Our definitions for the terms *quantifying* and *student quantification* align with constructivist views of meaning, as each individual constructs and reinforces his own quantifications through his own experiences (Thompson et al., 2014). We situate these definitions from a constructivist perspective partially because students may not share conventional meanings for quantifiers in mathematics (Sellers, Roh, & David, 2017; Dubinsky & Yiparaki, 2000; Epp, 1999). Student quantification can be regarded as a meaning for quantifiers as described by Thompson et al. (2014) because quantification is comprised of an *individual's* mental actions or schemes that are easily triggered as a result of the person's understanding (or assimilation to a scheme). In particular, our definition for student quantification emphasizes that a student quantifies in ways that *he* deems necessary based on *his own* interpretation of a given statement, which also aligns with a constructivist view of meaning. Thus, when we refer to a *student's meanings for a quantified variable*, we refer to a student's own constructed quantification for a specific variable in the given statement from the *student's* perspective.

Methodology

We conducted a two-hour long clinical interview (Clement, 2000) with a Calculus student, whom we call Zack, in the spring of 2016. Zack had completed a first semester Calculus course and was currently enrolled in a second semester Calculus course at the time of the interview. We report Zack's interview because of the various meanings for quantified variables that we found across different moments of his interview and our ability to triangulate his words, gestures, and markings on graphs.

Tasks

We asked Zack to interpret and evaluate several complex mathematical statements, shown in Table 1. We did not present Zack with the symbolic representations of the conclusion of each of the statements in Table 1, but we provide these representations in this paper to display the logical differences in the statements. Statement 2 is the IVT and the only true statement. The other three statements reorder the quantifiers and variables in the IVT, but maintain the hypothesis.

Table 1: Statements Presented in Clinical Interviews

Statements	Symbolic Representations
Statement 1 (S1): Suppose that f is a continuous function on the closed interval $[a, b]$, where $f(a) \neq f(b)$. Then, for all real numbers c in (a, b), there exists a real number N between $f(a)$ and $f(b)$, such that $f(c)=N$.	$\forall c(\exists N\, f(c) = N)$

Statement 2 (S2): Suppose that f is a continuous function on the closed interval $[a, b]$ where $f(a) \neq f(b)$. Then, for all real numbers N between $f(a)$ and $f(b)$, there exists a real number c in (a, b), such that $f(c)=N$.	$\forall N(\exists c\, f(c) = N)$
Statement 3 (S3): Suppose that f is a continuous function on the closed interval $[a, b]$, where $f(a) \neq f(b)$. Then, there exists a real number N between $f(a)$ and $f(b)$, such that for all real numbers c in (a, b), $f(c)=N$.	$\exists N(\forall c\, f(c) = N)$
Statement 4 (S4): Suppose that f is a continuous function on the closed interval $[a, b]$ where $f(a) \neq f(b)$. Then, there exists a real number c in (a, b), such that for all real numbers N between $f(a)$ and $f(b)$, $f(c)=N$.	$\exists c(\forall N\, f(c) = N)$

We first presented each of the statements shown in Table 1 one at a time and asked Zack to explain in his own words the meaning of each statement and also asked him to determine if each statement was true or false. Zack was asked to justify his evaluations and we allowed Zack to draw his own graphs to explain his thinking about his evaluation of each statement. After Zack evaluated all four statements, we provided him with several graphs and asked him if he could use the graphs to support his evaluations of each of the four statements. We allowed (and often asked Zack to) highlight the variables in a given statement on the given graph after he referenced them. These markings as well as his gestures of sweeping or pointing on the graphs were used in the data analysis as an indicator of characteristics for his meanings for the quantified variables in that statement in a given moment.

Data analysis

Our analysis was conducted in the spirit of grounded theory (Strauss & Corbin, 1998). The use of grounded theory allowed new categories to emerge from our data that have not yet been described in the literature regarding students' meanings for quantifiers. We noticed that Zack's meanings for a particular quantified variable with the same statement changed at different moments in the interview. Thus, we also employed Thompson et al.'s (2014) construct of "meanings in the moment" to analyze Zack's meanings for quantified variables. We marked a new moment when Zack was presented with a new interview prompt or task, when he changed his evaluation of a statement, or if he provided a different meaning for a quantified variable while working with the same statement. Every time we found a new meaning for quantified variables in a moment, we added this new meaning into our overall coding system. We also compared Zack's meanings against other students' meanings we interviewed. From this process, similarities and differences in student meanings for quantified variables were refined into four categories. Finally, using the four meanings for quantified variables, we re-analyzed all student interviews and refined our previous coding for each student moment as necessary to ensure that these categories were reliable for all moments, as well as with other students.

Results

We found Zack used four different meanings for quantified variables, which we call MQ1-MQ3 and NQ. Evidence of these meanings came from moments across different moments of Zack's interview. In the subsections that follow, we explain each of the four meanings for quantified variables and provide examples from different moments of the interview when Zack used each of the four meanings.

MQ1: Checking the predicate holds for at least one element

We found that in some moments, Zack described his imagined process of checking the predicate of the statement for *at least one* element of x. We classified his meaning as MQ1 whenever he appeared to strategically search for at least one value of x, within his domain of discourse, that satisfies the predicate.

Although MQ1 is consistent with the mathematical convention for existentially-quantified variables, in the following moment, Zack used MQ1 for a variable attached to a *universal* quantifier in the given statement. Zack quantified the variable N in Statement 2 ($\forall N(\exists c\, f(c) = N)$) as follows: "I have read the first part of the second sentence, 'for all real numbers N between $f(a)$ and $f(b)$.' So that made me think, or realize, that there exists a number N between my output variables $f(a)$ and $f(b)$ on this curve." Although Statement 2 contained the phrase "for all N," Zack's interpretation indicates that he was looking for (at least) one N-value as he stated that, "there *exists* a number N."

MQ2: Checking the predicate holds for exactly one element

In some other moments, Zack emphasized that he was looking for *exactly one* value satisfying the predicate. We use MQ2 to refer to Zack's meaning when he appeared to mentally search (or suggested he imagined searching) through every element in the domain of discourse to ensure that *exactly one* value satisfies the predicate. MQ2 follows the mathematical convention for variables attached to "there exists a unique." However, as we see in the moment below, Zack used MQ2 despite the absence of the word "unique" in the provided statements.

We highlight one moment with Zack where he appeared to use MQ2 for the variable N in Statement 4 ($\exists c(\forall N\, f(c) = N)$). Zack first stated that the graph in Figure 1 was "still a function because [Figure 1 is] still in a parabola shape." He then labeled $f(a)$ and $f(b)$ on the graph, and then proceeded to chose a specific value of c, drew the vertical line shown on the graph, and wrote $f(c)$=N at two different points on the curve. Next, he concluded that Statement 4 was false for this graph and explained his reasoning in the following transcript.

Zack: I don't know if I would use this graph to prove this statement […] I'm getting two output variables from the *c*. So if it was […] a regular parabola, I would say […] If I choose *c* in between *a* and *b*, I am only gonna get one *N*. […] But […] I get two outputs for a *c*.

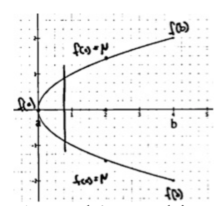

Figure 1. Zack's markings on provided graph for S4.

Zack's explanation above suggests that he anticipated finding one value of N (Lines 3-5). Yet, he found two specific N-values that satisfied the predicate for his chosen c-value (Lines 2, 5), which led him to complete his search process for *exactly one* N-value that satisfies the predicate. Zack evaluated Statement 4 as false because *more than one* element of N satisfied the predicate for the given graph. Zack ultimately determined that this statement was false for this graph because there was more than one N-value for his chosen c, and thus, we claim that Zack utilized MQ2 for N in Statement 4 in the moment above.

MQ3: Checking the predicate holds for all elements

In contrast to the moments in which Zack employed MQ1 or MQ2, we found some moments when he described his imagined process of checking the predicate $f(c)$=N for *all* values of either c or N. We classified this type of student quantification as MQ3.

We classified Zack's meaning for a quantified variable as MQ3 whenever we observed the following behaviors: (1) he chose a value or values from his own identified domain of discourse and determined whether or not his chosen value(s) satisfy the predicate and (2) he repeated (or imagined repeating) checking the predicate for all elements within his domain of discourse.

MQ3 is akin to the mathematical convention for universally-quantified variables. However, students may use MQ3 for existentially-quantified variables, as shown in the moment with Zack below. In this moment, we focus on Zack's quantification for the variable c in Statement 4 ($\exists c(\forall N\, f(c) = N)$. Even though c is an existentially-quantified variable in the given statement, Zack's quantification for c does not follow convention in this moment.

Zack: If I were to input c, whatever number c may be, and that's just arbitrary. By choosing that number, I know that I am gonna get N […] So, in this case c equals $^{-}1$ (*marks* c=$^{-}1$ *on x-axis*) […]
Int: Is there any particular reason why you picked this c […]?
Zack: No. I could have […] represented c as 2 (*points to the number 2 on the x-axis*) […] I would say c only represents one input-output relation at one time. […] I think what I am trying to say is I can choose […] any number between a and b for an input variable, and that could be c. So yeah if I choose again if I choose c to be -1 then I know that my N would be this number right here (*points to N on the curve*). If I represent any other x number to be c, then that output would have to be unique to that input.

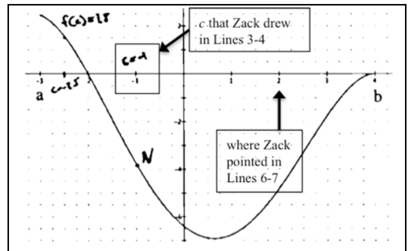

Figure 2. Zack's markings on provided graph for S4.

The transcript above indicates that Zack's domain of discourse was the interval (a, b) (Lines 9-10) and he checked the predicate for a specific value of c in his domain of discourse (Lines 2-3). Initially, he checked the predicate for just this value (Lines 2-3), but also referred to his choice of c as *arbitrary* (Line 2). Although Zack chose to check one specific value of c, he did not claim that this was the *only* value for c that could have been chosen. Instead, he accepted multiple values of c in his consideration of the predicate (Line 6). Furthermore, Zack also used words such as *whatever number c* (Line 1) and *any number between a and b* (Line 9), which indicate that Zack considered not only multiple values of c, but *all* the values of c within his chosen domain of discourse, (a, b). He also discussed his stipulations for checking the predicate for *any* value for c (Line 8). Since Zack explained the satisfaction of the predicate for *any other* values of c (Line 11), we conclude that his language suggests an imagined search through all values of c, and thus, we conclude that he quantified c with MQ3.

NQ: No quantification

Thus far, we have detailed several different ways that Zack quantified variables. In some other moments, Zack did not quantify a variable in the given statements (see Table 1). Regardless of the presence of the quantifier words in a statement, in these moments Zack focused on certain attributes of *x other than the quantity* and often attended to properties of a variable without attending to the number of elements in the domain of discourse. Indeed, Zack did *not* search for a specific number of elements of x that satisfied the predicate in these moments. We refer to this type of student quantification (no quantification) as NQ. We illustrate characteristics of NQ from a moment in which Zack first analyzed Statement 3 ($\exists N(\forall c\, f(c) = N)$, without being given any graphs. In this moment, we highlight Zack's quantification for both variables c and N.

Zack: If I draw this line…I am now going to write *c* in between these two [*a* and *b*] such that for a real number *c* in interval (*a*, *b*), if I put […] *c* into the function, […] then I get my number *N*. So, right here (*marks N on the line*). […] I will get my output variable *N*.
Int: […] In your own words how would you explain this? […]
Zack: So I know that I can only work between my *x* values of *a* and *b* on a closed interval. […] I know that *c* lies in the interval between *a* and *b*. So I am just gonna put it right in the middle. If I put this *c*-value into the function, I get *f*(*c*), which is equal to my number *N* in between *f*(*a*) and *f*(*b*).

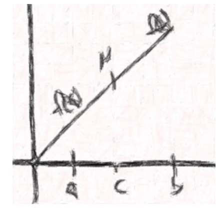

Figure 3. Zack's hand-drawn graph for S3.

Zack stated that he knew that *c* has to be in the interval (*a*, *b*) and also stated that *N* was between *f*(*a*) and *f*(*b*) (Lines 2, 9). Thus, he recognized a domain of discourse for *c* and *N*, respectively. However, Zack does not refer a specific number of *c*-values or *N*-values that he is checking to ensure that *f*(*c*)=*N*. Rather, he stated that he was drawing his graph in such a way that his *c would* yield *N* (Lines 1-4). We take Zack's words as indicative that he is *interpreting* the predicate and drawing his graph in such a way to ensure that he gets *N*-values that satisfy the predicate, *f*(*c*)=*N*. Thus, we conclude that Zack used NQ for both *c* and *N* in this moment.

Conclusion

Zack used four different meanings for quantified variables throughout his interview, which we refer to as MQ1-MQ3 and NQ. MQ1-MQ3 are akin to mathematical conventional uses of the existential, existential unique, and universal quantifier meanings, respectively. Zack also exhibited one other meaning for quantified variables, which we categorized as "No quantification" (NQ). NQ is not characteristic of any conventional mathematical meaning for quantified variables, and we conjecture that in moments where Zack used NQ, he lacked a mental search for a search for a number of elements of either variable *c* or *N* that satisfied the predicate. In these moments where he used NQ, he appeared to only interpret the meaning of the predicate instead of checking the validity of the predicate.

The four categories of meaning are highlighted in Table 2. In this table, we provide descriptions of evidence that we considered in our classifications and the mental actions, which we theorize comprise each meaning for quantified variables. We utilize *x* as an arbitrary quantified variable and X as a generic domain of discourse in Table 2, as these meanings applied to either variable *c* or *N*. We categorized Zack's meaning for a quantified variable based on crucial observable behaviors that distinguished his meaning from another meaning, even if he did not exhibit all observable behaviors listed. These crucial behaviors are italicized in Table 2.

Table 2: Student Meanings for Quantified Variables

Meaning	*Mental Actions*	*Observable Evidence*
MQ1: Checking the predicate holds for at least one *x* in X	1. Identify the domain of discourse, X. 2. Choose (or imagine choosing) one value (x_0) for *x* from X, then check if the predicate is satisfied by x_0 (i.e. $P(x_0)$ is true). 3. Repeat (or imagine repeating) this mental action until at least one value of *x* in X is found that satisfies the predicate. May complete without exhausting all values of *x*.	• Marks off the domain of discourse, X. • Marks one value of *x*, x_0, in X & explains or illustrates whether or not this value of *x* satisfies the predicate. • May mark more values of *x* & may explain or illustrate that at least one value of *x* in X satisfies the predicate. • *Uses phrases such as there is, some, or at least one to refer to the values of x in X that satisfy the predicate.*

MQ2: Checking the predicate holds for exactly one *x* in X	1. Identify the domain of discourse, X. 2. Choose (or imagine choosing) one value (x_0) for x from X, then check to determine if the predicate $P(x)$ is satisfied by this value of x. 3. Repeat (or imagine repeating) step 2 until all the elements of x in X are exhausted to ensure that exactly one value of x in X satisfies the predicate.	• Marks off the domain of discourse, X. • Marks one value of x, x_0, that satisfies predicate. • *Claims that the value, x_0, is the only value that satisfies the predicate.* Explains or illustrates that other elements of x do not satisfy the predicate. • Uses phrases such as there is exactly one to refer to the values of x in X that satisfy the predicate.
MQ3: Checking the predicate holds for all *x* in X	1. Identify a domain of discourse, X. 2. Choose one value (x_0) for x from X, then check if the predicate is satisfied by x_0 (i.e. $P(x_0)$ is true). 3. Repeat (or imagine repeating) step 2 until all the values of x in X are exhausted.	• Marks off the domain of discourse, X. • Marks one value of x, x_0, in X & explains or illustrates whether or not this value of x satisfies the predicate. • *Explains or illustrates that the predicate holds for every x.* One possible illustration may be sweeping along X. • Does not use the phrases there is, there exists, or for some, but may use words all, every, each, any or arbitrary to refer to values of x in X that satisfy the predicate.
NQ: No quantification	1. Identify the domain of discourse, X. 2. Choose (or imagine choosing) one value (x_0) for x from X & interpret predicate $P(x)$ using the chosen x_0. (i.e. $P(x_0)$ means…)	• Marks off the domain of discourse, X. • May mark a value of x in X. • *Interprets the given predicate $P(x)$ in their own words, but does not explain how many values of x satisfy $P(x)$.*

For all four categories, including MQ1-MQ3, Zack often used meanings for quantified variables in unconventional ways, i.e. he used these meanings *regardless of the given quantifier in the given statement*. For example, Zack quantified a variable with a meaning that is more akin to a mathematical meaning for a universally-quantified variable even though the variable is existentially quantified in the given statement and vice versa in different moments.

Discussion

All four meanings for quantified variables that emerged from our study are applicable to analyze students' meanings for quantified variables in other mathematical contexts. Our discovered four meanings may explain findings in previous research, and they have potential to guide teaching in many content domains.

The four categories of meaning that emerged in this study have explanatory power for previous research findings. Students' reasoning from a given statement may not be perceived as erroneous if that reasoning is based on a different interpretation of the variable given in the statement. As previously mentioned, prior research has found that students may determine that a few examples are sufficient to prove a universally-quantified statement (Barkai et al., 2002). This behavior could be explained if the student interpreted the given universal statement with MQ1, checking the predicate for at least one value of x in X. If the student perceives that the statement is implying that there should be at least one x that satisfies the predicate, then this meaning explains their acceptance of few examples to prove the statement true. As another example, other studies have noted that some students state that one example is insufficient for an existentially-quantified statement (Tirosh & Vinner, 2004). This type of reasoning is not an erroneous argument if a student's current meaning for x is MQ3, searching through all elements of x to ensure that all values of x satisfy a given predicate. Thus, if a part of a quantified statement leads a student to believe that a variable should be quantified in a way different than intended, then students' arguments may also deviate from convention.

These categories for student meanings for quantified variables may also be used by a variety of undergraduate mathematics teachers to aid them in characterizing their own students' meanings. All undergraduate mathematics courses involve quantified statements, and as such, all undergraduate mathematics instructors should be attuned to students' types of quantification. Beyond having a variety of meanings, different parts of a mathematical statement may cause students to quantify in unconventional ways. Students may even skip over quantifier words altogether and interpret pieces of these statements rather than quantifying variables. Thus, we view one of the primary uses of our findings as a tool for educators to identify students' meanings and address their current meanings through questioning and activities that promote reflection of differences in types of quantified variables. Our findings suggest that quantification as a mental process for students is much more complicated than researchers and teachers may expect, and Calculus students in particular could benefit from learning opportunities that would help them confront their various meanings for quantified variables. We hope that teachers and curriculum writers will consider thoughtful questions and activities that will give students an opportunity to become aware of their meanings and address inconsistencies in their meanings for quantified variables.

GENERALIZATION OF AN INVARIANT RELATIONSHIP BETWEEN TWO "QUANTITIES"

Halil Ibrahim Tasova
University of Georgia
halil.tasova25@uga.edu

Kevin C. Moore
University of Georgia
kvcmoore@uga.edu

In this report, we present an analysis of two prospective secondary mathematics teachers' generalizing actions in quantitative contexts. Specifically, we draw from a teaching experiment to report how Lydia and Emma engaged in different generalizing processes for the same task. Based on these differences, we found Lydia's generalizing actions (i.e., coordinating quantities) to be a more productive generalization than Emma's (i.e., slopes of tangent lines). The former was extendable to a new case, instance, or situation, whereas the latter was constrained to a specific representational system.

Keywords: Cognition; Algebra and Algebraic Thinking; Design Experiment

Several researchers have illustrated that teachers' covariational reasoning is critical to supporting their students in understanding major pre-calculus and calculus ideas (Ellis, 2007a; Confrey & Smith, 1995; Thompson, 1994; Thompson, 2011). Moreover, Ellis (2007a) reported that quantitative reasoning is an integral part of students constructing productive and global generalizations. In this paper, we characterized two pre-service teachers' (PSTs') generalizing actions during a teaching experiment focused on graphing and modeling covariational relationships. We give specific attention to how two PSTs' generalizing actions differed when reasoning about the rate of change between the distance a rider has traveled (i.e., arc length) around a Ferris wheel and the rider's vertical distance from the horizontal diameter of the Ferris wheel (i.e., height). More specifically, this paper reports (a) the generalizing actions of two PSTs, one which coordinated quantities, and one which focused primarily on steepness of tangent lines and (b) implications of those generalization actions on their later activities.

Theoretical Framework

We investigated PSTs' generalizing actions about relationships between quantities in dynamic situations. We use *quantity* to refer to a conceptual entity an individual constructs as a measurable attribute of an object (Thompson, 2011). Relatedly, Ellis, Tillema, Lockwood, and Moore (2017) introduced a generalization framework (Table 1) involving three major forms of students' generalizing—relating, forming, and extending—by building on Ellis' (2007b) taxonomy of generalizations, in which students' generalizing actions were viewed as different than students' final statements of generalization. In this paper, we are using this framework to illustrate two PSTs' generalizing actions by situating "generalization" within the perspective of the learner and with sensitivity to their reasoning about quantities. In other words, we do not take mathematical correctness as a necessary criterion of generalization, instead focusing on the process of how individuals identify their own patterns/similarities determined across cases.

Ellis et al.'s (2017) framework has two major forms of generalizing—intra-contextual forms and inter-contextual forms—in which students' generalizing actions occur within one context, task, or situation in the former and across situations, contexts, or tasks in the latter. Intra-contextual forms of generalizing include students searching for and identifying similar elements, patterns, and relationships across cases, numbers, or figures in order to form a similarity or regularity and extend it to new cases, instances, situations, or scenarios. Inter-contextual forms of generalizing include students forming similar relationships across contexts, problems, or situations and transfer. In this study, we illustrate several intra- and inter-contextual generalizations and their relationships to forms of abstraction presented in the work of two PSTs.

Table1: Ellis et al. (2017) generalization framework

Intra-contextual forms of generalizing		Inter-contextual
Forming	Extending	Relating
Relating Objects • Operative • Figurative • Activity Search for Similarity or Regularity Identify a Regularity • Extracted • Projected Isolate Constancy	Continuing Operating • Near • Projection Transforming • Constructing a Quantity • Recursive Embedding Removing Particulars	Relating Situations • Connecting Back • Analogy Invention Relating Ideas or Strategies (Transfer)

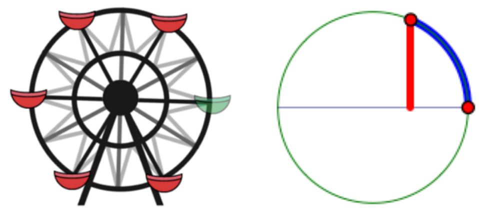
Methods

The data we present and analyze is from a teaching experiment (Steffe & Thompson, 2000) conducted over the course of a spring semester at a large public university in the southeastern U.S. with two PSTs. Our goal in the teaching experiment was to investigate the PSTs' ways of thinking and create models of their mathematics. Specifically, we explored how PSTs conceived of situations quantitatively and represented particular quantitative relationships under particular coordinate system constraints. In this paper, we focus on Lydia and Emma, who, at the time of the study, were two junior undergraduate students enrolled in both content and pedagogy courses. They had completed at least two additional courses beyond a traditional calculus sequence with at least a C as their final grade.

Lydia and Emma participated in 12-videotaped sessions (interview and teaching sessions) and we digitized their written work. Each session was approximately 1-2 hours in length. The second author served as the teacher-researcher (TR), and at least two project members observed each teaching session. We analyzed PSTs observable and audible behaviors (e.g., talk, gestures, and task responses) in details by relying on the generative and axial methods (Corbin & Strauss, 2008) combined with conceptual analysis techniques (Thompson, 2008). We drew on Ellis et al.'s (2017) analytic framework for categorizing students' generalizing actions and reflection generalizations in order to identify forms of generalization and abstraction.

Analysis and Findings

In this section, we analyze Lydia and Emma's activities during two tasks—Taking a Ride Task and Circle Task—from the teaching experiment to illustrate their generalizing actions and implications of those generalizing actions. For the Ferris wheel task (Figure 1a), we draw attention to how Lydia and Emma used the same verbal statement to describe their identified regularity, but these verbal statements signified different reasoning and generalizing actions. Then, for the Circle Task (Figure 1b), we show implications of those generalizing actions for Emma and how those generalizing actions influence Emma's activity in a later session.



(a) (b)

Figure 1. (a) Ferris Wheel and (b) simplified version used during the Circle Task.

Taking a Ride Task

The Taking a Ride Task occurred during the first session of the teaching experiments. The PSTs watched an animation of a Ferris Wheel rider that was indicated by a green bucket (see Figure 1a) who travels at a constant speed counterclockwise starting from the 3 o'clock position (Desmos, 2014). Then, we asked them to describe how the height of the rider above the horizontal diameter of the Ferris wheel changes in relation to arc length it has traveled. Both Lydia and Emma described the height as increasing less and less for the first quarter of a rotation. However, their generalizing actions entailed marked differences, which we will illustrate below.

Lydia's generalizing actions. In the Taking a Ride Task, Lydia, first, *identified a regularity* in directional changes of height with respect to the arc length it traveled (i.e., height is increasing or decreasing as the arc length increases). In other words, we inferred from her activity she identified a predictable stable feature of the riders' height from horizontal diameter in relation to arc length it traveled for each quarter turn. We note that, for the second quarter turn, she continued her generalizing actions with a *minor accommodation*. That is, she did not fully extend her identified regularity of directional changes of height in relation to arc length to the next case (i.e., second quarter turn); she conceived that the height began to decrease as the arc length continued to increase.

The TR then asked Lydia if she could provide more information—in addition to her observation that the arc length increases and the height increases during that first quarter—about how the height and arc length change in relation to each other. Lydia used the spokes of the Ferris wheel (i.e., each of the black bars connecting the center of the wheel to its edge) to partition the Ferris wheel into equal arc lengths. This partitioning activity was to become an important tool for Lydia to *establish a way operating* with respect to identifying how height changes in relation to arc length.

(a) (b) (c)

Figure 2. Lydia engaging the Ferris wheel task.

After Lydia used the spokes to create equal partitions in arc lengths (see the green dots in Figure 2a), she drew associated heights (see the green bars in Figure 2a). Then, with support from the TR's questioning, Lydia constructed successive amounts of change in height corresponding to successive equal changes in arc length (see Figure 2b, circled in blue). That is, Lydia's partitioning activity led her to *construct a quantity*, namely change in height. The TR next asked Lydia if she noticed anything to describe the relationship between height and arc length in the first quarter of trip. The following excerpt demonstrates her response.

Lydia: Um, the distance from A to B and then B to – the distance from – Okay, so this is A, B, and C [*labels as shown in Figure 2c*], from B to C the distance is less than from A to B.

TR: So what distance is less?

Lydia: Um, from point B to C [*motions along arc*], um, that distance [*indicates circled vertical distance from Figure 2c*] from – is less than the – from A to B [*unclear if pointing along arc or along vertical distance*], I feel like.

TR: Like when you're saying distance, what do you mean? Do you mean like –

Lydia: Vertical distance.

TR: Vertical distance, okay, gotcha.

Lydia: Yes. And then also if we were to say at the top this is D [*labels pi/2 on circle d*], then from C to D [*motions along arc then vertically down to the center*] is less than B to C [*unclear motion*].

We inferred from her activity that she was *establishing a way of operating* that involved the construction of a new quantity (i.e., change in height) and associated partitioning activity. With that quantity constructed, she was then able to *search* for regularity or pattern in that quantity's variation (e.g., decreasing increases). After conceiving that change in height decreased along with those equal partitioning in arc length as shown in Figure 2, Lydia concluded that "as the arc length is increasing... [the] vertical distance from the center is increasing ... but the value that we're increasing by is decreasing." We interpreted this to indicate that Lydia had *identified the regularity* in how height changes in relation to arc length in the first quadrant. To say more, we inferred that she *extracted* this regularity because she identified a common feature of a change in one quantity (i.e., height is increasing less and less) across multiple cases relying on a change in another quantity (i.e., with respect to equal increase in arc length). We did not have evidence that she could generalize her regularity to any size of equal partitions (i.e., a *projected* regularity).

Emma's generalizing actions. In the Taking a Ride task, Emma began similarly to Lydia. She initially drew several consecutive vertical line segments (see red line segments in Figure 3) and discussed the directional variation of these segments with respect to traveling along the arc. Thus, Emma also *identified a regularity* in directional changes in the height of the rider (i.e., the height is increasing or decreasing). She specifically explained, "you're going to be increasing your heights or your distances from the center until you get to 3 pi over 2, and then, you're going to go back to decreasing your heights." As such, she made a *minor accommodation* to her identified regularity in the directional change in height with respect to the arc length for the first quarter rotation in order to extend it to other quarter turns.

Noticing that Emma used the phrase "slowly increasing" to describe the height of the rider above the horizontal diameter, the TR asked Emma to explain more. Emma drew a blue line segment from the 12 o'clock to the 3 o'clock position (see Figure 3) and responded, "there isn't like a linear trend that the lines [*the vertical red segments in the Figure 3 representing the different heights of the rider along the ride*] follow…. Like the lines [*referring to the vertical red* *segments in Figure 3*] don't increase at the same rate." We inferred that she used an *analogy invention* by creating a new situation (i.e., a linear trend by drawing a linear line) with the purpose of comparing and contrasting the two situations in order to show the increase in height was not linear. Although her associating the current situation with an analogous situation did not provide an explanation of why the height increased "slowly" over the given interval, she determined the increases in height were not constant or "linear".

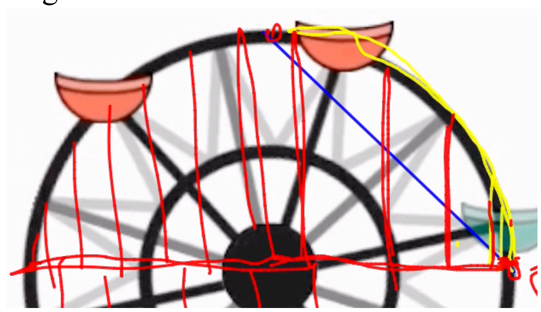


Figure 3. Emma engaging the Ferris wheel task.

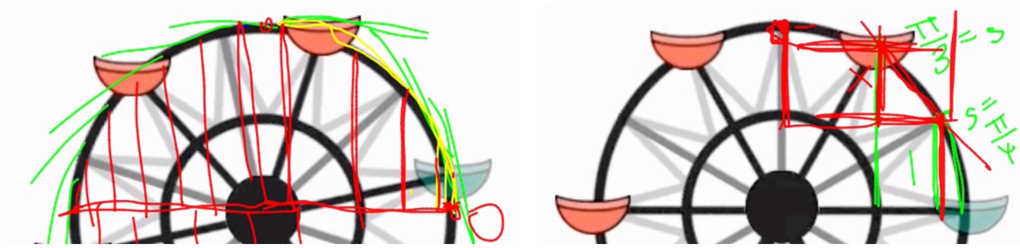
Continuing, Emma explained, "The lines increase … more steeply, and then, they slowly increase less and less [*makes a curved shape with her hand*] as you reach that inflection point at the top [referring to the point at the 12 o'clock position]." For the second quarter, she said, "They [*i.e., the heights*] start decreasing at a slower rate and then begin to decrease at a faster rate as you reach pi." It is important to note that, in contrast to Lydia, we did not have evidence that Emma coordinated the quantity of arc length beyond imagined movement in order to investigate how the increase or decrease in height changes. Although she imagined the movement at the beginning as height increasing steeply, her overall reaction to the first quarter in height was "increasing less and less", which was akin to Lydia's statement. The underlying generalizing activity of this statement, however, was quite different than that of Lydia's, which we illustrate below.

The TR returned Emma's attention to the first quarter turn and asked her to discuss how she saw the height increasing at a steeper and then slower rate. She referenced "the concavity" of the Ferris wheel in the first quarter, saying, "Well, you can see that the concavity of the – of like, I guess the arc length, the line that follows the circle…". An explanation for Emma's actions is that they were influenced by a prior context or information (i.e., *transfer*) such as presented relationships between the concavity of a curve and classifications of rates of change (e.g., concave down means increasing or decreasing at a decreasing rate).

As Emma continued, she transitioned to comparing the steepness of tangent lines that she drew along the Ferris wheel, starting at the 3 o'clock position and ending at the 9 o'clock position, as seen in Figure 4a. She said,

> …like, if these are the tangent lines showing the slopes and then you start to hit a slope that's more horizontal [*moves to the top of the circle and draws tangent lines*] as you reach your maximum point where you start decreasing … more steeply as you get back down, so like you – like these are horizontal [*motioning to the top of the wheel*]; these are vertical [*motioning to the left side of the wheel*]. So, you can see the steepness of your increasing or decreasing….

Here, Emma compared the steepness of tangent lines, concluding the tangent lines were becoming horizontal or less steep in the first quarter turn and they were getting vertical or steeper in the second quarter turn. She related these features to the height increasing at a decreasing or increasing rate. Similar to her reference to concavity, an explanation of her actions is that they were influenced by prior knowledge (i.e., *transfer*) relating the slope of lines tangent to a function graph to classifications of rate. Thus, by means of the generalizing action of the *transfer*, Emma *identified a regularity* in the steepness of tangent lines as the rider rotated around the Ferris wheel. We inferred that Emma began to identify regularity by *extracting* a few cases (i.e., multiple tangent lines that were getting steeper/horizontal, see Figure 4a), and then she immediately described a predictable feature of the entire interval, which was a *projected* identification of a regularity.



