaborative design; (3)

a concern with developing theory and knowledge related to both classroom learning and capacity for sustaining change in systems (Fishman, Penuel, Allen, Cheng, & Sabelli, 2013, p. 136).

Through our work, we are gaining a better sense of teaching practices and classroom routines that support modeling. We are contributing to the understanding of what is possible in early elementary grades and how these processes support the development of critical 21st century skills. As we continue in our research to consider what constitutes the practice of Mathematical Modeling (MM) and how it could be implemented in classrooms at different grain size, we invite the larger PMENA community to build on this knowledge. Over the past decades, working group leaders have individually and in subgroups, been theorizing about as well as collecting, analyzing, and reporting on data relating to mathematics modeling. This Working Group builds on and extends the work of previous Model and Modeling tradition by discussing current work from leading scholars from diverse perspectives.

Relevance to Psychology of Mathematics Education

The purpose of this working group is to invite individuals across the research community interested in synthesizing the literature and collaborating on research focused on mathematical modeling along the developmental continuum. Our goal of mapping a learning progression of mathematical modeling from K-12 education, particularly starting from elementary to middle grades is critically important to provide coherence in the mathematics curriculum.

The primary focus for this working group will be around the following three goals:

1. Examine current research and discuss the nature of mathematics modeling and detailing the development of teachers' content knowledge, teaching practices and students' modeling competencies.
2. Map the learning pathways for mathematical modeling and task design for K-6 mathematics education and explore how mathematical modeling can bridge equity and social community in teaching and learning mathematics for all students.
3. Analyze dialogue and collaboration among individuals and groups conducting research on student- and teacher-related outcomes related to implementing mathematical modeling, ways mathematical modeling promotes 21st century skills, and ways in which early modeling can develop interdisciplinary skills in STEM.

Related Research

Mathematical proficiency, in today's world, moves beyond computational ability. It includes the development of 21st century skills (i.e., critical thinking, creativity, communication, and collaboration), conceptual understanding of mathematics (NCTM, 2014), and mathematics that has practical relevance outside of the classroom (Gravemeijer, Stephan, Julie, Lin, & Ohtani, 2017). Mathematical modeling (MM) is a powerful tool for developing students' 21st century skills (Suh, Matson, & Seshaiyer, 2017), advancing their conceptual understanding of mathematics, and for developing their appreciation of mathematics as a tool for analyzing critical issues in the world outside of the mathematics classroom (Greer & Mukhopadhyay, 2012). It provides the opportunity for students to solve genuine problems and to construct significant mathematical ideas and processes instead of simply executing previously taught procedures and is important in helping students understand the real world (English, 2010).

There is broad agreement among mathematics educators on the relevance of mathematical modeling in schools, however, the field has yet to come to a consensus on the definition of mathematical modeling or on how it might be taught and learned in schools (Kaiser, 2017). Although mathematical modeling has been reserved for secondary and college students, its enactment in schools contributes to broad educational goals that are relevant to learners of all ages (Ferri, 2018). In addition, scholars have argued that engaging in mathematical modeling is important for elementary school students (Carlson, Wickstrom, Burroughs, Fulton, 2016).

Mathematical modeling has received increased attention in the United States since the release of the Common Core Standards in Mathematics (the Common Core hereafter) in 2010. Modeling is incorporated as a specific area of expertise that teachers should cultivate in students across Grades K–12. The Common Core's Standards for Mathematical Practice, SMP4 is called *Model with Mathematics.* Although SMP4, as a mathematical practice, cuts across Grades K–12, mathematical-modeling opportunities are not highlighted in connection with the K–8 content standards presenting an implementation challenge for teachers (Cirillo, Pelesko, Felton-Koestler, & Rubel, 2016). Modeling with mathematics, the topic of SMP4, refers to both modeling mathematics and mathematical modeling. The distinction between modeling mathematics and mathematical modeling is not clear to many teachers (Meyer, 2015), nor is it clear in Common Core documents or in mathematics education literature (Cirillo et al., 2016). The key difference between mathematical modeling and modeling mathematics is where the mathematical activity begins. Modeling mathematics begins in the mathematical world (Van de Walle, Karp, & Bay-Williams, 2016), whereas mathematical modeling begins in the unedited real world (Pollak, 2007). The explicit focus on getting a problem outside of mathematics into a mathematical formulation and explicitly translating the mathematical solution back into the real world is what differentiates mathematical modeling from modeling mathematics. The real-world focus also distinguishes mathematical modeling from problem solving and application problems (Lesh & Caylor, 2007; Schukajlow et al., 2012).

One of the ways, the researchers in this working group approached MM in the elementary grades was to immerse students in a real world situation within their local context that was relatable and personally meaningful. In bringing mathematics closer to the social community spaces, mathematical modeling became a vehicle that bridged teaching and learning mathematics closer to all students. Reform mathematics have advocated for mathematics to be more related to students' lives by building on community and cultural knowledge and practices with issues that matter to them, which then helps students view mathematics as a vehicle through which they learn to be active change agents for social justice (Bartell et al. 2017; Civil 2007).

To keep the initial problem open, students were encouraged to develop the habit of mind of being problem posers by identifying the many questions around the real phenomenon, then defining a mathematical problem that can be solved by way of mathematics. After the identification process of the problem, the modeler makes assumptions, eliminates unnecessary information, and identifies important quantities in order to develop a solution. This mathematical solution focuses on the usefulness of mathematics to solve a real-world problem. It should be noted that there can be several mathematical solutions for a given real-world situation. After solving the problem the results are translated back to the real-world and interpreted in the original context. The problem-solver then validates the solution by checking whether it is appropriate or reasonable for the purpose. This process of making assumptions, identifying variables, formulating a solution, interpreting the result, and validating the usefulness of the solution is iterative in nature and is modified or changed and repeated until a satisfactory solution has been obtained and communicated (Blum, 2002).

It is important to note that teachers play a crucial role in MM. The teacher must be able to: (1) find appropriate questions to move students through the modeling cycle, (2) handle discussions in nondirective but supportive ways, (3) allow students time for productive struggle, and (4) provide scaffolding without directing the problem (Burkhardt, 2006). Teachers also need to develop problem-posing expertise (Suh et al., 2017) and to base their instructional decisions on responses to students' work (Bleiler-Baxter et al., 2016). Thus, learning teach mathematical modeling requires teachers to develop multiple knowledge bases. For example, teachers must understand modeling processes and tasks, including the potential mathematical content embedded within tasks; learn about students' mathematical and personal experiences to predict the strategies they might use when responding to modeling tasks; know what content is on the mathematical horizon in order to anticipate what mathematical ideas students might construct and learn to engage individual and groups of students in the modeling process. (e.g. Blum, 2011; Ferri, 2018).

Previous work with elementary school children demonstrated it is feasible for them to develop a disposition towards realistic mathematical modeling (Lieven & De Corte, 1997). One of the issues in implementing MM at the elementary level is that MM can be difficult for both teachers and students to implement (Blum & Ferri, 2009). MM can be difficult for teachers to implement as they must be able to merge mathematical content and real-world applications while teaching in a more open and less predictable way (Blum & Ferri, 2009). Mathematical modeling can be a challenge for students because each step of the modeling process presents a possible cognitive barrier (Blum & Ferri, 2009). As stated in the Common Core Standards for Mathematical Modeling, *"Real-world situations are not organized and labeled for analysis; formulating tractable models, representing such models, and analyzing them is appropriately a creative process. These real-world problems tend to be messy and require multiple math concepts, a creative approach to math, and involves a cyclical process of revising and analyzing the model"* (Carter et. al., 2009). To model, students need support to develop mathematical modeling competency i.e., the ability to independently carry out the various phases of the modeling process (Vorhölter & Kaiser, 2016) and its related sub-competencies (Schukajlow et al., 2015). Based on the Standard for Mathematical Practice 4 in the Common Core: Model with Mathematics, Bleiler-Baxter, Barlow, and Stephens (2016) designated the mathematical modeling sub-competencies needed by students as: simplification (e.g., making assumptions), relationship mapping (e.g., identifying important quantities and their relationships), and situation analysis (e.g. interpreting results in the context of the situation). In addition, students need to develop a metacognitive modeling competency as this is "indispensable in order to enable students to solve complex modeling problems independently, which is an indispensable part of true modeling activities" (Vorhölter & Kaiser, 2016, p. 279).

In a previous PMENA report, Suh, Matson, Williams and Seshaiyer (2016) reported the challenges and affordances of mathematical modeling in the early grades.

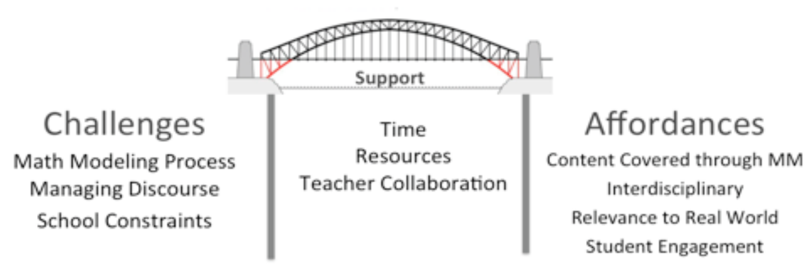

Figure 1. Challenges and affordances of mathematical modeling.

Teacher Challenges. The challenges teachers faced when implementing mathematics modeling in the elementary grades included: a) Novelty and ambitious nature of the *modeling process*-When implementing MM in the classrooms for the first time, teachers found it was difficult to move students through the full process as it was a novel approach and students had never been introduced to creating and validating their mathematical models; b) *Managing discourse*- Another difficulty encountered by teachers in the MM process was in defining their role as facilitators. The teachers commented that "...it is really difficult as a teacher to help students find a direction to go with their solution but not direct or guide them toward a teacher goal."; and c) *Constraints around mandated standards*-Participants acknowledged that MM takes time to implement in the classroom and that additional class time to implement these tasks would be helpful. An additional challenge noted by teachers was that mathematical modeling didn't go the way they expected it to and they wrestled with the need to meet state standards.

Affordances of Mathematical Modeling. The main affordances our teacher-designers mentioned were that mathematical modeling provided opportunity for content to be covered without direct instruction, had interdisciplinary connections, and provided mathematical relevance, and student engagement: a) *Content covered without direct instruction-* When teachers implemented MM in their classrooms for the first time they were amazed at the amount of content that could be covered without direct instruction. Students could see how the mathematics could serve their needs as they used the mathematics they learned while other times, the mathematics related to future learning objectives which allowed them to revisit their model as their learning progressed; b) *Interdisciplinary opportunities*-Another positive take-away from implementing MM in these teachers' classrooms for the first time was how MM created a space where content covered was interdisciplinary connecting to social studies, STEM and language arts; c) *Relevance*-By providing authentic tasks for students to grapple with through the MM process, mathematics became relevant to the students; d) *Student engagement*-A number of our teachers indicated how engaged their students were in their MM tasks. Mathematical modeling inspired these teachers' endeavors and provided pictures of practices that served as the proof of concept they needed to sustain their professional commitment to mathematical modeling.

Support Teachers Need. The three main areas of support teacher-designers requested were access to MM resources, pictures of practice, time and collaboration with like-minded teachers: a) *Resources and pictures of practice*-Teachers indicated a desire to use MM in their classrooms but indicated a need for a bank of open-ended MM lessons and new ideas for continuing to create these lessons; b) *Time*-Teachers expressed the need for more time to work through and become comfortable with implementing the modeling process in their classrooms. Teachers noted it was only in working through the MM cycle several times that they felt comfortable with the process and felt their students were able to understand the whole MM process; and c) *Teacher collaboration*-Teachers indicated a desire to continue to work with a cohort to build MM lessons; to observe other teachers implement MM in their classrooms; and to work alongside a colleague who valued MM and with whom they could share ideas.

Other related research the team will share include, Carlson, Wickstrom, Burroughs & Fulton's (2016) work, *A Case for Mathematical Modeling in the Elementary School Classroom*, where they provide a teaching framework for MM using the "organize - monitor - regroup" cycle to support the teachers' work in engaging young students in modeling. Wickstrom, Carr and Lackey (2007) will showcase an engaging article using mathematical modeling to explore Yellowstone National Park. Suh, Matson, & Seshaiyer (2017) will also share ways in which mathematical modeling enhanced students creativity, collaboration, critical thinking and communication skills and exposed students to interdisciplinary themes of service learning and STEM integration.

Plan for Active Engagement of Participants

The working group will meet three times during the conference and virtually during the course of one year. In each session, PMENA members will engage in mathematical modeling while sharing their perspectives in teaching and learning mathematics, considering synergistic areas fruitful for future research and practice, and finding collaborators within our group.