(a) (b)

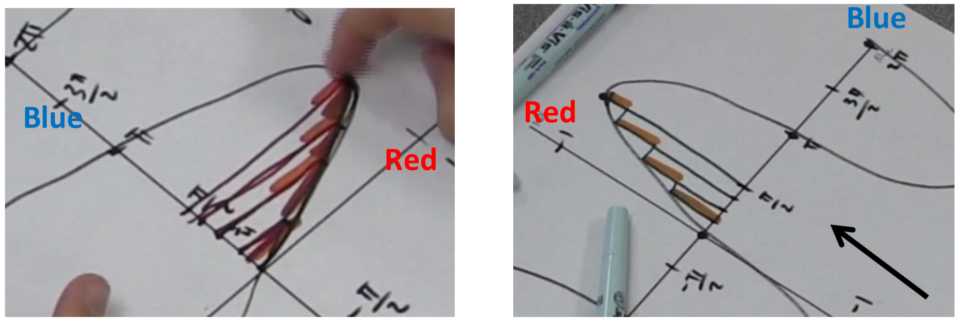
Figure 4. (a) Emma draws the tangent lines; (b) Emma identifies the amount of change in height.

It is important to note that when we asked Emma to talk about height increasing slowly (or at a decreasing or increasing rate), she persistently described tangent lines or some other idea vaguely connected to the tangent lines (e.g., ambiguous values of derivative functions as the values of the slope of tangent lines). In fact, when the TR guided her in identifying amount of changes in height in relation to each equal arc length increments along the Ferris wheel as shown in Figure 4b, she neither spontaneously noted that changes in height were decreasing, nor did she relate the changes in height to her slope of tangent lines. She instead reverted back to discussing the steepness of tangent lines and associating those features with increasing or decreasing “rates” of height. We inferred that her image of tangent lines and their steepness has little to do with explicitly coordinating changes in height with systematic changes in arc length.

The Circle Task

In the Circle Task, which occurred during a later teaching experiment session, PSTs watched an animation of a point moving along the circle and without any physical context like an amusement park ride (see Figure 1b). The TR asked them to graph the relationship between the height of the point above the horizontal diameter of the circle (i.e., the red segment in Figure 1b) and the arc length (i.e., the blue arc in Figure 1b). In this section, we only provide Emma’s data, because she engaged in generalizing actions including both coordinating quantities (i.e., Lydia above) and the steepness of the tangent lines (i.e., Emma above) in order to show how the former generalization enabled her to accommodate to new situations; however, the latter generalization did not. In addition, due to space constraints and because her activity was consistent with that described above, we will not describe Emma’s generalizing actions in a great detail. Therefore, we will only provide implications of those two different generalizing actions as it relates to Emma considering a new situation.

Emma graphed the relationship between quantities on a Cartesian coordinate system in which the vertical axis was labeled “blue” and the horizontal axis was labeled “red” (Figure 5a). She then described how the red segment changed in relation to the blue arc by coordinating quantities. She equally partitioned the arc length on the horizontal axes and determined the corresponding changes in the red segment and indicated those changes by orange line segments (Figure 5a). She explained, “… over the same arc lengths, my heights are, um, increasing but at a decreasing rate, so like, the rate that they're increasing is less and less each time." Verbally, this is nearly the same statement that she used in the Taking a Ride task in order to refer to how the height changes, but in this case it stemmed from her coordinating quantities and their changes.



(a) (b)

Figure 5. Emma's graphs in two differently-oriented Cartesian coordinate system.

Next, we asked Emma to graph the same relationship in a differently-oriented coordinate system (i.e., the vertical axis labeled as red and horizontal axis labeled as blue). She graphed the relationship as shown in Figure 5b. Importantly, she identified and illustrated (Figure 5b) that the amount of change in red was decreasing with sensitivity to the alternative orientation of the coordinate axes. Because Emma had briefly mentioned comparing tangent lines at the onset of the problem, we raised this idea in order to determine if she connected it to her partitioning activity. Referring to the graph in Figure 5b, she explained, "it's increasing at a decreasing rate, so like, the slope follows this change." She further explained that the slopes became more horizontal and she estimated the slope of the tangent lines in each increment by estimating the vertical change. In this case, her generalizing activity relative to the steepness of the tangent lines was compatible with her generalizing activity relative to coordinating quantities.

Turning to Figure 5a, Emma conceived the slopes of the tangent lines to indicate something different than that from coordinating quantities. She claimed the red quantity "is increasing at a decreasing rate", when considering the orange line segments (Figure 5a). She also claimed, "Slope is increasing at an increasing rate", when considering slopes of the tangent lines (e.g., becoming steeper and estimated the slope of the tangent lines). The TR drew her attention to these differing claims, which did not perturb Emma. Rather, these conclusions existed independent of each other. She transformed her coordinating quantities to take into account a different coordinate orientation, but her image of slope and associated generalizations were specific to a particular orientation. We do not mean to imply a deficiency in Emma's reasoning, but rather point out that due to its roots in "steepness", her generalizations regarding tangent lines and "rate" did not take into account different orientations (e.g., dy/dx versus dx/dy).

Discussion

In summary, after both reasoning about directional change in height, Lydia and Emma used similar verbal statements to describe their identified regularity in the relationship between height and arc length. Lydia's initial generalization was connected to coordinating the quantities of height, arc length, and their changes. Emma's initial generalization, along with her scheme and mental actions, primarily involved associating the steepness of tangent lines along the circle with the "rate" of height. We did not have evidence that the quantity of arc length and its variations were central to Emma's reasoning. Thus, we can claim that Emma and Lydia made similar generalized statements, but the objects that were associated and what regularity they identified were different.

Byerley and Thompson (2017) reported teachers holding different meanings for a slope, and illustrated that some of these meanings are useful in limited circumstances. For instance, they identified slope as an index of steepness as such a meaning, which correspond to Emma's case. Specifically, in Emma's case, her generalization slope as an index of steepness in association with "rate" did not enable her to conceive invariance among graphs in different coordinate orientations. With respect to Figure 5a, her meaning led her to conclude "increasing at an increasing rate." With respect to Figure 5b, her meaning led her to conclude "increasing at a decreasing rate." On the other hand, when coordinating quantities, Emma was able to conceive invariance in "rate" among the two graphs; both represented red increasing at a decreasing rate with respect to blue. Ellis (2007a) argued that generalizations rooted in coordinating quantities are more powerful, and we interpret Emma's activity as such in that her generalization rooted in quantities was more flexible than that rooted in the perceptual steepness of a tangent line.

ON HOW PARTICIPATION IN A MODELING COMPETITION OCCASIONS CHANGES IN UNDERGRADUATE STUDENTS' SELF-EFFICACY REGARDING MATHEMATICAL MODELING

Jennifer A. Czocher
Texas State University
Czocher.1@txstate.edu

Sindura Subanemy Kandasamy
Texas State University
s_k252@txstate.edu

Though scholars have long called for applications and modeling to be explicitly added to classroom agenda (Niss, Blum, & Galbraith, 2007), opportunities for undergraduates to engage in modeling in the classroom remain scarce. We share the efforts of a national organization (SIMIODE) to provide extra-curricular opportunities for undergraduate STEM majors to engage in authentic, open-ended modeling tasks using differential equations through a modeling competition. In this preliminary report, we document changes in twenty-one undergraduates' self-efficacy regarding their own modeling competencies, develop hypotheses about what aspects of the competition occasioned those changes, and how these changes may benefit students.

Key words: self-efficacy, mathematical modelling, differential equations

Educators have increasingly turned to mathematical modeling to resolve the *relevance paradox* of mathematics in the curriculum. The relevance paradox refers to the disparity between the objective relevance of mathematics for society and the subjective irrelevance of mathematics perceived by many students who study it (Niss & Hojgaard, 2011). Even at the post-secondary level, interest in mathematics is associated with seeing its practical relevance (Liebendörfer & Schukajlow, 2017). Since Mathematical modeling promotes interdisciplinary thinking (Bliss et al., 2016), fosters mathematical reasoning as a basis of decision making (OECD, 2017), and develops communication skills (Niss & Hojgaard, 2011), many instructors endeavor to engage students in mathematical modeling. Rising demand for instructional materials for the advanced mathematics of STEM majors has led organizations like the Systemic Initiative for Modeling Investigations & Opportunities with Differential Equations (SIMIODE) and the Community of Ordinary Differential Equations Educators (CODEE) to develop authentic modeling experiences that engage students in problems from (for example) mathematical biology or systems engineering. Because opportunities to engage in authentic modeling in STEM classrooms remain scarce, SIMIODE began hosting an extra-curricular mathematical modeling competition that would introduce students to authentic modeling problems in differential equations and build their self-confidence to carry out modeling. The present study investigated changes in student self-efficacy from before to after participating in the event. In this paper, we report on preliminary results of the pilot run and develop hypotheses for a large-N nationwide competition that will be hosted in April 2018.

Cognitive Perspective on Modeling and Empirical Background

From multiple perspectives on modelling, we adopt the cognitive perspective which views modeling as an iterative process (Kaiser, 2017). In this view, modeling is studied as a suite of interrelated competencies that transform a real-world problem into a mathematical problem by building a cognitive correspondence between the two. The competencies include identifying relevant variables, simplifying relevant quantities and their relationships, estimating parameters, and expressing the quantities and relationships mathematically (Maaß, 2006). Other modeling competencies include validating the appropriateness or reasonableness of the model and communicating results, findings, or consequences of using the model.

In post-secondary classrooms, models are foundational to STEM disciplines, often augmenting or replacing "real world situations" as the object of study. For example, one studies the "heat equation" or the "particle in a box." The former stands for a range of imaginary situations where heat energy transfers between an object and its environment while the latter is an imaginary physical system determined by second-order differential equation. The complexity of mathematical theory and procedures in advanced STEM courses, along with departmental pressures sometimes overwhelm instructors' intentions to use modeling to motivate course content. Within differential equations, scholars have focused largely on student achievement of curricular aims. For example, Czocher (2017) found that consistent emphasis on mathematical modeling principles, even in lecture, could positively impact engineering students' learning of differential equations. Others have shown that drawing on "experientially real" starting points to instruction can positively impact student learning of content (e.g., Rasmussen & Blumenfeld, 2007). However, the complexity of mathematical theory and procedures in advanced mathematics courses, along with time constraints, departmental pressures, and beliefs about non-lecture approaches, sometimes overwhelm instructors' desires to use research-based innovations in their classrooms (Johnson, Keller, & Fukawa-Connelly, 2017). These facts point to the need to document the advantages of modeling at the post-secondary level.

Affective factors such as interest, motivation, and self-efficacy are also important to developing modeling competencies. We take self-efficacy to be a problem-specific assessment of an individual's confidence in their ability to successfully address a mathematics problem (Hackett & Betz, 1989, p. 262). Schukajlow et al. (2012) found that for ninth graders, student-centered instruction using modeling tasks was the most beneficial for increasing student affect and Zbiek and Conner (2006) reported that a modeling approach deepened prospective secondary mathematics teachers' motivation to learn new mathematics content. Since self-efficacy plays a role of all aspects of goal-setting, persistence, and effort (Bandura, 2006), we interpret the literature to mean that finding ways to increase STEM students' self-efficacy in modeling may go hand-in-hand with increasing their modeling competencies and their willingness to engage in activities designed to improve their modeling competencies. Thus, there is a pressing need to gain a sense of whether and how engaging in mathematical modeling might impact undergraduate students' self-efficacy about modeling competencies.

Methods

Twenty-six students participated in teams of 2 or 3 led by an instructor-coach in an intensive week-long modelling competition. Each team selected one of three challenging problems framed to be about *changes* in relevant quantities, necessitating the use of differential equations. The teams created a written overview of their models and argued for its merits. At the end of the week, teams gathered at the competition site where coaches offered critiques and additional factors to consider in their models. The teams amended their models and the competition culminated in a 10-minute peer-reviewed presentation of their solutions. The final models were subsequently ranked by the judges and winners were notified following the competition.

We explored changes in student self-efficacy regarding modeling competencies (Maaβ 2006), including: identifying important variables, estimating parameters, making simplifying assumptions, mathematization, validation, communication. We developed a self-efficacy scale (Bandura, 2006), implemented as a matched pair of online surveys. Survey items asked students to rate their confidence in carrying out the modeling competencies for a problem about modeling the spread of solar panel adoption in the 21st century. They responded on a 100-point scale, with 10-unit intervals from 0 (“Cannot do”); through intermediate degrees of assurance, 50 (“Moderately certain can do”); to complete assurance, 100 (“Highly certain can do”). The pre-event survey items in Table 1 were changed to past tense for the post-event survey and the context for Item 1 was changed to modeling the spread of smart home appliances in the 21st century. The survey also collected demographic information about the students’ majors. Twenty-one students completed both the pre- and post-event surveys. Nine students were mathematics majors, three were applied mathematics majors and the rest were a mix of computer science, statistics, and engineering majors. A set of six dependent sample t-tests was performed on the mean difference between pre- and post- scores at significance level of $\alpha = .05$ for each item (a post-hoc Bonferroni correction was planned, but not needed).

Results and Discussion

Participants collectively showed gains in their self-efficacy in all 6 questions (Table 1). Students' self-efficacy for mathematizing $(t = 4.503, df = 20, p = 0.000)$, identifying important variables $(t = 2.832, df = 20, p = 0.027)$, and ability to communicate the usefulness of their model $(t = 2.104, df = 20, p = 0.048)$ has increased where as their self-efficacy in simplifying $(t = 1.330, df = 20, p = 0.198)$, validating $(t = 1.722, df = 20,\ p = 0.101)$and estimating parameters $(t = 0.377, df = 20,\ p = 0.710)$ remain statistically unchanged.

Table 1 Self-efficacy items (pre-event survey) and targeted modeling competency

Rate your level of confidence by recording a number from 0 to 100 using the scale given below: **0 10 20 30 40 50 60 70 80 90 100** **Cannot do at all — Moderately can do — Highly certain can do**	**Competency**	**Mean Difference (post – pre)**
1. Create a differential equation model for the spread of the use of electric powered vehicles in the United States during the twenty-first century.	Mathematizing	19.524
2. In (1) identify the important variables leading to a reasonably accurate prediction.	Identify variables	10.000
3. In (1) make simplifying assumptions to reduce the number of important variables.	Simplify	6.190
4. In (1) consult appropriate resources to check whether your model was reasonable.	Validating	7.143
5. In (1) convince a solar power car manufacturer that your model would be useful for its purpose.	Communicating	10.952
6. Estimate the parameters α and β in the following differential equation which describes the time rate of formation of material A, $'(t) = \alpha A(t)^{\beta}$, given a set of data from observations for time, t, and amount of material A, at time t, i.e. A(t).	Estimating	1.905

The competition reproduced some of the favorable factors leading to success in modeling observed by Carlson, Larsen, & Lesh (2003), such as externalizing and communicating reasoning, providing and receiving feedback from their peers and others, revising their initial models, and having extended time to fully engage with the problem. Though we cannot say what aspect(s) of the modeling competition may have contributed causally to any changes in self-efficacy, we can hypothesize that these factors, taken together, contributed to the students’ increased self-efficacy in mathematical modelling. Participant self-selection led to two methodological complications: (1) participants with high self-efficacy may not show gains and

(2) the student sample was exceptional in their self-assessment of mathematical content knowledge (nearly all stated they usually get A's in mathematics). Another limitation of this study is that the survey used an *atomistic* (Boesen et al., 2014) approach to assessing students' self-efficacy by asking them about each modeling competency independently. Future research should develop parallel measures for holistic self-assessments. We anticipate that the larger sample will reveal stronger relationships among student beliefs about the relevancy of mathematics, their personal achievements during the competition, and self-efficacy regarding subsets of the modeling competencies which are emphasized in the competition. Middleton and Spanias (1999, p. 81) argued that it is better to develop students' intrinsic motivation in mathematics, rather than providing extrinsic incentives for achievement. We hypothesize that the modeling competition, which addresses the relevance paradox through providing opportunities for students to engage in challenging and authentic discipline-specific problems, may be one avenue for doing so.

DIFFICULTIES OF LOGICAL NATURE IDENTIFIED IN STUDENTS IN A FIRST COURSE OF CALCULUS

Antonio Rivera-Figueroa

kaguirre@uam.mx

This paper reports some results of an investigation about the difficulties of logical nature that students have in a first course of Calculus. The instrument used was designed with questions of the basic contents of Calculus and was applied to students who had already taken a first course of it. It was found that difficulties of a logical nature persist in most of the students such as modus ponens, affirmation of the consequent, handling of quantifiers, denial of statements, which complicate the comprehension of basic concepts of Calculus.

Keywords: Advanced Mathematical Thinking, Reasoning and Proof.

The study of Calculus in a mathematics career at the university is really a course on its foundations. This brings up two important elements: the language accompanied by mathematical symbology and logical reasoning. Regarding the latter, we emphasize the students' difficulties in distinguishing between necessity and sufficiency in a condition, as well as in the interpretation of the universal and existential quantifiers and, finally, in the denial of propositions.

In relation to the above, we pose the following question: what are the difficulties of a logical nature in the courses of Calculus that students have during their first year in a major in mathematics? This report gives account of three common situations in the course of Calculus that illustrate the difficulties mentioned above.

Theoretical Framework

M. Artigue classifies the difficulties of access to Calculus in three categories: (1) those associated with the complexity of the basic objects of Calculus, (2) difficulties associated with the conceptualization and formalization of the concept of limit and (3) difficulties related to the necessary rupture between algebraic reasoning and calculus reasoning (Artigue, 1995). In the same sense, R. Moore identifies seven difficulties in the comprehension of a mathematical proof in students with little experience (Moore, 1994). We emphasize that logic impacts each of the seven difficulties. Dubinsky & Yiparaki (2000) and Epp (2003) showed that a significant number of students confuse the management (and order of placement) of universal and existential quantifiers in a mathematical proposition.

On the other hand, when asked for a proof of a contradiction theorem, a large number of students do not identify either the reason for the beginning of the proof or when it has ended. According to U. Leron, proofs by contradiction are difficult for students to digest, they represent a psychological problem that involves mathematical thinking (Leron, 1985).

Finally, investigations in logical reasoning account for the complex paradigm of negations (Evans & Handley, 1999). Also, it has been reported that the verbal and mathematical contexts can influence when making a logical inference (Stylianides, Stylianides, & Philippou, 2004); for axample, when we ask about the existence of the limit of a quotient sequences whose denominator tends to zero, prior knowledge of the prohibition of dividing by zero can act as a "distractor" to infer that, necessarily, the limit of the quotient does not exist.

Conceptual framework

In this research we deal with the term *difficulty* as it is exposed in the researches and theoretical contributions on the difficulties of access to the Calculus of Artigue (1995) and in understanding a proof Moore (1994). For the difficulties in logical reasoning, we rely on Evans & Handley (1999), Evans, Handley, Neilens & Over (2007), and Inglis & Simpson (2008).

We will understand by logical reasoning (conditional) the inferences that can be made from a rule in the form "$P \rightarrow Q$" and a given premise (Evans *et al,* 2007; Inglis & Simpson, 2008). In this report we focus only on the valid inference *modus ponens* (MP) and on the invalid inference *affirmation of the consequent* (AC).

Methodology

The research instrument consisted of a questionnaire of 15 multiple-choice questions and interviews. The questionnaire was accessed during a 90-minute online session. The instrument was applied to 73 students from two of the most important educational institutions in Mexico. The students who participated in our research had just passed their first Calculus course. Each question was designed within the context of the Calculus and is supported by the research findings of Moore (1994), Artigue (1995) and in the investigations on logical reasoning Evans & Handley (1999), Evans *et al* (2007) and Inglis & Simpson (2008).

Discussion and Results analysis

We report the analysis and discussion of questions 3, 13 and 15, of our questionnaire. Question 3 presents a wrong process of solving an equation. It starts with the equation and, through a succession of implications, it ends with a result. The student was asked to decide if the procedure was correct or not. Of course, the student had the option of verifying that the result obtained was not a solution to the equation, so he could suspect that the process was wrong; nevertheless, approximately 50% of the participants concluded that the process was correct. In general, the other half argued that the supposed solution did not satisfy the equation, for example, one of them argued: "algebraically everything seems to me to be correct, but when substituting the value, we conclude that 4 = 1". Another student said, "I do not remember the reason well, but, according to me, there is no solution within the real numbers (sic)". In fact, few found the wrong step in the resolution process, which resulted from a non-reversible implication. This reveals a lack of understanding in the reasoning of the type MP and AC. The conditional "if-then" and "only if" are usually interpreted individually as the double conditional, "if and only if" (Epp, 2003).

Question 13 refers to the following statement:

> If $a \in \mathbb{R}$, such that $0 \leq a \leq \xi$, for all $\xi > 0$, then $a = 0$, of which the following statement is made: the statement is contradictory, since a particular case of the inequality $a \leq \xi$, is $a = \xi$, with ξ a positive number. However, the statement concludes that $a = 0$.

Almost half answered that the statement is true, that is to say that the statement is contradictory. One of the justifications for this choice was obtained in an interview.

> *Teacher:* Regarding question 13, I'm interested in knowing what you thought when you answered the question for the first time.
>
> *Student:* It seemed logical to me to think about this example. If you set to epsilon with value equal to 3 you can take any a other than zero that is less than or equal to 3.

To expand this question, a complementary activity was carried out in the classroom, which consisted of completing the following statement: let $a, b \in \mathbb{R}$, if for any $\varepsilon > 0$ it is satisfied that $0 \leq |a\text{-}b| < \varepsilon$, then __________.

Some students tried to solve the inequality, which reveals a lack of familiarity with statements of the MP form. Others related the statement with the concept of upper bound; the majority related it with the definition of limit or continuity of a function, which is illustrated in Figure 1, 'it has to comply with some continuity, but I do not know how to express it'. Others related it to the definition of integral that involves partitions of superior and inferior sums. This suggests the influence of their previous knowledge in his reasoning, as suggested by Stylianides *et al* (2004), although the statement to complete had nothing to do with functions, nor partitions. Only 13% of participants in this complementary activity were able to deduce $a = b$.

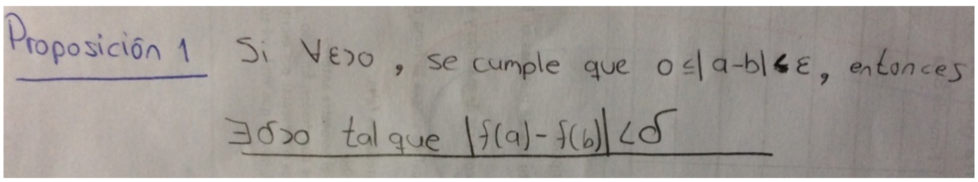

Figure 1. Student's answer in the complementary activity.

Both the online questionnaire and the complementary activity corroborate the difficulty that students have to understand the meaning and interpretation of the universal quantifier in a particular context of the Calculus, in a form of reasoning MP.

Our last example (question 15) has the purpose of identifying the difficulties that students present to recognize the end of a proof by contradiction (Moore, 1994). This reasoning entail, three difficulties: to understand the process of a demonstration by contradiction (Leron, 1985), to deny the statement (Evans & Handley, 1999) and to identify the contradiction to finish the proof.

The proposition to prove was: For all $\varepsilon > 0$ there exists $n \in \mathbb{N}$ such that $0 < \frac{1}{n} < \varepsilon$. We provided the following answers to conclude the proof: (a) there exists $\varepsilon > 0$ such that for all $n \in \mathbb{N}$, $0 < n \leq {}^{1}/_{\varepsilon}$, (b) the natural numbers are bounded superiorly, (c) there exists $\varepsilon > 0$ and there exists $n \in \mathbb{N}$ such that $0 < {}^{1}/_{n} < \varepsilon$, (d) there exists $n \in \mathbb{N}$ such that $0 < {}^{1}/_{\varepsilon} < {}^{1}/_{n}$ for some $\varepsilon > 0$.

Note that answers (a) and (b) are equivalent and correct. The first is the result that is obtained, immediately, of denying the statement, and the second is its translation to the concept of bounded set. The purpose of putting these two correct answers was to find out if they manage to recognize the contradiction in different versions.

Several students chose option (c); their arguments were: "because we wanted to proof that, for a given epsilon, there was such a number with such property" or "because we will have found then an n for the given epsilon that fulfills the thesis (sic)". In other cases, we found these justifications: "because it is the opposite of what I want to demonstrate" or "it is the negation of the statement", which allows us to conclude that these students conceive the contradiction obtained with the denial of the statement.

Of those who answered correctly, most chose option (b), which is a translation of the contradiction. In contrast, we mention the case where some students chose item (a), but their arguments do not reflect an understanding of what a contradiction proof means: "the conclusions must be related to the initial proposition" and "the rest of the paragraphs do not make sense because they say different things from the proposition".

Conclusions

The difficulties of a logical nature were manifested in most of the participants in different aspects, for example, in the use of existential and universal quantifiers, in some forms of conditional reasoning and in the denial of propositions. All this prevents the understanding of basic concepts of Calculus, because it is not necessary to advance too much in these courses so that these difficulties arise.

Although the participants were students in the second semesters of the major in mathematics, these difficulties of a logical nature persist in a significant number of them.

Based on the results of the investigations related to the logical aspects and in our own study, we consider it convenient to look at the elaboration, design and application of didactic strategies that promote and favor a better performance in the logical reasoning of the students in the context of the Calculus, and so in these courses, special attention is paid to the type of logical difficulties reported**.**

En este artículo reportamos algunos resultados de una investigación acerca de las dificultades de naturaleza lógica que tienen los estudiantes en un primer curso de Cálculo. El instrumento empleado en la experimentación fue diseñado con preguntas en el contexto de los contenidos básicos de Cálculo, y se aplicó a estudiantes que ya habían acreditado un primer curso del mismo. Encontramos que en la mayoría de los estudiantes persisten dificultades de naturaleza lógica —tales como modus ponens, afirmación del consecuente, manejo de cuantificadores, y negación de enunciados— que impiden la comprensión de conceptos básicos del Cálculo.

Keywords: Pensamiento matemático avanzado, Razonamiento y prueba.

El estudio del Cálculo en una carrera de Matemáticas en la Universidad es realmente un curso sobre sus fundamentos. Con ello surgen dos elementos importantes: el lenguaje acompañado de la simbología matemática y el razonamiento lógico. Al respecto destacamos las dificultades de los estudiantes para distinguir entre los significados de las condiciones de necesidad y las condiciones de suficiencia en una proposición, así como en el manejo de los cuantificadores universal y existencial y en la negación de proposiciones.

En relación con lo anterior, nos planteamos la siguiente pregunta: ¿cuáles son las dificultades de naturaleza lógica en los cursos de Cálculo que tienen los estudiantes durante su primer año en una carrera universitaria de matemáticas? En este reporte, damos cuenta de tres situaciones en el Cálculo que ilustran las dificultades antes mencionadas.

Marco Teórico

M. Artigue clasifica las dificultades de acceso al Cálculo en tres categorías: (1) aquellas asociadas a la complejidad de los objetos básicos del Cálculo, (2) dificultades asociadas con la conceptualización y la formalización del concepto de límite y (3) dificultades vinculadas con las rupturas necesarias entre el razonamiento algebraico y el razonamiento en cálculo (Artigue, 1995). En el mismo sentido, R. Moore identifica siete dificultades en la compresión de una prueba matemática en estudiantes con poca experiencia (Moore, 1994), destacamos que la lógica impacta en cada una de las siete dificultades. Dubinsky & Yiparaki (2000) y Epp (2003) muestran que un número considerable de estudiantes confunden el manejo (orden de colocación) de los cuantificadores universal y existencial en una proposición matemática.

Por otra parte, al realizar en clase una prueba de un teorema por contradicción, algunos estudiantes no tienen claro el porqué del inicio de la prueba, ni cuándo ha finalizado. De acuerdo con U. Leron, las pruebas por contradicción resultan difícil de digerir para los estudiantes, representan un problema psicológico que involucra pensamiento matemático (Leron,1985).

Finalmente, investigaciones en el razonamiento lógico dan cuenta del complejo paradigma de las negaciones (Evans & Handley, 1999). También, se ha reportado que los contextos verbal y matemático pueden influir a la hora de realizar una inferencia lógica (Stylianides, Stylianides & Philippou, 2004); por ejemplo, al preguntarnos por la existencia del límite de un cociente de sucesiones cuyo denominador tiende a cero, el conocimiento previo de la prohibición de dividir entre cero puede fungir como un "distractor" para inferir que, necesariamente el límite del cociente no existe.

Marco conceptual

En esta investigación manejamos el término *dificultad* como se expone en las investigaciones y aportaciones teóricas sobre las dificultades de acceso al Cálculo de Artigue (1995) y en la comprensión de una prueba Moore (1994). Para las dificultades sobre el razonamiento lógico nos basamos en Evans & Handley (1999), Evans, Handley, Neilens & Over (2007), e Inglis & Simpson (2008). Entenderemos por razonamiento lógico (condicional) a las inferencias que se pueden realizar a partir de una regla en forma "$P \to Q$" y una premisa dada (Evans *et al*, 2007; Inglis & Simpson, 2008). En este reporte nos enfocamos sólo en la inferencia válida *modus ponens* (MP) y en la inferencia inválida *afirmación del consecuente* (AC).

Metodología

El instrumento de investigación consistió en un cuestionario de 15 preguntas de opción múltiple y entrevistas. El acceso al cuestionario fue durante una sesión de 90 minutos en línea. El instrumento se aplicó a 73 estudiantes de dos de las instituciones educativas más importantes de México. Los estudiantes que participaron en nuestra investigación recién habían aprobado su primer curso de Cálculo. Cada pregunta fue diseñada dentro del contexto del Cálculo y están apoyadas en los hallazgos de las investigaciones de Moore (1994), Artigue (1995) y en las investigaciones sobre el razonamiento lógico Evans & Handley (1999), Evans *et al* (2007) e Inglis & Simpson (2008).

Análisis y discusión de resultados

Reportamos el análisis y la discusión de las preguntas 3, 13 y 15 de nuestro cuestionario.

La pregunta 3 presenta un proceso erróneo de resolución de una ecuación. Se parte de ésta y, mediante una sucesión de implicaciones, se llega a un resultado. Se le pidió al estudiante que opinase si era o no correcto el procedimiento. Por supuesto, tenía la opción de verificar que el resultado obtenido no era solución de la ecuación, de manera que podía sospechar que el proceso era erróneo; no obstante, aproximadamente la mitad de los participantes concluyeron que el procedimiento era correcto. Los estudiantes restantes expresaron que la supuesta solución no satisfacía la ecuación, por ejemplo, algunos argumentaron: "algebraicamente todo me parece correcto, pero al sustituir el valor llegamos a que 4 = 1". Otro expresó "no recuerdo bien el motivo, pero, según yo, no tiene solución dentro de los reales". En realidad, pocos encontraron el paso erróneo en el proceso, mismo que resultaba de una implicación no reversible. Esto revela falta de comprensión en los razonamientos del tipo MP y AC. Los condicionales "si-entonces" y "sólo si" suelen interpretarse de manera individual como la doble condicional, "si y sólo si" (Epp, 2003).

La pregunta 13 se refiere al siguiente enunciado:

> Si $a \in \mathbb{R}$, es tal que $0 \leq a \leq \xi$, para toda $\xi > 0$, entonces $a = 0$. En este caso se le pide al estudiante que opine sobre la veracidad o falsedad de la afirmación: "el enunciado es contradictorio, pues un caso particular de la desigualdad $a \leq \xi$, es $a = \xi$, con ξ un número positivo. Sin embargo, el enunciado concluye que $a = 0$".

Casi la mitad contestó que la afirmación es verdadera, es decir que el enunciado es contradictorio. Una de las justificaciones de esta elección la obtuvimos en entrevista:

Profesor: Con respecto a la pregunta 13, me interesa saber lo que pensaste al responder la pregunta por vez primera.

Estudiante: Me sonó lógico pensar en este ejemplo. Si fijas a épsilon con valor igual a 3 puedes tomar cualquier *a* diferente de cero que sea menor o igual a 3.

Para profundizar en esta pregunta, se realizó una actividad complementaria en el salón de clases, la cual consistía en completar el siguiente enunciado:

Sean $a, b \in \mathbb{R}$, si para toda $\varepsilon > 0$ se cumple $0 \leq |a\text{-}b| < \varepsilon$, entonces _________.

Algunos estudiantes intentaron resolver la desigualdad, esto revela una falta de familiaridad con enunciados de la forma MP. Otros relacionaron el enunciado con el concepto de cota superior; la mayoría, lo relacionó con la definición de límite o de continuidad de una función, lo que se ilustra en la Figura 1, “tiene que cumplir algo de continuidad, pero no sé expresarlo”. Otros tantos, lo relacionaron con la definición de integral que involucra particiones de sumas superiores e inferiores. Esto sugiere la influencia de su conocimiento previo en su razonamiento, Stylianides *et al* (2004), aunque el enunciado a completar nada tenía que ver con funciones, ni particiones. Sólo el 13% de participantes de esta actividad lograron deducir $a = b$.

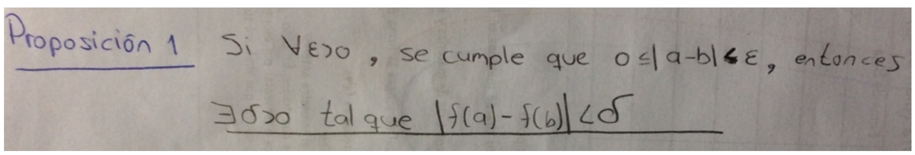

Figura 1. Respuesta de estudiante en actividad complementaria.

Este par de actividades corroboran la dificultad que tienen los estudiantes para comprender el significado e interpretación del cuantificador universal en un contexto particular del Cálculo, en una forma de razonamiento del tipo MP.

Nuestro último ejemplo (pregunta15) tiene como propósito identificar las dificultades que los estudiantes presentan para reconocer el final de una prueba por contradicción (Moore, 1994). Este tipo de razonamiento conlleva tres dificultades: comprender el proceso de una demostración por contradicción (Leron, 1985), negar el enunciado (Evans & Handley, 1999), e identificar la contradicción con la que finaliza la prueba.

La proposición por demostrar fue: Para toda $\varepsilon > 0$, existe $n \in \mathbb{N}$ tal que $0 < \frac{1}{n} < \varepsilon$. Propusimos las siguientes respuestas para dar por concluida la prueba: (a) existe $\varepsilon > 0$, tal que para toda $n \in \mathbb{N}$, $0 < n \leq 1/\varepsilon$, (b) los números naturales están acotados superiormente, (c) existe $\varepsilon > 0$ y existe $n \in \mathbb{N}$ tal que $0 < 1/n < \varepsilon$, (d) existe $n \in \mathbb{N}$ tal que $0 < 1/\varepsilon < 1/n$, para alguna $\varepsilon > 0$.

Notemos que las respuestas (a) y (b) son equivalentes y son las correctas. La primera es el resultado que se obtiene de manera inmediata de la negación del enunciado y la segunda es su traducción al concepto de conjunto acotado. La finalidad de poner estas dos respuestas correctas fue para averiguar si logran reconocer la contradicción en diferentes versiones.

Varios estudiantes eligieron la opción (c); sus argumentos fueron del tipo: “porque se quería demostrar que, para una épsilon dada, existía dicho número con tal propiedad” o “porque se habrá hallado entonces un *n* para la épsilon dada que cumpla la tesis (sic)”. En otros casos encontramos justificaciones del tipo: “porque es lo contrario de lo que quiero demostrar” o “es la negación del enunciado”, lo que nos permite concluir que estos estudiantes conciben la contradicción obtenida con la negación del enunciado.

De los que respondieron correctamente, la mayoría escogió la opción (b), que es una traducción de la contradicción. En contraste, mencionamos el caso donde algunos estudiantes eligieron el inciso (a), pero sus argumentos no reflejan una comprensión de lo que significa una prueba por contradicción: “las conclusiones deben estar relacionadas con las observaciones iniciales” y “los demás incisos no tienen sentido porque dicen cosas distintas a la proposición”.

Conclusiones

Las dificultades de naturaleza lógica se manifestaron en la mayoría de los participantes en diferentes aspectos, por ejemplo, en el uso de los cuantificadores existencial y universal, en algunas formas de razonamiento condicional y en la negación de proposiciones. Todo esto impide la comprensión de conceptos básicos del Cálculo, pues no es necesario avanzar demasiado en estos cursos para que estas dificultades surjan. No obstante que los participantes fueron estudiantes de segundo semestre de una carrera de matemáticas, estas dificultades de naturaleza lógica persisten en una cantidad significativa de ellos.

Con base en los resultados de las investigaciones relacionadas con los aspectos lógicos y en nuestro propio estudio, consideramos conveniente mirar hacia la elaboración, diseño y aplicación de estrategias didácticas que promuevan y favorezcan un mejor desempeño en el razonamiento lógico de los estudiantes en el contexto del Cálculo, y así en estos cursos se preste especial atención en el tipo de dificultades lógicas reportadas.

This paper discusses a student coordinating and comparing amounts of change in two covarying quantities' magnitudes (as opposed to numerical values). We describe not only his coherent system of mental actions involved in coordinating magnitudes, but also how this system affords his reasoning about graphical concavity and a quotient between magnitudes.

Keywords: Cognition, Algebra and Algebraic Thinking, Design Experiments

Quantity, Covariation, and Quotient

Many researchers have attempted to understand how students and teachers coordinate and compare quantities (Carlson, Jacobs, Coe, & Hsu, 2002; Johnson, 2015). We adopt Thompson's (1994) conceptualization of a quantity that entails reasoning about a quantity's *magnitude* (i.e., amount-ness) while anticipating infinitely many associated value-unit pairs, and thus does not require physically carrying out a measurement process to obtain a quantity's values. This distinction between a quantity's magnitude and its value enables us to account for reasoning about a quantity's variations that are not constrained to the availability of values; one can imagine a varying segment as entailing a magnitude (i.e., lengthiness) varying in flux.

Imagining variations in a quantity's magnitude positions a person to reason covariationally. Carlson et al. (2002) specified levels of mental actions involved in coordinating quantities covariationally, among which students' coordination of amounts of change in one quantity with respect to changes in another (i.e., MA3) is central to our work. To illustrate, a student reasoning about covarying quantities B and K can envision the magnitude ||B|| (denoted in blue, Figure 1a) accumulating in equal accruals, construct the magnitude ||K|| (denoted in red, Figure 1a) accumulating in corresponding accruals, and conceive ||K|| increasing by decreasing amounts (denoted in light blue, Figure 1b) with respect to ||B||. One can also re-present these variations on two orthogonally-oriented bars and a Cartesian coordinate system (Figure 1c-d).

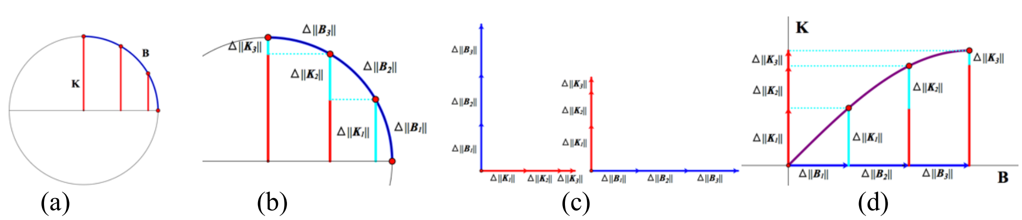

Figure 1. ||K|| increases by decreasing amounts for equal increases in ||B||, which can be represented on (a-b) a circle, (c) two orthogonally-oriented bars, (d) and a coordinate system.

Although coordinating amounts of change is fundamental to rate of change reasoning, Thompson and Carlson (2017) identified that students' construction of rate of change was also related to conceptualizations of ratio, quotient, and proportionality. A productive meaning of rate of change entails a quantitative meaning for quotient as a multiplicative comparison of two quantities' magnitudes with the intention of determining their relative size (Byerley & Thompson, 2017). Relevant to the aforementioned example, a quantitative quotient meaning regarding amounts of change magnitudes involves making additive comparisons of two accumulated magnitudes to determine accruals in those magnitudes (e.g., conceiving $\Delta||B_1||$ and $\Delta||K_1||$) and multiplicatively comparing those magnitudes (e.g., conceiving $\frac{\Delta||B_1||}{\Delta||K_1||}$ or $\frac{\Delta||K_1||}{\Delta||B_1||}$).

Methods

We conducted fourteen teaching experiment (Steffe & Thompson, 2000) sessions with a pre-calculus student, Caleb, who, at the time of the study, was a sophomore majoring in music education. Our overall goal was to characterize his mental actions involved in reasoning with dynamic situations from a quantitative and covariational reasoning perspective. We used session videos, transcripts, and digitized copies of Caleb's written work for both on-going and retrospective conceptual analyses (Thompson, 2008) to develop working models of his thinking.

In the tenth teaching session, we designed and used the Changing Bars Task (Figure 2) to gain insights into Caleb's magnitude reasoning. On the circle (left, Figure 2), the red segment represents a dynamic point's height magnitude above the horizontal diameter and the blue segment represents the point's counterclockwise arc magnitude traveled from the 3 o'clock position. A student can move the point along the circle between the 3:00 and 12:00 position. With respect to the orthogonally oriented bars (right, Figure 2), while a student dragging an end-point of a red bar to manipulate its length, the blue bar varies accordingly. For an increasing red bar from zero to the radius length of the circle, the blue bar in pairs (1)-(2), (3)-(4), and (5)-(6) increases at a constant, increasing (i.e., the red bar increases at a decreasing rate with respect to the blue bar; the normative solutions to the task), and decreasing rate with respect to the red bar, respectively. The only difference between the corresponding pairs is the orientation of the bars. We asked Caleb to choose which, if any, of the orthogonal pairs accurately represents the relationship between the red and blue segments on the circle, and to graph the relationship.

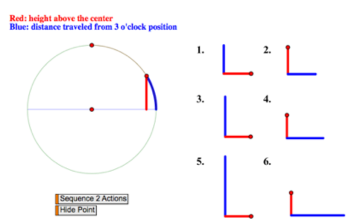

Figure 2. Changing Bars Task (numbering of the six pairs was edited for readers)**.**

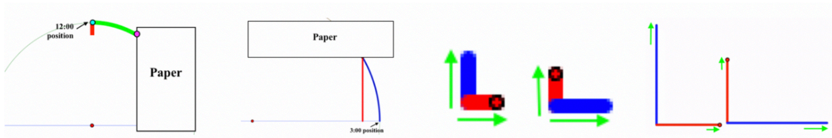
Results

Comparison Between Amounts of Change in Two Quantities' Magnitudes

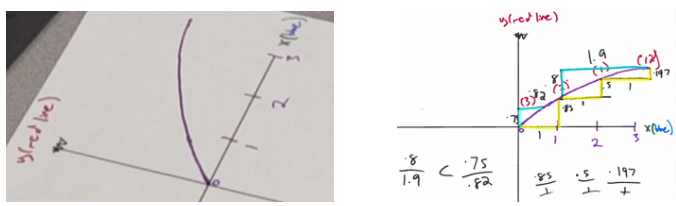
Caleb first focused on the circle to identify the appropriate relationship between height and arc length. Drawing attention to the variation near the 12:00 position, he used a paper to cover a portion of the circle's circumference and observed that the amount the height increased was "small" (see the red segment denoted in Figure 3a) but the arc traveled was "considerable" (see the green arc denoted in Figure 3a). In contrast, he observed that, near the 3:00 position, the change in magnitude of red and blue was "almost equal" (Figure 3b). We interpret that Caleb was not only comparing amounts of change in height and arc magnitude, but was also aware that the results of such comparisons were not constant as the dynamic point traveled.



(a) (b) (c) (d)

Figure 3. Annotated recreation of Caleb's using paper to compare amounts of change in arc length and height at around (a) the 12:00 position and (b) the 3:00 position; Caleb's choice of two pairs of bars at (c) the beginning state and (d) the final state (the direction and length of each arrow indicates the direction and magnitude of change respectively).

Turning his attention to the orthogonal pairs, he made use of this observation to select two pairs (the normative solutions) in which the blue bar changed by "almost equal" amount as the red near their minimal amounts (Figure 3c) and changed by noticeably larger amounts than the red near their maximum amounts (Figure 3d). Transitioning to a graphical representation, Caleb produced a graph (Figure 4a) and explained that the graph should start with having "a slope of 1" to re-present the amount the red segment changed being "almost equal" to the blue and should gradually level out to re-present the blue segment increasing by a larger amount than the red. He was able to mentally coordinate and re-present amounts of change magnitudes in blue and red on the horizontal and vertical axis respectively and to anticipate how joining these orthogonally-oriented magnitudes would result in a graph with particular concavity. Together, we interpret Caleb's ways of comparing and coordinating magnitudes of quantities to be coherent and stable across multiple representations (i.e., circle situation, orthogonal bar pairs, and graph).



(a) (b)

Figure 4. Caleb's (a) initial graph and (b) graph with estimation of quotient values.

Quotient as Relative Size of Two Quantities' Magnitudes

Observing that Caleb consistently attended to changes in two intervals only (one close to the 3:00 position and one close to the 12:00 position), we prompted him to describe the relationship throughout the entire first quarter circle. He then drew in successive horizontal and vertical segments (denoted in yellow in Figure 4b) to represent equal changes in the blue and decreasing changes in the red, respectively. He also estimated a value for each increment and wrote three quotients (i.e., ".85/1," ".5/1," ".197/1"), concluding that the ratios of how much the red increases to how much the blue increases decreased. He explained that his choice of making the change in blue a size of 1 for each increment was only for convenience in that it allowed direct additive comparisons, saying "if you divide these out [*scratching out the '1's in the denominators as seen in Figure 4b*] it would just be 0.85, 0.5, 0.197, you see them decreasing." He further explained that he could have used contrasting sizes for those intervals. He illustrated by drawing in the segments denoted in blue in Figure 4b and wrote down an estimated number for each segment, claiming that, although he did not know the values for ".8/1.9" and ".75/.82", he knew that the former is greater than the latter due to his previous conclusions. We interpret that Caleb was multiplicatively comparing amounts of change in two quantities' magnitudes and anticipating each quotient as representing a relative size of the magnitude of change in blue with respect to that in red. Although he made use of numerical values, his reasoning was not constrained by those values; rather, he used numbers to convey particular features of the relationship between the two magnitudes. Additionally, he could hold the covariational relationship in mind and anticipate variation of quotient values across *any* intervals.

Discussion

Contributing to Thompson et al.'s (2014) call for more detailed characterization of students' magnitude thinking, our analysis suggests that a student's mental actions involving magnitudes can be generative for productive mathematical meanings that include graphical concavity and quotient. In contrast to the teacher participants in Thompson et al.'s (2014) study who had poor understandings of magnitude, quotient, and rate of change, Caleb's disposition of reasoning with magnitudes afforded his reasoning about quotient (and potentially rate of change) productively. Specifically, his ability to compare magnitudes multiplicatively supported his quotient understandings that entailed flexible partitions or intervals, which were critical for constructing rate of change meanings. Our findings also contribute to the covariation frameworks of Carlson et al. (2002) and Thompson and Carlson (2017). Carlson et al. (2002) suggested that coordination of uniform successive amounts of change in quantities is fundamental to understanding average and instantaneous rate of change (i.e., MA3, MA4, and MA5). In this study, we identify a student whose ability to coordinate quantities does not originate from constructing successive changes in quantities (including their magnitudes). Rather, his way of thinking aligns with Thompson and Carlson's (2017) *chunky continuous covariation* that entails reasoning with covariations regarding intervals of any sizes. We call for future investigations to focus on the extent to which a student can reason with smooth variations across interval chunks, which may provide further insights into the constraints and affordances of students' magnitude reasoning regarding rate of change and other more advanced concepts.

National data reveals that more than half of freshmen who declared STEM majors at the start of college left these fields before graduation. Our research suggests that students' difficulties with algebra cause significant problems in many first-year math courses. This paper presents our analysis of student challenges with algebra in calculus and the nature of their errors.

Keywords: Algebra, Calculus, Common Error

Background

Over the past several decades, much attention has been focused on the need for improved mathematics and science teaching and learning in the United States. The pressure for global competition and changing demands of the workforce have propelled the conversation regarding learning outcomes in science, technology, engineering, and mathematics (STEM) forward. Given that calculus courses are often the gatekeeper to disciplines in STEM, at least one calculus course is typically required for all STEM majors. Bressoud, Mesa, & Rasmussen (2015) suggest that the requirement of a calculus course is often an insurmountable obstacle or one that discourages students from pursuing STEM majors. In fact, research has shown more than half of students are deterred from a career in STEM due to challenges completing calculus (Crisp, Nora, & Taggart, 2009; Mervis, 2010). Recent studies by Stewart (2017) and Stewart and Reeder (2017) suggest that college students' weaknesses with algebra play a major role in their success in calculus. Stewart (2017) further suggests college instructors face the challenge of working with students everyday who can seemingly make sense of complex mathematical concepts but are unable to solve problems related to those concepts due to their difficulties with algebraic procedures.

The goal of this research is to analyze students' difficulties with algebra and how these difficulties impact their work in calculus problems. We assert that the unresolved high school algebra knowledge wrapped inside the calculus problems are major cause of failure for many students when taking calculus. While resolving algebra deficiencies that students bring with them will be challenging, "it cannot be simply ignored and remain as an everyday accepted or out of our hands part of teaching university level mathematics courses" (Stewart, 2017, p. 15).

The following research questions guided this study: (a) What were the most common algebra errors in both the algebra and calculus problems? (b) To what extent where the algebraic errors made on the algebra and calculus problems aligned and (c) What were the students' perceptions of their challenges with algebra and calculus related to these problems?

Method

This qualitative research study involved 275 university Calculus I students at the end of their 16-week course. Students were asked to first solve the Calculus I problems (Stewart, 2014) and then the algebra problems, identify what caused them the most challenge, algebra or calculus, and provide a brief response about what challenged them while solving the problems (see Table

1). Collected data were de-identified and incomplete data sets were removed. The result was N = 84 complete sets of data. The research team analyzed each problem to develop initial codes. The initial codes were used by researchers to code data independently for both calculus mistakes in the calculus problems and algebra mistakes in both the calculus and algebra problems. A second meeting of the research team established the codebook after assuring inter-coder reliability. Using our codebook (see Table 2), each set of problems were analyzed and coded independently by two researchers who then met to review the codes and establish 100% agreement.

Table 1: The Calculus and Algebra Problems

Calculus Problems	Algebra Problems
1. Implicitly differentiate. $\sqrt{xy} = 1 + x^2y$ 2. Find the critical numbers of the function $f(t) = t\sqrt{4 - t^2}$ 3. Evaluate the limit. $\lim_{t\to 0} \frac{\sqrt{1+t} - \sqrt{1-t}}{t}$	1. Solve for y. $5 + xy = 10 + x^2y$ 2. Solve for y. $\frac{1}{2\sqrt{5x}}(5 + xy) = 10x + x^2y$ 3. Solve for t. $\frac{1}{\sqrt{t+1}} - \frac{1}{t} = 0$ 4. Solve for y. $\frac{2y^2}{2\sqrt{y^2 - 9}} + \sqrt{y^2 - 9} = 0$
My main problem with the test was: Algebra ☐	Calculus ☐

	22. Operations with Fractions	

Results

Our results are presented in three sections which correspond to our research questions on common errors, comparing calculus and algebra contexts, and student perceptions.

Common Errors

Analysis of the algebra and calculus problems revealed that the student errors were numerous and significant with algebra in both sets of problems and calculus related errors were frequent in the calculus problems as well. The most common algebra errors made in both sets of problems were errors working across the balance point in equations, cancelling, operations with radicals, appropriate application of the distributive property, and incomplete algebra (work that was not completed due to confusion). While the students' work with the calculus problems were replete with algebra errors, they also made many calculus errors. The most common among these were incorrectly taking the derivative implicitly, using the product rule improperly, failing to identify undefined points as critical, incorrectly taking the limit, and avoiding algebra.

Comparing Calculus and Algebra Contexts

Of the 84 students in the sample, 58 of the students made a total of 102 algebra errors on the calculus questions; the other 26 students made no algebra errors. Thus, 69% of the students in the sample made some type of algebra error on the calculus problems. However, of the 102 algebra mistakes made on calculus problems, only 26 times (25.5%) students made the equivalent mistake on the associated algebra problem. In fact, only 24 of the 58 students who made algebra errors on the calculus problems repeated their mistakes on the algebra problems. Yet, on the algebra problems, these 58 students made a total of 130 algebra errors on the algebra problems; that is, they made more algebra mistakes on the algebra problems than they had on the calculus problems from which the algebra problems were derived. Further, the patterns of the mistakes made differed (see Figure 1 below).

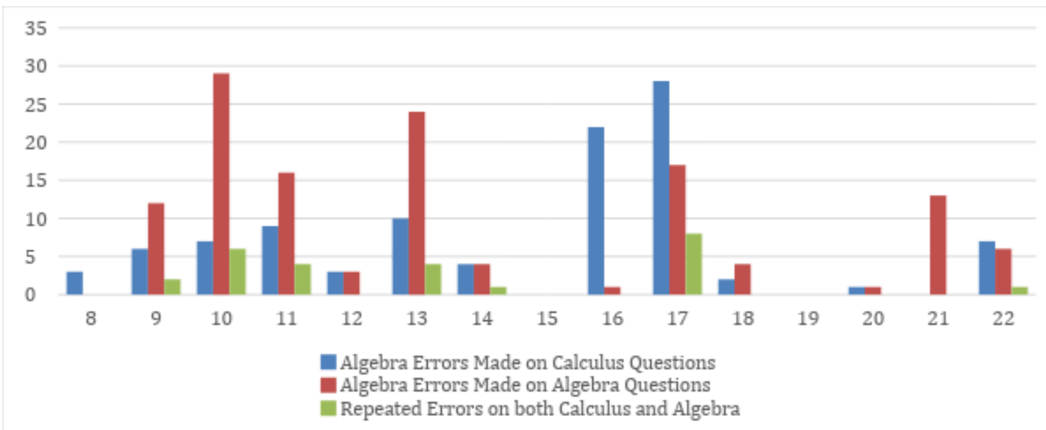

Figure 1. The algebra errors of the 58 students who made algebra errors on calculus problems.

These students did not tend to repeat the same type of algebra errors on both the calculus and algebra problems. Students were much more likely to make errors in with the balance point (error code 10) or cancelling (error code 13) on the algebraic problems than on calculus based problems. Students were much more likely to have sign errors (error code 16) on calculus problems. Errors while working with radicals (error code 17) were also more likely to appear on calculus problems than algebra problems. Yet, of the 28 students who made an error with radicals on the calculus problems, only 8 of these students repeated the error when presented with an algebra problem dealing with a radical; another nine students had a radical error on an algebra problem when they had not made the error in the calculus portion of the exam.

Student Perceptions

Our final research question aimed to provide insight on the students' perceptions about their abilities with algebra and calculus as presented in the problems they were asked to solve. Of the 84 participants who completed all the mathematical problems, 73 chose to provide a response to our short-answer item. When asked to select which gave them more challenge, algebra, calculus, or both, 57% indicated algebra, 31% indicated calculus, while 12% indicated both. Their comments overwhelmingly expressed recognition that algebra causes them difficulties, frustration, anxiety, and in some cases, hopelessness about their abilities to succeed in mathematics.

Discussion and Implications

We believed most students would solve algebra problems correctly when these problems were in isolation from calculus, but make predominantly algebraic mistakes in the context of calculus problems with algebra problems embedded. However, we found that students struggled with the isolated algebra problems as well as the calculus problems.

While the problems presented students challenges with both calculus and algebra, the student responses overwhelmingly indicated they had frustration and concerns with their algebra abilities. In the words of one student "I knew how to start the problem, but could not finish because of the difficulty of the algebra involved." So, while these students may have the prerequisite knowledge of algebra, they may not have had the opportunity to develop the strong procedural fluency necessary for algebra to function as a versatile tool in calculus as expected or required. Their challenges with algebra create difficulties for us, and them, as we try to make sense of what calculus they are learning. The challenges and misconceptions students bring with them to their university mathematics courses are difficult to remedy, even if identified. As Smith et al. (1993, p. 152) suggest, the misconceptions developed by students are "… persistent and resistant to change are likely to have especially broad and strong experiential foundation."

EL EFECTO DE LOS ESTADOS EPISTÉMICOS (CERTEZA, DUDA) SOBRE EL APRENDIZAJE. MICROANÁLISIS DE UNA INTERACCIÓN

Mirela Rigo-Lemini
Centro de Investigación y Estudios Avanzados del I. P. N.
mrigolemini@gmail.com

La investigación se centra en fenómenos del convencimiento de hechos de las matemáticas (H) que surgen en el ámbito educativo. Se aportan evidencias empíricas de que la seguridad en H puede inhibir el aprendizaje de las matemáticas y la duda en H, impulsarlo. Las evidencias provienen de un caso de interacción entre una pareja de estudiantes de secundaria que intercambian argumentos en torno a la resolución de una tarea de comparación de razones.

Keywords: Affect, Emotion; Cognition; Reasoning and Proof

Antecedentes y Preguntas de Investigación

La investigación se centra en fenómenos del convencimiento (seguridad, confianza, duda… los que aquí se denominan *estados epistémicos de convencimiento* o *ee*) de hechos de las matemáticas que surgen en el ámbito educativo. Expertos (e.g., Foster, 2016) han aportado evidencias de la influencia (positiva o negativa) de los ee en el aprendizaje de las matemáticas: un contenido matemático que no es asimilado con convencimiento, aunque sea comprendido, posteriormente no se usa (Fischbein, 1982); la sobre-confianza o seguridad en un argumento inhibe la posibilidad de considerar un argumento distinto (Fischbein, 1982; Inglis, Mejía-Ramos & Simpson, 2007). En continuidad con esos trabajos, en éste se plantea: ¿Los ee tienen influencia sobre el aprendizaje de las matemáticas? ¿Cómo inciden y qué tipo de repercusión ejercen? Aquí se muestra que los ee tienen un efecto como impulsores o como inhibidores del aprendizaje. El argumento se sustenta en el caso de una interacción entre un par de alumnos de secundaria que intercambian argumentos en torno a una tarea de comparación de razones.

Marco Teórico Interpretativo

Apoyados en conceptos provenientes de la neurobiología de Damasio, la autora del presente escrito y sus colaboradores consideran a los ee como parte del ámbito afectivo, específicamente como un cierto tipo de emociones (Rigo & Martínez, 2017). En tanto emociones, los ee se expresan corporal y cognitivamente; en la Tabla 1 aparecen criterios para identificarlos.

Tabla 1. Criterios para la identificación del convencimiento de una persona

Discurso verbal y corporal	La persona: -Recurre a enfatizadores del lenguaje (modo indicativo de los verbos) (e.g., tengo; mitigadores: convendría); -Utiliza un tono de voz firme y enfático y posiblemente más alto de lo usual; -Acude a enfatizadores corporales, como gestos y movimientos del cuerpo que reafirman sus ideas.
Determinación	La persona manifiesta de manera espontánea y determinada su adhesión a la veracidad de un enunciado matemático. Busca convencer a otros, aún cuando están en su contra.
Consistencia	La persona muestra consistencia en sus distintas intervenciones.

Sobre la teoría del aprendizaje significativo de Ausubel

Para Ausubel, Novak y Hanesian (1978), una condición para el aprendizaje significativo consiste en que los nuevos contenidos de conocimiento sean potencialmente significativos para el aprendiz, es decir, que puedan ser vinculados de modo no arbitrario y sustancial (no al pie de la letra) con lo que el alumno ya sabe. Otra condición para el aprendizaje significativo consiste en que el material de aprendizaje sea lógicamente significativo, es decir, que se pueda conectar de manera sustancial y no arbitraria con cualquier estructura cognoscitiva apropiada. Ausubel sugiere otras variables de tipo afectivo, motivacional y social, que también influyen en el aprendizaje significativo.

Metodología y métodos de recuperación de datos empíricos

En el estudio se aplicó en forma individual un cuestionario a alumnos pertenecientes a escuelas con estándares altos de calidad. En el cuestionario se planteó una tarea de corte realista basada en la comparación de razones. En la tarea se proponen tres ofertas para la compra de videojuegos: en una se ofrece pagar 2 y llevarse 3 (3x2); en otra, se ofrece el segundo videojuego a mitad de precio y en la otra se ofrece el 70% de descuento en el segundo videojuego. La pregunta es ¿cuál de las ofertas es la que más conviene? (tomada de Gómez et al., 2013). Se formaron parejas de alumnos, cada uno integrada por estudiantes que en el cuestionario sostuvieron una postura distinta y explícita. En la interacción se solicitó a los participantes que intentara convencer a su compañero de que su resolución a la tarea era la adecuada; uno de los investigadores actuó como coordinador del diálogo. Cada interacción fue videograbada y luego transcrita. Aquí se presenta un microanálisis -cualitativo- del diálogo de una de las parejas. Los datos empíricos y las transcripciones provienen de Gómez (2017).

Análisis interpretativo de los datos empíricos y algunos resultados

El análisis se centra en el alumno V, quien expresó nítidamente sus ee, los cuales surgieron en la interacción con J y el investigador. En la Tabla 2 se exponen los fragmentos más significativos de sus participaciones. En la columna central de esa Tabla aparecen fragmentos de la transcripción de la interacción. En su lado derecho, están los argumentos a favor de la oferta 70%, así como los ee que experimentaron los estudiantes en torno a dichos razonamientos. En el lado izquierdo, aparece la misma información pero relacionada con la oferta 3x2.

Tipo relativo
Certeza
Enfatizadores del lenguaje: “por obvias razones”</td></tr>
</table>

V poseía conocimientos previos que le permitieron diseñar una estrategia de tipo aditivo A: para la comparación de parejas de magnitudes se fija primero una de ellas y luego se compara aditivamente la otra. Además, V tenía experiencias previas en las compras, las que dejó ver a través de argumentos extra-matemáticos (EM). En la interacción, V acudió a esa estrategia A (v. columna derecha Tabla 2: en ci, 1ªP y 2ªP) de la que derivó la respuesta 3x2, la cual reforzó con justificaciones EM (en 1ªP, 2ªP y 4ªP). Cuando V, a solicitud del investigador, obtuvo correctamente otra respuesta (70%) mediante A (en 2ªP) o a través de otra estrategia (Building up, 3ªP), él de todos modos regresó a su respuesta 3x2, apelando siempre a justificaciones EM. Lo mismo hizo ante el argumento de José (en 4ªP). Es hasta el cf que V adoptó una nueva forma de argumentar, con perspectiva relativa, y una nueva solución, omitiendo los argumentos EM.

Durante la interacción, V no parece haber construido nuevos aprendizajes significativos que tuvieran repercusiones visibles (en el corto plazo); muestra de ello es que a lo largo de toda la interacción (con excepción de 5ªP) siempre regresó a su respuesta inicial y a sus argumentos EM. Es hasta el cf que V muestra haber conseguido nuevos aprendizajes, al resignificar la comparación de parejas de magnitudes a partir de una perspectiva relativa.

Aquí surgen 2 preguntas. ¿Por qué V no parece haber logrado nuevos aprendizajes durante la interacción (sino sólo hasta el final)? ¿Por qué sí consigue un aprendizaje significativo en su cf?

La tarea era lógicamente significativa para estudiantes del nivel de V; además, la tarea era potencialmente significativa para V. No fueron entonces factores cognoscitivos los que impidieron que, durante la interacción, V progresara en sus aprendizajes. Quedan entonces los factores afectivos; éstos pudieron haber influido en su desempeño, pero no hay evidencia de que fueran factores tan definitivos. Aquí se argumenta que es probable que haya sido la confianza que V experimentó durante la interacción, la que impidió de manera importante que él haya conseguido un aprendizaje significativo durante la mayor parte del intercambio; y que fue la confianza moderada o la duda, lo que, en buena medida, posibilitó al final ese aprendizaje.

V dejó ver desde el inicio una sobreconfianza en A, en sus argumentos EM y en la respuesta 3x2 que se derivó de A y de EM. Muestra de esa sobreconfianza son los indicadores que aparecen en la primera columna de la Tabla 2, sobre todo 1ªP. Era natural que V tuviera esa confianza, ya que sus argumentos (A y EM) le eran muy familiares y A estaba basado en principios aritméticos básicos. Pero estos ee tuvieron sus efectos negativos en el aprendizaje de V. Si bien V aplicó correctamente estrategias distintas a A (e.g, Bu) o derivó otras soluciones (70%), no parece haberlo hecho, de entrada, con toda la convicción necesaria para considerar estos nuevos contenidos, ponderarlos y compararlos objetivamente con lo propuesto inicialmente por él; indicadores de la falta de esa convicción aparecen descritos en la columna derecha de la Tabla 2. Es posible que esa falta de convicción haya sido resultado de la sobreconfianza en A, EM y 3x2, la cual lo llevó a centrarse firmemente en esos contenidos y le impidió, de entrada, asumir compromisos de seguridad con otras opciones distintas (Fischbein, 1982; Inglis et al, 2007); y es posible que esa escasa convicción en Bu y 70% impidió, a su vez, que esa nueva estrategia y solución tuvieran un uso posterior (Fischbein, 1982). No obstante, y a pesar de todo esto, sus actividades en 2ª y 3ªP fueron sensibilizando a V, aunque imperceptiblemente, en esas otras estrategias y resultados y fue así disminuyendo su sobre-confianza en su propuesta inicial, hasta llegar a un estado de confianza o incluso de duda en torno de esa resolución inicial (4ªP). Estos cambios en los ee -decremento en la confianza en respuesta 3x2 (v. columna izquierda Tabla 2) y apertura de credibilidad a otras estrategias y respuestas (v. columna derecha Tabla 2)- permitieron a V ser sensible a la propuesta matemática de J. Y esa confianza o duda, más cautelosa (4ª P), en su propuesta inicial, acompañada de una confianza en la estrategia relativa (5ªP), le permitieron a V hacer en el cf una comparación más objetiva entre todas las estrategias disponibles -lo que no pudo hacer durante la interacción- y optar por una estrategia matemática de tipo relativo hacia la que mostró certeza y en la que ya no necesitó de los argumentos EM.

Consideraciones finales

El análisis expuesto ofrece evidencias empíricas de que, al igual que las variables cognoscitivas, los estados epistémicos (que aquí se conciben como pertenecientes al ámbito afectivo) sí pueden contribuir (o por el contrario, pueden frenar) al surgimiento, precisión, integración y otros aspectos cualitativos de los nuevos aprendizajes; en particular, se deja ver empíricamente que la certeza ejerce un efecto inhibidor de la edificación o establecimiento de los nuevos contenidos, y que la duda actúa como impulsor del aprendizaje.

THE EFFECT OF THE EPISTEMIC STATES (CERTAINTY, DOUBT) ON LEARNING. MICRO ANALYSIS OF AN INTERACTION

The research focuses on mathematical facts (H) convincing phenomena that arise in the educational field. Empirical evidence is provided that the certainty in H can inhibit the learning of mathematics and the doubt in H, boost it. The evidence comes from a case of interaction between a couple of high school students who exchange arguments around the resolution of a ratio task.

Keywords: Affect, Emotion; Cognition; Reasoning and Proof

Antecedents and Research Questions

The research focuses on convincing phenomena (security, confidence, doubt ... those that are here called epistemic states of convincement or ee) of mathematical facts that arise in the educational field. Experts (e.g., Foster, 2016) have provided evidence of the influence (positive or negative) of the ee in the learning of mathematics: a mathematical content that is not assimilated with conviction, even if it is understood, later it is not used (Fischbein, 1982); the over-confidence or security in an argument inhibits the possibility of considering a different argument (Fischbein, 1982, Inglis, Mejía-Ramos & Simpson, 2007). In continuity with these works, in this one it is posed: Do ee have influence on the learning of mathematics? How do the ee affect learning and what kind of effect do they have? Here it is shown that ee have an effect as drivers or inhibitors of learning. The argument is based on the case of an interaction between a couple of high school students who exchange arguments around a ratio task.