Session 1: Exploring the Nature of Mathematical Modeling in the Early Grades

The first session will focus on better understanding the nature of mathematical modeling in the elementary grades while considering the student perspective and recognizing the importance of teachers knowing their students and the contexts that are meaningful to their students. We will investigate how K-6 teachers demonstrate the interdisciplinary nature of mathematical modeling, the diversity of mathematical approaches taken by student modelers, and the multiple pathways the teacher can use to elicit students' mathematical thinking. We will explore how mathematical modeling bridges equity and social community in teaching and learning mathematics for all students. Exemplar tasks that emphasized local contexts and tapped into students' funds of knowledge and student artifacts will be shared to illustrate the child's perspective and the developmental progression. These topics will facilitate group discussions exploring the learning progression for mathematical modeling thinking and habits of mind that can develop for emergent mathematical modelers from an early grade. We will map out productive learning pathways for mathematical modeling and task design for K-6 mathematics education and beyond.

Session 2: Identifying the Knowledge of Content and Pedagogy Needed for Mathematical Modeling in the Elementary Grades

In our second session, we will focus on clearly defining modeling teaching practices and competencies needed for mathematical modeling and outlining research goals and objectives to monitor the enactment of these practices. We will detail classroom routines, such as the "organize - monitor - regroup" cycle (Carlson, et al. 2017), and the Pedagogical Practices for Mathematical Modeling (Suh, Matson, & Seshaiyer, in press) as we share designed activities and lesson vignettes to solicit more ideas around high leverage MM teaching practices. We will explore what mathematical knowledge is needed to "successfully" facilitate mathematical modeling tasks in elementary grades. We will examine current research and discuss the nature of mathematics modeling and detailing the development of teachers' content knowledge, teaching practices and students' modeling competencies.

Session 3: Finding the Synergy between Mathematical Modeling and the 21st Century Skills Frameworks and PBLs in STEM

The third session will outline several 21st century skill frameworks and teaching approaches and how mathematics educators, researchers and practitioners can find a synergistic way to bring important process skills without overwhelming teachers and students. We will discuss the ways elementary teachers can make connections between the problem-based ways they have engaged students in mathematical modeling and STEM. The teachers are able to take advantage of interdisciplinary opportunities across the subjects they teach and find complementary connections between subjects and common classroom practices that support MM. We will analyze dialogue and collaboration among individuals and groups conducting research on student- and teacher-related outcomes related to implementing mathematical modeling, ways mathematical modeling promotes 21st century skills, and ways in which early modeling can develop interdisciplinary skills in STEM

Anticipated Follow-up Activities and Goals of Working Group

In the spirit of exploring the theme of 2018 PMENA on changing mathematical and pedagogical demands for PK-6 education and supporting *all* students through a concerted focus on equitable teaching practices. In addition, this working group will attend to the interdisciplinary nature of mathematics and how it connects to social justice, STEM and civic responsibility for our citizen in our country. Each session will engage participants to share their research interests related to mathematical modeling and form groups that might pursue research collaboratively based on the interests of the participants. We will also work on book chapters for the handbook. Some of the questions that we will engage in include:

- What defines successful mathematical modeling at different grade levels?
- How does mathematical modeling support each and every learner?
- How does mathematical modeling connect one to issues of social justice, STEM and civic responsibility of citizens?
- What can we learn from teachers who implement MM regularly in their classrooms?
- How is mathematical modeling ambitious teaching and how can we support teachers enacting MM through lesson plans and other resources?
- How can we map out the learning pathways of MM across grade levels?
- How and what can we learn about models elicited from student artifacts from MM tasks?
- What do “successful” modeling practices look like in our elementary mathematics classrooms? How are they similar or different from practices in secondary classrooms?
- What does it mean to “see the math” in the components of mathematical modeling?
- How do teachers select and/or develop modeling problems? How can Professional Learning Communities or Teacher Study Groups help teachers anticipating how students will answer the MM questions?

Our goal is for the working group leaders to propose an edited handbook or a special issues journal venue for mathematical modeling where participants interested in submitting manuscripts can work together to provide a comprehensive research trajectory documenting the progression of mathematical modeling from emergent levels to more sophisticated levels of modeling.

Acknowledgments

This working group was funded by NSF 1441024-STEM C

Though teacher preparation programs include university coursework and fieldwork in K-12 school settings, they are often disparate experiences. This group of mathematics teacher educators (MTEs) has been working to integrate these preparation efforts by purposefully designing coursework around McDonald et al.'s (2013) learning cycle to include mediated field experiences. Such experiences are embedded within public school classrooms and are organized around core teaching practices so that pre-service teachers (PSTs) engage in authentic learning; they learn mathematics and ways to teach mathematics through the act of teaching. Our goals as a working group are to establish cross-cutting and essential features of these mediated field experiences and identify future research questions and ways to standardize data collection to create clear lines of investigation to explore the impacts of such experiences.

Keywords: Teacher Education-Preservice, Teacher Education Programs, Field Experiences; Practice-based; Mediated Field Experiences; School-Embedded Courses

Motivations for This Working Group

Mathematics teaching is a complex professional practice; relational in nature and requiring a deliberate, coached effort to learn and do well (Grossman, Hammerness, & McDonald, 2009). Teacher preparation programs include both university course work and clinical field experiences, yet decades of research indicate that the two are often disparate experiences for pre-service teachers (PSTs)(Grossman et al., 2009; Korthagen & Wubbels, 2001; Lampert & Graziani, 2009; McDonald, Kazemi, & Schneider-Kavanagh, 2013). The clinical component of mathematics teacher preparation—in the form of PSTs observing and taking increased responsibility in PK-12 classrooms—can be influential in the development of teachers' practice (National Research Council, 2010) and current standards for the preparation of mathematics teachers call for increased opportunities for PSTs to learn via clinical experiences (Association of Mathematics Teacher Educators, 2017).

Embedding university courses within K-12 schools where PSTs have opportunities for interactional clinical experiences with the support of a mathematics teacher educator (MTE) is a promising model to support the development of skilled practice (Virmani et al., 2017). Horn and Campbell (2015) present a hybrid space situating coursework and field work together as "mediated field experiences." Within a mediated field experience, PSTs are provided opportunities, structure, and support to apply knowledge of teaching by confronting specific situations and determining ways to integrate realities of the classroom with teaching ideals. For example, PSTs may be asked to create a lesson plan, teach a lesson, or reflect about a teaching experience; however, without an MTE to "mediate" the implementation, the PSTs may apply their university knowledge problematically, or they may not notice or make sense of particular features of the teaching practice that produce unexpected results (Campbell & Dunleavy, 2016). Because of the unpredictable nature of teaching and learning, flexibility is key within the mediated field experience. Horn and Campbell (2015) found MTEs often modified the focus of what was mediated according to what happened during their observations of PSTs.

Despite a growing body of literature that focuses on the need to more deeply connect field experiences to teacher preparation coursework, there is little evidence for what aspects contribute to PSTs' development of the knowledge, skills, and dispositions that help them meet the realities of the classroom. The central aim of our Mediated Field Experience (MFE) Working Group is to explore the essential features of our school-embedded mediated field experiences that take place during PSTs' preparation, describe ways mediated field experiences can transfer to a variety of contexts (different types of institutions and courses), and establish future research questions leading to identification of ways mediated field experiences impact PSTs learning.

Background of Our Work

During a NSF-funded conference held in 2015, ten MTEs, five on this current proposal, began collaborating about ways to use MacDonald et al. (2013) learning cycle of enactment and investigation (see Figure below) to create mediated field experiences in various math methods and content courses to prepare PSTs at our respective institutions. The "pedagogies of practice in professional education" (Grossman et al., 2009) framework underpins this cycle; PSTs with mentors decompose and approximate practice in increasingly authentic settings. Instructional activities act as containers in which PSTs engage in the act of teaching by preparing activities, including rehearsing during university class time, enacting activities with children in authentic classroom settings, and then reflecting and analyzing their learning about content, student thinking, and pedagogy (Kazemi, Franke, & Lampert, 2009). Our working group, was particularly interested in investigating ways embedding our courses into the schools while using McDonald et al.'s (2013) learning cycle could support PSTs' development of core teaching practices. By situating the learning within practice, we aimed to develop a community of practice in which PSTs, MTEs, classroom teachers, and elementary students learned from each other as they engaged with core teaching practices within carefully selected instructional activities.

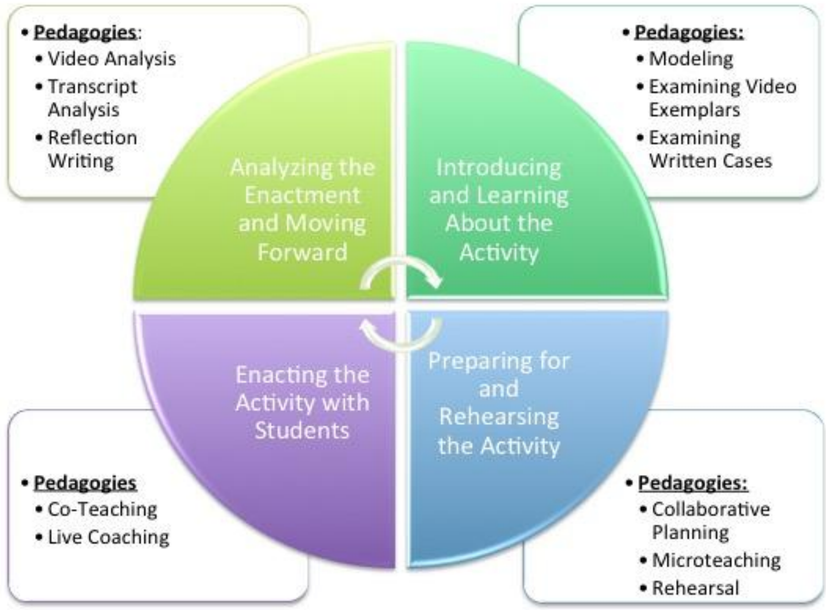

Figure 1. Cycle for collectively learning to engage in an authentic and ambitious instructional activity (McDonald, Kazemi, & Kavanagh, 2013, p. 382).

We used Dr. Elham Kazemi's work at the University of Washington to guide our pilot study. Since their teacher preparation work is a graduate program focus with the support of graduate student and funding for cooperating teacher involvement, we wanted to examine ways to implement McDonald et al.'s (2013) cycle of enactment in different contexts teacher preparation courses without additional university classroom supports, varying in intensity of integration of methods and content courses, within a K-12 school setting. From our work together, five key themes emerged (Virmani et al., 2017):

1. PSTs work in a P-12 classroom with students and at least one teacher educator in a face-to- face setting.
2. MTEs use time-outs or planned/unplanned pauses in ways that (a) provide opportunities for all teachers to think in the moment (e.g., make sense of student thinking, discuss a next teacher move), and (b) position students as powerful and productive thinkers.
3. Participants, including PSTs, MTEs, & classroom teachers, approach a lesson with a shared curiosity and/or plan to learn something particular about teaching and learning.
4. Classroom visits focus on observing, studying, and/or trying something related to eliciting student thinking in ways that can't be as authentically explored in the university classroom without students.
5. All participants debrief, analyze, and reflect on the experience individually and collectively. This includes conversations with a teacher educator centered on making meaning of classroom events in terms of student thinking.

Since this initial pilot study, a subgroup has continued to work together in developing and studying the affordances of school-embedded methods and content courses. Recently, at the Association of Mathematics Teacher Educators (AMTE) conference in February 2018, we presented our initial analysis on debriefs, or reflective conversations, occurring at various stages within the learning cycle. Debriefs took place between the whole group of PSTs, MTEs, and the classroom teacher and provided opportunities for PSTs to immediately talk about what happened during their interactions with students and share common experiences. These debriefs produced more authentic conversations about teaching, learning, and students and provided opportunities for MTEs to name or "label" what PSTs saw in the classroom and connect it to course materials (readings, theory, etc.). Further, there were many areas of growth made visible via debriefs including: core teaching practices, PSTs identity development, and the attention to student thinking and viewing students as competent sense makers.

At the AMTE conference, we connected with other MTEs engaged in similar work at their institutions. We found there is a need in the math education field to better understand how to support the work of embedding teacher preparation coursework in schools via mediated field experiences while using McDonald et al.'s (2013) learning cycle to support the development of core teaching practices. Together, as a working group, we aim to study our different models of these mediated field experiences to identify essential features which would allow these experiences to transfer into a variety of contexts and begin initial efforts of investigating the impacts of these experiences on PSTs' development.

Review of the Literature and Background Information

Recently, AMTE published the *Standards for Preparing Teachers of Mathematics* (2017) outlining standards and related indicators for effective programs for preparing beginning teachers of mathematics. The standards list five key domains including (1) well designed and integrated partnerships with all partners productively engaged (2) opportunities for PSTs to develop content knowledge and mathematical practices through sustained, quality experiences, (3) opportunities for PSTs to learn to teach mathematics which includes knowledge of content, students, and contexts in which they teach (4) opportunities for PSTs to learn through clinical experiences where they learn from their own teaching and the teaching of others, and (5) recruitment and retention. Research across decades has shown, however, that there are numerous barriers to accomplishing these standards with traditional models of field experiences that are separate from university-based teacher preparation coursework (Akerson, Morrison, & McDuffie, 2006; Borko & Mayfield, 1995; Fryholm, 1996; Gainsburg, 2012; Zeichner & Tabachnick, 1981).