Theoretical Interpretive Framework

Based on concepts from Damasio's neurobiology, the author of this paper and her collaborators consider the ee as part of the affective field, specifically as a certain type of emotions (Rigo & Martínez, 2017). As emotions, the ee express themselves bodily and cognitively; in Table 1 there are criteria to identify them.

Table 1: Criteria for the identification of the person's convincement

Verbal and corporal speech	The person: -Appeals to language emphasizers (indicative mode of the verbs) (e.g., I have, mitigators: would agree); -Uses a firm and emphatic tone of voice and possibly higher than usual; -Employs body emphasizers, as gestures and body movements that reaffirm their ideas.
Determination	The person manifests spontaneously and determined his adherence to the veracity of a mathematical statement. He seeks to convince others, even when they are against him.
Consistency	The person shows consistency in their different interventions.

On Ausubel's Theory of Significative Learning

For Ausubel, Novak and Hanesian (1978), a condition for significative learning is that the new knowledge contents are potentially significative for the learner, that is, they can be linked in a non-arbitrary and substantial way (not at the bottom of the letter) with what the student already knows. Another condition for significative learning is that the learning material is logically significative, that is, can be connected in a substantial and non-arbitrary way with any appropriate cognitive structure. Ausubel suggests other variables of affective, motivational and social type, which also influence significative learning.

Methodology and methods of empirical data recovery

In the study, a questionnaire was applied individually to students belonging to schools with high quality standards. In the questionnaire a realistic task was proposed based on the comparison of mathematica ratios. The task proposes three offers for the purchase of video games: one offers to pay 2 and take 3 (3x2); in another, the second videogame is offered at half price and in the other, 70% discount is offered in the second videogame. The question is, which of the offers is the best one? (taken from Gómez et al., 2013). Pairs of students were formed, each composed of students who in the questionnaire held a different and explicit position. In the interaction the participants were asked to try to convince their partner that their resolution to the task was appropriate; One of the researchers acted as coordinator of the dialogue. Each interaction was videotaped and then transcribed. Here a microanalysis -qualitative- of the dialogue of one of the couples is presented. The empirical data and the transcriptions come from Gómez (2017).

Interpretive analysis of the empirical data and some results

The analysis focuses on student V, who clearly expressed his ee, which emerged in the interaction with J and the researcher. Table 2 shows the most significant fragments of their participation. In the central column of that Table appear fragments of the transcription of the interaction. On the right side, there are the arguments in favor of the 70% offer, as well as the ee that the students experienced regarding said reasoning. On the left side, the same information appears but related to the 3x2 offer.

V had previous knowledge that allowed him to design an additive type strategy (A): for the comparison of pairs of magnitudes, one of them is fixed first and then the other is additively compared. In addition, V had previous experiences in shopping, which he showed through extra-mathematical arguments (EM). In the interaction, V resorted to strategy A (v. Right column Table 2: in iq, 1stP and 2thP) from which he derived the 3x2 response, which he reinforced with EM justifications (in 1stP, 2thP and 4thP). When V, at the request of the researcher, correctly obtained another answer (70%) through A (in 2thP) or through another strategy (Building up, 3thP), he anyway returned to his 3x2 response, always appealing to EM justifications. He did the same with José's argument (in 4thP). It is until fq that V adopted a new way of arguing, with a relative perspective, and a new solution, omitting the EM arguments.

During the interaction, V does not seem to have built significative new learning that would have visible repercussions (in the short term); proof of this is that throughout the entire interaction (with the exception of 5thP) he always returned to his initial response and his EM arguments. It is up to fq that V showed to have obtained new learnings, by re-signifying the comparison of pairs of magnitudes from a relative perspective.

Here two questions arise. Why V does not seem to have achieved new learning during the interaction (but only until the end)? Why does he get significative learning in his fq?

The task was logically significative for students at the V level; in addition, the task was potentially significative for V. It was not then cognitive factors that prevented, during the interaction, V from progressing in their learning. There are then affective factors; these may have influenced their performance, but there is no evidence that they were such definitive factors. Here it is argued that it is likely that was the confidence that V experienced during the interaction, which impeded significantly that he has achieved significant learning during most of the exchange; and that it was moderate confidence or doubt, which, to a great extent, made his learning possible in the end.

V showed from the beginning an overconfidence in A, in his EM arguments and in the 3x2 response that was derived from A and from EM. Sample of this overconfidence are the indicators that appear in the first column of Table 2, especially 1stP. It was natural for V to have that confidence, since his arguments (A and EM) were very familiar to him and A was based on basic arithmetic principles. But these ee had their negative effects on the learning of V. While V correctly applied strategies other than A (e.g., Building up, in 3thP) or derived other solutions (70%, in 2ndP), it does not seem to have done it, right away, with all the conviction necessary to consider these new contents, weigh them and compare them objectively with what was initially proposed by him; indicators of the lack of that conviction are described in the right column of Table 2. It is possible that this lack of conviction was the result of the overconfidence in A, EM and 3x2, which led him to focus firmly on these contents and it prevented, at the outset, assuming security commitments with other different options (Fischbein, 1982, Inglis et al, 2007); and it is possible that that little conviction in Bu and 70% prevented, in turn, that this new strategy and solution had a later use (Fischbein, 1982). However, despite all this, his activities in 2ndP and 3rd P were sensitizing V, although imperceptibly, in these other strategies and results and thus reducing their over-confidence in their initial proposal, until he reached a state of confidence, even doubt, about his initial resolution (in 4th P). These changes in ee - decrease in confidence in 3x2 response (see left column Table 2) and openness of credibility to other strategies and responses (see right column Table 2) - allowed V to be sensitive to J's mathematical proposal. And that more cautious confidence or doubt (4th P) in his initial proposal, accompanied by a confidence in the relative strategy (5th P), allowed V to make a more objective comparison between all the available strategies, in the fq - what he could not do during the interaction - and opt for a mathematical strategy of a relative type towards which he showed certainty and in which he no longer needed the EM arguments.

Final Remarks

The above analysis offers empirical evidence that, like cognitive variables, epistemic states (which are conceived here as belonging to the affective sphere) can contribute (or on the contrary, can stop) to emerge, precision, integration and others qualitative aspects of the new learnings; in particular, it is empirically shown that certainty exerts an inhibiting effect on the construction or establishment of new contents, and that doubt acts as a driver of learning.

THE PARALLELOGRAM PROBLEM: SUPPORTING COVARIATIONAL REASONING IN THE CONSTRUCTION OF FORMULAS

Irma E. Stevens
University of Georgia
istevens@uga.edu

I studied preservice teachers' uses of covariational reasoning with a dynamic situation to construct a formula to represent the covariational relationship between one of the interior angles of a dynamic parallelogram and its area. I propose a definition for reasoning covariationally with formulas, provide a first order model of what it means to do so, and then provide the results of the analysis of two students' activities with this task, highlighting the bidirectional relationship between students' images of a situation and their representation of it.

Keywords: Algebra and Algebraic Thinking, Cognition, Design Experiments

Students' understandings of modeling problems, variables, and equations have long been identified as a source of difficulty in research on mathematics education (Stephens, Ellis, Blanton, & Brizuela, 2017). Students interpret symbols as static unknowns (Dubinsky, 1991) and fixed, given referents (Gravemeijer, Cobb, Bowers, & Whitenack, 2000). Thompson and Carlson (2017, p. 425) describe this reasoning as one with constants (i.e., person envisions a quantity as having a value that does not vary ever) versus parameters (i.e., person envisions the quantity as having a value that can change from setting to setting but does not vary within a setting) or variables (i.e., person envisions that the quantity's value varies within a setting). I attempted to support preservice teachers' construction of variables through interviews using area formula contexts by incorporating ideas of covariational reasoning—students conceiving of situations as composed of quantities that vary in tandem (Carlson, Jacobs, Coe, Larsen, & Hsu, 2002). I propose covariational reasoning with formulas to be simultaneously imagining two quantities represented via symbols as variables that represent covarying quantities in a situation. I report on the relationship between students' perceptions of a dynamic situation and symbols in formulas.

Background

In this study, I adopt the radical constructivist perspective (von Glasersfeld, 1995) that individuals actively construct quantities—measurable attributes (Thompson & Carlson, 2017, p. 425)— and that an individual's image of a situation is projected from their mental organization of sensory data. My definition of image is rooted in Piaget's (1967) descriptions of images as shaped by mental operations individuals perform. Thompson notes that "the image is shaped by the operations, the operations are constrained by the image, for the image contains vestiges of having operated, and hence results of operating must be consistent with the transformations of the image" (Thompson, 1996). Similarly, Thompson and Carlson (2017, p. 448) emphasized the idea that students' constructions of symbolic expressions are constrained by the quantitative structures they construct about a situation. The formulas I intend for students construct stem from reasoning with dynamic area situations, a context other researchers are exploring as a productive way for K-8 students to construct formulas (e.g., Matthews & Ellis, in press).

Methods

In this study, four volunteer preservice teachers from a large public university in the southeastern U.S. partook in a videotaped sequence of 3-5 individual clinical (Clement, 2000) and exploratory teaching interviews (Steffe & Thompson, 2000) lasting 1.5-2 hours each over the course of four weeks during the summer. The students had just completed their first or second semester in a four-semester secondary mathematics education program and had completed a Calculus sequence and passed at least two other upper level mathematics courses. The students had also completed a secondary mathematics topics course designed from the *Pathways Curriculum* (Carlson, O'Bryan, Oehrtman, Moore, & Tallman, 2015) and thus had opportunities to reason quantitatively and covariationally with dynamic situations. I only focus on two students' second interview session, their first exploratory teaching session. I encouraged the students to think aloud (Goldin, 2000). The goal of my questioning was to build viable models of the *students' mathematics* (Steffe & Thompson, 2000). I conducted open (generative) and axial (convergent) analyses (Strauss & Corbin, 1998) to inform these second order models.

First Order Model of Parallelogram Problem

I presented students with a manipulative (Figure 1a) and following prompt: "Describe the relationship between the area inside the shape (shape formed by two pairs of parallel lines) and one of the interior angles of the parallelogram (up to a straight angle)." In the following first order model, I will use $\overline{AB}$ to indicate the physical segment from point A to B, AB_{unit} to indicate the length of $\overline{AB}$ measured in the unit specified, and AB as a measurement parameter for the situation (i.e., I anticipate measuring $\overline{AB}$ but have no specific unit of measure in mind).

Figure 1 offers a sequence of mental actions for a student's construction of a formula that relies on conceiving of two quantities, area within $ABCD$ and $\angle DAB$ (Figure 1b), and conceiving of them as variables within a formula through covariational reasoning. First, the student conceptualizes the area of a parallelogram as equivalent to the area of a corresponding rectangle through a translation (Figure 1c-e). Second, the student makes the following conclusion about covariational relationship between the angle measure and the rectangle: For equal changes in angle measure from $m\angle DAB = 0 \text{ to } \pi/2$ radians, the amount by which the area increases for each successive equal change in angle measure is less each time (Figure 1f-h). The student understands the height of the parallelogram as the height above the center of a circle measured in radii that they assimilate to this situation (Figure 1i) and assimilates it to the sine relationship (see Moore (2014) for details). Using $\sin(\theta)$ to denote the height assumes the unit is the radius of the circle (i.e., AB_{radii}) because sine outputs a result measured in radii. The radius, the length AB, can be measured with any other unit length, u, making the measurement for the height using that same unit $AB_u \sin(\theta)$, where AB_u is the measurement of the radius using any unit. Thus, the final formula for the area of the parallelogram that relates the area to the angle measure is $Area{=}AD{\bullet}AB_u \sin(\theta)$. This conception of a formula treats $Area$ and θ as variables and AB_u as a parameter based on the unit choice chosen for the situation for θ and AD.

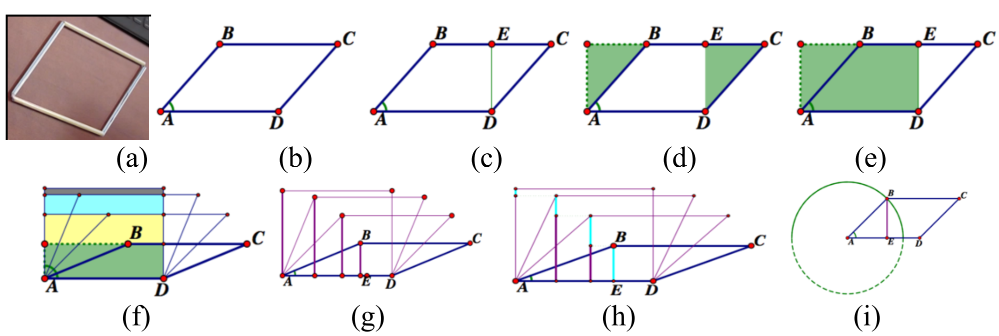

Figure 1. Sequence of mental actions to construct formula in Parallelogram Problem.

Results: Students' Image Structuring of the Parallelogram Problem

The following categories illustrate how different images informed students' conceptions of the relationship between angle measure and area and a formula for the area of the shape.

Unstructured Initial Images of Directional Covariational Relationships Between Quantities

Three of the four students stated at some point that the area of the parallelogram remained constant as they changed the angle measure. In their justifications, they made note of properties of the manipulative such as the constant lengths of the sides of the parallel lines (Charlotte, Alexandria) or noting that as two of the interior angle measures decrease, the remaining two interior angles increase by the same amount (Charlotte). Alexandria's image changed when she considered small angle measures; Charlotte was perturbed when she did so, saying, "It's like to a certain point I believe [the area remains constant], and then it's hard to believe it."

Comparison of Resulting Measurements from Formulas

Charlotte constructed two formulas, one for a rectangle and one for a parallelogram at another angle. She wanted to compare the measures of the area for the shape as a rectangle by multiplying *XC* (Figure 2, left) to the measure of the area of the shape as a parallelogram with a given angle measure (Figure 2, middle). This comparison of static figures was problematic for her when she realized she did not know which values to use to compare to one another.

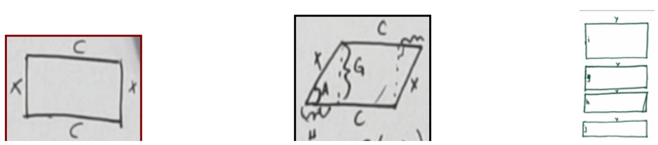

Figure 2. Charlotte's two instances (left, middle) of the situation from which she constructed two formulas and her construction of rectangles from parallelograms at "extreme" angles.

Equating Known Formulas with Images

Charlotte later noticed she could move her triangle on the left (Figure 2, middle) to the right side and form a rectangular shape (as in Figure 1d-e) and concluded that to find the area of the parallelogram shape, she should also multiply *CX* (i.e., the side lengths) "because I think that that's just a rectangle like looked at a different way" resulting in constant area for changing angles. This reasoning is problematic if the parallelogram is not precisely a rectangular shape.

Using Knowledge of Relationships between Area Formulas for Rectangles and Parallelograms to Reason with a Dynamic Image

With prompting, Charlotte carefully drew each rectangle in Figure 2(right) she was imagining forming separate from the corresponding instance of a parallelogram. She was explicit about constructing the *y* length to remain constant and the heights to decrease. When asked if it now looked like the rectangles were getting smaller, she said, "Yep. Now they do. It's easier to see like through the rectangle than when it's slanted. Especially since like I got something to compare. So like, here [*pointing to the parallelogram*], I can't necessarily see that *y* is the same, but since I like made a conscious effort to draw these lines the same, I can tell that these are-the distances between both of them are getting smaller." At this point, the quantitative structure Charlotte constructed was sufficient for her to reason using directional covariation.

Alexandria similarly constructed an image of directional covariation, and she also thought the growth in area was proportional to the angle measure and spent a considerable amount of her activity on this problem trying to find the scale factor to construct a formula. Her image changed when she constructed the corresponding heights for each marked angle measure in her diagram (similar to Figure 1g), and highlighted the segments that represented the change in height for each successive equal change in angle measure (similar to Figure 1h). She concluded, "The change in height increases" and abandoned her idea that relationship was proportional. She proceeded to construct a formula using reasoning the previous section outlined.

Conclusions and Discussion

Alexandria successfully illustrated the potential of reasoning covariationally with quantities constructed in dynamic situations to construct formulas that treat symbols as variables. However, both students' operations were still constrained by their images of both the situation and their formulas in the moment, which perturbed students if their justifications for the relationships they conceived were rooted in (i) images of other quantities changing or remaining constant in the situation (i.e., other angle measures and side lengths) and gross visual comparisons of area at random angle measures (ii) images of formulas as solely representations of measurement processes for static figures. These images impacted their understandings of their formulas.

STUDENTS' CONSTRUCTION OF MATHEMATICAL GENERALIZATION IN A TECHNOLOGY-INTENSIVE INSTRUCTIONAL ENVIRONMENT

Xiangquan Yao
Pennsylvania State University
xzy73@psu.edu

Generalizing is widely considered to be essential to the learning and doing mathematics. Using design experiment methodology this study investigates middle school students' construction of mathematical generalization when learning geometric transformations in a technology-intensive instructional environment. The study reported different types of mathematical generalizations students constructed when engaged in instructional activities about geometric transformations.

Keywords: Mathematical Generalization, Dynamic Geometry Software

Making generalization is fundamental to mathematics and a crucial component of mathematical thinking. Developing learners' capacities towards making and justifying generalizations about mathematical relationships has been a pivotal goal of mathematics education for decades (Davydov, 1990). Indeed, three of the eight Standards (i.e., reason abstractly and quantitatively, look for and express regularity in repeated reasoning, and look for and make use of structure) for Mathematics Practices in Common Core State Standards for Mathematics directly relate to generalizing activities. Despite this, literature continues to highlight challenges associated with developing K-16 learners' abilities to generalizing mathematical ideas. To develop instructional activities that help students become more proficient at constructing mathematical generalization, it is important to understand the forms that the constructive process might take and the conditions that might affect the ways that individuals engage in the construction of mathematical generalizations. Meanwhile, researchers have provided evidence that mathematics-specific cognitive technologies influence both the technical and conceptual dimensions of a mathematical activity (Zbiek, Heid, Blome & Dick, 2007). The current study aimed to understand students' construction of mathematical generalizations in a technology-intensive instructional environment and was guided by one questions: (1) what mathematical generalizations do students construct when learning geometric transformations in a technology-intensive instructional environment?

Theoretical Framework

When studying students' construction of a mathematical generalization, we need to consider what comes before generalizing, what becomes generalized, and what generalizing yields. Pirie and Kieren (1994) perceived mathematical understanding as dynamic, leveled but nonlinear, recursive process. According this model, *Primitive Knowing* is the starting place for the growth of any new mathematical understanding. When *Image Making*, a learner engages in specific activities aimed at helping him to develop initial conceptions and ideas for the meaning of a mathematical object. By the stage of *Image Having*, a learner can carry out these specific activities with a general mental plan. At the layer of *Property Noticing*, a learner reflects on his mental image and recognizes attributes and features of it. When *Formalizing*, a learner abstracts a method or common quality from the previous image and has a class-like mental object that is not dependent on meaningful images. When *Observing*, a learner reflects on and coordinate such formalizing activity and express such coordination as theorems. *Structuring* occurs when a learner is aware of how a collection of theorems is inter-related and calls for justification of statements through logical argument. Pirie and Kieren's model provides a useful framework to trace the development of a mathematical generalization in the continuum of mathematical understanding.

Methodology

This study was frame by a design experiment methodology (Cobb et al., 2003). The goal of this design experiment was to explore how students construct mathematical generalizations when interacting with the teacher and dynamic geometry software in learning geometric transformations and what sorts of interventions become important in facilitating students generalizing practices. The participants were 7 middle school students who enrolled in a summer enrichment program for two weeks. Prior to this design experiment, a pre-assessment was designed to gather information about students' understanding of geometric transformations. Van Hiele-like levels of learning geometric transformations (Soon, 1989) was used to guide the design of the pre-assessment. Data from the pre-assessment indicated all the participants were able to recognize geometric transformations and perform transformation motions. This data was used in designing activities for the planned experiment. The transformation unit in the design experiment focus on examining properties of geometric transformations, identifying defining parameters of geometric transformations, and exploring composition of transformations.

Data processing and analysis consisted of three phases. In Phase I, each piece of video data was segmented based on transitions in mathematical activities. Generalizing episodes were then identified within those mathematical activities. In particular, an instructional activity was identified as a generalizing episode if the participants were engaged in at least one of the following four activities: (1) identifying a property of a mathematical object, (2) extending one's reasoning beyond the range in which it originated, (3) searching for a procedure, and (4) deriving a generality from known properties. Each generalizing episode was then transcribed verbatim. The transcript included descriptions of the participants' interactions with the teacher and technology. In Phase II, Pirie and Kieren's (1994) model was used to trace the development of each generalizing episode. Critical moments of interactions among the participants, the teacher, and the technology were included in each event map. In Phase III, all of the observations, conjectures, and generalizations which the participants shared in each generalizing episode were identified and categorized based on their level of generality and connections to a broader mathematical structure.

Results

The participants in the study constructed a variety of mathematical generalizations when engaged in activities related to geometric transformations. Based on their levels of generality and attentiveness to broader mathematical structures, these generalizations were categorized into three types: property-based generalizations, construction-based generalizations, and theory-based generalizations. *Property-based generalizations* are mathematical properties abstracted from empirical cases and extended beyond the cases in which the properties originated. *Construction-based generalizations* are construction procedures that allow learners to produce desired configurations through using a series of primitive construction commands. *Theory-based generalizations* are mathematical statements learners deduce from definitions, properties, and theorems through chains of logical reasoning. In this study, 44 generalizations were shared in 14 generalizing episodes. Among these generalizations, 24 were property-based generalizations, 8 were construction-based generalizations, and 12 were theory-based generalizations. Table 1 summarizes the frequencies of the different types of generalizations and the number of generalizing episodes in which each type of generalization was observed. Note that the total number of generalizations reported in Table 1 only includes those that the participants shared during whole-class discussions. Analysis of participant artifacts revealed that some of the generalizations that the participants constructed were not shared during whole-class discussions. Therefore, the total number of generalizations reported in the table may not be representative of the total number of generalizations participants produced during the study. Further, the participants often produced more than one generalization within one generalizing episode.

Table 1: Types of Mathematical Generalizations

Type of Generalization	Number of Generalizations	Number of Generalizing Episodes
Property-based generalization	24	10
Construction-based generalization	8	7
Theory-based generalization	12	4
Total	56	14

Although property-, construction-, and theory-based generalizations vary in their levels of generality and attentiveness to broader mathematical structures, they are closely linked. Property-based generalizations can be assembled to form a construction-based generalization form a geometric construction. Construction-based generalizations rely on properties of geometric objects, which might come from property-based or theory-based generalizations. A figure produced through a geometric construction is essentially a conceptual entity, although the figure might mobilize perceptual activities. In a dynamic geometry environment, a geometric construction can lead to the discovery of a new generalization or extension of the domain of validity of an existing generalization. Theory-based generalizations are generalizations that learners construct through reasoning about properties of mathematical objects. Explicit use of mathematical structures to deduce new knowledge characterizes theory-based generalizations. A theory-based generalization might build on a property-based generalization and it can also be used to form a geometric construction. Numerical and visual-graphical evidence plays an important role in the discovery of the properties and relationships of geometric objects.

Analysis of event maps of the generalizing episodes revealed patterns of distribution of the different types of generalizations along the layers of mathematical understanding. *Property-based generalizations* occurred frequently at the *Property Noticing* and *Formalizing* stages. *Construction-based* and *theory-based generalizations* were advanced at the *Formalizing* layer. The distribution of these types of generalizations suggested that the *Formalizing* stage included property-, construction-, and theory-based generalizations. Therefore, Property Noticing and Formalizing were the two main layers of understanding at which generalizations became observable. The fact that the Formalizing level included three types of generalizations revealed that mathematical ideas constructed at the same layer of understanding might have different natures and levels of generality. Although property-, construction-, and theory-based generalizations became observable only at the *Property Noticing* or *Formalizing layers*, *Image Making* and *Image Having* activities were crucial in the construction of generalizations, especially when the participants could not immediately develop a useable mental image for solving the problem at hand. Indeed, event maps of the exemplary generalizing episodes illuminated that Image Making and Image Having activities were prominent in many generalizing episodes.

Generalizing Episode 1 illustrates the findings from this study. In this generalizing episode, the teacher created an image of a 180° rotation and an image of a reflection to demonstrate the concept of orientation preserving and then asked students whether or not the image of the rotation could be produced by a reflection. The students made a conjecture that the composition of two reflections could produce the same image as the 180° rotation. After two attempts, the two images still did not match. The teacher then engaged the students in *Image Reviewing* and pointed out that the two images shared the same orientation. In response to the *Image Reviewing* activity, another student suggested translating the image of the composite reflection to the image of the 180° rotation. The student then made the two images match through continuously dragging and adjusting the two segments (*Image Making*). After the students made the two images match, the teacher asked what they noticed about the two reflection lines. The students observed that the two segments seemed to be perpendicular and verified their observation with measuring tool in GSP (*Property Noticing*). The teacher then asked the students how to find the two reflections if the angle of rotation is 75°. Students made a conjecture that the angle of the two reflection lines might be 37.5° since, in the previous case, 90° was one half of 180° ((*Property Noticing*). In an attempt to find the two reflection lines, the students folded back to *Image Having* and asked the teacher to draw two segments whose angle was 37.5°. The teacher drew the two segments, adjusted their angle to 37.5°, and executed the two reflections. It turned out that the two images did not match. The students then folded back to *Image Making* and tried to move the two reflection lines to match the two images. The teacher pointed out that the two segments shared an endpoint which might cause the problem (*Image Reviewing*) and then demonstrated how to construct two reflection lines with a fixed angle measure (*Primitive Knowing*). After the teacher constructed the image of the composite reflection, the students noticed that the center of rotation was the point of intersection of the two reflection lines when the two final images matched (*Property Noticing*). The teacher then asked students to find the two reflections whose composition would produce the same image as that given by a 125° rotation with a minimum number of guesses and checks. In doing so, the teacher moved the students in the direction of formalizing a general procedure for finding two reflections. The students suggested drawing two segments passing through the center of rotation with a fixed angle of 62.5° (*Formalizing*). This indicates that the students were starting to formalize the procedure. The teacher then synthesized this formal procedure and asked students to draw a picture to capture this generalization.

MIDDLE GRADE STUDENTS' UNDERSTANDING OF MEDIAN AND MODE

Md Amiruzzaman
Kent State University
mamiruzz@kent.edu

Keywords: Middle School Education, Learning Trajectories (or Progressions)

Measures of Central Tendency (MOCT), which include mean, mode and median, are important mathematical/statistical concepts; hence, they are typically included in mathematics curriculum as early as middle grades (Amiruzzaman & Kosko, 2016). However, most research related to MOCT has generally focused on the teaching and learning of arithmetic mean, with a little study of median or mode (Amiruzzaman & Kosko, 2016; Amiruzzaman, Kosko, & Amiruzzaman, 2017). In the past, a few studies focused on students' conceptions of median and/or mode have found that high school and college-level students tend to have more difficulty calculating median and mode than the arithmetic mean (Amiruzzaman & Kosko, 2016; Amiruzzaman, Kosko, & Amiruzzaman, 2017). This study focused on a small group of middle grades (i.e., sixth-grade) students, especially to perform more in depth analysis of students' initial understanding and how their understanding has developed through actions of working with mathematical problems and manipulative. In this study, a classroom based teaching experiment was used to build our models of participants' conceptions of median and mode. Total of six students (5 males and 1 female) participated in the study, and the study consisted of 14 teaching experiment episodes (approximately 45-50 minutes/episode) across 14 weeks in spring 2015. The initial tasks focusing on median and mode for the initial episode were prepared ahead of time; however, tasks for following episodes were prepared based on the analysis of the prior episode. This study presents data from episodes 6 to 8 to illustrate preliminary findings for learning trajectories of the participating students, Alice and Bob.

In episode 6, both Alice and Bob described the median as the middle value of a data set, and generally were able to identify the median with data sets with an odd number of elements. However, when Alice and Bob were asked to find the median for data with an even number of elements, both of them that claimed there was no median. In episode 7, both Alice and Bob described that a dataset may have only one mode. However, in episode 8, it was observed that a number-line manipulative helped Alice and Bob to understand the concepts of median and mode better. The findings of this study indicate that middle grade students' conceptions of median and mode may require a more visual manipulation of the data elements. Working with data and seeing how the data elements are distributed helps to understand the concepts of median and mode better. One of the implications of this study is that students' conception of the median and mode are more complex than previously recognized. In regards to practice, these findings suggest that practitioners (i.e., mathematics teachers) should use manipulative, so that students could manipulate data and understand its distribution before they learn about the definitions of these concepts.

COLLEGE ALGEBRA STUDENTS' CONCEPT IMAGES OF PARABOLAS

Monica Anthony
University of Maryland, College Park
mrd@umd.edu

Keywords: Cognition, Post-secondary Education

Concept image is the set of all mental pictures associated with the concept name and the properties associated with the concept, acquired through experiences with examples and nonexamples of the concept (Tall & Vinner, 1981). Given the importance of representations in developing understanding of mathematical concepts, this study documents the concept images of parabolas held by students in a college-level Algebra class, and identifies potential influences on students' understandings. Students' concept images of parabolas are of interest because parabolas are both mathematical objects and representations of symbolic algebra.

Clinical interviews were conducted with two students from a college-level Algebra course at a large mid-Atlantic public university. The cognitive tasks during the interview aimed to activate different parts of students' concept image of parabola. A representational fluency analytical framework was used to characterize the coherence of students' concept images, as the level of coherence of an individual's concept image impacts their ability to successfully navigate between the elements. In addition to clinical interviews, select sessions of the college Algebra course were observed and the assigned textbook was examined, providing insight to potential influences on students' concept images.

Findings suggest that participants' concept images are not coherently connected, as demonstrated by their low levels of sophistication in representational fluency. Both participants relied on the algebraic definition of parabola, as a graph of a quadratic function, throughout the tasks. Participants were preoccupied with remembering rather than reasoning. Despite awareness of processes and procedures regarding parabolas and quadratic functions, participants were unsuccessful in transposing within and translating between representations. Participants acted inconsistently across the different tasks, suggesting that different elements of their concept images were activated. Participants showed a lack of understanding of the parabola's vertex, possibly due to the over-emphasis on solving for only one coordinate of key points when graphing parabolas in both the course textbook and lecture. Although participants in this study completed advanced mathematics courses at the secondary level, their intellectual behaviors during the clinical interviews reflect those of secondary students who are learning about parabolas or quadratic functions for the first time, as seen in related research. Thus this research suggests that emphasis on symbolic manipulation and algorithms at the secondary and early college level may fail to facilitate students' visualization of concepts and create the relational connections between symbolic and graphical representations that are necessary for conceptual understanding.

Instrument development should adhere to the *Standards* (AERA et al., 2014). "Content-oriented evidence of validation is at the heart of the [validation] process" (AERA et al., 2014, p. 15) and is one of the five sources of validity evidence. The research question for this study is: What is the evidence related to test content for the three instruments called the PSM3, PSM4, and PSM5? The study's purpose is to describe content validity evidence related to new problem-solving measures currently under development. We have previously published validity evidence for problem-solving measures (PSM6, PSM7, and PSM8) that address middle grades math standards (see Bostic & Sondergeld, 2015; Bostic, Sondergeld, Folger, & Kruse, 2017).

We chose a design-science based methodology to develop the PSM series. This methodology is useful for measure development, gathering data from the measure, drawing reasonable conclusions from the data, revising the measure, and repeating the cycle. Three forms of data were collected sequentially to explore test content validity evidence. Our data analysis approach used traditional methods (Sireci & Faulkner-Bond, 2014). Broadly speaking, all reviewers on the expert panel agreed the items were open, complex, and realistic. Mathematicians confirmed that each item could be solved in two or more ways. Students expressed that the items were complex, solvable, and realistic.

Results indicated that items were both representative and relevant of the construct. Supplementing this conclusion with the knowledge that the definition is sufficiently bounded and test construction followed the *Standards* (AERA et al., 2014), leads to a conclusion that the PSMs have adequate test content validity evidence. This is the initial step in building a validity argument; next steps are to gather evidence related to response processes, relations to other variables, internal structure, and consequences from testing.

TEACHING RATE OF CHANGE TO STUDENTS WITH DISABILITIES USING AN INTEGRATED CONCRETE-REPRESENTATIONAL-ABSTRACT APPROACH

Kaitlin Bundock
Utah State University
Kaitlin.bundock@usu.edu

Sharlene A. Kiuhara
University of Utah
s.kiuhara@utah.edu

Rate of change is a challenging area of mathematics spanning multiple grades and courses, and is related to functional skills such as accurately reading maps and calculating interest (Herbert & Pierce, 2012). To date, no research has been conducted to determine effective ways to teach rate of change to students with disabilities. Across multiple grade and ability levels, instruction incorporating an integrated concrete-representational-abstract (CRA-I) approach increases math achievement (Strickland & Maccini, 2012). CRA-I is often paired with cognitive strategies instruction, such as problem-solving heuristics, as well as student verbalizations to help build conceptual understanding (Watt, Watkins, & Abbitt, 2016). Writing To Learn (WTL) may provide a platform for incorporating problem-solving heuristics and written explanations of student thinking into CRA-I interventions, with the goal of increasing students' conceptual and procedural understanding of rate of change (Gersten et al., 2009).

In this study, we used a single-subject multiple-probe design across participants to evaluate whether an intensive intervention consisting of CRA-I, a problem-solving heuristic, and writing to learn helped ninth-grade students with disabilities improve their understanding of rate of change. The participants included four ninth-grade students with disabilities below state proficiency levels in math. Results indicated that the multi-component intervention, implemented across seven weeks, may improve students' with disabilities understanding of rate of change. All four students improved their scores on math assessments, and maintained improvements on post-instruction assessments administered one to seven weeks following the completion of the intervention. Two of the four students also moderately improved their scores on writing assessments. The results of this study support the use of instructional strategies, such as CRA-I, heuristics, and writing, that build both conceptual and procedural knowledge. Additionally, the results of this study indicate the importance of incorporating writing activities in math to help students develop the ability to explain and justify their reasoning.

The research questions explored include: (1) What is the effect of implementing an integrated concrete-representational-abstract (CRA-I) instructional sequence incorporating writing to learn and cognitive strategies on students with disabilities' proficiency in solving rate of change problems, and (2) Do students with disabilities find the multi-component (CRA-I + writing to learn + cognitive strategies) intervention to be socially acceptable?

AN ANALYTIC FRAMEWORK FOR ASSESSING STUDENTS' UNDERSTANDING OF PROOF COMPONENTS

Kimberly Conner
University of Northern Iowa
kimberly.conner@uni.edu

Keywords: Reasoning and Proof, Assessment and Evaluation, High School Education

Researchers have used a variety of frameworks to evaluate students' work that differ in focus but all yield a single score or level (e.g., Healy & Hoyles, 2000; Knuth, Choppin, & Bieda, 2009; Lee, 2016). By assessing students' work holistically, none of the frameworks are able to differentiate, for example, between instances whether an empirical solution was produced due to the student's content knowledge or to their understanding of proof (e.g., Knuth et al, 2009). For students who are still learning to construct proofs, attention to multiple characteristics of their work can serve to not only characterize students' current understanding but also suggest possible areas for growth in their mathematical and proof understanding.

The proposed framework (Table 1), based on Stylianides (2007) definition of proof, attends to multiple aspects of students' work, including categories that assess whether students demonstrated an awareness of a proof component (e.g., attention to the justification requirement) and categories that assess students' ability to correctly apply the given component (e.g., uses mathematically accurate justifications). The poster will include examples of 9th graders' coded work, produced at the end of an introduction-to-proof design research study, selected to illustrate the framework and the distinctions between it reveals. As the field seeks to move the teaching and learning of proof in K-12 classrooms forward, it is important that we look for ways of identifying the skills and understanding students have developed, which can then be leveraged in future instruction.

Table 1: Analytic Framework for Assessing Students' Understanding of Proof Components

Stylianides (2007) definition	**Framework Categories**	
A connected sequence of assertions	Assertions follow a logical flow	Identifies and uses the correct hypothesis
Uses set of accepted statements	Attention to the justification requirement	Uses mathematically accurate justifications
Modes of argumentation	Attention to the generality requirement	Overall type of argument
Modes of argument representation	Forms of expression used	Relationship between written text and other forms of expression, if applicable

UNDERGRADUATE STUDENTS' CONSTRUCTION OF GENERAL STATEMENTS

Duane Graysay
Syracuse University
dtgraysa@syr.edu

Introduction

Construction of general statements is essential mathematical activity (Mason, 2008). Advanced mathematical study should support students' development of abilities to generalize and conjecture (CUPM, 2015). This is particularly important for undergraduate students who self-select to pursue careers in studying and teaching mathematics. Understanding how students construct such statements can help instructors plan to support students' development of mathematical practices. This presentation shares findings of empirical research into the question: How do undergraduates in mathematics-intensive degrees, near the end of their degree programs, approach the construction of general statements?

Method

Six secondary mathematics education majors and four mathematics majors, each within three semesters of completing their mathematics program of study, were recruited from a large Mid-Atlantic public university. Data were collected via individual task-based interviews. Tasks were *populating tasks,* defined as tasks that present a set of *general properties* that could be true for some, but not all, elements in a broad collection. The broad collection is the *universe* of the task. The task prompts are to identify a *domain,* i.e., a subset of the universe, describing cases that have the general properties. Using inductive, qualitative methods (Corbin & Strauss, 2008), responses were sorted by similarities in ways of using cases, descriptions of sets within the universe, and inductive or deductive reasoning. Essential characteristics of each category were identified and used to characterize the category as an *approach.*

Findings and Implications

Approaches fell into three broad categories: Generalizing, Specializing, and Direct. Generalizing approaches involve forming an initial domain case-by-case, then expanding that domain. Approaches differed in the method of expansion: either by inductively describing a set containing the cases, or by systematic testing of new cases to eliminate nonessential characteristics, thus expanding the domain. Specializing approaches involve generating sets to satisfy a subset of general properties, then reducing the initial sets to a subset satisfying all of the general properties. A Direct approach involve deducing logically necessary characteristics for a case to have the general properties. The use of specific cases and inductive reasoning by these students, though useful, has implications for those who go on to further study in areas of mathematics in which specific cases are difficult to construct and for those whose future careers involve shepherding the growth of deductive reasoning in others.

QUANTIFYING ANGULARITY: CIRCLES OPTIONAL

Hamilton L. Hardison
Texas State University
HHardison@txstate.edu

Keywords: Cognition, Geometry and Geometrical and Spatial Thinking, High School Education

Angle measure is a pervasive topic in school mathematics and is often introduced in the elementary grades. Extant literature (e.g., Moore, 2013) and standards (e.g., CCSSM) have emphasized quantifications (Thompson, 2011) of angularity whereby multiplicative comparisons of circular arcs are used in service of measuring angles. Although circular quantifications of angularity are productive, mathematics educators cannot take for granted that all students can make the requisite multiplicative comparisons, much less generalize them as holding invariant across all circles. Therefore, examining other quantifications of angularity is paramount.

I present two non-circular quantifications of angularity, which I abstracted from my conceptual analysis (von Glasersfeld, 1995) of two ninth-graders' activities throughout a yearlong teaching experiment (Steffe & Thompson, 2000) focused on quantifying angularity. Rather than measuring angles by measuring arcs, Bertin and Kacie each developed quantifications of angularity entailing extensive quantitative operations (Steffe & Olive, 2010) enacted on the interiors of angles (e.g., angular iteration). Additionally, both students established re-presentable templates for familiar angles (e.g., right, straight, and full angles), and permanently assigned these templates dedicated degree measures (e.g., a right angle is a 90° angle). Bertin and Kacie could make and measure other angles by subdividing these familiar templates into equiangular parts and performing corresponding numerical computations on the dedicated measures. A distinguishing factor in Kacie's and Bertin's quantifications was how each student mentally subdivided angles into smaller equiangular parts. Bertin indicated the equipartitioning operation (i.e., the *simultaneous* insertion of same-sized parts intended to exhaust a whole). In contrast, Kacie indicated the equisegmenting operation (i.e., the *sequential* insertion of same-sized parts intended to exhaust a whole). Although both students constructed powerful quantifications of angularity, neither student developed a circular quantification of angularity during the teaching experiment; therefore, I hypothesize extensive quantifications of angularity necessarily precede circular quantifications of angularity. As such, students in elementary grades may be better supported if teachers begin instruction in angle measure with the intent of fostering extensive quantitative operations on angles (e.g., iterating and partitioning). At the very least, students who develop non-circular quantifications of angularity should be celebrated in mathematics classrooms.

Keywords: mathematical modeling, cognitive resources, mathematics achievement

Mathematical modeling (Lesh & Doerr, 2003) is a thinking process in which students need to apply a wide range of cognitive attributes – one component of intellectual resources related to knowing-how (Bailin, 2002). Students can develop cognitive attributes in mathematical activities and some of those cognitive attributes are used when students solve test problems. Common cognitive attributes used in mathematical modeling and solving test problems – *analyze*, *select*, *compute*, and *represent* in this research (adopted from the TIMSS 2011 assessment framework; Mullis, Martin, Ruddock, O'Sullivan, & Preuschoff, 2009) – allow us to connect mathematical modeling as classrooms practices and mathematics achievement. Thus, the purpose of this research is to quantitatively and empirically investigate the relationships between students' development of mathematics cognitive attributes and their achievement.

We collect data of students from grades 4 to 8 (over 15,000 students at each grade) who took the Iowa Assessment from 2006 to 2012. We apply the generalized DINA (GDINA; de la Torre, 2011) to students' responses, which produces a database about sets of cognitive resources individual students are expected to attain. In the secondary analysis, students' national standard scores are matched to their mastery patterns. Then, the linear regression analysis is employed to show which cognitive resource contribute to better mathematics achievement while effect sizes of each cognitive attribute are estimated.

The findings show that the four cognitive attributes together are positively correlated to mathematics achievement. In addition, students who master *select* or *compute* are likely to have higher achievement scores with large degrees of effects. Master of *analyze* is also important only with a combination of mastery of *select*. Longitudinally, *select* and *analyze,* which are used at the beginning stages of mathematical modeling, have maximum effects on achievement at grade 7. The effect sizes of *compute* seems monotone increasing from grade 4 to 8 with a remarkable drop at grade 7. The effect sizes of *represent* are generally small showing a gap between middle and elementary school levels.

We suggest several implications based on the findings: students need to have opportunities to develop the four cognitive attributes based on the positive relationships between mathematical modeling and achievement. However, teachers need to have instructional emphases on different stages of mathematical modeling depending on grade levels: representing a solution at elementary-school levels because of the effect size gap, analyzing a problem situation and selecting strategies at middle-school levels, and computation across grades 4 to 8.

ELEMENTARY STUDENTS' ATTEMPTS TO IDENTIFY AND JUSTIFY PATTERNS WITH A GRAPH THEORY PROBLEM

Jenna R. O'Dell
Bemidji State University
jodell@bemidjistate.edu

Keywords: Elementary School Education, Problem Solving, Reasoning and Proof

Elementary students are not typically encouraged or given the opportunity to provide generalizable arguments in mathematics classes (Carpenter, Franke, & Levi, 2003). When they are given the opportunity, they generally limit their argument to giving an example. However, it has been documented that elementary students are capable of making conjectures and developing mathematical claims (Ball, 1993). Many researchers have recommended that all students in all grade levels should engage in mathematical proof and reasoning (e.g., Carpenter et al., 2003; NCTM, 2014). In this study, I explored whether students were able to provide justifications or state generalized patterns of a graceful label for different types of tree graphs.

Ten Grade 4 and 5 students participated in seven semi-structured, task-based interviews (Goldin, 2000). The interviews each lasted between 35 and 45 minutes and took place at an after-school program in the Midwest. During the interviews, students worked on the Graceful Tree Conjecture. They examined graceful labelings of star graphs, path graphs, and caterpillar graphs. All interviews were video recorded, transcribed, and analyzed. For analysis, I documented each instance where students found patterns or made a mathematical argument.

I found that all of the students were able to describe patterns for gracefully labeling star graphs. Three students found and described patterns for path graphs, but all ten students were able to find a graceful label. For caterpillar graphs, three students described a pattern they found through trial-and-error, and three students used their pattern from path graphs to develop a pattern for caterpillar graphs.

When students present an argument, they either appeal to authority, use an example, or give a generalized argument (Carpenter et al., 2003). I found because of the nature of the problem—graph theory—the students had no prior experience and thus they were not able to appeal to authority. The most common way students tried to justify their pattern was through providing an example. When asked how they knew that a labeling was graceful, the students would explain their pattern using a one specific example. One student even went as far as explaining her labeling would work for a graph containing 20 nodes. Several times the students would attempt to give a generalizable argument, but they struggle with the knowledge of how to do that and did not have the appropriate language.

EXAMINING TEACHER CANDIDATES' RESPONSES TO ERRORS DURING WHOLE-CLASS DISCUSSIONS THROUGH WRITTEN PERFORMANCE TASKS

Erin E. Baldinger	Matthew P. Campbell	Foster Graif
University of Minnesota	West Virginia University	University of Minnesota
eebaldinger@umn.edu	mpcampbell@mail.wvu.edu	fgraif@umn.edu

Effectively leading whole-class mathematics discussions is made more difficult when students' contributions are incomplete, imprecise, or not yet correct, and not easily correctable—what we call "errors." Through purposefully designed opportunities to investigate, enact, and reflect on teaching, teacher candidates (TCs) can develop skill to productively respond to errors in whole-class discussions. We investigate how TCs respond to errors when engaging in a written performance task that calls for TCs to play out discussions in response to a classroom scenario. We consider what the performance task reveals about TCs' practice and perspectives, with implications regarding theory and practice.

Keywords: Teacher Education-Preservice, Instructional Activities and Practices

Whole-class mathematics discussions are critical spaces in which students can participate authentically in mathematics and develop a broad set of mathematical proficiencies and practices (Kilpatrick, Swafford, & Findell, 2001). Effectively leading discussions is complex work comprised of eliciting, responding to, and building upon student contributions toward mathematical goals (Boerst, Sleep, Ball, & Bass, 2011). Contributions that are incomplete, imprecise, or not yet correct present an additional challenge for teachers wanting to keep student reasoning central, make progress toward identified goals, and not convey erroneous ideas. We contend that, through purposefully designed opportunities for representing, decomposing, and approximating practice (Grossman et al., 2009), teacher candidates (TCs) can develop skill to productively respond to student errors in whole-class discussions. We share our use of written performance tasks in which TCs produce dialogues and rationales for their dialogues in response to a classroom scenario. Our analyses provide a window into TCs' practice and perspectives and offer implications regarding theory and practice of mathematics teacher education.

Literature Overview

All mathematics teachers have the opportunity to respond to student errors as part of the work of teaching, and there is a robust literature base exploring the role of errors in the mathematics classroom. Understanding teacher responses to student errors requires first defining the term "error." Nesher (1987) argues that making errors are the way in which students contribute to their own learning process. This perspective is echoed in later literature, which emphasizes viewing students as sense-makers and identifying opportunities to build on student thinking (e.g., Van Zoest et al., 2017). Following Brodie (2014), we define errors as incomplete, imprecise, or not yet correct contributions that are more complex than mistakes that are easily correctable. Errors occur "among learners within and across contexts" (Brodie, 2014, p. 223), and move beyond mistakes such as misspeaking or accidently doing an incorrect computation. Taking this view on the role of errors makes it imperative to understand the ways in which teachers respond to errors. One common approach is for teachers to make corrections (e.g., Tulis, 2013), quickly highlighting the error and introducing correct ideas into the discussion. Another approach is to avoid errors (e.g., Bray, 2011; Santagata, 2005) and steer the conversation toward correct contributions. These actions potentially remove the opportunity for students to make sense of errors. If students make sense of mathematics at least in part through their errors, then productive teacher responses ought to support that sense-making. Teachers must notice students' mathematical reasoning (Jacobs, Lamb, & Philipp, 2010) and navigate the in-the-moment work of building understanding (Bray, 2011; Leatham, Peterson, Stockero, & Van Zoest, 2015).

An added layer of complexity in responding to errors results from the context in which the error occurs. In whole-class discussions, the teacher must navigate the needs of the student who contributed the error along with the needs of the rest of the class, who may or may not share that student's conception. Leading whole-class discussions requires responding to student reasoning and making student contributions central to the mathematical work of the class (Boerst et al., 2011). In this context, teachers must find ways to navigate making student contributions central at the same time as a desire to have the conversation focus on correct responses. We extend the work on both errors and whole-class discussion in secondary mathematics by considering whole-class discussions as the particular context for responding to errors. We examine the ways in which teachers may respond to errors through analyzing representations of their practice.

Theoretical Framework

We take the perspective that, to develop skilled practice, TCs must not only have opportunities to think about and reflect on teaching using representations of practice such as observation, written vignettes, and video, but also the opportunity to approximate the work (Grossman et al., 2009). This can occur when TCs meaningfully engage in interactive and contingent aspects of teaching in settings of reduced complexity and authenticity. Through opportunities to enact teaching practices in response to student contributions, TCs demonstrate and further develop adaptive skill that coordinates pedagogical approaches, the goals of a particular approach, and a vision of mathematics teaching (Ghousseini, Beasley, & Lord, 2015). These opportunities also provide a lens for teacher educators and researchers to assess TCs' developing practice and their coordination of approaches and goals.

This theoretical perspective frames our use of pedagogies such as coached rehearsals (Lampert et al., 2013), and as teacher educators and researchers we strive to find multiple approximations and strategies for assessing TCs' practice. We use written performance tasks (e..g, Bray, 2011) as an additional way to put TCs in the position to make sense of and respond to student reasoning. In designing these tasks, we draw on research around scripting classroom interactions (Crespo, Oslund, & Parks, 2011; Zazkis, 2017). TCs are presented with a realistic classroom scenario involving whole-class discussion and student errors. TCs demonstrate, through written dialogue, how they might continue the discussion. These dialogues represent, in part, TCs' imagined response to a particular student contribution. They also represent TCs' sense of how students might contribute further, giving insight into TCs' view of what is reasonable or desirable in a classroom episode. TCs also provided a rationale for why they continued the discussion the way they did. In this paper, we explore what these performance tasks say about TCs' developing practice, building on preliminary work (Campbell, Baldinger, Selling, & Graif, 2017). We ask: (1) what are the features of TCs' dialogues written in response to a student error made during a whole-class discussion; (2) what are the features of TCs' rationales for their dialogues written in response to a student error made during a whole-class discussion; and (3) in what ways do TCs' dialogues relate to their rationales, and what do these relationships suggest about TCs' coordination of approaches and goals in their responses to student errors in whole-class discussions?

Methods

We describe our analyses of one performance task we designed, with a scenario centered on the use of a card sorting activity (Baldinger, Selling, & Virmani, 2016) intended to elicit and refine the following definition of a polygon: “a 2-dimensional (plane) figure, where each side is a straight-line segment that intersects exactly one other side at each endpoint.” In the scenario, the whole-class discussion began after students had worked in small groups. The teacher asked for students to name cards that they easily knew were polygons. One student, Rosalia, offers Shape Q (see Figure 1) and, after a back-and-forth with the teacher, shares that it is a polygon because “it is a square” and that “all the sides are straight lines.” After the teacher asked for another example of a polygon, Jessie offers Shape J (see Figure 1), stating that it was square, like Shape Q. TCs dialogues began following Jessie’s contribution. After writing their dialogues, TCs wrote rationales describing why they continued the discussion as they did.

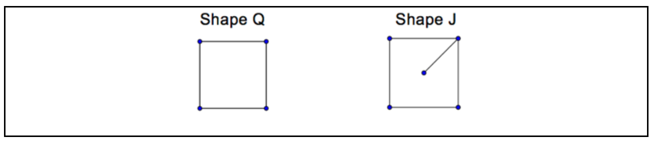

Figure 1. Two cards presented in the scenario as examples of polygons

We collected responses from 25 secondary mathematics TCs in methods courses at two large, public research institutions. Seventeen participants were engaged in a yearlong post-baccalaureate licensure program at one institution. Eight participants from a second institution were enrolled in a shared methods course across multiple licensure programs. The methods courses in both programs incorporated practice-focused teacher education pedagogies, such as coached rehearsal. The full performance assessment (including two scenarios) was administered using Qualtrics in October 2016. TCs completed the assessment individually during the methods class. Response times for the full assessment ranged from 11:24 (minutes and seconds) to 42:37, with a median duration of 25:34.

We used a priori and emergent codes to describe features of TCs’ response to student errors in the dialogues. Examples of codes included talk moves used by TCs, such as re-voicing (Chapin, O’Connor, & Anderson, 2013), asking funneling or leading questions, and a focus on comparing the two shapes. We used similar codes to describe the features of TCs’ rationales. Examples of codes for the rationales included the rationale mentioning wanting to resolve the error, or the rationale mentioning the need to recognize and/or value student contributions. Using these codes for the dialogues and the rationales, we developed a series of yes or no questions to ask of each dialogue and rationale. These questions fell into three main categories: attending to the error, attending to the mathematics, and attending to students. Two authors independently answered the questions for each dialogue and rationale. Inter-rater reliability was assessed and disagreements were resolved through discussion.

Next, we engaged in a process of analytic memo writing and theme building (Miles, Huberman, & Saldaña, 2013) to identify the most salient features in the dialogues and in the rationales. As we looked at counts of dialogues or rationales with particular features, we kept in mind that the absence of evidence was not the same as evidence of absence. For example, though 15 TCs explicitly mentioned that Jessie’s contribution contained an error, other evidence demonstrated that all participants understood Jessie’s error. To address the relationships between TCs’ rationale and dialogue, we utilized a matrix highlighting relationships among dialogue features and rationale features (Miles et al., 2013). We used the three categories of questions in our analyses of the dialogues and the rationales to explore connections between the two. This allowed for a coordination of TCs' approaches to responding to errors, as demonstrated through the dialogue, and TCs' goals for responding to errors, as demonstrated through the rationale.

Findings

We report findings for each research question around the three analytic themes: (1) attending to the error, (2) attending to the mathematics of the task, and (3) attending to the students.

Theme: Attending to the Error

RQ1: Features of TCs' dialogues. One striking feature of the dialogues was the way in which the error was resolved or corrected in a few lines. This occurred in nine of 25 dialogues. In five cases, the original student corrected their own error, as in the example below:

> Teacher: It does look like a square but what is different about Shape J and Shape Q?
> Student: There is a line from one corner of the square to the center.
> T: Correct, what do you think we can conclude by noticing the line from the corner?
> S: We can conclude that this is not a polygon, because they are not all connected.

In the remaining four cases, another student corrects or resolves the error. Six additional dialogues included a last turn of talk in which the teacher posed a question that was potentially leading toward resolving or correcting the error through the next student response. These 15 cases illustrate the common approach of resolving errors quickly, and often in a one-on-one exchange between teacher and student, or as the result of a pointed question from the teacher.

In contrast, some TCs wrote dialogues in which the error was not resolved. One TC used a "tabling" move—explicitly pausing the conversation without resolving the error. Five dialogues ended with the teacher asking for a student to contribute a new card to the discussion, which signaled the discussion moving on without immediate resolution of the original error. One TC did not explicitly address Jessie's contribution and centered the dialogue around a third shape:

> T: Does anyone have another example of a polygon?
> S: Shape M [a parallelogram].
> T: Why do you think shape M is a polygon?
> S: All the sides are straight.
> T: Before I get another example, I want us to take a look at what we have up here. How are these shapes up here different from one another? Do we all believe they are all polygons?

This set of cases suggest a recognition of approaches, such as eliciting new ideas, that can continue a discussion while a student error is not necessarily resolved in the moment.

RQ2: Features of TCs' rationales. An explicit part of a majority of the rationales (15 of 25) was an acknowledgement that Jessie has made an error (or, in some TCs' word, a "mistake"). This indicates that: (1) TCs recognized the mathematical issue at hand, and (2) TCs' dialogues were constructed in a way where responding to an error was a key factor. Five of these 15 rationales mentioned wanting Jessie to correct her own error, and six of the 15 mentioned wanting other students to recognize Jessie's error. The different ways in which TCs characterize Jessie's contribution ("misconception", "holes in [her] logic", a key consideration is missing) could impact the way in which TCs conceive of how to respond and, furthermore, what might be convincing to Jessie. These differences could result in different approaches to the dialogue.

RQ3: Relationships between TCs' dialogues and rationales. Of the 15 TCs who mentioned the error in their rationales, six resolved the error in their dialogues. An additional four dialogues approached resolution in their final talk turn. The remainder responded to the error in other ways, such as moving on to discuss a new card. This indicates that for the TCs who focused on the error in their rationales, the typical response was to move toward resolving it, with a smaller number of TCs addressing the error through continued discussion.

It is also interesting to note what is not included in the rationales, given the features of the dialogues. For example, no TCs mentioned that Jessie's error needed to be or could be resolved quickly. While many of the TCs who acknowledged that Jessie's contribution was an error also suggested it needed to be resolved at some point, no one suggested that this would necessarily happen in a few turns of talk. Yet, in many dialogues, the error was resolved or was soon-to-be resolved. We see this incongruity as potentially highlighting an implicit expectation that some conclusion be reached in the assigned five to eight lines of dialogue. It may also be that TCs do not wish to correct an error with their immediate response, but feel that what one TC referred to as, "a few well-placed questions," could be a sufficient way to respond to and resolve an error.

Another example is that no TCs mentioned any external factors, such as time, curriculum, or testing, as influencing their dialogues. While, as an approximation of practice these performance tasks are intended to reduce complexity, it is interesting to see how TCs' dialogues could still have less-than-productive features that are commonly explained by appealing to these constraints. This represents another incongruity, in which TCs do not explicitly appeal to common classroom constraints, yet still put forward a dialogue in which student reasoning and mathematical meaning are not kept central. Overall, these tensions between TCs' approaches and goals highlight the support TCs need around productively responding to errors.

Theme: Attending to the Mathematics of the Task

RQ1: Features of TCs' dialogues. TCs attended to mathematics in their dialogues in several different ways. Almost all dialogues (23 of 25) included a teacher move drawing attention to the difference between Shapes J and Q. Of these 23, 17 dialogues had this as the first teacher move. This approach to the mathematics is necessarily dependent on the particular task being discussed, and some dialogues contained approaches that might be used in multiple contexts. For example, six dialogues used the word "definition". This shows attending to the specific features of a polygon under consideration. Seven dialogues introduced an additional shape to the discussion (as shown in the dialogue above), with the shapes chosen reflecting attention to the features of the definition requiring exploration. The approaches of focusing on the definition and introducing a new example are teaching moves that can be used across contexts. The two TCs who did not explicitly address the differences between shapes J and Q introduced new shapes to the discussion, indicating that all 25 dialogues attended to key mathematical ideas.

RQ2: Features of TCs' rationales. Half (13 of 25) the TCs mentioned moving toward the mathematical goal—establishing and clarifying the definition of a polygon—in their rationales. In some cases, this was fairly general, with references to the "definition" or "objective." In other cases, TCs highlighted specific mathematical features of the goal. For example, one TC explained that their dialogue was constructed in order to support Jessie to, "realize the other defining feature of a polygon, that sides can only meet one other side at the endpoints."

In addition to the 13 TCs who mentioned the goal, eight TCs wrote about a desire to have students consider the differences between Shapes J and Q, though they did not explicitly connect that idea to pursuing the goal of the activity. Five of those eight further specified the key difference that Shape J has an "extra segment" that intersects with two other segments at one endpoint and does not intersect with another segment at the other endpoint. Finally, one other TC generally mentioned students needing to consider "one more property of a polygon."

Altogether, 22 of 25 TCs referenced something related to the mathematics of the activity. There was a strong emphasis on an aspect of the provided definition of polygons that does not come out in either student's contribution—that each side is a line segment that intersects exactly one other side at each endpoint. We use these analyses as evidence that TCs attended to the mathematics of the scenario, which has implications for the dialogue they constructed.

RQ3: Relationships between TCs' dialogues and rationales. The prevalence of attention in TCs' rationales to the mathematics of the scenario is closely connected to our finding that almost all the TCs focused the discussion in some way on the differences between Shapes J and Q. It is possible that focusing students' attention on the differences between the shapes (with a pointed prompt, for example) is seen as the way to make progress toward the goal of the activity.

We identified two interesting exceptions to this trend. The two TCs who did not draw any attention to the differences between Shapes J and Q in their dialogue either elicited a new card from students or offered a new shape that was not represented on another card. These cases illustrate how a discussion, in response to this scenario, can focus on key mathematical ideas without an explicit prompt about the differences. Given the role that introducing a new shape played in dialogues that did not result in a quick resolution of the error, we consider this approach productive, assuming the decisions made about the new shapes are purposeful.

Another exception is represented in the second dialogue above, where the teacher starts by asking for a new card and ends with a question about the differences among the three cards. This TCs' rationale was one of the few that made no explicit reference to the mathematics of the task. Instead, the rationale emphasized a goal that students maintain "skepticism" and be able to "speak up when something does not seem right to them." This provides an interesting case of how a focus on providing space for students to reason, even without mentioning particular mathematical ideas, may give rise to productive approaches to responding to errors.

Theme: Attending to the Students

RQ1: Features of TCs' dialogues. TCs brought students into their dialogues in multiple ways. Nine introduced a new student, sometimes using a new name. Three others reintroduced Rosalia. Some TCs used moves such as orienting students to one another (5), re-voicing (9), recording student thinking (2), and using positive language to describe student thinking (8). "Telling" in the discussion was also sometimes used as a way in which TCs attended to students, and nine dialogues included some form of telling. Many dialogues attended to students using more than one of these approaches, and 21 of 25 dialogues attended to students in at least one of these ways. Of the four remaining dialogues, all included some form of leading or funneling questions, and several were not written as a true dialogue (i.e., not in transcript form), which showed little explicit attention to including student voice. Among the 21 dialogues attending to students, all had a teacher talk turn between every student talk turn. These results highlight the variety of approaches TCs use in imagining responses in these hypothetical scenarios.

RQ2: Features of TCs' rationales. A key feature of the rationales was a desire to respond in a way that valued students' opportunities to reason mathematically. Nine TCs made specific mention of approaches and goals such as: "exploring", "discovery", "comparing", "critical thinking", or "connecting" in reference to student thinking. Four other TCs discussed wanting to value or draw on Jessie's or Rosalia's reasoning. This signals a set of principles in which student reasoning should be supported and made central.

Other TCs' rationales focused on the specific moves they used in their dialogue. Two TCs highlighted "orienting" moves in their dialogue (e.g., having a student re-voice or reason about a peer's contribution). In four other cases, TCs mentioned what we called "telling" moves (e.g., restating and summarizing ideas, giving new examples), and recording ideas. While moves such as these do not necessarily explicitly draw upon student reasoning in the way that orienting moves do, they are powerful moves that support students' sense making and reasoning. Other mention of moves in rationales raised questions for us. For example, some TCs mentioned the use of "guiding questions," positioning this approach as productive. However, as we interpreted these cases, we inferred "guiding" to mean "leading" or "funneling" and not as something that was necessarily responsive to or supportive of student thinking. In total, 18 TCs mentioned valuing student reasoning or using specific teaching moves related to student thinking.

RQ3: Relationships between TCs' dialogues and rationales. We focus here on the four dialogues that were not coded as attending to students. What is striking in these cases is that all four of the related rationales mentioned attending to or valuing students in different ways. For example, one TC wrote that they wanted to "use Jessie's mistake" to "help the class understand." However, this TC did not produce a true dialogue. Rather, they listed questions and answers without any evidence of student voice. Another TC mentioned wanting students to do the mathematical work, saying "The kids need to come up with the other rules and they will end up sorting that out." The associated dialogue in this case has six talk turns focused on the differences between Shapes J and Q, and then a note from the TC that they would "move on from here and see how everything else was sorted to see if we can add to our rule." These findings point to a need to be cautious what taking what a TC says about their approaches and goals for teaching, even in the context of a specific scenario, and making claims about skilled teaching practice.

Discussion and Conclusion

Our use of a written performance task provided a lens for investigating TCs' developing practice. We gained insight into their coordination of approaches and goals related to responding to student errors in whole-class discussion. In both the approaches (represented by the dialogues) and the goals (represented by the rationales), three themes emerged that characterized TCs' perspectives on responding to errors: attending to the error, attending to the mathematics, and attending to students. At times, dialogues and rationales presented approaches and goals in alignment with one another. However, in several notable cases, we observed incongruities between TCs approaches and goals around responding to errors.

Our results suggest several potential areas for growth around teacher learning. In cases where approaches and goals are mostly congruent, we observed TCs wrestling with the dilemmas highlighted in earlier literature around responding to student errors. In the cases where approaches and goals were not congruent, we saw misalignment in two directions. Some TCs wrote about productive goals for responding to errors in their rationales but their dialogues did not have features associated with productive responses. Other TCs wrote dialogues that included productive responses to student errors, but rationales that did not clearly articulate productive goals for their responses. This suggests that part of the work of teacher education is to provide TCs with productive approaches to responding to errors in concert with developing their understanding about why those approaches are productive. Approximations of practice support this work, providing opportunities for TCs to demonstrate and further develop adaptive skill in interactive and contingent moments of teaching.

Next steps for this work include examining the ways in which TCs' responses to the performance tasks change over the course of their participation in the methods course. This will allow us to explore how coordinating approaches and goals changes over time. Additionally, we plan to explore how the responses to the written performance task relate to features of TCs' rehearsals and enactments focused on leading whole-class mathematics discussions.

This paper examines the implementation of an instructional module on Preservice Elementary Teachers' (PSETs) professional noticing of children's mathematical thinking as defined by Jacobs, Lamb, and Philipp (2010). The module focuses on professional noticing skills through the content focus of early algebraic reasoning and uses complex video vignettes from whole class instruction in authentic elementary mathematics classrooms. It was found that two of the three components of professional noticing (attending and interpreting) showed statistically significant increases in a treatment group that did not occur in a comparison group. The deciding component remains a challenge that warrants further research.

Keywords: Teacher Education-Preservice, Teacher Knowledge, Professional Noticing, Algebra and Algebraic Reasoning, Instructional Activities and Practices

Introduction

Developing responsive mathematics teaching practices is a persistent challenge for teacher educators. Over the past decade, teacher noticing and variants of such noticing (i.e., professional noticing of children's mathematical thinking, etc.) have risen in prominence as a construct of great interest among mathematics education researchers (Schack, Fisher, & Wilhelm, 2017; Sherin, Jacobs, & Philipp, 2011). Much has been learned about teachers' development and performance of noticing practices. However, vexing questions remain regarding the fundamental nature of such noticing and the extent to which the practice should be considered a net (capturing as much of the activity as possible) or a filter (distilling the activity to key moments to act upon) (Thomas, 2017). These questions are exacerbated in complex environments featuring multiple actors, converging mathematical topics, and varied avenues for sound instructional decision-making. While research suggests that productive experiences help teachers engage in more sophisticated forms of noticing, in more complex contexts, the impact of such experiences (and even the nature of noticing itself) becomes less clear (Castro-Superfine, Fisher, Bragelman, & Amador, 2017). For this study, we focus on the impact of a professional learning experience conducted with preservice elementary teachers (PSETs) aimed at developing their noticing capacities in a complex mathematical environment. Given our prior focus on noticing performance with respect to individual students' counting/arithmetic strategies (Schack, Fisher, Thomas, Eisenhardt, Yoder, 2013), we elected to contextualize noticing within mathematical activities of multiple children and their early-algebraic reasoning. The research question guiding this inquiry was*: To what extent can teacher educators facilitate the development of PSETs' professional noticing of children's mathematical thinking in the context of algebraic thinking in whole class settings?*

Theoretical Framework

Teacher Noticing and Professional Noticing

Variants of teacher noticing have been the focus of research for some time (Mason, 2002; Sherin et al., 2011; Schack et al., 2017). While teacher noticing has been organized around two related components, “attending to particular events in an instructional setting” and “making sense of events in an instructional setting” (Sherin et al, p.5), Jacobs et al. (2010), posit a third related component, *deciding*, which refers to teachers’ responses ostensibly built upon interpretations of children’s activities. These interpretations are, themselves, “derived from events and behaviors to which teachers had attended” (Thomas, 2017, p. 508). The assemblage of attending, interpreting, and deciding as interrelated component skills has been referred to as professional noticing of children’s mathematical thinking, hereinafter as simply professional noticing (Jacobs et al., 2010). Further, professional noticing is typically considered a complex and challenging practice to develop (van Es, 2011), and, as with most complex practices, there are varying perspectives on how such practices may be implemented. In some instances, professional noticing may “be used as a filter to identify only the most impactful moments” while from other perspectives, noticing may be “focused on capturing and interpreting as much of the instructional landscape as possible” (Thomas, 2017, p. 508). While the former perspective is represented by the Mathematically Significant Pedagogical Opportunities to Build on Student Thinking (MOST) analytic framework (Leatham, Peterson, Stockero, & Van Zoest, 2015), the latter is typified by the research of Wells (2017) and Schack et al. (2013). It is this latter perspective of more inclusive professional noticing that we use for this study.