One such barrier lies in the separation of theory and practice. "What remains to be developed is… pedagogies of enactment through which novice teachers are supported in actually doing the practice of teaching" within their teacher preparation programs (Kazemi, Franke, & Lampert, 2009, p. 12). In many teacher preparation programs, instruction focuses on learning *about* strategies and practices for teaching rather than directly enacting and honing these skills (Grossman et al., 2009). This separation of theory and practice is problematic; as Lampert (2005) describes,

> …learning about a method or learning to justify a method is not the same thing as learning to do the method with a class of students, just as learning about piano playing and musical theory is not learning to play the piano (p. 36).

One way to bridge the theory/application gap, is to engage in practice-based learning, where PSTs directly learn via the *act of teaching*. The term *practice* conveys a variety of perspectives in the research literature related to teacher preparation (Lampert, 2010). *Practice- based learning* describes types of field experiences or programs situating PSTs' learning in K-12 classrooms coupled with instruction as well as training or coursework focusing explicitly on the work of teaching (Forzani, 2014). Grossman et al. (2009) describe how a core-practice approach in teacher education necessitates organizing coursework and fieldwork around *practices* of the teaching profession while simultaneously providing PSTs ample opportunities to "practice" and enact these teaching practices. Other research within the teacher education community has identified "core" or "high-leverage" teaching practices that effective teachers use while teaching (i.e., Ball & Forzani, 2009; McDonald, Kazemi, & Kavanagh, 2013; NCTM, 2014).

The *Standards for Preparing Teachers of Mathematics* (2017) describe standards for effective teacher preparation programs that are practice-based. They call for PSTs' development of teaching practices based on the National Council of Teachers of Mathematics (2014) identification of eight effective mathematics-teaching practices. These standards require teacher preparation programs to provide scaffolded and multiple opportunities for PSTs to integrate their learning and incorporate practice-based experiences in authentic classrooms throughout the program, not just in student teaching. Moreover, these standards call for teacher preparation programs to be actively involved *in partnership with* the schools that their candidates are placed in, working toward shared goals for instructional improvement and student learning.

> Only when preparation programs purposefully engage with schools, not just in schools, will their clinical preparation become truly robust in ways that maximize candidates' skill development and therefore their abilities to support the mathematics learning of students (p.37).

These practice-based experiences must provide PSTs opportunities to develop skills with teaching practices, gain mathematics content knowledge and insight into students as mathematical learners, and reflect critically and regularly about mathematics teaching and learning. Responding to this call, the question of how we might structure learning experiences to integrate content knowledge, theory, and practice is central for practice-based teacher education and the focus of our working group through studying our mediated field experiences.

Approximations of Practice to Develop Adaptive Expertise

Additionally, Grossman et al. (2009) argue PSTs need opportunities to engage in "approximations of practice" in both the university classroom and through authentic K-12 classroom settings. Lampert & Graziani (2009) highlight the importance of instructional activities or "enact-ables" that PSTs could rehearse, enact, and receive feedback on in this work. McDonald et al.(2013) propose a *cycle for learning* (Figure above) that is flexible in a variety of settings where PSTs learn to enact teaching practices and involves: learning about the instructional activity (including envisioning the practice), preparing for enacting these practices (including rehearsing), having opportunities to enact the practices with real students in actual K-12 classrooms, and analyzing and reflecting upon these enactments. Horn and Campbell's (2015) work emphasize the need for mediation of these learning experiences. By purposefully designing teacher preparation coursework to include the pedagogies of enactment through our mediated field experiences in K-12 school settings, we are working to develop PSTs ability to develop core teaching practices. However, further research is needed to provide empirical evidence that these efforts produce well-prepared beginning teachers of mathematics.

Some argue that too much specification could lead to "deskilling" teachers, others argue that the ability to specify and codify common practices is a precondition of a profession (Ball & Forzani, 2009). With this commitment to specification and building core practices or instructional routines, there has been less attention given to what it would take to help teachers develop *adaptive expertise* (Darling-Hammond & Bransford, 2005; Hatano, 1988). Adaptive experts are not only highly skilled in the performance of a limited number of tasks, but are also able to adapt and extend their routines, by accepting new possibilities or attempting to solve old problems in different ways (Chi, 2011). Given that teaching requires such adaptive expertise, as the complex interactions of a classroom can never be fully specified, Janssen (2015) has argued that research on practice-based teacher education will also need to attend to the more adaptive and improvisational dimension of practice. The field has started to see emerging research that supports using enactable activities such as instructional routines to help novices start to develop adaptive expertise. However, we need more empirical evidence that field-based teacher education organized around enactable instructional activities, like our mediated field experiences, significantly impact PSTs' practice in ways *that are not possible without those experiences*.

Connection to PME-NA Goals

The new AMTE (2017) standards urge teacher educators to develop innovative, practice-based models for supporting PST learning through the purposeful integration of coursework and field experiences. Though the McDonald et al. (2013) learning cycle is well-grounded, we can not expect teacher preparation programs to change until there is robust, empirical evidence that the learning cycle is effective in preparing PSTs and is best achieved via mediated field experiences in authentic school settings. Across our various projects, we have found mediating and entering authentic settings alongside PSTs provides incredible opportunities to learn with and from children. But this shift also inserts MTEs into the central conflict PSTs have long navigated alone: how to support a range of learners to meaningfully engage in high-quality mathematics instruction. It is not surprising that in challenging classroom settings, PSTs often forfeit the principled vision of high-quality instruction described in their teacher preparation programs for lower expectations for traditionally-underserved students (Frykholm, 1996). By entering into real classrooms with PSTs, we as MTEs have committed to support PSTs in navigating the realities of the classroom through these mediated field experiences.

The research proposed by this working group exemplifies PME-NA's commitment to equitable teaching practices and addressing the needs of all students. We want to investigate how these mediated field experiences help PSTs learn to build off of student thinking instead of directing or leading the students to follow their thinking. Our initial findings indicate that PSTs are able to understand the need for and develop equitable teaching practices to meet the needs of all learners by providing preservice teachers the opportunities to practice such core teaching practices like eliciting and responding to student thinking in a real elementary or secondary classroom. While working with the K-12 students, receiving feedback on their teaching, and reflecting on their experiences, PSTs are able to recognize the importance of providing all students with the opportunities to engage in challenging mathematics and practice pedagogical strategies that allow all students to participate (e.g., think pair share, or turn and talk). These mediated field experiences are an example of a transformation in the preparation of teachers of mathematics at all levels with hopes to make changes to the mathematical and pedagogical demands in the K-12 school setting through better preparation efforts for PSTs.

Goals of the Working Group

This working group has three main goals that it hopes to achieve during its time at PME-NA. Our first goal is that we would like to come together to identify features of each MTE's implementation of these mediated field experiences that are similar across institutions. We hope to identify these cross-cutting features so that we may start to establish a consensus for which ones might be essential to include when creating these experiences for our PSTs. Our second goal is to describe ways mediated field experiences can transfer to a variety of contexts (different types of institutions and courses), and our third is to develop clear lines of investigation by posing research questions, identifying the data to be collected, and standardizing the collection process across researchers to address the questions posed. By developing a clear research agenda, we hope to explore the impacts of these field experiences for PSTs.

Identifying Cross-Cutting Features to Develop "Transfer"

Across the working group, a variety of models for mediated field experiences have emerged (Virmani et al., 2017). These models range from exploratory integration of pedagogy and content courses within classrooms to those that have seized the opportunity to fully integrate a majority of coursework at school sites. Although these models and levels of integration differ, two main themes emerged across the models: (a) composing coursework around the practice of teaching, and (b) developing partnerships with teachers and schools. It is our hope that during these working group sessions, we will be able to dive deeper into these two themes to identify essential elements of these mediated field experiences that provide the PSTs the opportunity to develop adaptive expertise.

A strength of our working group is that we have MTEs from a variety of institution types, (e.g., large state schools, small liberal arts schools), programs (elementary, secondary, undergraduate and/or graduate), and courses (methods/pedagogy courses and content courses). The diversity in our group members affords us the opportunity to identify the essential features that can be utilized by virtually any MTE to support PST learning through teaching and their development of adaptive expertise. We would like to show other MTEs how McDonald et al.'s (2013) learning cycle can transfer into a number of different contexts with differing levels of support and that the University of Washington's model, while it is productive and researched, is not the only way this work can be done.

Creating Clear Lines of Investigation

The AMTE standards promote the idea of improving the connections between preparation coursework and clinical experiences, however there is a lack of empirical evidence or practical guidance for *what works* and *how to do it.* Our third goal of this working group is to collectively develop a clear research trajectory for studying and improving our work across institutions using evidence of learning to inform the revisions of (a) our collective theory of action, and (b) our individual program models. Our process for outlining a research trajectory for designing, implementing, studying, and revising these *mediated field experiences* in teacher education will be informed by educational design research methodology (Cobb, Jackson & Sharpe, 2017) and/or case study research design, based on the research questions that emerge from our working group discussions. Anderson and Shattuck (2012) describe design-based research (DBR) as,

> A methodology designed by and for educators that seeks to increase the impact, transfer, and translation of education research into improved practice. In addition, it stresses the need for theory building and the development of design principles that guide, inform, and improve both practice and research in educational contexts" (p.16).

In addition to DBR, some contributors are interested in case-study methodology. Case study lends itself to providing a "how" and "why" description of the mediated field experiences from variety of settings (Merriam, 2009; Yin, 2008). Once we collaboratively create our research questions during a working group session, some contributors plan on developing cross comparative case studies that address our research questions.

Given the multiple learners involved in these mediated field experiences, empirically documenting the results of our designs means tracing several lines of investigation simultaneously as we study how each of the following groups engages in *and develops as result of* learning opportunities in mediated field experiences:

A. K-12 students in the partner classrooms
B. Pre-service teachers (PSTs)
C. Cooperating classroom teachers (CTs)
D. Teacher educators (TEs)

The third goal of this working group requires us to work together in small groups to develop a clear research trajectory for each of the above lines of investigation based on researcher interest.

Plans for Active Engagement of the Working Group

Three working group sessions are planned to address the goals detailed above.

Session 1: Sharing our Experiences Implementing Mediated Field Experiences

In the first session, each of the eight working group members will share their current structure for implementing mediated field experiences at their institution, including current findings and research practices; each presentation will last approximately ten minutes. We will use Google Slides so that all presentation slides are in one slide deck to minimize transition time and a Google spreadsheet to organize the details of the different aspects of each implementation. Participants currently engaging in similar work will be invited to include their implementation data into the spreadsheet and included in the analysis. We end with a whole group discussion where participants begin initial identification of common features across institutions and settings.

Session 2: Co-Developing a Vision for Mediated Field Experiences

In our second session together, we will continue to collectively analyze the different features of the mediated field experiences across institutions. All participants will break into small groups, based on interest, where each group will analyze a different feature across institutions. Using open-coding techniques, each breakout group will work to classify a certain feature as essential or not across institutions. As a whole group, we will share findings and discuss disagreements to identify essential features of these mediated field experiences. We will work to organize these features to help others see how these ideas can "transfer" into different contexts. Our goal is to establish what features are "essential" to these experiences or which features lead to specific learning outcomes so that other MTEs may begin to see how they could incorporate these ideas into their own teacher preparation coursework or programs.

Session 3: Standardizing Our Data Collection to Create Clear Lines of Investigation

For our last session, we will identify the research questions that stem from our analysis and the data we want to collect to investigate how this is impacting PSTs' learning along with the learning of the others involved (K-12 students, classroom teachers, and even the teacher educator). Again, participants will break out into different groups based on their research interests--which aspect of their implementation would they like to discuss and investigate? For instance, some working group members are interested in creating observational tools to measure current PST teaching practices and provide a framework for giving feedback to PSTs both in the moment of teaching and after the fact. Some MTEs are interested in investigating the impact of these mediated field experiences on PSTs' content knowledge, and others are interested in exploring which instructional routines are helpful in supporting PSTs develop adaptive expertise. We also want to standardize data collection so that researchers can pool data and make claims across institutions, which will take place while working in the break out groups based on researcher interest. We will end the session with a whole-group share out of research questions, data collection procedures, and next steps the small groups want to take.

Next Steps and Future Directions

Members of this group have been working together since 2015 and all on this proposal plan to continue this work after our proposed meeting sessions. Our first steps are to publish our current findings. We are in the process of completing a manuscript for the *Mathematics Teacher Educator* that details our findings from our initial efforts mediating field experiences, and we are submitting a proposal to AMTE's 2019 Annual Conference where we plan to present on our observations of PST learning against the AMTE Standards. At this 2019 conference, we plan to meet again as a group to share our experiences and any further insights we have made. Each breakout group from Session 3 will continue pursuing the research agenda they set up for themselves based on their research questions and goals. Some members of the group are planning to apply for an NSF DRK-12 Grant to support an investigation of following our PSTs into the field to investigate any lasting impacts of the mediated field experiences on their teaching practices or preparedness to teach in their own classrooms. Finally, we will continue to share resources and pool data using our shared Google folder and work to disseminate new findings to the field.

The early results of our work has been so positive that a long-term goal is to motivate programmatic shifts at our individual institutions for different areas of preparation and encourage other MTEs to reconsider the structure of their coursework and fieldwork in their preparation programs.

Launching cognitively demanding tasks is a much valued, but little understood aspect of ambitious mathematics teaching. This working group supports the development of shared descriptions, theories, and tools to support teachers, teacher educators, and researchers in understanding and developing effective launching. We will begin to develop a shared understanding of the purposes of effective launches, as well as common challenges teachers face, and structures and skills that teachers can call upon when launching. The working group will provide a set of common artifacts that will ground discussion of purpose, structure, and skill. These artifacts will include demonstrations and video of launches and launching tools for teachers and teacher educators. The working group will support ongoing discussion and collaboration between researchers, teacher educators, and practitioners in the field that will contribute to our knowledge of effective launches.

Keywords: Classroom Discourse, Instructional Activities and Practices, Curriculum, Problem Solving

Introduction

The Problem

Mathematics education researchers and practitioners have long understood how cognitively demanding tasks can provide essential opportunities for student reasoning, problem solving, and conceptual learning. Almost as soon as researchers began touting the importance of demanding tasks, they have recognized that how teachers introduce, or launch, those tasks to students can fundamentally affect the quality of learning opportunities for students (Stein & Lane, 1996). Research has documented how teachers can reduce the demand of the task (and the quality of the learning opportunities) by introducing a specific method or procedure during the launch or by placing too much emphasis on the answer (Stein & Smith, 1998). On the other hand, when teachers help students make sense of the context, focus on important mathematical relationships, and clarify important vocabulary, students are able to have richer, more productive discussions about their solutions (Jackson, Garrison, Wilson, Gibbons, & Shahan, 2013). Clearly, skillful launching is an important element of a problem-solving lesson.

Despite the apparent widespread agreement on the importance of effective launching, it remains undertheorized and under-researched. Teachers looking for support in launching have few resources, and mathematics teacher educators and researchers do not have a widely shared detailed understanding of the purpose and structure of an effective launch, nor do they necessarily agree on the kinds of challenges that teachers face while launching demanding tasks.

This Working Group will provide a forum for researchers, teacher educators, and practitioners to share localized knowledge in an effort to build a shared understanding of launching. In particular, participants will identify and share understandings of launching through experiencing, analyzing, and observing a variety of launches and other activities. Participants will also examine a variety of tools designed to research, evaluate, plan, and teach launching. Finally, participants will have opportunities to identify potential projects for research, development and dissemination, while seeking out collaborators for these projects. In particular, researchers and practitioners will be encouraged to pool their resources and expertise to describe and share localized knowledge and develop theory and tools that will reflect and inform practice.

Literature Review

The importance of launching stems from an emphasis on tasks and their implementation in supporting ambitious learning goals for mathematics students. Almost 30 years ago, the National Council of Teachers of Mathematics (NCTM) publicly advocated for mathematics instruction that supported students in gaining deep, conceptual understanding of important mathematical ideas, and developing this understanding in the context of reasoning and problem solving (NCTM, 1989). During the 1990's researchers documented essential features of classrooms that supported these new, ambitious goals (see, for example, Hiebert et al., 1997; Yackel & Cobb, 1996).

One especially important aspect of teaching for understanding was cognitively demanding tasks that would present students with opportunities to use what they knew to solve non-routine problems, and, in the process, reason and justify their thinking to their peers. In short, if teachers wanted their students to learn how to reason and solve problems, they needed to give their students problems that they did not already know how to solve (Stein & Lane, 1996). Researchers began by describing the characteristics of demanding tasks themselves, helping teachers identify and adapt tasks for their students (Stein, Grover, & Henningsen, 1996; Stein & Lane, 1996). Such tasks proved challenging to enact, however. Stein and Smith (1998) identified maintaining the cognitive demand of these tasks as a major challenge for teachers, describing six factors associated with the maintenance of the demand, and seven factors associated with the decline of these demands.

Others have sought to support teachers in maintaining demand through describing specific effective teaching practices. O'Connor, Anderson, and Chapin (2003) documented and described specific moves that supported discourse around demanding tasks. Stein, English, Smith and Hughes (2008) described five practices that teachers use to focus discussions on important student thinking and structure the content of those discussions so that students are more likely to make connections between solutions and connect those solutions to important underlying mathematical ideas.

One crucial aspect of enacting demanding tasks is how a teacher introduces, or "launches" the task. Early research indicated that although tasks may be designed to provide opportunities for problem solving and reasoning, the way teachers launched the task could lower the demand as experienced by students (Stein & Lane, 1996). Two of the seven factors associated with lowering the cognitive demand (Stein & Smith, 1998, cited above) seem especially germane to launching. First, teachers could indicate or even demonstrate a specific solution path, thus transforming the task for students from problem solving to replicating the teacher's solution. For instance, if students are told that a 30-pound bag of sand sells for $6 at the hardware store, and a 50-pound bag of sand sells for $9 at the lumberyard and asked which is the better deal, the teacher might suggest that they choose an amount of money that they can spend at each store and then see how much sand they get for that amount. Such a suggestion would take away the opportunity for students, themselves, to come up with this strategy, but would also make it less likely that students might come up with a variety of different strategies which would then provide opportunities for reasoning and making connections.

Second, teachers could also clarify specific aspects of the task, removing ambiguity and foreclosing opportunities to make sense of problematic situations. For instance, if students were asked to describe what was the best deal, a video streaming plan that costs $40 per month with unlimited streaming, or a plan that costs 50 cents per hour of streaming, the teacher could add that the customer's family streamed 75 hours of material each month. This would change the problem from one in which students would have to explain how each of the two plans might be better, depending on how much streaming the customer planned to do, to a problem with one clear answer, where students would not need to figure out that there could be two different answers depending on the anticipated streaming time.

Despite the clear evidence that ineffective launching can undermine students' opportunities to learn from demanding tasks, there has been little research on effective launching that could provide guidance for teachers and teacher educators. Early guidance was clearly directed towards helping teachers new to problem-based lessons develop a culture of inquiry in their classrooms. Effective launching included setting expectations for student collaboration, as well as managing the logistical challenges of extended group work (Stein, Smith, Henningsen, & Silver, 2009). Effective launches included clear descriptions of the final product, clear instructions for logistical details such as who sat where, and what tools were available for student use, and discussions of what good cooperative work looked and sounded like.

Jackson, Garrison, Wilson, Gibbons, and Shahan (2013) described several effective launching practices that led to deeper and more productive concluding discussions. The effective launches they studied shared these four features:

- Clarified context
- Highlighted important mathematical relationships
- Developed common language
- Maintained the cognitive demand

This framework certainly advanced our understanding of launching. However, applying the framework gives rise to difficult questions. How does one highlight the important mathematical relationships, for instance, without indicating potential solution paths? How does one clarify the context without removing ambiguity? How might effective teacher moves differ depending on the task or the students? A greater understanding of what effective teachers *actually do* when they launch, along with more of a shared understanding of the purpose of a launch might inform these questions.

A second article for practitioners described a specific technique for launching tasks, the think-aloud strategy borrowed from literacy research (Trocki, Taylor, Starling, Sztajn, & Heck, 2014). The authors described teachers engaging in thinking aloud when first presenting a problem, providing a model of how one might interrogate the problem, make sense of it, and begin to think about how to solve it. This technique, if properly applied, supported productive discourse and led to students' success on similar problems without lowering the cognitive demand of the tasks. However, the authors also warned against lowering the demand by introducing a procedure or method for solving it, and the teachers who used this specific technique worried about "crossing the line" into doing too much of the work for their students.

More recent research on teachers and their understanding of launching documented this dilemma quite clearly. González and Eli (2017) described how future and current teachers conceived of launching. They found that practicing teachers were keenly aware of the need to support students in making sense of the problem and providing access to the context, while at the same time not giving the problem away or telling them too much. More specifically, constraining a problem might make it more likely for the students to attend to the mathematical goal of the lesson but might also foreclose opportunities for modeling and problem-solving. González and Eli also found their participants saw launching as accomplishing a wide range of goals, including activating prior knowledge, motivating and engaging students, previewing and reviewing work necessary for the solution, providing hints, and clarifying important terms. Pre-service teachers were, on the whole, more concerned with motivation and engagement, while practicing teachers were more concerned with providing mathematical support through activating prior knowledge or clarifying important aspects of the problem.

Clearly, launching is an important aspect of enacting demanding tasks, fraught with possible dilemmas. However, there is little research to inform teachers and teacher educators. There is no published research on how curriculum materials support teachers in launching, but a cursory examination of a number of materials demonstrate a lack of alignment between and within curricula. Methods texts do describe the importance of involving students in the context, activating prior knowledge, being sure the problem is understood, and establishing clear expectations (see, for instance, van de Walle, Karp, & Bay-Williams, 2013 and Markworth, McCool, & Kosiak, 2015). However, there remains the difficult balance between some of the suggestions (solve a simpler version of the task, brainstorm possible strategies) and the warning to not lower the cognitive demand.

Despite this lack of theoretical background or specific research guidance, teachers have been launching demanding tasks for decades. Researchers have yet to tap what could be a potentially rich source of knowledge. Indeed, this gap between research and practice is a perennial problem for mathematics education and education at large. 20 years ago, Kennedy described the difference between the "expert knowledge" of researchers and the "craft knowledge" of practitioners (Kennedy, 1999). Earlier work also described this gap (see, for instance, Cuban, 1993; Lampert, 1985). This has led to calls for a new knowledge base for teaching that connects expert and practitioner knowledge, in which researchers collaborate more closely with teachers and practicing teachers have a greater say in identifying research problems and contexts (Hiebert, Gallimore, & Stigler, 2002). Launching is a potentially rich field for such collaborations.

Another potential source of knowledge about launches comes from other content domains. Science education researchers and teacher educators have also worked to introduce demanding tasks that support ambitious science teaching. Windschitl, Thompson, and Braaten (2008) write that science investigations often begin with "readings, video-clips demonstrations or even 'pre-modeling' laboratory activities" which will "motivate interest in some aspect of the natural world" and provide resources for students to "develop a tentative representation of the phenomenon." In addition, they suggest a number of "starter questions" that can engage students in inquiry. This description of how science teachers might launch inquiries are similar to videos used frequently in mathematics classes as a way to introduce problems. (See Meyer, 2011 for examples of math problems launched with videos).

Genesis of this Working Group

The desire for a working group focused on launching has grown out of several recent experiences shared by some of the group's organizers. This work began with a group of mathematics methods instructors designing a module to support pre-service teachers in learning to launch. The lack of research and theory on launching was evident to this group as they worked together to depict a launch. There were few common images of effective launches in the research literature, nor were there descriptions of the kinds of problems that students and teachers experienced during launches. As a result, the content and design of the module were based on designers' best guesses, representing untested hypotheses based on their experience and judgement.

Analyzing data and sharing results from pilots of this module further demonstrated the need for greater shared understanding of launches. In working to determine what students may have learned from the module, designer-researchers uncovered their own unstated assumptions about launching and found that they were quite different. For instance, while one researcher assumed that any discussion of solution strategies to the problem should not occur during the launch, another researcher saw such sharing as a common launching move that could be accomplished without lowering the cognitive demand of the task.

In 2016 these designer-researchers found both a high level of interest and a marked lack of consensus when they presented an early version of their work at PME-NA (Wieman & Jansen, 2016). The session was extremely well-attended and prompted animated discussion about how the launch depicted in the module did, or did not, represent good launching practice and how it compared with launches that attendees showed as models for their pre-service teachers. After this session, the presenters continued the conversation with participants and expanded it to include others not in attendance. This discussion resulted in a symposium at the 2018 AMTE annual meeting (Wieman, Jackson, Kelemanik, Land, & Tyminski, 2018). This symposium brought together researchers who had studied launches, teacher educators who were teaching teachers to launch effectively, and professional developers with extensive experience in schools. Again, this symposium was well attended, and generated extensive discussion, as well as a clear diversity of thought and experience. This working group seeks to expand the work begun at the symposium. Many of the activities and discussions planned for the three sessions of the working group will allow the participants delve deeper into issues raised at the symposium, and explore some of the ideas planned, but not addressed, in that session.

Goals of the Working Group

The leaders of this working group have the following long-term goal:

- Support mathematics teachers in launching tasks effectively, mathematics teacher educators in supporting teachers learning to launch, mathematics education researchers in generating knowledge about launching, and curriculum writers in supporting teachers launching by creating empirically-based, shared knowledge about launching cognitively demanding tasks.