Returning to the notion of professional noticing as a complex practice, studies have demonstrated that preservice teachers at different levels of practice (i.e., elementary, middle level, secondary) can engage in productive professional noticing (Floro & Bostic, 2017; Krupa, Huey, Leisseg, Casey, & Monson, 2017). However, there is some emerging conjecture that professional noticing considerations and development may vary somewhat depending upon grade level (Krupa et al., 2017). Germane to this study, though, are inquiries of noticing performance within elementary grades. In a previous study, we found evidence that PSETs may advance their practice of professional noticing as measured via growth in the component skills of attending, interpreting, and deciding (Schack et al., 2013). Using a video-based instrument, we found statistically significant performance gains in each of the component skills (attending, interpreting, and deciding) with the largest gains occurring in the deciding component. Note, though, that this study was conducted in the context of a single child’s mathematical activity along a mathematical progression of counting and arithmetic reasoning (Steffe, von Glaserfeld, Richards, & Cobb, 1983; Thomas and Tabor, 2012). There has been some study of preservice teachers’ professional noticing performance that have grounded such noticing in complex pedagogical domains such as the enactment of specific mathematical practices (Floro & Bostic, 2017). However, this study is unique in that we have adopted an inclusive professional noticing perspective to examine PSET performance within a complex mathematical domain – namely early algebraic reasoning.

Early Algebraic Reasoning as a Complex Domain

Mentioned earlier, our previous research focused on the professional noticing of an individual child’s mathematical thinking in the area of counting and arithmetic strategies. We relied upon a highly descriptive framework detailing children’s early arithmetic strategies and changing conceptions of unit (Steffe et al., 1983; Wright, Martland, & Stafford, 2006). While this context proved fruitful for the development of foundational noticing capacities (Schack et al., 2013), we concluded that such contexts did not accurately represent the "blooming, buzzing confusion of sensory data" that occurs when multiple children are acting and interacting upon a convergence of mathematical topics (Sherin & Star, 2011, p. 69).

Representative of such mathematical convergence, early-algebraic reasoning comprises and intertwines several mathematical domains including properties of operations, equality, patterning, symbolic representation, and functions (Kaput, Carraher, & Blanton, 2007; Russell, Schifter, & Bastable, 2011; Warren, 2005). As with other domains such as counting and arithmetic reasoning (Steffe, 1992; Thomas and Tabor, 2012), each of the converging domains of early-algebraic reasoning may be thought to have some manner of developmental progression. Further, these progressions have been defined via empirical study for some of these domains (Clements & Sarama, 2009). However, the convergence of these individual progressions and resultant *conglomerate trajectory* may be rightly considered a significantly complex area of mathematical content rife with possibilities and pitfalls regarding the myriad aspects to which one might attend, interpret, and respond instructionally. While there are many other domain convergences and conglomerate trajectories within the mathematics education landscape, early-algebraic reasoning should be one of the first encountered by children and enacted by their teachers. As such, this represents a rich mathematical context for the study of professional noticing.

Methodology

Participants

Participants in the study included 296 preservice elementary teachers (PSETs) enrolled in an elementary mathematics methods course at one of five universities in the south central United States. Among the total participants, 171 completed the measures as part of an intervention group and the remaining 125 were in the comparison group. Participants with any missing scores on the professional noticing measure were removed, thus resulting in an intervention sample size of 147 and comparison sample size of 121.

Instructional Module

PSETs in the intervention group experienced an instructional module focusing on professional noticing and early algebraic thinking. The in-class module was taught by three professors at two of the institutions in the study. The three-session module gradually introduces each of the three components of professional noticing. The first session of the module, which focuses on just the attending and interpreting components, begins with a discussion of a prerequisite reading on the early understanding of equality and a review of the three components of professional noticing. Then, the PSETs analyze two videos with class discussion, match equality tasks to the Common Core State Standards for Mathematics, use their professional noticing skills to analyze children's written work, and complete a play-by-play storyboard from a video of whole class completing an algebraic task. The second session adds deciding and includes video analysis and discussions of authentic classroom experiences as well as analysis of children's written work. The final session includes all three components but focuses more deeply on productive decision making through the video analyses and discussion. All three sessions contain homework consisting of readings, mathematical tasks, or video analyses focused on algebraic thinking.

Measurement and Scoring

All PSETs in the comparison and intervention sites completed pre- and post-assessments to measure their professional noticing skills. All pre-assessments were administered near the beginning of the semester and the post-assessments were administered at the end of the instructional module for the intervention sites and near the end of the semester for the comparison group. The professional noticing measure consisted of a 74 second video involving a group of second grade students grappling with the task “10 + 10 = ___ + 5” where they were discussing the missing number in the mathematical sentence. In the video, four children provided different answers and explanations for the task. The explanations for each child are provided in Table 1.

Table 1. Transcripts of Individual Student Responses

Student	Answer	Transcript of Student Explanation
1	25	“I added 10 and….I added both 10’s and the 5. Ten plus 10 is 20 and add a 5 equals 25.”
2	20	*<No explanation - blurts answer out of turn>*
3	4	“Cause if you add a 5…and then you count up by 5’s up to 4, it’d be 20.”
4	15	“Because I counted 15, 16, 17, 18, 19, 20” (*using his right hand to track the count*). Teacher (in background) asks: “Why did you start with 15?” Student stated: “Because I thought to myself 5 plus 10 equals 15, but then I thought of adding 15 with the 5 and I counted up and it was 20.”

PSETs are asked to view the video and describe what they would do next if they were the teacher (deciding), what mathematical thinking and actions they observed (attending), and what the children understood about mathematics that influenced their answers (interpreting). Decision trees were used to aid in the scoring process. All responses were scored on a scale from 0 to 3 with a score of 3 representing the most advanced responses (See Table 2 for examples). All responses were scored using a double-blind process and any scores not in agreement between the two scorers were discussed and negotiated. In general, PSETs were assigned higher scores when they thoughtfully addressed the diversity in responses instead of focusing on one response or their own assumption of what the intended outcome should be in this situation.

Table 2. Sample PSET Responses

Component	Score	Sample Response
Attending	0	The children were explaining how they got the answer to the problem.
	2	Some of the kids added the first side of the problem, then added 5 and thought that was the answer. Other students were able to understand that the equal sign meant both sides had to be the same, and they were able to move numbers around to make them equal.
	3	The children were given the equation 10+10=___+5. The first child to respond was adding all the numbers together, he said the answer was 25. He was under the impression that the blank should be the sum of all the numbers. Another student said he thought the number should be 4 because it would take 4 5's to make 20 which is what 10 and 10 made. The last student came to the conclusion that it should be 15. He explained that 15 and 5 added together made 20 which is what 10 and 10 made.
Interpreting	0	I would make sure that the students understood what the equal sign meant. I would use manipulatives to show this.

	1	I was surprised to find such an interesting method for finding the answer. It was obvious that he understood the relation of counting by 10s and 5s.
	3	Some students were getting the correct answer (15) but he did not know where he got it from, or he could not explain it. Another student was adding all the numbers together to get the blank number so he needed to break down the number sentence into smaller parts to better understand it.
Deciding	0	I would have the children come up to the board and list a few different ways and ideas that work and don't work.
	1	Next I might show a true expression that looks different on both sides. I might ask, "Are both of these sides equal to each other?" Then I would use student responses to guide the discussion. Some sample questions I may ask along the way would include: How did you get that answer? Are both sides the same? Are both sides different? How are both sides the same? How are both sides different?
	2	I would continue to ask students for more strategies. I would write those strategies on the board. Then I would try some of the strategies on the board to show which ones were correct and which ones were incorrect. I would emphasize that there are multiple ways to solve this problem. I would explain that many of the students had the right answer, but got to it in different ways. I would encourage the students who solved it incorrectly towards the correct answer. It seems like they are thinking in the correct way, but that they had a few miscalculations. I would address those, so that the student still feels successful.
	3	I would have other students see if they can explain the last students thinking since he is on the right track. This would get all the students involved without saying that the other students who shared their opinions were wrong.

Results

When comparing the mean scores for the three professional noticing components (See Table 3), we found that the attending and interpreting scores increased from pre- to post-assessment in the intervention group, but slightly decreased, but not significantly, in the deciding component. The comparison participants decreased in all three components. Not all intervention participants improved, however, and Table 4 outlines the number of participants in each group that increased, stayed the same, and decreased from pre- to post-assessment.

Table 3: Mean Scores of Professional Noticing Components

	Treatment		Control	
	Pre	Post	Pre	Post
Attending	1.020	1.340	0.959	0.826
Interpreting	0.769	1.218	0.876	0.661
Deciding	1.361	1.340	1.554	1.446

Table 4: Noticing Score Changes

Component	Change	Treatment (%; N = 147)	Control (%; N = 121)
Attending	Increase	38	23
	Same	41	47
	Decrease	20	30
Interpreting	Increase	46	18
	Same	37	55
	Decrease	16	26
Deciding	Increase	29	28
	Same	39	32
	Decrease	31	40

In order to determine whether the increases from pre- to post-assessment in attending and interpreting and the decrease in deciding were statistically significant, Wilcoxon signed rank tests were conducted. The test was significant for attending ($Z = -3.219$, $p = .001$) and interpreting ($Z = -3.961$, $p < .001$), but not for deciding ($Z = -.384$, $p = .701$). Noting that an effective intervention should raise scores to above the level of the control group (which scored higher on interpreting and deciding at pre-test than the treatment group did), Mann-Whitney U tests were conducted to determine whether the treatment group's post-assessment scores were higher than the maximum (i.e., pre-) scores from the control group. The test was significant for attending ($U = 6913$, $p = .001$) and interpreting ($U = 7172$, $p = .004$). The test was also significant for deciding, but in the other direction; the control group received higher deciding scores than the treatment group ($U = 7654$, $p = .039$).

Discussion and Conclusion

Previous research by this team revealed that professional noticing was a teachable skill when taught in a one-on-one teacher to student setting (Schack et al., 2013). In a similar study using an intervention and control group, but within a one-to-one teacher to student setting, PSETs in the intervention group showed statistically significant growth in all three areas of professional noticing (Fisher, Thomas, Schack, Jong, & Tassell, 2017). However, in that same study, the comparison group did not show statistically significant increases in attending and interpreting, but they did show a statistically significant increase in the deciding component. This opens the discussion to the pedagogy taught in the mathematics methods course and how it could potentially impact the deciding component scores.

To further advance the research, this video vignette of a whole-class discussion focused on an algebraic concept was used to determine if the professional noticing skills were still teachable when expanded to a more complex setting. It is interesting to note that attending and interpreting skills both still revealed a statistically significant increase in the intervention group, but both components decreased in the comparison group. These results indicate that attending and interpreting are both responsive to intervention in the varying settings (one-on-one vs. whole class) but deciding needs further research and discussion.

Many questions still remain within the deciding aspect of professional noticing; However, we believe there is still much to learn from the results. Perhaps more research should be conducted on what constitutes effective deciding. While defined mathematical practices provide some organization for considering such decisions, there are myriad decisions a teacher might make in each moment and the productivity of such decisions likely varies greatly according to many different factors (e.g., instructional goals, students' mathematical needs, availability of resources, etc.). This variability is further compounded when considering potential decisions within complex mathematical domains such as the early-algebraic convergence.

While we recognize that many limitations exist with this study, such as the short timeline for learning and assessing these skills (4-6 weeks for implementation sites) or the less-than-diverse sampling that can be very difficult to overcome in a study of elementary education majors, perhaps the most troublesome limitation is the quantification of qualitative responses. For example, scorers credited more highly PSET responses that formally addressed each of the student's thinking in the video vignette, while realizing the difficulty of doing so in an authentic setting.

However, many times, responding to each child may have diminished the robustness of the decision. There remains a delicate balance in how to best quantify two different, yet both important, aspects in this situation: teaching to all and productive decision-making. We believe there should be a place for both, but these results suggest we may not have found the best way to measure their intersection as productive decision-making can be quite circumstantial and adequate measurements for those circumstances do not exist.

In summary, we remain optimistic that teacher educators can facilitate the development of PSETs' professional noticing skills within the context of algebraic thinking in whole class settings. We are most hopeful that this facilitation exists at least within the attending and interpreting components. More difficult to demonstrate, however, is the deciding component, thus we encourage the development of measurement tools that consider the complexities of classroom contexts when measuring productive decision-making. Tools that could potentially be used for both research purposes and teaching more productive decision-making for preservice and inservice teachers would be most desirable.

Mi Yeon Lee
Arizona State University
mlee115@asu.edu

We investigated how pre-service teachers (PSTs) interpret their calculations in proportional tasks. A written questionnaire was administrated to 199 PSTs and an inductive content analysis approach used for data analysis. We found that one item that asked PSTs to interpret the meaning of their results had unusually low success; open coding on the responses revealed several common themes. We argue these common errors cannot be dismissed as simple unit or rounding mistakes; they are a reflection on how respondents think about quantities, story problems, and the nature of mathematics itself. We end with suggestions on how to address this problem.

Keywords: Preservice Teacher Education, Teacher Knowledge, Proportional Reasoning, Problem Solving

Introduction

Proportional reasoning has been widely investigated as a key type of reasoning that both students and teachers in K-12 mathematics struggle with (Beckmann, 2015; Byerley, 2017; Langrall, 2000; Son, 2013; Tourniaire, 1985) and is also cited in the Common Core as one of the eleven mathematical domains that span mathematics from elementary to high school (National Governors Association Center for Best Practices, 2010). We surveyed 199 preservice elementary school teachers on 10 tasks that involve proportional reasoning, and the responses revealed that the PSTs struggled to interpret the meanings of their own calculations. This issue was most clearly illustrated in the task that required students to interpret their own calculations in order to give an answer. In this report we will share the major themes we found amongst PSTs that had difficulty answering this task. Our research questions include: (1) How do PSTs solve a proportional reasoning problem including a unit rate? (2) What kind of challenges in reasoning could cause a PST to struggle with answering a proportional reasoning question?

Theoretical Perspective

We approach our research questions and data analysis from a theoretical framework of quantitative reasoning (Smith & Thompson, 2007; P. W. Thompson, 1993, 2011). A quantity is a measurable attribute (such as length, elapsed time, volume, etc.) of an object (such as a car, a person, the Earth, etc.), and a "person constitutes a quantity by conceiving of a quality of an object in such a way that he or she understands the possibility of measuring it" (P. W. Thompson, 1993). This way of thinking in word or story problems stands in marked contrast to more procedural ways of reasoning such as key-word approaches (replacing "and" with "+" and "less than" with "-", etc.) Quantities as defined by Thompson occur only in the mind of a thinker, who conceptualizes them by making sense of a quantitative situation. Quantitative reasoning, then, is "the analysis of a situation into a quantitative structure--a network of quantities and quantitative relationships" (P. W. Thompson, 1993). A person is reasoning quantitatively when he or she is reasoning about quantities, instead of numbers, undefined variables, or memorized procedures. In the task and responses we present below, the prompt deliberately did not ask for a numerical answer; instead, it asked a yes/no question that required respondents to engage in three steps: a) decide what calculations would be relevant and useful to answering the question, b) carry out those calculations accurately, and c) interpret the meaning of their calculated results to answer the prompt. Our analysis focuses mainly, though not exclusively, on the written work that illustrates the third part of this process in our PST population.

Methodology

The proportional reasoning questionnaire was given to 199 elementary preservice teachers over 3 semesters at a large Southwestern university in the U.S. All participants were juniors who enrolled in an elementary mathematics content course covering patterns, functions, and modeling. They were on average 1.5 years away from being becoming full-time elementary school teachers including grades K through 8.

The participants completed a written questionnaire including 10 problems about proportional reasoning and we focused one of the problems (see Figure 1). In the questionnaire, PSTs were explicitly asked to solve all problems using quantitative approach (e.g., using pictures) first rather than using a standard algorithm and to provide their work along with clear justification. The written questionnaire including the problem in Figure 1 was administrated to all PSTs in six sections of a mathematics concept course in the middle of spring 2015, fall 2015, and spring 2016 and it was assigned as take-home homework right after teaching proportional reasoning.

One author came up with a first draft coding strategy for the problems based on the format of the questions. The other author then coded over half the data and looked at how well the coding strategy worked, suggested modifications, and the two authors together agreed on the next draft to the coding strategy. All the data was then coded but several smaller coding strategy changes were also implemented and those sections were recoded. The other author then coded a random subset of responses to verify that the strategy was being implemented uniformly. There was 100% agreement on the coding of 95% of the examples.

Once the initial coding was done we decided that we would like to focus on a specific phenomenon: the cases where preservice teachers either incorrectly interpreted the results of their own calculations, or did not interpret their results at all. We therefore chose to focus on our data on the "Dr. Lee's Car" item out of the ten problems.

Dr. Lee drove 156 miles and used 6 gallons of gasoline. At this rate, can he drive 561 miles on a full tank of 21 gallons of gasoline? Solve this problem and justify your reasoning.

Figure 1. "Dr. Lee's Car" Item

Results & Discussion for "Dr. Lee's Car" Item

We decided that since the prompt asked for a decision of Dr. Lee's driving ability, and not for a numerical answer, that a correct answer would say that Dr. Lee could not drive 561 miles on 21 gallons of gasoline. 152 preservice teachers made correct final statements such as "No", "He cannot go 561 miles", "He can go only 546 miles", "He has miles left over", or "He would need more than 21 gallons"; 9 of these teachers still had problems interpreting their own results despite their correct final answer. 36 preservice teachers answered "Yes" or "He can go 561 miles"; only 4 were due solely to arithmetic errors and the other 32 teachers had problems interpreting their own results. 11 preservice teachers gave no final answer, but 5 of them completed all of the necessary calculations yet did not interpret them to answer the question. Overall, 46 out of 199 teachers, or 23.11% of the teachers, demonstrated some problem with interpreting the results of their own calculations.

Table 1: Summary of all responses

	Correct answer: "He can't make it"	Incorrect answer: "He can make it"	No final answer	TOTAL
Total responses:	152	36	11	199
Responses with interpretation errors:	9	32	5	46

Amongst the 143 teachers that made relevant and accurate computations *and* correctly interpreted those results to answer the prompt, there were three solution techniques: to compute how many miles the car could go with 21 gallons, to compute the gas efficiency needed for both trips, or to compute the gallons needed to complete the second trip. Examples of each strategy are displayed below.

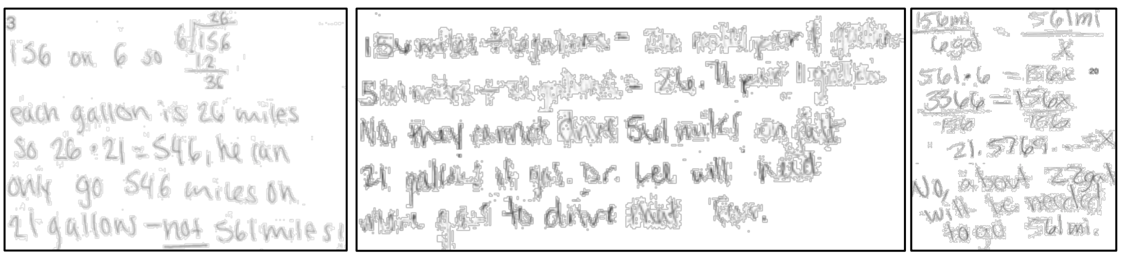

Figure 2. 3 Correct Solution Methods

Among the 46 teachers who had problems interpreting their own calculations, we found several themes.

Whole Number Bias (8.5% of respondents)

By far the most common problematic interpretations revolved around a strong bias towards either only calculating whole numbers, or rounding all values to whole numbers. 17 of the 45 preservice teachers who struggled to interpret their own work did so at least in part because they chose not to reason with decimal numbers. We hypothesize that these teachers looked for similarities in the results of their calculations without attending to the measures that they represented.

5 of the 199 teachers rounded both gas efficiency rates to 26 miles per gallon and concluded that Dr. Lee could make his trip. If a preservice teacher wanted to compare miles per gallon rates to evaluate whether Dr. Lee can make the trip or not, it is clearly relevant that 26.7 mpg is not the same as 26 mpg. Therefore, a teacher that rounded to 26 mph made a problematic interpretive decision when transferring work from calculator to paper, or when deciding to end their long division after finding the whole number part of their response.

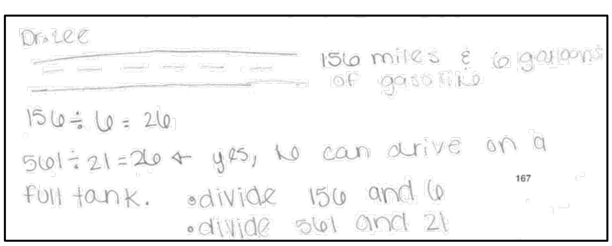

Figure 3. All calculations end in whole numbers

8 out of the 199 teachers found that the gas efficiency rates of both trips was approximately the same, and concluded that Dr. Lee could complete his trip; 4 teachers qualified their answers by saying that Dr. Lee could just barely make it. In doing so they neglected to keep track of the meaning and significance of their own calculations. The equality of both efficiency rates is irrelevant; rather, it matters whether the needed gas efficiency of the hypothetical trip is *less than or equal to* the known efficiency of the car.

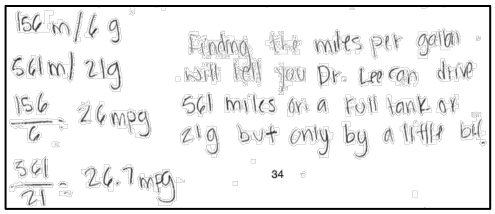

Figure 4. Yes, but only by a little bit [of what?]

5 of the 199 teachers found that it would require approximately 21.5 gallons for Dr. Lee to complete his trip, and concluded that his trip was possible. What matters is whether the gas the trip requires is *less than or equal to* the gas that Dr. Lee has available to him in a full tank, not whether they are approximately equal.

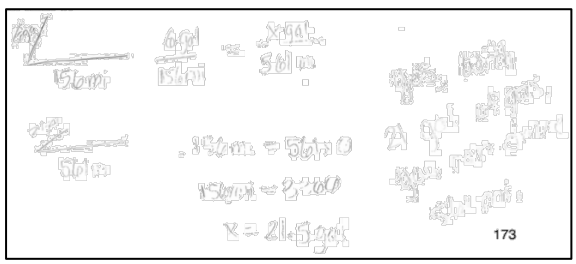

Figure 5. Yes, but only by a little bit [of what?]

Mixed Up Quantities (7.5% of respondents)

The next most common mistake is that preservice teachers did not keep track of the quantitative meaning of their results. These mistakes cannot simply be dismissed as writing down the wrong unit if we start with a presupposition that every calculation should have meaning to the person doing the calculating. We hypothesize that 16 out of the 45 preservice teachers who struggled to interpret their own work did so at least in part because they carried out operations on numbers without following them with operations on quantities.

9 out of 199 teachers calculated values and then ascribed the wrong quantitative meaning to them. For example, they calculated the gallons needed to complete a trip of 561 miles (21.5 gallons) but then wrote down 21.5 miles, calculated the gas efficiency of the shorter trip (26 miles per gallon) but then wrote down 26 gallons, or calculated the relative size of the trips in both gallons and miles (561 miles is 3.5 times as large as 156 miles, and 21 gallons is 3.3 times as large as 6 gallons) and then concluded that the difference meant that "Dr. Lee will be pushing [the car] .2 miles!".

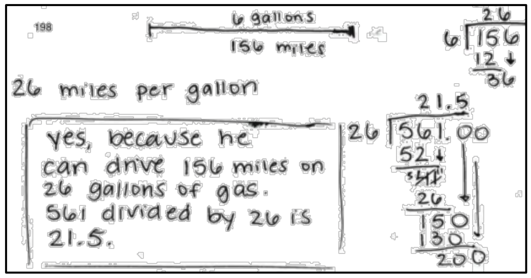

Figure 6. Mixed Up Quantities

6 out of the 199 teachers found values that would enable them to answer the question and interpreted the quantitative meaning of that value correctly, but then did not keep track of the meaning of a difference. 4 teachers correctly set up a proportion to find a value of 546, but then said that this means Dr. Lee *can* make the longer trip; 2 of those teachers interpreted the result of the calculation 561-546=15 to mean that Dr. Lee could drive an extra 15 miles. They did not keep track of the meaning of the difference as the miles that Dr. Lee *could not* drive on a full tank. 2 teachers calculated other differences (in the gas efficiencies of each trip, and gallons of gas used in each trip) and also concluded that Dr. Lee could make the trip.

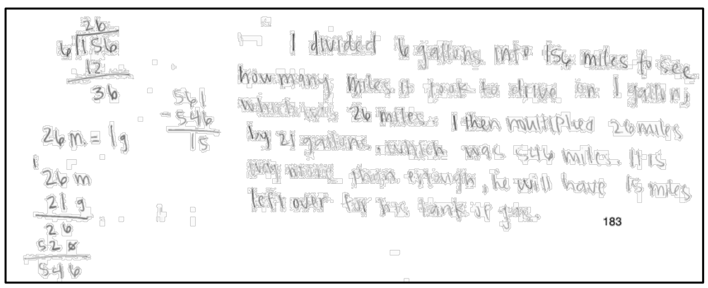

Figure 7. Directionless difference

Values Are Answers, No Meaning (3.0% of respondents)

5 of the 199 teachers reached the values they needed, of either the number of miles Dr. Lee could travel on 21 gallons, or the gas efficiency of both trips, but simply did not answer the question. While this may be an oversight, it may also illustrate a belief that mathematics is about finding numerical answers.

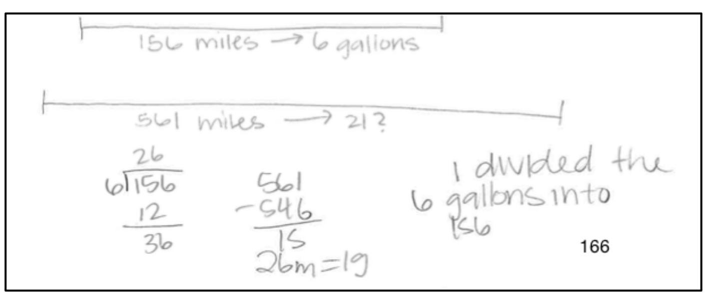

Figure 8. No answer

Chunky Gas (2.0% of respondents)

4 out of 199 teachers reasoned only in chunks of 6 gallons. 3 of the teachers concluded that Dr. Lee could not make the trip, and 1 concluded that he could, but all only calculated the miles

that 6, 12, 18, and 24 gallons would enable Dr. Lee to drive. We commonly see such chunky thinking in more abstract contexts like linear equations, slope, and accumulation in calculus (Castillo-Garsow, 2013; P. W. Thompson, & Carlson, M. P., 2017), but we were surprised to find it in such a concrete example.

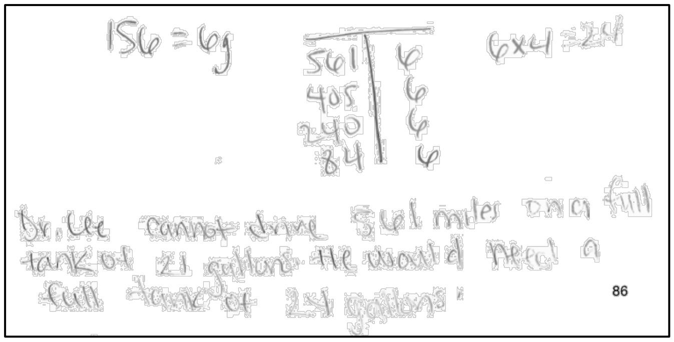

Figure 9. Gas comes in 6 gallon chunks

Equality is Everything (1.5% of respondents)

3 of the 199 teachers used cross-multiplying and looked for the equality of both sides. This strategy is appropriate when checking whether two fractions are equal, but not an appropriate strategy for determining whether one unit rate or gas efficiency is greater than or equal to another. Moreover, the resulting numbers (3276 and 3366) do not have clear quantitative meanings, as can be seen from their incoherent units of “dollar-gallons”.

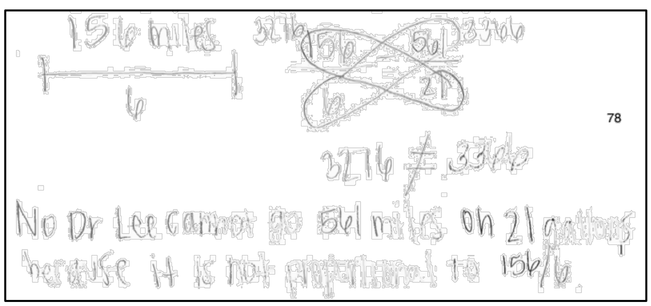

Figure 10. Equality is Everything

Conclusions & Further Thoughts

One of the enduring problems of mathematics education research is how to improve mathematics education in a way that benefits students both inside and outside the classroom. The days when a human calculator was valued and useful are over; now as technology develops, a person’s ability to interpret the significance of mathematical outputs has been more emphasized than simple calculation. In the Common Core, the ability to interpret the meaning of one’s answer is central to at least five of the eight Mathematical Practices: make sense of problems, reason quantitatively, construct viable arguments, model with mathematics, and attend to precision (National Governors Association Center for Best Practices, 2010). It is deeply concerning that over three semesters at a large university’s Teacher’s College, almost a fourth of PSTS struggled to interpret the meaning of their own calculations on a sixth-grade level task. There are several implications for students in such a teacher’s classroom. Teachers that struggle to assign meaning to their calculations will certainly also struggle to impart that skill to students, but there are also further concerns. Such a teacher is also likely to avoid an area he/she feels weak in, which can be reflected in the problems he/she chooses to assign to students or to do with students in class. Additionally, such choices can also convey beliefs to students about what mathematics entails or what kinds of problems should be present in a mathematics class. We also want to note that quantitative reasoning is not only applicable to real world or story problems; for example, students need to reason about the abstract quantities represented by the independent and dependent variables in order to make sense of functions.

The only foreseeable solution to this problem lies in making teachers' *quantitative reasoning* a core focus of both preservice teacher education and inservice professional development. Such a solution would be best implemented by refining the structure and content of current methods courses and professional development opportunities; a separate course might imply that quantitative reasoning is a special and separate topic only applicable to a narrow section of mathematics. The work that has been done on mathematical knowledge for teaching (MKT) shows how crucial it is to student achievement that teachers have a deep understanding of the meaning underlying the procedures they carry out (Hill, 2005; Silverman & Thompson, 2008). We have four specific recommendations for teachers of teachers from our experiences in analyzing this data set: (1) Discontinue the use of the cross-multiplying procedure (where the intermediate results have no clear quantitative meaning and incoherent units such as dollar-gallons) in favor of finding unit rates, or finding the relative size of one pair of measurements and then applying it to the other. (2) Focus explicitly on reasoning with non-integer measurements of quantities. (3) Tasks necessitating proportional reasoning should be given interspersed with tasks that sound similar but do not involve proportional quantities, so that teachers need to genuinely assess whether proportional reasoning is appropriate for each task. Looking back, this was a missing piece in our own data collection. (4) Most significantly, tasks that require teachers to ascribe meaning to their own calculations should be the norm and not the exception. The overall arching problem identified in this data set is that teachers are adept at carrying out calculations without having coherent meanings for their own results. A teacher who cannot make sense of his or her own calculations has no chance of helping students to understand their own.

Despite the recognized importance of mathematical proof in secondary education, there is a limited but growing body of literature indicating how preservice secondary mathematics teachers (PSMTs) view proof and the teaching of proof. The purpose of this survey research was to investigate how PSMTs in Australia and the United States perceive of proof in the context of secondary mathematics teaching and learning. PSMTs were able to outline various mathematical and pedagogical aspects of proof, including: purposes, characteristics, reasons for teaching, and imposed constraints. In addition, PSMTs attended to differing, though overlapping, features of proof when asked to determine the extent to which proposed arguments constituted proofs or to decide which arguments they might present to students.

Keywords: Reasoning and Proof, Teacher Education-Preservice, Mathematical Knowledge for Teaching, High School Education

Introduction

The importance of proof in the discipline of mathematics, and subsequently in the teaching and learning of mathematics, is recognized in the literature worldwide (e.g., Hanna & de Villiers, 2008; Stylianou, Blanton, & Knuth, 2009), and is echoed in recent policy documents and national curriculum (e.g., ACARA, 2017; Common Core State Standards Initiative, 2010). This importance largely rests on the notion that engaging in proof helps students reason about mathematical ideas as they critique arguments or construct their own logically sound explanations or justifications. In fact, both the Australian and United States mathematical proficiencies and practices reference the importance of the reasoning abilities of students, with emphases placed on constructing, justifying, and communicating arguments. However, research has revealed that secondary mathematics teachers often hold a limited view on the purpose of proof instruction and its appropriateness for all students (Bergqvist, 2005; Knuth, 2002). Specifically, teachers often relegate proof to verifying formulas in high school geometry, neglecting the explanatory role proof can play in the learning of mathematics at all levels (Hanna, 2000; Knuth, 2002). Moreover, teachers often focus on the structure rather than substance of a proof and have difficulty evaluating proofs presented pictorially (Dickerson & Doerr, 2014; Tsamir, Tirosh, Dreyfus, Barkai, & Tabach, 2009).