In the service of this long-term goal, the organizers' aims during the three sessions at this conference are to:

- Facilitate an ongoing discussion about launching, surfacing assumptions about effective and ineffective launching practices.
- Provide a set of common artifacts to initiate this discussion and prompt participants to develop and share other artifacts to facilitate ongoing discussion and study.

- Foster collaboration and exchange between researchers, teachers and teacher educators, supporting productive partnerships that will add to the shared knowledge base about launching.
- Identify key research questions about launching that can help guide the field, and these partnerships.

Questions We Will Be Examining

The sessions will provide participants an opportunity to examine the following questions:

- What is the purpose of an effective launch?
- What challenges do teachers face when planning, enacting and evaluating launches?
- What are typical experiences for students in launches?
- Do effective launches look different depending on the task?
- How do we support teachers and pre-service teachers in developing skill in planning, enacting and reflecting on launching (and how might we improve these efforts)?
- How do we support teacher educators and professional developers in helping others get better at launching (and how might we improve these efforts)?

Connection to the Conference Theme

One of the central questions stemming from the conference theme of "Looking Back, Looking Ahead: 40 years of PME-NA" is how do we support ALL students through equitable teaching? At its heart, launching is a part of ambitious teaching that provides access and opportunity for ALL students to grapple with challenging mathematics. The small amount of extant research on launching begins to describe some of the conditions that must be present in order for all students to learn from engaging in demanding tasks and how those conditions might, or might not, be present for diverse groups of students. Beginning research has shown that how a teacher enacts a launch can either open up access to a wider range of students through establishing those conditions for all students, or how it can close off access to opportunities to learn for groups of students by failing to establish, or actively undermining those conditions. In addition, effective launches have the potential to support students in developing mathematical authority and agency as they make sense of the task at hand. The lack of research and work on launching represents an ongoing challenge to the field, and advancing this knowledge provides possible ways to address fundamental problems of access, authority and agency in an arena in which teachers actually have power and control. Effective launches have the potential to contribute greatly to equitable opportunities to learn from demanding tasks, and ineffective launches can really negatively affect students' access to those opportunities.

Plan for Sessions/Participation

The sessions for this working group will ground discussion and work in a series of shared artifacts. These artifacts will serve as a set of common points of reference for participants as they examine their own assumptions and work to answer the central questions of the working group. The sessions will begin by having participants experience a variety of launches, and then discuss their features and the assumptions about purposes, and challenges that lay beneath them. Participants will then look at a variety of tools that teachers, teacher educators and researchers use to support and study effective launching, connecting those tools to the central questions of purpose, structure and challenge. Finally, the group will begin to identify specific research projects that will add to the shared knowledge base for effective launching.

Session One

The main goal of this session will be to introduce the central questions of the working group and to begin sharing assumptions and knowledge about launching. The session will feature three actual launches that differ in important and interesting ways (i.e. content, grade level, length, extent to which students reason and talk about the problem or the context, extent to which the teacher introduces representations or tools, etc.) Participants will begin by writing down some thoughts about launches then watch a video of a launch and engage in a discussion in which they compare the launch they just watched with the purposes, structures, and challenges they envision for launches. Then, participants will experience two more launches facilitated by organizers of the working group, both of which are clear routines with specific structures, and both of which differ in significant ways from each other and from the initial example. Again, these will provide common experiences which will allow participants to engage in more conversation about the purpose, structure and challenges of launches. By the end of the first session, the group will have developed some general areas of agreement, some ongoing open questions, and have some common images and shared vocabulary that they can use as touchstones for further discussion.

Session Two

The main goal of this session will be to continue the discussion of purpose, structure and challenge of launches, with a particular focus on tools for teachers, teacher educators and researchers. As in the first session, participants will engage with a common set of artifacts, which will then act as the basis for further discussion.

The session will begin with participants planning a launch using a set of common curriculum materials. Groups will share the kinds of issues they thought about, questions they asked themselves, how their understanding of purpose, structure and challenge informed their planning, and how they used the materials to support their planning. Participants will then watch a video of a teacher engaging in a think-aloud while planning a launch for the lesson using the same materials. They will talk about how their own planning compared with that of the teacher in the video, and what issues they face in supporting teachers in planning and enacting launches.

Participants will then examine and analyze a variety of launching tools. Organizers will have available a set of planning tools, a set of observation/evaluation tools, and a set of curriculum materials. Participants will examine and analyze the tools with the following questions in mind:

- What assumptions do these tools seem to have about the purpose, structure and possible challenges of an effective launch?
- What specific scaffolds or supports do the materials offer?
- How do participants envision teachers engaging with these tools? How do the tools align (or not) with how participants think teachers (or teacher educators, or researchers) work, think and make decisions?
- How might we revise these tools in light of the conversations we have been having?
- What questions do we have about these tools and their use?

Depending on the feeling of the group, we might look at one or two of the tools as a large group, deciding which tools and in what order based on the conversation from the first session and the first half of the second session. Alternatively, we might create separate groups, each of which concentrate on specific tools. Participants could engage with whatever tool they find most interesting or compelling. There would be time at the end of the session for each group to share their findings with the whole.

Session Three

The main goal of the third session is to identify, support and stimulate further work. This could take several different forms, but in general will involve brainstorming, identifying and exploring possible projects and/or partners and making commitments for future work. Depending on the emerging interests and dynamics of the group, each of these processes could take place in the context of a whole group session, smaller group sessions, or some combination of the two. There will also be an opportunity for participants to share work that they have already begun, and possible opportunities for them to pilot materials and instruments or ask for help analyzing data or providing feedback. Finally, the organizers will bring some specific projects to the table for those interested. These may include initial planning for a conference devoted to the topic, researching curricular supports for launching, developing and research specific launching routines or researching teacher planning and enactment of launches. The session will end with participants writing and sharing specific commitments to future work.

Possible Future Work

We are hopeful that this working group will facilitate collaborations and identify possible avenues of further work that could result in a wide variety of products and future work together. We see this work unfolding in three interconnected arenas, theoretical and empirical research on launching, materials and tools for teacher education, and materials and tools for classroom teachers.

Theoretical and Empirical Research on Launching

One goal for this working group is to encourage and facilitate work that leads to more detailed theoretical frameworks for enacting and studying launching. We anticipate that discussions at the working group will stimulate theoretical pieces that clearly define the purpose of a launch, as well as hypothesize potential challenges that teachers and students face during the launch. This work would both inform and be informed by empirical work that could validate and refine this theory.

Materials and Tools for Teacher Education

Another goal of the working group is to stimulate the development and dissemination of materials that could support teacher educators in supporting pre-service and in-service teachers in learning to launch more effectively. These could include protocols and templates for planning, evaluating, and enacting launches, similar to those shared in session two described above. They could also include representations, approximations and decompositions of practice (Grossman, et al., 2009), which could support teachers in focusing on specific aspects and issues in launching.

Materials and Tools for Classroom Teachers

A final goal of the working group is to stimulate the development of tools for teachers in launching complex tasks. In addition to the tools described above for teacher educators, the working group will support curriculum developers and professional developers as they create and refine materials for teachers.

Possible Products

Ideally, each of these three areas will support each other. Tools for teacher educators could also work as supports for teachers, while also providing data collection tools for researchers. Theory could support the design of such materials.

Specific products growing out of this working group could take a variety of forms, forms that span the three areas above, or concentrate in one single area. Some possible outcomes we envision are:

- Groups of people working to develop, refine and disseminate specific routines or structures for launching tasks
- Research projects examining launches.
- A conference on launching
- An edited book on launching, with articles that might, in part, stem from work catalyzed by this working group
- A practitioner book about launching
- A series of research articles, perhaps in a special issue of a research journal, on launching
- Exploring funding opportunities to help support any of the projects above
- Curriculum development or research

Mathematical play has a fairly short history, with strong roots further back in time (e.g., Papert, Montessori), and understanding the role of mathematical play from early childhood to adulthood is, as yet, unmapped. This working group will provide a community space to explore and discuss mathematical play broadly, ranging from early childhood to undergraduate learners, with an emphasis on physical and digital interactions designed specifically to support mathematical play. Each day will focus specifically on a different approach to and definition of mathematical play. Day 1 will focus on early childhood mathematical play with pattern blocks; Day 2 will focus on mathematical play in videogames; and Day 3 will focus on using Rubik's Cubes to investigate undergraduate mathematics, namely algebraic groups. Throughout the sessions, we will be examining threads of common ground that will assist in developing a more flexible and appropriate model of mathematical play that can inform design of environments and activities across age groups, content, and context.

Keywords: Instructional activities and practices; Design experiments; Technology

Mathematical play has a fairly short history, with strong roots further back in time (e.g., Papert, Montessori). The majority of research on this topic stems from early childhood research on play, and researchers have begun to map out the phenomenon of mathematical play in young children (see Wager & Parks, 2014, for a review). This approach identifies the mathematical play children naturally engage in during open-ended play activities, and explores how to further mathematize that play and the consequent learning. In addition, researchers have explored how mathematicians in the course of their work engage in mathematical play (e.g., Holton, Ahmed, Williams, & Hill, 2001). Given that young children and mathematicians both engage naturally in mathematical play, there is an intriguingly underexplored area of promise between those two populations. A small number of researchers have examined how to support students in approaching mathematics problems with a playful bent (e.g., Steffe & Wiegel, 1994; Holton et al., 2001), but understanding the role of mathematical play from early childhood to adulthood is, as yet, unmapped.

This working group will provide a community space to explore and discuss mathematical play broadly, ranging from early childhood to undergraduate learners, with an emphasis on physical and digital interactions designed specifically to support mathematical play.

The Origin of this Working Group

The authors have been engaging in researching mathematical play in their own arena of interest for some time and are beginning to engage in conversations across age groups (e.g., early childhood, undergraduate), content (e.g., patterns, fractions, algebraic groups), and contexts (e.g., Rubik's cubes, videogames). This working group proposal is the first collaborative effort from this diverse group of researchers.

Our goal for this working group is to facilitate mathematical play experiences and discussions around open research questions that transcend our individual lines of research, such as:

- What is the nature of mathematical play across the age/grade bands?
- What are the features, characteristics, and affordances of mathematical play?
- How might context (e.g., physical, digital) influence mathematical play?
- How might content (e.g., fractions, group theory) influence mathematical play?
- How might factors such as gender, race and ethnicity, and parental income/education level influence experience of and access to mathematical play?
- How are mathematical play and mathematical learning related?
- How does mathematical play influence problem solving?
- How do mathematicians (experts) engage in mathematical play, and how might that mindset be fostered for learners (novices)?
- When might a didactical introduction to the content support more productive mathematical play?
- How might mathematical play support or influence learning in other disciplines (e.g., a broader STEM perspective)?

Although answering all of these is beyond the scope of possibility for our working group, we will use these questions to facilitate and orient discussions during each of the three days, and as potential topics for future collaborative investigations.

Definitions of Mathematical Play

There are a variety of definitions of mathematical play, each emerging from different contexts and with different ages. In this section, we briefly review a selection of those definitions in order to contextualize the activities we have planned for the working group sessions.

Steffe and Wiegel (1994) conducted a teaching experiment with a digital microworld designed to support operations with quantities, and the role of the instructor was directly to shift students from engaging in independent mathematical activity into engaging in mathematical play. Appropriately, they then defined mathematical play as “independent mathematical activity with a playful orientation” (p. 27). Sarama and Clements (2009) took a different approach: instead of focusing on supporting the shift from independent mathematical activity to mathematical play, they distinguish between *play that involves mathematics* and *mathematical play*. They give examples of the former, including a store in the classroom where one student plays the shopkeeper, and another purchases toy dinosaurs for a dollar apiece, and the students engage in play while also engaging in counting, place value, and practicing arithmetic. For mathematical play, on the other hand, children play with the mathematics itself, and the authors describe a four-year-old who is playing with three of five train engines, and first describes those three train engines as being numbers 1, 2, and 3 – thus missing engines numbered 4 and 5. Then she decides that the trains she has are actually numbered 1, 3, and 5, leaving trains 2 and 4 missing – as Sarama and Clements (2009) note, “she was playing with the idea that counting words themselves could be counted” (p. 327), that is, she was playing directly with mathematics.

Holton et al. (2001) define mathematical play as “that part of the process used to solve mathematical problems, which involves both experimentation and creativity to generate ideas, and using the formal rules of mathematics to follow any ideas to some sort of a conclusion” (p. 403). They identify six components of mathematical play:

(1) It is a solver-centred activity with the solver in charge of the process;
(2) It uses the solver's current knowledge;
(3) It develops links between the solver's current schemata while the play is occurring;
(4) It will, via 3, reinforce current knowledge;
(5) It will, via 3, assist future problem solving/mathematical activity as it enhances future access to knowledge;
(6) It is irrespective of age. (p. 404)

They additionally note that mathematical play will not necessarily directly lead to a correct solution of the problem being played with – in fact, one of the important components of mathematical play is that it "provides a non-threatening environment where incorrect solutions are not read as mistakes and may lead to a better understanding of the problem and/or the confrontation of misconceptions" (p. 404).

Another framework for mathematical play (Williams-Pierce, 2016, 2017) also highlights the importance of a non-threatening environment where mistakes are perceived as natural and appropriate. This framework emerges from a blend of scholarship on mathematical learning and videogames research, the latter of which has embraced the conceptualization of *failure* as an important and often enjoyable experience within the realm of gameplay (e.g., Juul, 2009; Litts & Ramirez, 2014). Williams-Pierce (2016, 2017) defined mathematical play as *voluntary engagement in cycles of mathematical hypotheses with occurrences of failure*, and describes five features of digital contexts that support such mathematical play:

(1) consistent and useful feedback;
(2) high enough levels of difficulty and ambiguity that players experience frequent failure that is closely paired with the feedback;
(3) non-standard mathematical representations and interactions;
(4) mathematical notation introduced late or not at all; and
(5) the legitimate possibility of alternative conceptual paths for successful progression.

Each of the definitions of mathematical play described above emerge from different contexts: some digital (Steffe & Wiegel, 1994; Williams-Pierce, 2016), some physical (Sarama & Clements, 2009), some paper and pencil-based (Holton et al., 2001). One of the crucial open questions that we highlighted above is how the definitions may vary in the features that they prioritize, due to the differing contexts. For example, might Holton et al. (2001) and Williams-Pierce (2016) find common ground if they examined similar contexts? Or are their approaches too fundamentally different to ever come to agreement? Each session of the working group is oriented around a specific definition and operationalization of mathematical play, so that attendees have concrete experiences grounded in different definitions to facilitate discussion across these different frameworks.

Working Group Schedule and Activities

For each of the three Working Group sessions, we plan to begin with a hands-on mathematical play activity designed from a different mathematical play approach. The first author has been involved in conducting PME-NA working groups in the past (Nathan et al., 2016, 2017), and found that beginning with a relevant activity quickly develops fruitful discussions between participants. In particular, working groups tend to have a variety of attendees with a wide-ranging level of expertise in the topic, and grounding the discussion in shared experiences serves to support a sense of community. Consequently, we will facilitate a mathematical play experience each day, then guide the discussion towards the mathematics at play (pun intended) and the specific characteristics of that mathematical play. During these group discussions, we will regularly orient the conversation specifically towards the open research questions listed above. We will take notes during these conversations, and conclude each session by collecting names and emails of working group attendees.

Each day will focus specifically on a different approach to and definition of mathematical play. Day 1 will focus on early childhood mathematical play with pattern blocks; Day 2 will focus on mathematical play in videogames; and Day 3 will focus on using Rubik's Cubes to investigate undergraduate mathematics, namely algebraic groups. While each day's session moves up in age (from early childhood to undergraduate), we will also be moving down in terms of established research. In particular, Day 1 showcases the most researched area of mathematical play and will be primarily about introducing attendees to the rich history of early childhood mathematical ply; Day 2 focuses on comparing two instantiations of mathematical play, and seeks to identify similarities and differences across the digital designed contexts; and Day 3 involves the initial design of an undergraduate mathematical play experience, and will focus on gathering input from the attendees on potential areas of redesign.

Day 1 Session – following Wager & Parks (2014)

The first session will focus on mathematical play in early childhood. Mr. Reimer will engage participants in a form of pattern block puzzle play that involves spatial reasoning and the composition and decomposition of shapes. While mathematical play is a generally new area of investigation, Wager and Parks (2014) found that "studies involving block play are the most well documented and longest established" (p. 217), although spatial learning with puzzle play is still under-examined. Furthermore, most geometry and spatial learning studies have taken place in artificial contexts (e.g., research labs), rather than natural contexts. Consequently, this activity relies upon early childhood play frameworks that emphasize child agency through spontaneous interaction, choice, and opportunities for repeated trials (Wager & Parks, 2014), with a focus on exploration with physical objects to support the development of mental transformations.

Mr. Reimer will bring sets of pattern block puzzles for the participants (see Figure 1) – for use in solo activity or small groups, depending upon the number of attendees. He will highlight the importance of spontaneous interaction, choice, and repeated trials, and throughout the session activity, he will provide orienting questions and comments–such as initiated constraints and challenges to extend or deepen the activity–to help participants explore possibilities and mathematize their play.

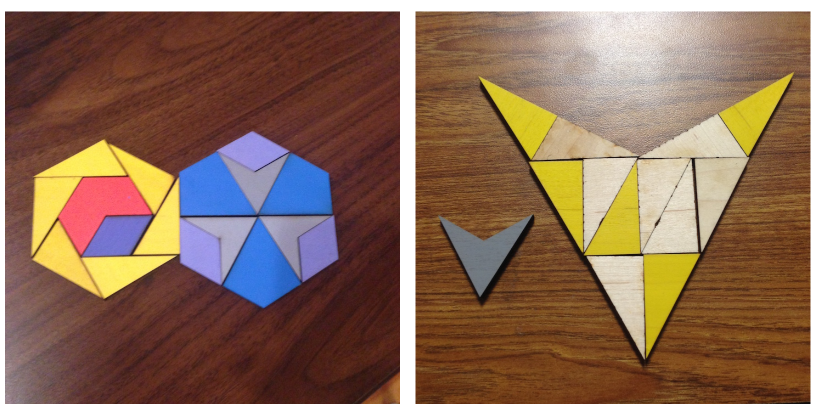

Figure 1. A sample of puzzle designs participants may create.

The activity will conclude with an open discussion that focuses on the affordances of the physical materials in encouraging mathematical play, the importance of orienting questions, and the role of narratives in describing and supporting participants' play activity. Then we will guide the discussion towards the open research questions listed above.

Day 2 Session – following Williams-Pierce (2017)

The second activity will focus on mathematical play in digital contexts. Dr. Williams-Pierce will coordinate this activity by bringing two games that were designed to support mathematical play: *Dragonbox 12+* by WeWantToKnow (a commercial learning game that focuses on balancing equations), and her in-revision game, *Rolly's Adventure* (which focuses on the development of understanding multiplying fractions). Both of these games support mathematical play and learning in distinctly different ways: *Dragonbox 12+* through faithfully enacting mathematical phenomena with novel representations and interactions; and *Rolly's Adventure* through secretly modeling the operation of multiplication and requiring players to engage repeatedly in interpreting feedback through failure in order to unpack that secret operation. See Figure 2 for screenshots of both games.

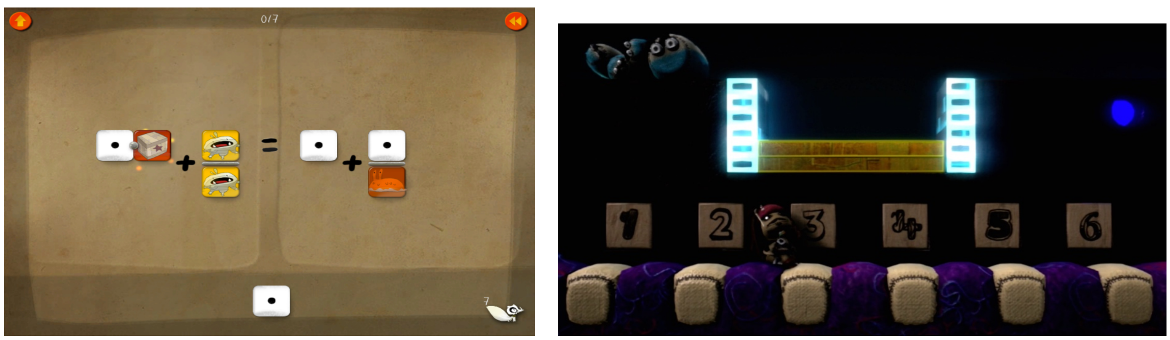

Figure 2. A screenshot each of *Dragonbox 12+* (left) and the original *Rolly's Adventure* (right).

We chose those particular two games for a variety of reasons. First, having the designer of *Rolly's Adventure* present means that she can unpack any of the hidden design decisions behind the game that may emerge as participant questions during play and discussion. Second, while the *Dragonbox* series is highly popular (with over a million downloads worldwide, and a *Wired* article that touted the original game's release; Liu, 2012), co-authors of this working group have strongly divergent views about how mathematical the play in *Dragonbox 12+* actually is. Consequently, we anticipate that these two games will provoke a lively discussion!

Both games are iPad games, and Dr. Williams-Pierce will bring ten iPads to share with participants, as well as instructions for installing her game for free on their own touchpad devices. Depending upon the number of attendees, this activity may be in pairs or small groups. Half the participants will play *Dragonbox 12+*, and half *Rolly's Adventure*, while taking guided notes on their experience of mathematical play with the games. These guided notes will be based upon the five features described above (Williams-Pierce, 2016, 2017). For example, the guided notes will include questions like: how does the game give you feedback on what you are doing well or poorly? How does the experience of *failure* influence how you attend to feedback? What, if any, is the role of mathematical notation? After playing, Dr. Williams-Pierce and Dr. Ellis – as the two authors who disagree about mathematical play in *Dragonbox 12+* – will co-facilitate a discussion about how the games instantiate those five features differently, and how the participants felt their experiences were or were not mathematical play.

Day 3 Session – following Holton et al. (2001)

First, Dr. Plaxco will discuss his preliminary work in designing activities to engage undergraduate students in mathematical play with Rubik's Cubes and connections to the cube's associated algebraic group structure. This will entail an introduction to several algorithms that can be useful for manipulating specific pieces on the cubes as well as a discussion of the usefulness of some group theoretical constructs (e.g. conjugation and commutators) in generating designs on the cubes (see Figure 3). Holton et al. (2001) note that "Mathematical play involves pushing the limits of the situation and following thoughts and ideas wherever they may lead. Hence there are no obvious short-term goals for mathematical play; it is designed to allow complete freedom on the part of the solver to wander over the mathematical landscape" (p. 403). Rubik's Cubes allow for such mathematical play, though players are typically less familiar with the rules and operations of the cubes because the setting is noncommutative, which allows for surprising results when trying to generalize from experiences, and because the "landscape" is rather large – a 3x3x3 cube has over $4.3\text{x}10^{17}$ positions.

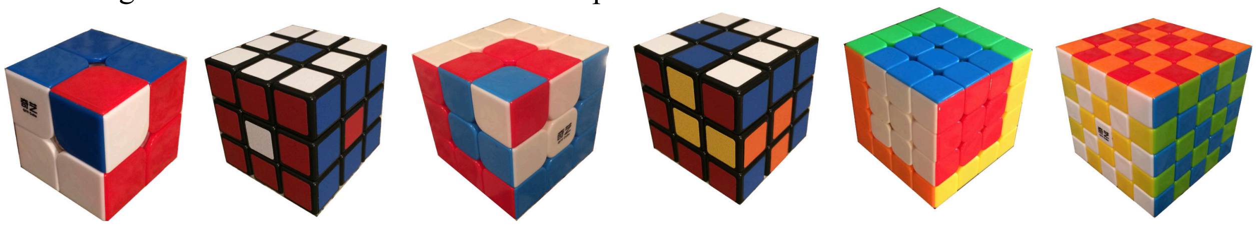

Figure 3. A Sample of Cube Designs That Working Group Participants May Attempt

Dr. Plaxco will distribute a class set of solved 2x2x2 and 3x3x3 Rubik's Cubes so that each member of the working group will have access to a cube. Members will also receive a laminated sheet with instructions for each of the algorithms discussed and a second sheet with possible designs that members can set out to re-create. One difficulty Dr. Plaxco has encountered with introducing Rubik's Cubes to students is the need for prolonged orientation to gain a sense of how to use algorithms to produce desired outcomes. Because of this, we will sequence the tasks so that participants will work to change a solved cube into increasingly difficult designs, incorporating longer algorithms and combining algorithms in new and different ways. Participants will also be invited to explore the possibilities of what they can create with the algorithms and generate their own designs on the cubes. We will give participants iPads to videotape their manipulations of their cubes in order to help them remember the sequences of moves they make. We will ask the participants to try and develop notations to help record these moves as well. This activity will culminate with a "Match Game" in which groups of participants will create designs, recording and notating the required moves and challenge other teams to re-create their designs. We will then close this session with a discussion of potential directions for activities with undergraduate students, including avenues for collaborations in researching mathematical play with the Rubik's Cubes.

After Dr. Plaxco's group activity, in order to conclude the working group, we will discuss our experiences across each of the three days. In particular, we will focus on the three mathematical play approaches emphasized on different days, and how the differing contexts and content may have influenced the development of these approaches, following the open research questions identified at the beginning of the document. We will seek to find threads of common ground that will assist in developing a more flexible and appropriate model of mathematical play that can inform design of such environments and activities across age groups, content, and tools. Finally, we will conclude by identifying next steps for the working group members, as outlined in the following section.