A recent study by Dickerson and Doerr (2014) suggested that teachers' ability to accept and promote less formal modes of proof representation (e.g., visual & concrete models) develops over time, with more veteran teachers less likely to impose strict standards for mathematical language and format. While both experienced and veteran teachers in this study appreciated the explanatory role of proof (Hanna, 2000), espousing proof as a vehicle to build student understanding of specific mathematics content and generalized thinking strategies, they differed considerably in terms of the value they afforded to explicit logic, detail, and precise language in writing proofs (Dickerson & Doerr, 2014). Views of proof as a formalistic mechanism are magnified for prospective teachers (Boyle, Bleiler, Yee, & Ko, 2015; Varghese, 2009) whose most recent experiences with proof are often in the context of upper-level mathematics courses. For example, in a study by Varghese (2009), secondary level student teachers expressed uneasiness with respect to teaching proof, with many indicating that proof should only be introduced to students planning to study advanced mathematics. Without a more complete understanding of the nature of proof and its role in learning mathematics, it is unlikely that beginning teachers will be equipped to enact proof instruction for all students as envisioned by mathematics education policies.

Purpose of the Study

The chief aim of our study was to investigate how preservice secondary mathematics teachers (PSMTs) in Australia and the United States perceive the importance and purpose of proof in the context of secondary mathematics teaching and learning. The overarching research question guiding this study was: *What are preservice, secondary mathematics teachers' conceptions of proof and proof teaching in a secondary classroom context?*

Theoretical Perspective

Our study is grounded in a situative perspective that takes into account what, when, and how mathematical knowledge is required in various practices such as teaching (Adler & Davis, 2006; Putnam & Borko, 2000). Specific to our study, Knuth (2002a, 2002b) demonstrated how teachers' conceptions of proof in the discipline of mathematics were sometimes at odds with their views on the role of proof in mathematics teaching and learning. This perspective also underlies the various frameworks that have been developed to delineate mathematical knowledge that would support the work of teaching proof (e.g. Lesseig, 2016; Steele & Rogers, 2012). For instance, Lesseig's (2016) Mathematical Knowledge for Teaching Proof (MKT for Proof) framework describes Common and Specialized Content Knowledge related to constructing and understanding proof, explicit knowledge of proof components, and the functions of proof that would support teachers' classroom work with proof. This particular framework provided a lens through which to analyze our data and grounded our subsequent interpretations of PSMTs' conceptions of proof and proof evaluations.

Methods

Participants and Contexts

The purpose of this study was to investigate PSMTs' conceptions of proof in the context of secondary mathematics teaching and learning. Data for this paper come from the results of a survey distributed to students enrolled in secondary mathematics teacher preparation programs across 6 different universities in the United States and Australia. Twenty-two PSMTs completed the survey, with exactly half of the participants from each country. The 11 PSMTs from Australia were all enrolled at the same university whereas the 11 PSMTs from the United States were split amongst five different universities. Half of the participants were in their first year of their preparation program, and the other half of the participants were in their second to third year of the program. All PSMTs had taken at least 3 college-level mathematics courses, with the majority of PSMTs (13) having taken 10 or more college-level mathematics courses. Exactly half had taken a course focusing on proof.

Data Collection

The survey was created in Qualtrics and was completed electronically. The three-part survey was qualitative in nature, with the majority of questions being open-ended.

Part I. The first part of the survey focused on PSMTs' conceptions of the nature and role of proof in mathematics and in teaching mathematics. This section included four open-ended questions: (1) What purpose(s) does proof serve in mathematics? (2) What makes an argument a proof? (3) If proofs are to be taught to students, what are your reasons for teaching proof? and (4) What will be the constraints, if any, on teaching proofs?

Part II. The second part of the survey focused on what secondary preservice teachers attend to when evaluating whether or not an argument is a proof. For five different statements, PSMTs evaluated between one and three student-generated arguments, decided whether or not each argument constituted a proof, and provided an explanation to support their decision. The five statements were drawn from the content areas of geometry, algebra, elementary number theory, and infinite geometric series. Student-generated arguments varied in clarity, generality, and approach. The survey purposefully included both symbolic and visual representations as well as deductive and empirical modes of argumentation.

Part III. The third part of the survey focused on what PSMTs attend to when deciding what kinds of arguments are most helpful for a group of students working on mathematical ideas underlying each of the five statements from Part II.. PSMTs were prompted to provide an explanation to support their selection of argument(s) they would share with students.

Analysis

Part I Coding. Once all survey responses were collected, the first two authors separately read through the Part I responses provided by PSMTs from their respective countries. Initial codes were drawn from the literature. For example, the codes VERIFY, EXPLAIN, SYSTEMATIZE, DISCOVER, and COMMUNICATE, adapted from de Villiers (1990), provided an initial lens to analyze questions 1 and 3. In addition, codes for question 2 such as LOGIC, THEOREM, and GENERAL were determined *a priori*, as they captured essential proof understandings one would expect from those familiar with mathematics, including future teachers (Lesseig, 2016). After the first pass of coding, researchers met virtually to discuss other themes that arose throughout the analysis and refined codes to incorporate these additional themes as well as to remove themes that were not applicable to certain questions. On the second pass of Part I, the first two authors analyzed the data from both countries using the agreed-upon codes. Once completed, they met virtually to discuss similarities and differences in their analyses and came to consensus on codes for each PSMT response to each question. The inter-rater reliability (IRR) was 85% for Part I and was calculated as the number of PSMT responses for which there was initial agreement on one or more codes (as more than one code could be used per response), divided by the total number of PSMT responses. A total of 60 responses were coded for Part I.

Parts II and III Coding. The codes used for the open-ended responses in Parts II and III were discussed and decided upon after researchers had read through all PSMT responses from their respective country. The first two authors then separately coded responses from both countries. After separately coding all data, the researchers discussed responses that did not initially have full agreement and came to consensus. The IRR was calculated at 83% for Part II, and 86% for Part III. There was a total of 134 responses coded for Part II, and a total of 50 responses coded for Part III.

Results

Findings for each of the three parts of the survey are presented below. For each of the survey parts, a table of researcher-generated codes has been provided to indicate the five most common responses offered by each cohort (see Tables 1-6). Overall, responses from both Australian and US cohorts appeared strikingly similar with little variation.

Part I – Conceptions of Proof and Proof Teaching

What purpose(s) does proof serve in mathematics? Participants indicated that proof establishes an axiomatic system to formalize mathematical knowledge, provides verification that a mathematical statement is true (or false), and helps to explain why a statement is true or makes sense. In this way, the notion of proof acting as a 'failsafe' during the teaching and learning of mathematics underpinned many statements regarding the purpose of proof. This response from Grant (Aus) describes the role proof plays in verification and systemization, "(proof serves) to establish fact, it provides the means where fundamental truths can be established which then provide the foundations for further understanding to be built."

Table 1: The purpose of proof in mathematics (PSMTs' conceptions)

Code	Code Description	PSMT (AUS)	PSMT (USA)	PSMT (Total)
SYSTEM	To establish an axiomatic system, referring to the formalization of mathematical knowledge	4	5	9
VERIFY	To provide verification that a statement is true or false	5	2	7
EXPLAIN	To explain why a statement is true or makes sense	2	4	6
BUILD-U	To build or deepen understanding of the mathematical concepts underlying the proof	1	2	3
COMM	To communicate mathematics	0	2	2

What makes an argument a proof? For the second survey question, participant responses aligned closely with the criteria identified as *Essential Proof Understandings* in Lesseig's (2016) MKT for Proof framework. Those criteria stipulate that a theorem has no exceptions, a proof must be general, a proof is based on previously established truths, and the validity of a proof depends on its logic structure. The most frequently elicited responses were that a proof is based on accepted statements, follows a logical structure, and removes any doubt about the veracity (i.e. truth or falsehood) of the statement.

Table 2: What makes an argument a proof? (PSMTs' conceptions)

Code	Code Description	PSMT (AUS)	PSMT (USA)	PSMT (Total)
THEOREM	It is based on accepted statements or theorems	2	7	9
LOGIC	It follows a logical structure	3	3	6
INFALLIBLE	It removes any doubt about the truth or falsehood of the statement	2	3	5
GENERAL	It proves the statement in general by covering all cases within the domain	2	2	4
VERIFY	It provides verification that a statement is true or false	2	0	2

If proofs are to be taught to students, what are your reasons for teaching proof? According to the proffered responses for survey question three, participants feel that proof should be taught to students to impart a variety of mathematical skills (e.g. logical reasoning), to build an understanding of the mathematical concepts underlying the proof, and to increase student agency. Walter's (US) response illustrates ways in which PSMTs' saw proof as valuable in promoting reasoning and argumentation skills that were useful beyond mathematics as well as a vehicle for both building and assessing understanding:

> The ability to convey reasoning and to justify in writing is a vital skill in the real world. In any job, you have to persuade others (often through proving that your way is right). Proofs also press for deep understanding and makes students' thinking visible to the teacher.

Table 3: Reasons for teaching proofs to students (PSMTs' conceptions)

Code	Code Description	PSMT (AUS)	PSMT (USA)	PSMT (Total)
T-SKILLS	To teach skills in logical reasoning, argumentation and problem solving	5	5	10
BUILD-U	To build or deepen understanding of the mathematical concepts underlying the proof	3	3	6
S-AGENCY	To increase or build student agency	2	4	6
DISC	To discover or explore an idea or create new knowledge	0	3	3
ASSESS-U	To assess student understanding	0	2	2

What will be the constraints, if any, on teaching proofs? Most respondents tended to assert that proof is a difficult topic, skill, or body of knowledge to teach. PSMTs' responses reflected their perceptions of the complexity of proof by way of questioning students' prior knowledge or ability to deal with the abstract nature of proof. PSMTs identified additional resource constraints such as a lack of time, curricular emphasis, or adequate preparation for teaching proof.

Table 4: The constraints on teaching proofs (PSMTs' conceptions)

Code	Code Description	PSMT (AUS)	PSMT (USA)	PSMT (Total)
S-KNOW	Students may not have the requisite mathematical content knowledge or skills for proof	3	4	7
TIME	Takes too much time to teach properly	2	4	6
CURRIC	There is not enough clear direction in standards or curriculum	3	3	6
ABSTRACT	Proof is too abstract for this age group	0	3	3
T-KNOW	Teachers may not have the knowledge and skills necessary to teach proof	1	2	3

Part II - Proof Evaluation

The purpose of Part II in the survey was to determine the extent to which PSMTs felt that proposed arguments constituted a proof, and ascertain the features of proof to which PSMTs attended. Participants attended to a variety of features in describing why they felt a proposed argument constituted a proof or identifying what they felt was missing in the argument. The most common rationales provided were in relation to whether (or not) the arguments proved the statement in general (i.e. they covered all cases within the domain), were based on accepted statements or theorems, and followed a logical structure, aligning with the top five characteristics of proof outlined in Part I of the survey. To a lesser degree, participants argued (in the affirmative or the negative) that the proofs were error-free and were easy to follow or understand. Table 5 below displays the counts for these top five characteristics evident in responses from US and Australian participants. Counts for two additional characteristics frequently cited in Part III are included for comparison.

Table 5: Characteristics PSMTs attend to when evaluating a proof.

	General	**Logic**	**Theorem**	**Correct**	**Clear**	Representatio	Accessible
AUS	23	20	9	15	8	4	0
US	26	17	16	9	10	6	0
TOTAL	49	37	25	24	18	10	0
	25.1%	19%	12.8%	12.4%	9.2%	5.1%	0%

*Percentages in Tables 5 and 6 are calculated based on total number of codes applied across responses. There were a total of 195 codes applied to the proof evaluation questions (Table 5) and 90 total codes in response to why an argument would be helpful (Table 6). Also, the last two columns have been included to facilitate comparison with the five most popular responses in Table 6.

Part III - Identification of proof features

Our intent in Part III of the survey was to identify features of proof that PSTs attend to when evaluating arguments or deciding which arguments to present in a classroom. In an identical manner to Part II, we assigned codes to responses regardless of whether PSTs referenced a particular feature in a positive or negative manner.

When deciding which arguments they might present to a group of students, PSMTs not only valued arguments that were correct and general (characteristics mentioned in Part II), but also considered pedagogical features such as whether the proof was accessible to students and how different representations might support student learning. As shown in Table 6, the mode of representation and clarity of the argument were the two most commonly mentioned characteristics across all four questions (20% & 18.9% respectively), yet when compared with findings from Part II, logic and theorem were not commonly espoused features. Several PSMTs attended to how accessible the argument might be for different levels of students.

Table 6: Helpful characteristics of proofs for students (PSMTs' perceptions)

	Representation	**Clear**	**Correct**	**Accessible**	**General**	Logic	Theorem
AUS	7	9	4	4	7	4	1
US	11	8	5	5	0	0	1
TOTAL	18	17	9	9	7	4	2
	20%	18.9%	10%	10%	7.8%	4.4%	2.2%

Discussion and Conclusion

Overall survey responses reveal that many PSMTs still hold rather formalistic views of proof. This is perhaps not surprising given participants' current status in teacher education programs. Participants' most recent experiences with proof have been in the context of taking pure mathematics courses wherein opportunities to consider proof from a teacher perspective are uncommon. However, we claim that to carry out the work of mathematics teaching wherein reasoning and proof remains central, PSMTs need to consider pedagogical aspects of proof. Specifically, our findings highlight the need to enhance PSMTs' views of the role of proof and extend their understanding and acceptance of other forms of proof that may be more accessible to secondary students.

PSMTs from both Australia and the US cited systematization and verification as the primary roles of proof. Proof was most commonly described as a mechanism for establishing truths in mathematics and demonstrating that a result is true beyond a reasonable doubt. Previous researchers (e.g., Knuth, 2002; Varghese, 2009) have discussed how this dominant view has the potential to limit teachers' perspectives on when and how proof should be utilized in secondary mathematics. However, in our case we see this not necessarily as a deficit, but as a common starting point. Indeed, a number of PSMTs also acknowledged the explanatory role of proof (Hanna, 2000) and recognized proving as a venue for students to both build and communicate understanding. Coupling verification with explanation, and explicitly discussing these complementary roles of proof in preservice teacher education (Bleiler-Baxter & Pair, 2017) has the potential to expand PSMTs' view of proof and their ability to integrate proof more consistently into their future teaching.

In light of our theoretical perspective, we noted that while many of PSMTs' responses were consistent across survey items, others appeared somewhat inconsistent. For example, when asked to identify necessary components of a proof, PSMTs stated in Part I that proofs should be based on established facts or theorems and follow a logical progression, and subsequently included statements about the logical structure or use of theorems in their rationales for the acceptance (or not) of the student-generated arguments as proof. On the contrary, despite the fact that only 20% of PSMTs explicitly mentioned that a proof must be general, generality was the characteristic attended to most often when PSMTs were asked to evaluate the student-generated arguments from Part II. Indeed, in their evaluations, PSMTs demonstrated a robust understanding of proof from a mathematics perspective, and made explicit statements that examples do not constitute proof. This understanding is particularly notable in light of prior research documenting students and preservice teachers' acceptance of empirical arguments as proof (Harel & Sowder, 2007; Simon & Blume, 1996). In addition, the characteristics PSMTs attended to when evaluating arguments in Part II did not necessarily map directly onto characteristics PSMTs used when deciding which proofs they might present to students in Part III, wherein the use of multiple representations that might be accessible to a range of students was valued. Differences across survey sections highlight the importance of considering PSMTs' actions across multiple settings. From a research perspective, these findings suggest that measures of PSMTs' proof conceptions should be situated in tasks of teaching (Steele & Rogers, 2012).

Finally, we note that merely knowing that a proof must be general was not necessarily sufficient, as PSMTs had different interpretations of what constituted generality. This finding was most evident in their assessment of two "non-traditional" arguments included in the survey, one a visual argument, the other a generic example proof (Karunakaran, Freeburn, Konuk, & Arbaugh, 2014; Mason & Pimm, 1984) for a claim about divisibility. Given their accessibility to students, visual arguments and generic example proofs have the potential to 'bridge the gap' from empirical toward more deductive modes of argumentation (Karunakaran et al., 2014). Thus, we contend that increasing PSMTs' proficiency with constructing and assessing generic example proofs and visual arguments is an important step toward enhancing the role of proof in secondary mathematics classrooms. It is worth noting that the invitation to participate in this study, which resulted in a convenience sample from participants from multiple universities in the US and one university in Australia, is a limitation in this study. Although results from students across universities and countries were similar, the different requirements for the programs at the different universities could have affected PSMTs' perspectives. A future direction could involve disaggregating the data by type of program in which the students were enrolled.

There is widespread agreement that reasoning and proof should be an integral part of *all* students' mathematical experiences across content areas and throughout the grades (Stylianou et al., 2009). Meeting this goal requires that PSMTs develop a nuanced understanding of the various purposes and characteristics of proof and what might be an acceptable proof given a particular purpose. This includes the ability to distinguish among a range of valid and invalid arguments presented visually, verbally, or symbolically, as well as the ability to determine which of those arguments might be accessible to students. Moreover, PSMTs need opportunities and experiences within their teacher preparation programs that allow them to confront (and reconcile) their views of proof from mathematical and pedagogical perspectives.

USING STRIP DIAGRAMS TO SUPPORT EXPLANATIONS FOR KEEP-CHANGE-FLIP FOR FRACTION DIVISION

Eric Siy
University of Georgia
ericsiy@uga.edu

Using memorized rules and algorithms without coherence and understanding is a perennial problem for teachers and students especially in the teaching and learning of fraction operations. I present data in which prospective middle school teachers explain a commonly used rule for fraction division—keep-change-flip. I argue that using both strip diagrams and a single, quantitative definition for multiplication support prospective teachers when explaining why the rule works. The results of the study provide impetus for both mathematics teachers and mathematics teacher educators to teach with coherence across multiple mathematical topics.

Keywords: Teacher Education-Preservice, Rational Numbers, Middle School Education

Curricular documents have highlighted the crucial role for representations in the learning and teaching of mathematics (National Council of Teachers of Mathematics [NCTM], 2000) and the development of well-prepared beginning teachers (Association of Mathematics Teacher Educators, 2017). Although there are many representations used in mathematics education, I focus on representations as models of problem situations, specifically strip diagrams. The importance of using representations in educational contexts is not new (Ball, Thames, & Phelps, 2008; NCTM, 2000), and researchers' work on teachers' use of representations has helped to identify related issues. First, teachers' conceptions of representations and their role in problem solving are relegated to the periphery of mathematical activity—representations are not "real" mathematics (Stylianou, 2010). Teachers prefer to prioritize abstract, procedural rules over productive representations (Eisenhart et al., 1993). Second, teachers' content knowledge constrains their pedagogical purposes for using representations (Izsák, Tillema, & Tunç-Pekkan, 2008), and teachers' mathematical knowledge has been shown to be primarily procedural without a strong grasp of the mathematical underpinnings (Mewborn, 2003). Prospective middle school teachers, in particular, frequently use the keep-change-flip procedure (KCF; i.e., $\frac{a}{b} \div \frac{c}{d} = \frac{a}{b} \cdot \frac{d}{c}$) to explain fraction division but have difficulty explaining why the procedure works (Li & Kulm, 2008). This procedural knowledge of mathematics could explain the reluctance of teachers to use representations when teaching (see Eisenhart et al., 1993). One viable avenue is to provide teachers with opportunities to learn with representations which influences both teachers' knowledge and use of representations (Jacobson & Izsák, 2015). In this report, I present such an opportunity. I examine how prospective middle school teachers use strip diagrams to solve fraction division problems in a content course and how leveraging the diagram supports productive explanations for the keep-change-flip procedure.

Theoretical Framework

Definition of Representations

Researchers who have studied representation use in class (e.g., Izsák, 2003; Saxe, 2012) have generally agreed to distinguish what is being represented and what is "doing" the representing (cf. von Glasersfeld, 1987). In this study, I refer to representations as observable geometric inscriptions that can be referred or pointed to as the object of discussion (Goldin, 2002). It is this indexical and communicative nature of representations allowing students to explain their thinking and for others to engage in another's way of reasoning. When students create a display to represent their thinking, they also have a communicative aspect. In other words, they tailor their display with an audience in mind (Saxe, 2012) and thus students select salient features to highlight and point when creating and talking about representations. Additionally, I frame representations as culturally and historically rooted. A representation's cultural and historical meaning grow out of how communities have interacted with an inscription over time (Blumer, 1986). For example, a class can ascribe the meaning to the inscription "=" as "execute the arithmetic to the left" if they are continually asked to solve result-unknown problems over time.

Strip diagrams. The Common Core authors recommended strip diagrams when reasoning about ratios and rates in 6th grade (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010). A strip diagram is usually drawn as a rectangle that can be partitioned into different sized parts where each part may refer to a quantity. Although researchers have identified the strip diagram as a feature of mathematics instruction in high performing countries such as Japan and Singapore, research on strip diagrams themselves is sparse especially in the United States (Murata, 2008; Ng & Lee, 2009).

Form-Function Relationships

Saxe's account (2012) of cultural forms and functions accounts for how historically-rooted artifacts change over historical time. *Forms* are socially-rooted systems of artifacts perceivable by members of the community such as the base-27 system of the Oksapmin peoples (Saxe, 2012) or a number line in a math class (Saxe, de Kirby, Le, Sitabkhan, & Kang, 2015). *Functions* are how the forms are used to achieve goals. To characterize cultural forms and their functions, the researcher must investigate the creation of a "common ground" or a taken-as-shared ways of talking and doing (Saxe et al., 2015). Saxe and colleagues identified three strands describing how individuals contribute to common ground. In this repor, I account for two of these strands:

1. *Microgenesis.* This process shows how individuals contribute to a common ground, often using a form in public, by describing how forms serve certain functions. For example, if a student wants to show how 3/2 is equivalent to 6/4, a student may create a strip diagram partitioned into three parts and partition each part into two in order to show six sub-partitions using a different color to show the relationship between the two partitions. The student is contributing to common ground by producing a particular form (strips with partitioned partitions) to describe fraction equivalency.
2. *Ontogenesis.* This process shows the continuity and discontinuity of forms to serve new functions. In some instances, if a new function is necessitated, some previously used forms may be employed (continuity) or new forms (discontinuity) may emerge to serve the new function and accomplish the goal.

Data and Analysis

Context of the Study

I analyzed four days of instruction from the second course of a sequence of two mathematics content courses for prospective middle school teachers (PSMTs) enrolled in a teacher education program. The same teacher taught both courses. The program was geared towards certification to teach mathematics in Grades 4–8. The objective of the course was to strengthen the students' mathematical understanding of middle school topics such as base-10, fractions, and ratios. The 13 PSMTs enrolled in the course were predominantly white women. Two class norms were developed in class by the time of the classes selected for analysis. First, students were expected to use a multiplicand-multiplier definition for multiplication, notated by equation $N \cdot M = P$ (Beckmann & Izsák, 2015). In this equation, N denotes the number of base units in one group (the multiplicand), M denotes the number of groups (the multiplier), and P denotes the total number of units in M groups. With this definition, the order of the factors matters e.g., 12 boxes with six donuts in each box ($12 \cdot 6$) is different from six boxes with 12 donuts in each box ($6 \cdot 12$) even if they are numerically the same number of donuts in total. The class was also expected to use the Common Core definition of fraction (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010) where the fraction a/b referred to the quantity formed by a parts of size $1/b$. Lastly, students were expected to explain their thinking with drawings rather than memorized algorithms or symbol manipulation. Specifically, students were expected to use strip diagrams and double number lines.

The teacher usually began class by orienting the PSMTs to the mathematical topic of the day. She gave the class a problem to solve and the PSMTs worked at their table with two to five other PSMTs. As they worked, the teacher walked around class, supporting or pressing the PSMTs. The teacher would redirect the PSMT if they breached any of the two sociomathematical norms. PSMTs were given the option of using iPads. After a period of time, PSMTs presented the strategies in whole-class discussion. To present their strategies, they could recreate their strategies on the mounted whiteboards or project their iPad screen on one of four mounted screens. Some students used the iPad's camera to project written work. The whole-class discussion focused on students' strategies and connections between different strategies.

Data Collection and Analytical Techniques

The main data corpus for this study was video and audio-recorded lessons from class. One stationary camera was set at the back of the class and captured the whole class within one frame. The other camera was also stationary during whole-class discussion but followed the teacher during small group discussions. Two microphones mounted on the ceiling captured audio during whole-class discussion while four flat microphones captured audio at each table. In post-production, all video and audio data were condensed into a single file. The two videos were synchronized and combined into a single frame. The file contained all the audio feeds such that I could select any audio and listen to one audio source.

The primary analytical techniques were modified from Saxe et al., 2015 and focused on identifying forms and functions of the representations to characterize the microgenetic process. To identify forms, I located PSMTs' inscriptions in the classroom data. I relied on both discursive and gestural indicators. As the PSMTs talked about their drawings, I noted when they physically gestured to an inscription or used pointing language such as "This is…" or "I drew…" Two grain sizes for forms emerged from this analysis. A *micro form* was a single geometric inscription as fine as a line or rectangle and a *coarse form* was a group of microforms used to address a larger goal such as an entire strip diagram with its annotations to solve a multiplication problem. To identify a function, I found pointing language referring to what a particular form represents e.g., "This is a cup" and annotations on the drawings. To address the ontogenetic strand, I searched for moments between problems wherein forms changed. I identified the difference between the question or problem that was asked before and after the change.

Results

Over the course of the lessons, the PSMTs used strip diagrams to explain their thinking. The coarse form changed when the problem type changed. In Table 1, I summarize and illustrate the coarse and micro forms used. As the lessons progressed, the function of a partition of a strip changed to accommodate multiple functions which allowed students to explain KCF.

Table 1: Coarse Forms and Functions of the Micro Forms

		Measurement Division Forms	
		First coarse form 	**Second coarse form** Micro forms	Whole strip	One of a base unit	One of a base unit
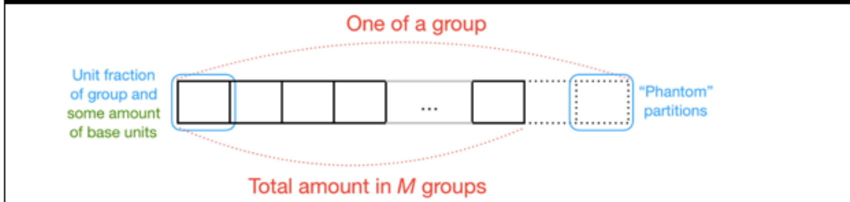
	Set of partitions	One of a group (N)	One of a group (N)
	One of a partition	Unit fractional amount of a base unit	Unit fractional amount of a base unit and a group
		Partitive Division Form	
			


Micro forms	Whole strip	One of a group (N)	
	Set of partition	Total amount in M groups (P)	
	One of a partition	Unit fractional amount of a group and some amount of base units	
	“Phantom” partitions	Partitions intended to complete one of a group	

Note: M, N, and P refer to quantities in the multiplication definition in Beckmann & Izsák (2015)

Measurement Division Forms

The first two lessons centered on solving measurement or how-many-groups division. The two coarse forms resembled the definition of a fraction where each strip stood for one of a base unit e.g., one cup and the partitions referred to a unit fraction of the base unit e.g., $1/n$ of a cup. The PSMTs indicated one of a group by highlighting a set number of parts (such as the different colors in Figure 1a). Using the set number of parts, they counted how many groups were in the total amount of base units. The second form resembles the first coarse form; however, the function of a partition changed to holding two referents, the base unit and the group.

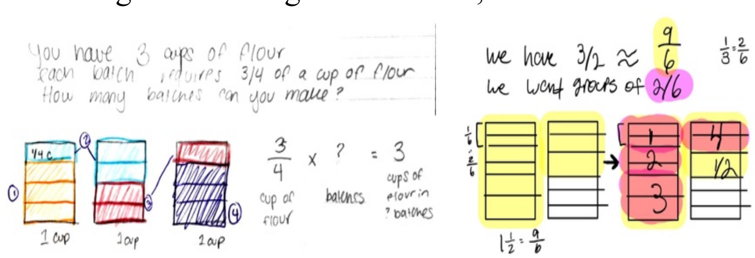


Figure 1. (a) Sophie’s Diagram for 3 ÷ 3/4 = ? (b) Jack’s Diagram for 1 ½ ÷ 1/3 = ?

In the first lesson, students created a word problem for the measurement division problem 3 ÷ 3/4 = ?. They solved the problem using strip diagrams and in some cases double number lines. All the strip diagrams produced resembled Sophie’s diagram in Figure 1a. Sophie created the word problem “You have three cups of flour. Each batch requires three-fourths cup of flour.

How many batches can you make?” During whole-class discussion, she explained, “I first drew three full cups each of those is a cup.” Based on the annotations at the bottom of her strip and her equation, Sophie created a whole strip as a cup. Because the class was annotating equations with one definition of multiplication and Sophie’s placement of cups as the multiplicand in her equation, I inferred she assigned cups as her base unit. She explained, “each of those is made of four parts, each of size one-fourth of a cup and then I colored three of them which is three fourths of a cup each makes a batch” thus a set of three partitions was one group or batch in her context. In the next lesson, PSMTs were also asked to create a measurement division problem for 1½ ÷ 1/3 = ? and solve the problem. Jack wrote the problem “You have 1½ liters of apple juice. You want to pour this apple juice into glasses, which can hold 1/3 liters each. How many glasses can you fill with your apple juice?” Similar to Sophie’s strategy, he created a whole strip indicating one cup of apple juice or one of a base unit. He shaded one and a half strip indicating the total amount he needed to count (see yellow partitions in Figure 1b). During whole-class discussion, Jack explained he anticipated the size of the partitions he wanted “[because] halves and thirds don’t mix perfectly…so I needed to put them in same sizes so the easiest one was sixths ‘coz that’s our common denominator–least common denominators.” Thus, he chose partitions that were 1/6 of the strip. He counted sets of two partitions showing one of a group or 2/6 of a liter. Finally, he commented on the left-over partition and described it simultaneously as one sixth of a liter and half of a glass. This signaled describing a partition with respect to both the group and base unit as a new function for a partition. The ontogenesis of this new function for the partition could perhaps be explained by the number choice of the problem in the first problem where the total number of partitions is divisible by the numerator of the divisor.

Partitive Division Form

The next two lessons centered on solving partitive or how-many-in-1-group division problems. The PSMTs initially worked on partitive division problems where the dividend was a whole number and the divisor was a fraction between zero and one. One coarse form emerged from solving these problems. They created whole strips referring to one of a group e.g., one serving and the partitions were a unit fraction of the group. They also referred to the partition as some amount of base units. Describing the partition with respect to both groups and base units is perhaps a function rooted in the function emerging towards the end of the measurement division lessons. Finally, students also distinguished some partitions. Jack called these partitions that “aren’t really there” as “phantom” partitions. The phantom partitions were drawn to complete one of a group because the sizes of the group that given in the problems were less than one.

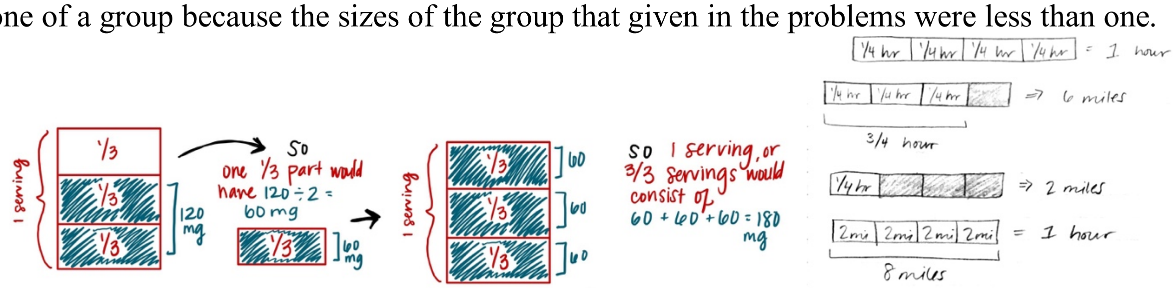

Figure 2. (a) Elizabeth’s Diagram for 120 ÷ 2/3 = ? (b) Catherine’s Diagram for 6 ÷ 3/4 = ?

First, the class worked on the problem “2/3 of a serving of noodles contains 120 mg of sodium. How much sodium is in one bowl of noodles?” Afterwards, they worked on the problem “Running at a steady pace, Anna ran 6 miles in 3/4 of an hour. At that pace, how far will Anna run in one hour?” Elizabeth and Catherine’s strip diagrams in Figure 2 are both exemplars of the coarse form PSMTs used when solving partitive division problems. In both diagrams, each whole strip denoted one of a group and assigned a subset of the partitions in a strip to denote the total amount of base units in *M* groups. In Elizabeth's first strip diagram, the set of blue partitions referred to 120mg of sodium and 2/3 serving. Catherine similarly drew her second strip with the total amount of miles in 3/4 hours. They then considered just one of these partitions and described the partition in both the quantity of the group and base unit similar to Jack's partition in the measurement division lesson. Elizabeth and Catherine also assigned equal amounts of the base unit in each partition. For Elizabeth, she annotated this in the middle of her drawing (Figure 2a) by labelling one of her partitions as both one-third of a serving and 60mg of sodium. Catherine showed this function for a partition in her third strip (Figure 2b) where she annotated one of her partitions as one-fourth of an hour and two miles. They both iterated this partition to complete the whole strip and counted the amount of base units in the whole strip. Although the functions for the whole strip and the partition shifted i.e., measurement division problems showed one of a base unit while partitive division problems showed one of a group, the function of the partition as both an amount of a group and base unit was present in both problem types.