Future Plans

This working group is the first step in establishing a network of support for designing and examining mathematical play at all ages. First, we will develop a plan for a white paper about mathematical play that draws out common themes across the differing ages and content that have been researched thus far, and identifies aspects of the frameworks and definitions that may be irreconcilable. For example, might unstructured mathematical play and structured mathematical play be fundamentally different? Are there commonalities about mathematical play that can be established across paper-and-pencil activities, physical manipulatives, and digital contexts? How might audience (e.g., voluntary players who can stop playing at any time, students who have no choice but to participate, research participants who chose to be part of the research) influence the experience of mathematical play? In this paper, we will explore those questions, and identify the particular next steps that should be undertaken to further understand and unpack the phenomenon of mathematical play. Second, we will investigate future potential conference proposals or journal articles that draws across different areas of mathematical play expertise, in order to begin productively synthesizing the phenomenon. For example, one of the discussions that developed during the crafting of this proposal revolved around the use of Holton et al.'s (2001) components of mathematical play for the Rubik's cube activity, and how certain aspects of the Williams-Pierce (2016, 2017) framework might apply better. One potential line of investigation then is to examine the possibility of synthesizing the two frameworks in a way that accounts for the very different contexts they initially emerged from.

Third, we will set up a listserv for the attendees, so that they find it convenient and simple to stay in touch with others interested in mathematical play. Immediately after the conference, we will share this listserv so that participants may continue discussing any potential collaboration plans developed through discussions during the working group. Finally, we plan to submit for an NSF Advancing Informal STEM Learning: Conferences grant in order to conduct yearly meetings that focus solely on mathematical play throughout the lifespan. The participants at the Mathematical Play Working Group at PME-NA 2018 will be the first list we contact to invite to apply for this opportunity.

This Working Group will continue the conversation started since PME-NA-34, with a goal to move forward the teaching and learning of mathematics involving students with learning disabilities or difficulties in mathematics (LDM). This Working Group is rooted in following premises: (1) students with LDM are capable of and need to develop conceptual understanding of mathematics, and (2) special education as well as inclusive classroom instruction need to transition toward this focus. Participants will continue (a) the collaborative research agenda for the group, and (b) the dissemination effort through publications that reflect the cross-disciplinary collaborative work of this group within the context of international perspectives.

According to US National Report Card (National Assessment of Educational Progress [NAEP], 2015), 85% of 4th grade students with disabilities performed below the proficiency in mathematics, and 100% of 8th grade students with disabilities performed below the basic level in mathematics. In fact, about five to ten percent of school-age children are identified as having mathematics disabilities and students whose math performance was ranked at or below the 35 percentile are often considered at risk for learning disabilities or for having learning difficulties in mathematics (LDM). In spite of substantial work on learning disabilities or difficulties in mathematics conducted and disseminated by special educators, it seems current practices remain highly ineffective in promoting desired changes.

That being said, emerging collaborations among special education and mathematics education researchers have been showing promising results. Whether this emerging research will change the current math instructional practice involving students with disabilities remain uncertain. "To most teachers, math is just about calculation" and calculation math is "drill and kill!" (Janell Uerkwitz, NSF-I-Corps program interview note, March 2nd, 2018**).** The underlying common approach the Working Group has been developing revolves around paradigm shift away from the focus on behavioral and procedural oriented teaching to guided constructivist approach that focus on conceptual learning and teaching.

The purpose of our Working Group is to not only facilitate the collaboration between math education and special education researchers with an intention to move forward the teaching and learning of mathematics involving students with LDM, but also to disseminate the work resulting from such collaboration to inform the research and practice in the field.

This Working Group is formed to create sustainable opportunities for collaborative work between researchers and practitioners from both the fields of math education and special education, who are working with students with LDM. Understanding how students with LDM develop mathematics concepts and skills and how teaching and instructional environment can promote this process is an important dimension of the psychology of mathematics education, has several implications for both research and practice. First, practitioners in both general and special education can benefit from diverse perspectives as well as empirical evidence and gain a

Hodges, T.E., Roy, G. J., & Tyminski, A. M. (Eds.). (2018). *Proceedings of the 40th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Greenville, SC: University of South Carolina & Clemson University.

richer understanding of how students with LDM learn mathematical concepts. Secondly, active study of the development of mathematics concepts and skills for students with disabilities provides both researchers and practitioners with mechanisms for moving toward a methodological focus on pedagogy rooted in assessment of what students with disabilities are capable of learning.

For the purposes of continuing the conversation around mathematics in special education, this group is concerned with students who have significant issues with mathematics, including:

- students with learning disabilities specific to mathematics (MD)
- students with cognitive differences in how they understand and process number
- students who are placed in special education and have difficulties with mathematics

We refer to these students as having learning disabilities or difficulties in mathematics (LDM) in the remainder of this paper.

History of the Working Group

Our PME-NA/PME Working Group has met six times; each year our group had good participation of both returning and new members. In 2012, 15 researchers (faculty and graduate students) and 2 practitioners met during PME-NA in Kalamazoo, MI. This first meeting specifically focused on better understanding mathematical learning disabilities (MD). The Working Group began with a discussion of the issues around identification and definition of MD. In particular, the group discussed the unique characteristics of students with MD (e.g., slow speed of processing despite average reasoning; fundamental issues with number sense; over learning of procedural knowledge at the expense of mathematical reasoning) and implications for instruction and assessment. We took up a theoretical stance that positioned disability as an issue of diversity and considered the origin of the disability as the inaccessibility of instruction rather than a defect within the individual. Members shared videotapes of various students with MD solving problems in assessment and teaching situations and discussed the need for teachers to target and teach toward the specific mathematical strengths and weaknesses demonstrated by the student. We further discussed at what point(s) the learning paths of students with MD may differ from what is documented among students in general education, how existing developmental trajectories may or may not fit the population of students with MD, and the need to expand or further document current trajectories to include students with MD. Moreover, discussions focused on issues surrounding motivation related to the design and use of instruction, mathematical tools, and mathematical tasks. A rich discussion was held concerning the nature and sequencing of mathematical tasks, the use of concrete and pictorial representations and the extent to which they are and are not supportive of the abstraction of mathematical concepts for this population, and the need for increased research to inform the creation of practitioner tools and resources.

During the first year of our Working Group, our focus was specifically on MD- those students with a biological and cognitively-based difference in how their brain processes numerical information. Based on our discussions during the first year of our Working Group we decided to expand from a narrow focus on MD to a more inclusive focus on students in special education who struggle with mathematics (i.e., learning disabilities/difficulties in mathematics, LDM). This not only avoids the definitional issues at the forefront of the field (i.e., the lack of assessments to accurately identify students with MD and the resulting conflation of low achievement and MD), but also more accurately reflects the diversity of interests of the members of this group.

In the second year of our Working Group (2013) fourteen participants focused on a collaboration that was a result of the contacts that were made during the first Working Group. In this collaboration two faculty members worked together on a teaching experiment about fraction knowledge, a compliment to a 2013 funded National Science Foundation (NSF) CAREER project (Hunt, 2013). Their collaboration resulted in each bringing unique expertise; the mathematics education scholar brought insight into the mathematical thinking of the student, while the special education scholar brought insight into learning differences. The goal of the teaching experiment was to document how the foundation scheme of unit fractions (1/n) evolves in the mathematical activity of two cases of students with learning disabilities. The students' evolving conceptions were supported by constructivist-oriented pedagogy. Video data segments (i.e., each girl's conceptualization of the multiplicative nature of and inverse relation ($1/m > 1/n$ if $m < n$) among unit fractions; the girls' solutions to novel problems) from this project served as starting points for discussions in the subsequent PME-NA Working Group meeting. Specifically, Working Group members used the video segments and descriptions of the collaboration as a springboard for discussing possible research questions and methods of data analysis to employ in future, collaborative work. It is collaborations like these that this Working Group is designed to foster.

In 2014, we met as a Working Group at the joint PME and PME-NA conference in Vancouver. There our Working Group continued to expand to 25 members, now including international members from outside of North America. During the meeting, two Working Group members (one from math education and one from special education) shared a multiplicative reasoning assessment tool resulting from their NSF-funded research project (Xin, Tzur, & Si, 2008). Upon examining this instrument, the group discussed alternative ways for assessing students with LDM and implications for intervention development. As a result of our collaboration in Vancouver, we had two main accomplishments. First, as a group we identified three research subgroups: (a) cognitive characteristics of students with LDM, (b) interventions for students with LDM, and (c) teacher preparation or professional development, that represented the interests of the members. Each research subgroup identified pertinent research questions and an agenda for further collaboration.

Second, as a group, we proposed an idea for developing a proposal for a special issue to be published in an influential special education journal to address the research around the intersection of math and special education. Later in the year, members of the Working Group developed the proposal for the special issue and worked extensively with the editors of a special education journal *Learning Disabilities Quarterly* (LDQ). The quality of our proposal led to the acceptance of this special issue proposal by the co-Editors of LDQ. Two members from the Working Group served as co-Guest Editors of this special issue and identified potential contributing works from the Working Group members. In addition, we invited a well-known scholar from the field of special education for co-authoring a commentary paper as part of this special issue.

In 2015 PME-NA, we continued and expanded collaborations between members of this Working Group, by focusing discussions around two central themes: (a) math concept development and corresponding methodologies for studying its emergence in students with special needs, and (b) designing research questions and writing a research plan around this topic. We invited interested researchers and educators to the Working Group sessions. We had several new members joining this Working Group including scholars from countries other than U.S. During the Working Group sessions, equity was brought up as a new discussion point. Following 2015 PME-NA, two members of this Working Group, along with a new member, formed a new collaboration; and they worked on writing a practitioner piece pertinent to differentiating instruction for diverse students—that article was accepted to MTMS.

In 2016, the Math and Special Education Working Session met twice during PME 40 held in Australia. Nine people from five continents attended these sessions, while another three people actively participate in our projects throughout the year. On the first day, there were several new members to the group, so we introduced each other and explained the history and goal of the working session: to promote cross-disciplinary work that supports the learning of math by students with mathematical learning difficulties. We then discussed a project that we started at PME 38 and have recently concluded. That is the special series of *Learning Disabilities Quarterly* (LDQ) on the subject of the intersection between mathematics and special education. As a result of this discussion, we came up with a number of new questions that we would like to explore (e.g., challenges and strategies of collaborative work between professionals/scholars from the field of math education and the field of special education) and consider questions from an international perspective.

On the second day of the Working Group session we discussed our next big project to work on as a group. We decided that we would like to produce a book that teacher educators can use for teaching undergraduate and graduate students about the intersection between mathematics education and special education. The group members committed to the collaborative work on this book project.

In 2017 during PME-NA39, a total of 26 people (including three members via Skype from UK and Canada) attended the Working Group sessions across three conference days. Day one, the group went over the history of the Working Group and reported the publication of the special series that this Working Group initiated in 2014 at the joint PME and PME-NA conference in Vancouver. All five papers of this special series plus an introduction paper (Xin & Tzur, 2016) have been published in the journal of LDQ (impact factor =1.028) across four issues (from LDQ Vol 39 (4) published in November 2016, to LDQ Vol 40 (3) published in August 2017). These papers address characteristics of individuals with LDM and interventions from different theoretical frameworks. From a socio-cultural framework, one paper addressed "mediational tools" that supported the development of math or language abilities of one individual with MD (Lewis, 2016). From a constructivist framework, another paper examines the partitioning and units coordination of 44 students with MD or at-risk for MD in terms of initial numeric and fractional reasoning (Hunt, Welch-Ptak, & Silva, 2016). From an integration of constructivist pedagogy and explicit strategy instruction, one intervention study paper reported the outcome of a RCT study that evaluated the acquisition and generalization effect of the PGBM-COMPS intelligent tutor program (Xin, Tzur, Si, Hord, Liu, & Park, 2017) on enhancing multiplicative reasoning and problem solving of students with LDM. Lastly, building on the framework of *Conversational Repair* from the field of linguistics, the second intervention study paper reported the effectiveness of a discourse-based intervention on math problem solving and reasoning (Liu & Xin, 2017).

During the second and third day of the Working Group sessions, the group engaged in heated discussion of the book proposal—the new project initiated by this group following the special series project. The discussion revolved around the purpose of the potential book, potential title of the book, potential audience and market of the book, unique selling point of the book, potential competitors of the book, and potential table of content. Between the Working Group sessions during the conference, the team conducted an initial search for similar books in the current market. Then, based on the review of these existing "similar" books, the Working Group had further discussion about the significance and unique feature of our potential book. Following PME-NA 39, the Working Group members have continued their work on the book proposal and produced an initial draft of the book proposal.

Issues Relating to Psychology of Mathematics Education

Historically, special education researchers and teachers focused almost exclusively on students' mastery of procedural skills, such as basic number combinations and ability to execute mathematical algorithms (Jackson & Neel, 2006; Fuchs et al., 2005; Geary, 2010; Swanson, 2007; Kameenui & Carnine, 1998). A recent literature review comparing instructional domains for students with disabilities found that the majority of research conducted in the field of special education addressed basic computation and problem solving, with the primary focus placed on mnemonics, cognitive strategy instruction (e.g., general heuristic four-step strategy: read, plan, solve, and check), or curriculum-based measurement (Van Garderen, Scheuermann, Jackson, & Hampton, 2009). Instructional practices mainly focused on task analysis (breaking up skills into decontextualized steps that need to be memorized and followed), flash cards, or general heuristics that do not help with domain knowledge learning and concept development (Cole & Washburn-Moses, 2010). In particular, the focus on primarily procedures-driven instruction and rote memorization of skills seems to result in students' incomplete and inaccurate understanding of fundamental mathematics concepts as well as a lack of retention and/or transfer (Baroody, 2011).

Importance of Both Conceptual and Procedural Knowledge

Crucial for rich mathematical understandings that enable retention and transfer of fundamental concepts is the iterative development of conceptual understanding along with procedural proficiency (Rittle-Johnson, Siegler, & Alibali, 2001; Rittle-Johnson & Koedinger, 2005). Rittle-Johnson and Alibali (1999) noted that conceptual knowledge supports procedural generalization. In particular, conceptual knowledge could aid children in mindfully avoiding the use of procedures that fail to work in novel situations. Additionally, an ability to understand and manipulate different mathematical representations to navigate conceptually a mathematical context contributes to conceptual understanding and procedural skill (Ball, 1993; Kaput, 1987; Rittle-Johnson et al., 2001). It seems that any investigation into mathematical cognition, whether related to disability or not, must fundamentally engage with issues of conceptual understanding (Hunt & Empson, 2015).

A focus on procedural skills limits students with disabilities' access to the general education curriculum, which is a requirement of the Individuals with Disabilities Educational Improvement Act (Maccini & Gagnon, 2002). In mathematics, access to the general education curriculum means addressing problem-solving, mathematical modeling, higher order thinking and reasoning, and algebra readiness as required by the new Common Core Standards (CCSSI, 2012). To accomplish these Standards, mathematics educators need to engage students actively in making conjectures, justifying and questioning each other's ideas, and operating in ways that lead to deep levels of mathematical understanding (Kazemi & Stipek, 2001; Lampert, 1990; Martino & Maher, 1999; Yackel, 2002).

Conceptual Diagnosis Based Pedagogy

A pedagogical approach to be explored and advanced during this Working Group's meetings is one that focuses on promoting conceptual learning in students with LDM. This approach is rooted in a constructivist stance (Piaget, 1985; von Glasersfeld, 1995), particularly the notion of assimilation, which stresses the need to build instruction on what students already know and are able to think/do. That is, teaching needs to be sensitive, relevant, and adaptive to students' available ways of operating mathematically (Steffe, 1990). To this end, teachers must learn how to: (a) diagnose students' available conceptions, and (b) design and use learning situations that both reactivate these conceptions and lead to intended transformations in these conceptions.

Building on Simon (2006)'s core idea of hypothetical learning trajectories, Tzur (2008) has articulated such an adaptive pedagogy, which revolves around the Teaching Triad notion: (a) students' current conceptions, (b) goals for students' learning (intended math), and (c) tasks/activities to promote progression from the former to the latter. Key here is that in designing every lesson one proceeds from conceptual diagnosis of the mathematics students are capable of thinking/doing. That is, assessment methods need to focus on dynamic (formative) inquiry into student understandings, as opposed to on testing correct and incorrect answers per se. This day-to-day diagnosis, obtained via engaging students in solving tasks and probing for their reasoning processes, gives way to selecting goals for students' intended learning. Building on this diagnosis, a mathematics lesson begins with problems that students can successfully solve on their own, which Vygotsky (1978) referred as the Zone of Actual Development (see also Tzur and Lambert, 2011). Recent studies of mathematics teaching in China (Jin, 2012; Tzur & Lambert, 2011) revealed a strategic, targeted method, bridging, which is geared specifically toward both: (a) reactivating mathematical conceptions the teacher supposes all students know, and (b) directing their thinking to the new, intended ideas.

Exemplar Research Activities with Students with LDM

Multiplicative Reasoning Project: From 2008 to 2015, two members of this Working Group (one from math education and one from special education) have been working collaboratively on a federal funded grant project (Xin, Tzur, and Si, 2008). This project integrated research-based practices from mathematics education and special education and was aimed to promote multiplicative reasoning and problem solving of elementary students with LDM. As an outcome of this collaborative project, the research team has developed an intelligent tutor, PGBM-COMPS. The PGBM-COMPS intelligent tutor draws on three research-based frameworks: a constructivist view of learning from mathematics education (Steffe & D'Ambrosio, 1995), data (or statistical) learning from computer sciences (Sebastiani, 2002), and Conceptual Model-based Problem Solving (COMPS) (Xin, 2012) that generalizes word-problem underlying structures from special education.

Rooted in a constructivist perspective on learning (Piaget, 1985; von Glasersfeld, 1995), the PGBM part of the intelligent tutor focused on how a student-adaptive teaching approach (Steffe, 1990), which tailors goals and activities for students' learning to their available conceptions, can foster advances in multiplicative reasoning. This approach eschews a deficit view of students with learning disabilities. Rather, it focuses on and begins from what they do know and uses task-based activities to foster transformation into advanced, more powerful ways of knowing. On the other hand, intelligent computer systems can play an important role in students' learning by effectively modeling their thinking and dynamically recommending tasks tailored to their conceptual profiles. Going hand-in-hand, the COMPS part of the program (Xin, 2012) generalizes students' understanding of multiplicative reasoning to the level of mathematical models. At this stage, students no longer rely on concrete or semi-concrete models for problem solving; rather, the mathematical models directly drive the solution plan.

The collaborative research team has conducted several piloting studies to field test the PGBM-COMPS intelligent tutor with elementary students with LDM. The preliminary studies have shown promising results—participating students with LDM who interacted with this intelligent tutor not only enhanced their problem-solving skills on a researcher-designed criterion test but also a norm-reference standardized test (Xin et al., 2017). In addition, the results of these piloting studies have shown success in promoting students' substantial conceptual advances (e.g., concept of number, multiplicative reasoning). In fact, a paper resulting from a randomized control trial (RCT) study of this project has been published (Xin et al., 2017) as part of the special series produced by this Working Group. As a follow up, the research team has continued on this line of work and recently embarked on a new NSF supported project (Xin, Kastberg, and Chen, 2015), which focuses on additive reasoning.

Most recently, building the data gleaned from Multiplicative Reasoning Project, the team members of this Working Group formed further collaboration and conducted a quantitative analysis of teacher-student interactions during discourse–oriented instruction involving elementary students with LDM in solving multiplicative word problem (under revision). The findings from this discourse analysis study indicate that with appropriate opportunities /prompting as well as guidance and support, students with LDM demonstrated various degrees of problem solving and reasoning in a discourse–oriented mathematics instructional environment. Findings of this study support the notion that quality classroom discourse and teachers' responsiveness to students' thinking contribute to students' learning and achievement.

Fraction Project. Another Working Group member is documenting learning trajectories of elementary school children with LDM as they come to understand fractions as quantities (Hunt, 2013). In its first year, this work produced models of children's key developmental understandings from semi-structured interviews with 44 second, third, fourth, and fifth graders with LDM (Hunt et al., 2016). Interviews followed a protocol that established a basis for questioning but also allowed for maximum researcher flexibility to fully examine student thinking and examine trends across the students' unique ways of reasoning. Two design experiments also took place during Year 1 to test an expanded group of tasks from which the trajectory is based. The design experiment exemplified Hunt's (2018) evolving characterization of knowing, learning, and teaching in terms of the mathematical knowledge students with learning disabilities (LDs) *do* possess. Utilizing an iterative, three phase qualitative analysis, Hunt (2018) illuminated two children's perceptions and meaning-making for the unit fraction concept observable through work in learning situations that supported partitioning and unit coordinating activity. The analysis revealed each child's evolving knowledge as a *complexity* consisting of the negotiation and construction of meaning among the child's mind, her participation in a learning environment, and the teacher's responsiveness to the child's ways of reasoning and making sense.

In Years 2 and 3, the researcher took up a teaching experiment methodology, much like those used in the collaborative pilot that resulted from this Working Group, to document how eight children with LDM constructed conceptions of number and fractions alongside the factors that supported, extended, or constrained their understanding. Data analysis within and across each of the eight cases is ongoing, yet initial findings from three of the cases can be shared. First, when engaging in tasks that support the construction of composite unit, the use of memorized fact combinations or teacher taught strategies eclipsed the use of two students' natural reasoning (Hunt, MacDonald, & Silva, in press) yet supported the third's (Hunt, Silva, & Lambert, 2017). All three students evidenced tacit ways of reasoning (e.g., 2 is contained in 3, 3 is contained in

4); two reverted to pseudo-empirical abstractions, tricks, or algorithms that they could not explain to solve the tasks. These ways of engaging in the tasks were counterproductive to these two students' reflection on their own actions upon units such that adaptations in their reasoning could occur. Conversely, the third student leveraged his knowledge of number facts and alternative representations to advance his fractional reasoning and compensate for his perceptual motor differences (2017). For all three students, teacher encouragement and support to engage in each student's own ways of reasoning was imperative. Second, Hunt and colleagues (under review) found evidence that confirms previous research (Geary, 2010) that two students sometimes lost track of counting during a count on, possibly due to working memory. Author conjectures that this learning difference interferes with the move from counting on to more sophisticated additive reasoning (e.g., breaking apart tens). Yet, in one case, the problem is alleviated through opportunities for within-problem reflection through experiences that the child has to construct addends involved in number problems through counting, sweeping small numbers as lengths, and improving the usability of small composites like 2, 4, 3, 5, and 6 (under review). Lastly, all three students evidenced an affinity towards symmetric notions of units coordination across learning situations and across natural and fractional number reasoning. Hunt is currently conducting cross-case analysis to discern whether the symmetry is indicative of unique trajectories in number and/or fractional reasoning.

As forgoing, this Working Group participants will use artifacts from projects described above as possible starting points to illuminate and further explore possible applications of student-adaptive pedagogy (conceptual diagnosis-based) as well as conceptual development trajectories in the design of effective/efficient assessment and intervention programs for students with LDM. We believe such approaches are complimentary and have the potential to become core methodological approaches for teaching and studying the conceptual understandings of students with LDM. In a similar way, this Working Group provides a venue to give and receive feedback on ongoing cutting-edge empirical work, which is reshaping how students with LDM are researched.

Plan for Working Group

The aim of this Working Group is to continue the conversation surround the intersection of mathematics education and special education. In particular, one of the major goals of this year's Working Group sessions is to revised and finalize the proposal for a new book that university professors and teacher educators can use for teaching graduate students about the intersection between mathematics education and special education.

This Working Group intends to accomplish the following:

- Review the draft of the book proposal
- Make addition or modification to current book proposal draft
- Finalize the content of the book (Table of Content)
- Identify potential team members who will work on each of the proposed chapters
- Each Team will brainstorm the outline of the chapter.
- Discuss the logistics of collaborations to carrying out the identified tasks following the PME-NA conference, and
- Discuss further collaborations leading to additional publication and funding opportunities.

These goals are further outlined across sessions as follows:

Session 1: Introduction and Progress-to-date
GOAL: **To identify participant's affinity for establishing potential sub-groups for collaborative work pertinent to math and special education.**

- Prior members will briefly introduce the Working Group's history and describe the collaborations that have emerged in prior years.
- Participants will each introduce themselves and their current research and interest in students with LDM.
- Form sub-groups or collaborative teams among participants based on their common (research) interests.
- Group(s) will be engaged in discussing common research agenda and potential collaboration opportunities.

Session 2: Book Proposal Development
GOAL**: Revised and finalize book proposal**

- Revise the content of the book proposal
- Revise the draft Table of Content; come up key words we think readers may use.
- Revise the list of book titles with which our book will compete and revisit /revise how our book will differ from these titles.
- Revise the selling points of our book based on draft book proposal

Session 3: Continue the ongoing collaboration
GOAL: **Establish next steps for both the sub-groups and the whole Working Group.**

- Identify potential team members who will work on each of the chapters, so that after this PME-NA conference, the team will continue their collaborative work in making the abstract for the chapter and even drafting the chapter.
- Team members work together and exchange ideas of how to approach each of the chapters, and perhaps discuss the logistics of collaborations to carrying out the identified tasks, and
- Discuss further collaborations leading to additional publication and funding opportunities.
- Determine what our next whole group meeting will entail (e.g., PMENA Working Group for the following year)

Anticipated Follow-up Activities

Throughout the year, the members of this Working Group will work collaboratively creating the outline of the chapter assigned, drafting the abstract and then the content for the chapter. In addition, the members of this working group will continue their effort in forming collaborative research agenda and conducting collaborative research that is relevant to the goal of this Working Group.