Explaining Keep-Change-Flip

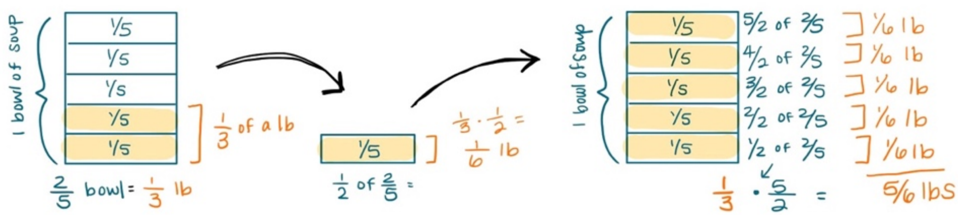

Figure 3: Elizabeth's Strip Diagram for 1/3 ÷ 2/5 = 1/3 · 5/2

PSMTs explained KCF with strip diagrams and the definition of multiplication when explaining partitive division problems when prompted by the instructor. The instructor asked the PSMTs to find ways to explain 1/3 ÷ 2/5 = 1/3 · 5/2. The PSMTs leveraged the function of a partition to describe both the base unit and the group. To explain the rule, PSMTs used a third function for a partition—describing the partition with respect to the size of the group of the total amount of base units. Consider Elizabeth's explanation for 1/3 ÷ 2/5 = 1/3 · 5/2.

Elizabeth drew the strip diagram in Figure 3 to show her thinking for 1/3 ÷ 2/5 = ? and explained her thinking in whole-class discussion. She created a partitive division word problem "A third of a pound of chicken is enough for 2/5 of a bowl of chicken soup. How many pounds of chicken is in 1 whole bowl of chicken soup?" Elizabeth's drew a strip diagram with the coarse partitive division form. First, she drew the strip on the left functioning as one of a group or one bowl of soup. She partitioned the strip into five parts and annotated her parts as 1/5 of the bowl and "colored in two of the fifths and called that 1/3 of a pound." The set of partitions referred to the size of the group, i.e., 2/5 of the bowl, but also the corresponding quantity in base units i.e., 1/3 pound of chicken. Using the function of the partition, she described one partition in two ways, as 1/5 of the bowl and 1/6 of a pound as seen in the middle of Figure 3. She iterated this part to build the whole bowl of soup and kept track of both quantities simultaneously to get 5/6 pounds of chicken in the whole bowl similar to the previous partitive division coarse forms.

To explain the equivalence 1/3 ÷ 2/5 = 1/3 · 5/2, Elizabeth described the situation considering two groups—the original group of one bowl and a new group of 2/5 of a bowl. Considering this new group, she explained the partition is also one-half of two-fifths of the bowl. This activity indicated a new function for a partition in addition to denoting a unit fractional amount of a group and base unit. She used the partition as a unit fractional amount of the size of the group of the total amount of base units in addition to one-fifth of the bowl and one-sixth of the pound. In other words, one partition refers to 1/6 pound of chicken, 1/5 of the bowl, and one-half of two-fifths of a bowl. She counted the five partitions in the whole strip and used the new function to get one bowl as five halves of two-fifths of the bowl.

Using the new group, Elizabeth created the expression $1/3 \cdot 5/2$ following the definition of multiplication used in class. In the annotation, she explained there is one third pound of chicken in one of the new group, two-fifths bowl (amount in one group, *N*) and there are five-halves of the new group in the whole bowl of soup (number of groups, *M*). In summary, Elizabeth's group changed from one bowl to two-fifths of a bowl when asked to explain KCF. Because of her new group, she added a new function to one partition. By using the class definition of multiplication, she annotated her thinking when she considered the new group to obtain the expression $1/3 \cdot 5/2$.

Two reasons could explain the ontogenesis of the new function when solving partitive division problems. First, the instructor's prompt of asking students to explain how to see $1/3 \cdot 5/2$ in their drawing seemed to initiate the creation of the function. If the PSMTs were to simply solve the partitive division problem, the third function for the partition may not have emerged. Second, the nature of partitive division problems may afford a flexible choice of groups. Elizabeth retained 1/3 in base units and flexibly chose her group as either the whole group or 2/5 of her group. In the problem Jack was solving, 1 1/2 and 1/3 both referred to base units and could potentially restrict a group to solely 1/3 of a base unit.

Discussion and Conclusion

The results of this study provide a characterization of how functions of inscriptions evolve over time. In this case, an evolving function for a partition in a strip allowed students to explain KCF. PSMTs' explanations of the algorithm were rooted in two practices—using strip diagrams and a definition of multiplication. Strip diagrams were not templates with predetermined rules and meanings. In fact, most of the forms were rooted in the activity of the class and previous uses of the strip diagram. Initially, PSMTs used the strip diagram to solve measurement division problems. By changing the number choices within the problem, a new function of the partition of a strip diagram emerged which proved to be useful in subsequent solutions. The strip diagrams remained relatively similar when solving partitive division problems. When prompted to explain KCF, the students used the partition in a new way not previously used in solving problems.

The results I report here provide future steps for both researchers and teachers. When analyzing inscriptions, researchers must attend and be explicit about the grain size of the inscription. By capturing two grain sizes, I was able to determine new uses for smaller inscriptions embedded in larger ones. Additionally, an analysis of inscription use in classrooms provides researchers with continuities and discontinuities between points in time in order to characterize teaching opportunities for new forms and functions to emerge. For teachers and teacher educators working with strip diagrams, activities wherein opportunities are provided to assign new functions to diagrams and its elements can equip students with ways of reasoning to be used in future tasks. Additionally, this report provides a case for using representations and how keeping coherent activity across multiple lessons provides students and prospective teachers with a powerful opportunity to learn mathematics.

QUANTITATIVE (AND NON-QUANTITATIVE) METHODS USED BY FUTURE TEACHERS FOR SOLVING PROBABILITY-BASED PROPORTION PROBLEMS

We have extended two perspectives of proportional reasoning to solve problems based in probability. Four future middle grade teachers were enrolled in a mathematics content course that emphasized reasoning about multiplication with quantities. The course expected future teachers to generate and explain methods for solving proportions. Probability had not yet been discussed in the course, which gave insight into how reasoning fostered in the course was invoked in novel tasks. All four future teachers could reason about multiplication with quantities to solve probability problems and could use quantitative methods that accurately reflected how empirical probabilities approach theoretical probabilities as the number of trials increase.

Keywords: Mathematical Knowledge for Teaching, Middle School Education, Probability, Teacher Education-Preservice

Proportional relationships and ratios form an essential domain in elementary and secondary education (e.g., Kilpatrick, Swafford, & Findell, 2001; National Council of Teachers of Mathematics [NCTM], 2000) but are challenging concepts for students to learn (e.g., Lamon, 2007). Siegler et al. (2010) stressed the importance of teachers helping students conceptually understand proportion problems before utilizing rote cross-multiplication procedures. Similarly, the Common Core State Standards for Mathematics stated students should be able to "understand ratio concepts and use ratio reasoning to solve problems… by reasoning about tables of equivalent ratios, tape [strip] diagrams, double number line diagrams, or equations" (National Governors Association Center for Best Practices & Council of Chief State School Officers, 2010, p. 42). Yet, studies have shown teachers have difficulties similar to their students when reasoning about proportional relationships (e.g., Orrill & Brown, 2012). Thus, it is important to understand how to better prepare teachers to reason about ratios and proportional relationships.

Additionally, standards documents (e.g., Conference Board of the Mathematical Sciences [CBMS], 2012; NCTM, 2000) emphasize the need for students to see mathematics as a coherent whole by developing connections across topics. To this end, ratios and proportional relationships can be situated within the multiplicative conceptual field (Vergnaud, 1994), which also includes multiplication, division, and fractions. Our project group has been investigating how future teachers (FTs) enrolled in content courses on multiplication develop a coherent perspective of the multiplicative conceptual field and construct viable arguments to solve tasks, especially using the multiple batches and variable parts perspectives on proportional relationships (Beckmann & Izsák, 2015). These two perspectives are explained in the theoretical framework section below.

In this study, we investigated how future middle grade teachers engaged in these two perspectives when generating and explaining methods to solve probability-based proportion problems. Due to the tendency for both students and teachers to solve missing-value proportion problems using the cross-multiplication procedure (Orrill & Brown, 2012), it is important to see if FTs can also reason quantitatively in these situations. Two potential ways FTs can reason quantitatively are through the use of the multiple batches and variable parts perspectives.

We focused on probability-based tasks for two reasons. The first is that we wanted to concentrate on a topic tied to the multiplicative conceptual field that had not yet been covered in the FTs' content courses on multiplication. By choosing a topic not covered in class, we could see if and how FTs utilized quantitative reasoning from instruction (i.e., the multiple batches and variable parts perspectives) in novel situations. Probability fit this criterion.

The second is that the variable parts perspective is rarely the focus of instruction (Beckmann & Izsák, 2015) but gives a more accurate representation of what transpires in probability tasks over a series of trials compared to the multiple batches perspective. For instance, if a spinner has five equal sectors and three of those sectors are red, the probability of the spinner landing on red is three-fifths. Yet, this does not mean as more spins are completed, three of each five consecutive spins will be red (a multiple batches approach). A more accurate representation is one based in the variable parts perspective: there are five equal-sized sectors and as the number of spins increases, each sector gets multiplicatively closer to containing the same fractional amount of the total spins (one-fifth). We mention "multiplicatively closer" because as more spins are completed, the additive difference between the number of spins in any two sectors may be growing. Therefore, as the number of spins grows, the number of spins landing on red will approach three-fifths of the total spins. On the other hand, as the number of spins increase, the fractional amount of the total spins in each of the sectors (the empirical probability) should be approaching the same number, namely the theoretical probability of landing in any sector.

Thus, there is merit in analyzing FTs' methods when solving probability-based proportion tasks. If FTs can access and utilize methods from the multiple batches or variable parts perspectives, it shows FTs can reason quantitatively in tasks that are typically solved using procedures. Further, if FTs can reason using the variable parts perspective, it shows the potential of introducing variable parts-based methods in FTs' mathematics content courses. To investigate this idea, we utilized the following research question: What methods do future middle grade teachers use when solving missing value proportion problems related to probability?

Theoretical Perspectives

In our courses with FTs, we use a quantitative definition of multiplication as a way to provide coherence among topics within the multiplicative conceptual field (Beckmann & Izsák, 2015). The definition of multiplication gives a foothold for FTs to reason about quantities in multiplicative situations and leads to four methods, two in each of the two perspectives (multiple batches and variable parts) on proportional relationships (Beckmann, Izsák, & Ölmez, 2015).

Quantitative Definition of Multiplication

Multiplication can be viewed quantitatively by considering equal-sized groups and units within those groups. We use this idea to produce the definition of multiplication in Figure 1. By consistently ordering the factors as multiplicand (N) times multiplier (M), the definition provides an organizational structure for tasks related to multiplication and allows for differentiation between multiplication, measurement (quotitive) division, and partitive division. An example is also given in Figure 1 to show how the definition of multiplication allows for this differentiation. Based on the choice of group from the situation, the definition of multiplication gives rise to four methods on proportional relationships found in the variable parts and multiple batches perspectives. We will now elaborate on these two perspectives and the four methods.

$$N \cdot M = P$$

How many base units make up one group exactly?

How many groups make up the product amount exactly?

How many base units make the product amount exactly?

Multiplication	**N • M = ?**	*If a baker can place 5 cookies on a plate and has 4 plates, how many cookies can the baker put on all of the plates?*	**5 • 4 = ?**
How-Many-Groups Division	**N • ? = P**	*If a baker can place 5 cookies on a plate, how many plates will the baker need to hold 20 cookies?*	**5 • ? = 20**
How-Many-in-1-Group Division	**? • M = P**	*If a baker has 4 plates to put cookies on and has 20 cookies total, how many cookies will the baker need to put on each plate?*	**? • 4 = 20**

Figure 1. A Quantitative Definition of Multiplication with an Example

Four Methods within the Two Perspectives on Proportional Relationships

In this section, we provide an overview of the two perspectives on proportional relationships and the four methods that arise from within these two perspectives. Due to page constraints, this overview is cursory. For a more thorough discussion of the two perspectives, see Beckmann and Izsák (2015). Similarly, for more information on the four methods, see Beckmann, Izsák, and Ölmez (2015).

The two perspectives on proportional relationships are known as *multiple batches* and *variable parts*. In the multiple batches perspective, two quantities measured by fixed units can be joined to form a "batch". A new pair of quantities, measured by the same units as above, is considered proportional to the original batch if the new pair of quantities is a multiple of the original batch. This corresponds to how-many-groups division in the definition of multiplication: the choice of a batch fixes the number of base units in the group (the multiplicand) and the number of groups (the multiplier) varies. In contrast, the variable parts perspective looks at proportionality by fixing the number of groups and varying the number of base units in the groups. This corresponds to how-many-in-1-group division in the meaning of multiplication. Beckmann and Izsák (2015) explained the variable parts perspective in the following way:

> …two quantities are said to be in the ratio A to B if for some-sized part there are A parts of the first quantity and B parts of the second quantity. In contrast to the first perspective [multiple batches], where A and B denote values based on a chosen measurement unit, here A and B specify fixed numbers of parts that can vary in size. (p. 21)

The difference between the two perspectives becomes more distinct when the four methods within these perspectives are shown. The *multiply unit-rate batch* and *multiply one batch* methods are situated within the multiple batches perspective and the *multiply one part* and *multiply whole amount* methods are situated within the variable parts perspective. Each of the four methods differs from the others by the choice of group. To clarify how these group choices affect the corresponding quantitative reasoning, we will consider the following example: *A spinner has five equal sectors with three of those sectors being red. If you spin the spinner 20 times, how many spins should land on red?* To explain how to solve this example, Figure 2 gives a math drawing and the corresponding definition of multiplication for each method. The group can be seen in blue and the number of base units in the group can be seen in red in each drawing.

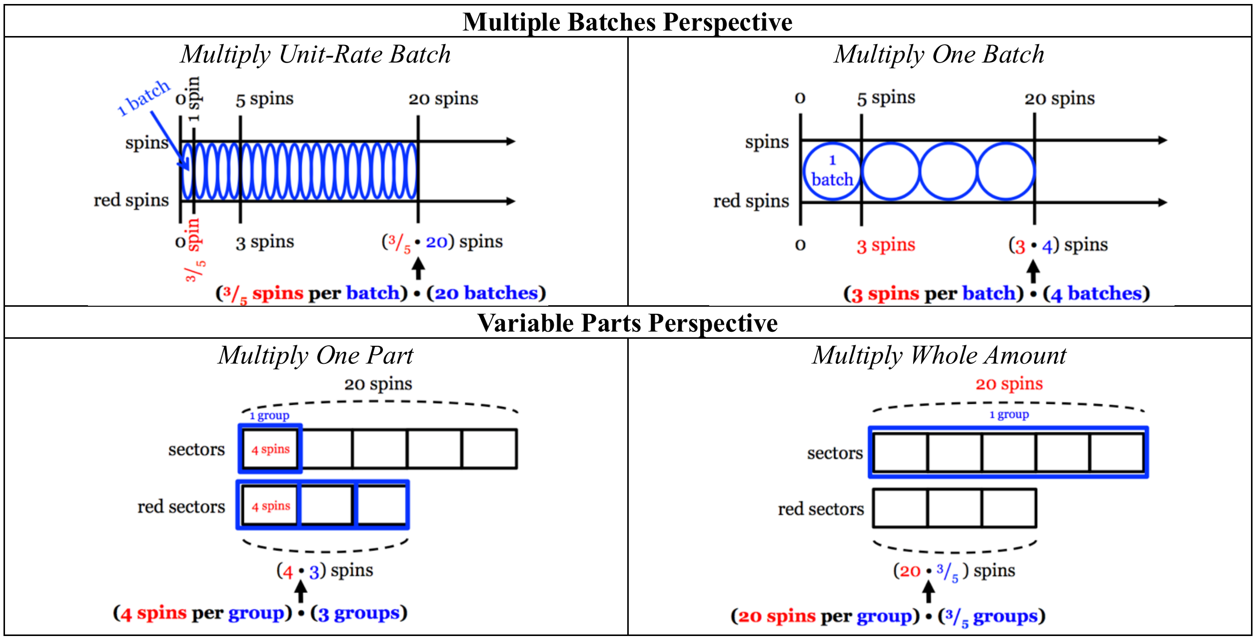

Figure 2. The Four Methods within the Two Perspectives

Data Sources

Data for this report come from a larger study at a public research university aimed at understanding how FTs in middle grade (4-8) and secondary (6-12) math education programs develop understanding of the multiplicative conceptual field. Participants in the larger study took part in six clinical interviews investigating ideas around the multiplicative conceptual field. Two cameras recorded each interview with one focused on a holistic view of the participant and interviewer and one focused on the participant's written work. The data for this report come from the sixth interview with four FTs in the middle grade program who were enrolled in the second content course focused on multiplication taught by the second author. The interview took place near the end of the Spring 2017 semester and focused on probability to see if the FTs could utilize multiplicative reasoning fostered in their content courses with yet-to-be covered topics. Each interview lasted approximately 75 minutes and the tasks used are found in Table 1.

Table 1: Tasks in Interview Involving Missing Value Proportion Problems

Task	Participant(s) Given Task	Wording of Task
1	All	If you were to spin the same spinner [on computer screen with 5 different colored sectors including red] 10,000 times or 100,000 times or 24 hundred thousand times, do you have any expectation about how many times it would land on red? Explain why or why not.
2	Nina Sophie Jack	If you were to spin the same spinner [on computer screen with 5 equal sectors, 3 purple, 2 blue] 10,000 times, 100,000 times or 240,000 times, do you have any expectations about how many times it would land on purple?
3	All	Suppose you want the spinner [5 equal sectors, 3 purple, 2 blue] to land on purple a total of 1500 times, about how many times should you expect to have to spin the spinner?
4	All	Please reconsider the spinner in Task 1. If you were to spin the spinner a bunch of times, say X times, or some specific large number of times, do you have any expectation about how many times it would land on red?

5	Sophie Molly	Please reconsider the spinner in Task 2. If you were to spin the spinner a bunch of times, say X times, or some specific large number of times, do you have any expectation about how many times it would land on red?
6a	Nina	If I wanted to get A spins to be yellow, what total number of spins would you tell me I should use? [Task is referencing a spinner with 10 equal sectors, 7 of which are purple, 3 are yellow]
6b	Sophie	Suppose I wanted to spin the spinner [referencing a spinner with 10 equal sectors, 7 of which are purple, 3 of which are yellow] enough times so that I got 2100 purples, could you give me a recommendation for how many total spins I should make?

Methods

Each interview was transcribed fully and augmented with relevant written work and hand gestures. All authors watched each interview alone and then as a group. The authors then identified all segments related to missing value proportion problems and coded these segments separately. Each author wrote notes and cognitive memos on (a) methods used, (b) concepts discussed related to the multiplicative conceptual field, (c) representations utilized, and (d) quotes that provided insights into methods/reasoning. At least two of the authors then met and discussed all authors' notes, referencing transcripts and videos as needed. Any discrepant interpretations were discussed until resolved. The first and second authors attended all meetings. These meetings led to the creation of the cumulative list of methods used by the participants seen in Table 2. The examples listed in the table do not exhaust all such instances of each method.

Table 2: Methods Used by the Participants During the Interview

Name of Method *Description*	**Example in Data**
Multiply One Part *Variable Parts Perspective* *See Figure 2*	"…we would take 1500 and divide that by 3, so that we know what each of the one-fifth parts are, because there are 3 one-fifth parts in this. And that will give us 500. So one-fifth of the total spins are 500 spins and… so then we'll multiply the 500 by 5 to get a whole, and that would be 2,500 spins." $1500 \div 3 = 500$ $500 \times 5 = 2500$ spins *–Molly, Task 3*
Multiply Whole Amount *Variable Parts Perspective* *See Figure 2*	"So if you have X spins, so if you're calling like X spins one round [annotates 'X' with 'x spins in 1 round']… then this would be one-fifth of that round [annotates '1/5' with '1/5 round']. So the question mark would be X… or not X. Question mark spins in one-fifth of a round [annotates '?' with '? Spins in 1/5 round']." $X \times \frac{1}{5} = ?$ x spins in 1 round; 1/5 round; ? spins in 1/5 round *–Molly, Task 4*
Multiply One Batch *Multiple Batches Perspective* *See Figure 2*	"Well, if you know that every 10 times you do it, it'll land on purple 7, that's like the same thing I was doing before where 10 times gives you 7 purple, how many spins gives you 2100 purple? That's multiplying by 300, so you'd have to do the same thing over here [to the 10 spins]." 10 spins = 7 P _____ 2100 P ×300 ×300 *–Sophie, Task 6b*

Multiply Unit-Rate Batch *Multiple Batches Perspective* *See Figure 2*	"If the spinner's going to land on a random spot for every spin, I think that for 1 spin, the chance is going to be three-fifths purple. And so, 10,000 spins, each one is also going to be three-fifths chance purple." $\frac{3}{5}(10,000)$ · purple *–Nina, Task 2*
Algebraic Manipulation *Writes a multiplication or division equation involving an unknown and uses numeric operations to solve for the unknown with no justification as to what the operations mean.*	Interviewer poses Task 6b, Sophie writes with no verbal justification: $X \cdot \frac{7}{10} = 2100$ $X = 2100 \times \frac{10}{7}$ $\frac{21000}{7}$ 2100 p *–Sophie, Task 6b*
Guess and Check *The participant guesses at a potential solution and uses numbers and operations in the context of the problem to check if the potential solution is correct.*	"And we want 1500 purple spins [writes '1500']. We're going to need, what, 3? We're going to need a minimum of 500 spins [writes '500']… other way around [crosses out '500', writes '4,500']. We'd need 45,000 [sic 4,500] spins. [writes '900 •3 = 2700'] Nope, that's not it [crosses out multiplication just written]…" 1500 ~~500~~ 4,500 *–Jack, Task 3*
"For Every" Language Connected with Fractions *Uses language such as "X for every Y" and states this is equivalent to either (a) "X/Y of the total", (b) writing the equation "(Total)•(X/Y)", and/or (c) writing the equation "(X/Y)•(Total)"*	"That if you spin it 10,000 times, 1 in every 5 times… or the red has the chance of being landed on 1 in every 5 times. So every 5 spins it has the chance of being landed on once, so that's the same as 10,000 times one-fifth." $10,000 \times \frac{1}{5}$ *–Sophie, Task 1*

Results

The results we present focus on the methods used by each FT when solving probability-based missing value proportion problems. Of note, all four FTs were able to engage in sound reasoning regarding the spins and spinners to solve the tasks. Additionally, all four FTs used at least one of the four methods from the two perspectives on proportional relationships during the interview, indicating they could reason about multiplication with quantities to solve probability problems. Lastly, though not always the initial method, all four FTs were able to use methods grounded in the variable parts perspective, showing this approach to proportional relationships is viable even in novel situations.

Sophie

Sophie's (all names are pseudonyms) initial method to solve four of her six interview tasks was not grounded in either of the two perspectives. Rather, Sophie used *"for every" language connected with fractions* to solve the first two tasks and *algebraic manipulation* for two other tasks (Tasks 3, 6b). When prompted for other methods to explain these tasks, Sophie justified her solutions from the multiple batches perspective, successfully explaining the *multiply one batch method* using both strip diagrams and ratio tables. Table 2 shows her typical reasoning for the *multiply one batch method*. For Sophie, using methods from the variable parts perspective only occurred when the questioning from the interviewer cued such reasoning. For instance, Sophie explained her equation, *X•1/5 = Red*, through the *multiply whole amount method* when asked to use the definition of multiplication in Task 4 and explained the *multiply one part method* only after being specifically asked to do so in Task 6b.

Jack

With the first two tasks, Jack justified his multiplication equations using *"for every" language connected with fractions*. He consistently discussed the spins landing on red as "1 out of every 5 times", an indicator of thinking about the spins from a multiple batches perspective. He approached Task 3 using *guess and check* (as seen in Table 2) but when that faltered, his language shifted from discussing the purple sectors as "3 out of every 5 times" to "3 parts of 5 that we need" and began reasoning using the *multiply one part method*. Using this method, Jack found the correct solution and provided justification with ease. Jack later revisited Task 3 and articulately explained the *multiply one part* and *multiply whole amount methods* using the definition of multiplication, drawings of spinners, and strip diagrams placed on a Cartesian coordinate system (a representation from the content course). Jack discussed his multiplication equation in Task 4 using *"for every" language connected with fractions* (again, discussing spins landing on red as "1 out of every 5 spins") but when asked about the definition of multiplication, he discussed his equation using the *multiply whole amount method*. Jack used multiple batches language throughout almost the entire interview and tended to justify his multiplication equations using such language. Yet, when these methods did not provide sufficient justification, Jack was able to discuss the two variable parts methods quite easily and with multiple representations.

Nina

Nina's use of the two perspectives was quite similar to Jack's. Nina completed the first two tasks using the *multiply unit-rate batch method* (see Table 2 for her typical explanation) and attempted Task 3 with the *multiply one batch method*. Though Nina found the solution, she was unable to justify it using her multiple batches method. After struggling for several minutes, her language shifted from discussing the purple sectors as "3 times for every 5 times" to "3 of my parts", which seemed to indicate a shift in thinking from a multiple batches perspective to a variable parts perspective. This shift allowed her to justify her answer using the *multiply one part method*. For the remainder of the interview, Nina did not use multiple batches methods again, nor did she use language that would indicate she was approaching the remaining tasks from the multiple batches perspective. Nina explained the *multiply one part method* in Task 4 when asked to use the definition of multiplication and though she used algebraic manipulation to initially solve Task 6a, she discussed the *multiply whole amount method* when asked for other methods.

Molly

Molly was the only FT to strictly use methods within the variable parts perspective throughout the interview. Molly regularly used how-many-in-one-group division to reason through the *multiply one part method* and was also facile in discussing the *multiply whole amount method*. A typical explanation of Molly's *multiply one part method* is in Table 2. When asked for differences between the two variable parts methods, Molly communicated these differences using equations, drawings of spinners, and strip diagrams. Molly needed no prompting to utilize the two methods within the variable parts perspective and used these methods to reason successfully throughout all interview tasks.

Conclusions and Implications

The results we present demonstrate that FTs taking a content course on multiplication can reason through missing value proportion problems using several methods that show conceptual understanding by reasoning with quantities. Thus, an increased focus on reasoning with quantities through a structured definition of multiplication could give FTs conceptual ways to approach problems that are frequently solved through rote procedure. Additionally, this study shows that FTs can use ideas from their content courses on multiplication to reason through novel tasks in the multiplicative conceptual field. This is promising because it indicates the FTs are beginning to see cohesiveness across topics within the multiplicative conceptual field and across mathematical ideas, which is a goal of recent standards documents (e.g., CBMS, 2012; NCTM, 2000). Though not typically the initial idea for the FTs, all four FTs could reason from the variable parts perspective and this perspective seemed to be advantageous at times compared to FTs' other methods. This result shows there is merit to giving FTs exposure to the variable parts perspective, a perspective that is typically overlooked (Beckmann & Izsák, 2015).

Future research in probability should explore the variable parts perspective. For example, a study could investigate if FTs can use the variable parts perspective to discuss the law of large numbers informally. Other studies could consider how FTs apply ideas from the multiplicative conceptual field to other mathematical areas, such as linear relationships and trigonometry. More specifically, investigating the accessibility and utilization of the variable parts perspective by FTs in these mathematical areas seems worthwhile. By investigating these topics, the field can gain a better understanding of FTs' abilities to reason quantitatively and the resources needed to support FTs in building connections between areas in the multiplicative conceptual field.

SECONDARY MATHEMATICS STUDENT TEACHERS' TYPES OF NOTICING WHILE TEACHING

Dawn Teuscher
Brigham Young University
dawn.teuscher@byu.edu

J. Matt Switzer
Texas Christian University
j.switzer@tcu.edu

The purpose of this paper is to describe secondary mathematics student teachers' types of noticing while teaching. We discuss the importance of focusing on the interrelatedness of the noticing skills rather than reporting on individual skills separately. We apply the types of noticing to videos of student teachers to identify their ability to elicit and interpret student mathematical thinking in-the-moment while teaching. Results suggest that our student teachers did elicit and attend to student mathematical thinking while teaching, but how they interpreted the elicited student thinking varied. We hypothesize three reasons for why student teachers may have interpreted student mathematical thinking at a general level.

Keywords: Teacher Education–Preservice, Teacher Knowledge, Mathematical Knowledge for Teaching

Teaching is a complex activity that requires teachers to make purposeful in-the-moment decisions to attend to some activities while disregarding others. Sherin and Star (2011) noted that teachers are "bombarded with a blooming, buzzing confusion of sensory data" (p. 69) that he/she must sift through to make in-the-moment decisions to support student learning. For preservice teachers (PTs), the cacophony of sensory data can be more difficult to sift through than experienced teachers resulting in PTs becoming overwhelmed, focusing on small tasks (e.g., one group of students, one solution strategy, one students' voice) and neglecting or missing other important aspects of teaching (e.g., multiple ways of student thinking, actions of all students in the class).

Researchers have used noticing to focus teachers' attention on important aspects of teaching; however, because teachers tend to notice a variety of information in a classroom (e.g., teacher actions, student actions, classroom management, posters on the wall) guidance on what to notice, especially for PTs, is necessary (Jacobs, Lamb, Philipp, & Schappleel, 2011; Sherin & van Es, 2005; Star & Strickland, 2008; Star, Lynch, & Perova, 2011; Stockero, 2014). Jacobs, Lamb, and Philipp (2010) extended the construct of teacher noticing to —professional noticing of children's mathematical thinking, which is conceptualized "as a set of three interrelated skills: *attending* to children's strategies, *interpreting* children's understanding, and *deciding* how to respond on the bases of children's understanding" (Jacobs et al., 2010, p. 172, *emphasis added*).

Mathematics education researchers have used Jacobs et al.'s (2010) framework to learn what teachers attend to and how teachers interpret and respond to children's mathematical thinking (e.g., Schack, Fisher, & Wilhelm, 2017). As a field, we have learned more about professional noticing, specifically researchers often focus on one of the three interrelated skills (attending, interpreting, or responding) in a reflective setting, thus artificially compartmentalizing these interrelated skills. We argue in this paper that investigating *the interrelatedness* of the noticing skills is critical to understanding how teachers apply these skills when teaching. We also share how we, as researchers, utilized professional noticing to determine how our secondary mathematics student teachers elicited and acted on student mathematical thinking (SMT) in-the-moment <u>*while teaching*</u>.

In this paper, we report on the following research question: To what extent do secondary student teachers elicit SMT and interpret that thinking in-the-moment while student teaching?

Theoretical Framework

To analyze and interpret our data we frame our view of eliciting and acting on SMT through Piaget's (1955) construct of decentering and Teuscher, Leatham, and Peterson's (2017) types of noticing.

The construct of decentering provides a powerful lens for examining student-teacher interactions because it focuses on the teacher's interpretations of students' verbal and written explanations to make in-the-moment decisions while teaching. We seek to draw inferences about how student teachers' understanding of SMT relates to their actions in-the-moment of teaching. According to Piaget (1955) decentering characterizes how the actions of an observer (i.e., student teacher) attempting to understand how an individual's (i.e., student's) perspective differs from his/her own. Steffe and Thompson (2000) and Thompson (2000) distinguished two ways in which individuals interact with others, which are described by the type of model that an individual creates of other's thinking. Thompson (2000) described individuals as participating unreflectively or reflectively. Individuals who participate unreflectively were describe as creating first-order models. "The models an individual constructs to organize, comprehend and control *his or her experiences*, i.e., their own mathematical knowledge" (Steffe & Olive, 2010, p. 16 *emphasis added*). Whereas, individuals who participate reflectively were described as creating second-order models, attempting to elicit and interpret SMT, and assist students in furthering their thinking based on the students' perspectives, not their own (i.e., decentering).

Teuscher et al. (2017) extended Jacobs et al. (2010) professional noticing framework describing types of noticing. These types of noticing were based on student teachers' written journal entries completed during student teaching. Attending to SMT was divided into two categories: *general observation* or *student mathematical thinking*. Interpreting SMT was also divided into two categories: *general interpretation* or *root interpretation*. Four types of noticing specifically connect the two skills of *attending to* and *interpreting* SMT. They were: (1) general observation, no interpretation; (2) general observation, general interpretation; (3) student mathematical thinking, general interpretation; and (4) student mathematical thinking, root interpretation (see Teuscher et al., 2017 for specific definitions). We seek to apply these four types of noticing to videos of student teachers by identifying their ability to elicit and interpret SMT in-the-moment <u>*while teaching*</u> (e.g., decentering). Specifically, we are interested in identifying what SMT student teachers attend to while teaching and in what ways they interpreted the SMT that was available to them.

Methods

Pairs of student teachers where assigned a 16-week placement at a junior high or high school. The university supervisor, first author, observed the student teachers once a week and provided feedback during their student teaching experience. Data were collected on four pairs of student teachers (eight student teachers) during two different semesters. The researchers purposefully selected four pairs of student teachers to allow for variability in the data set. All eight student teachers' lessons observed by the university supervisor were videotaped. The researchers analyzed three lesson videos (beginning, middle, and end of student teaching) for each student teacher, 24 total, and coded each using the *Practice of Probing Student Thinking* Framework (Teuscher, Switzer, & Morwood, 2016) to identify instances where student teachers appeared to elicit and act on SMT. We chose probing student thinking because it allowed the researchers to identify instances of SMT and possible interpretations of the student thinking by the student teachers.

To identify a subset of instances of probing student thinking to analyze, we compared the researchers' instances to the student teachers' instances of probing student thinking and found 27 overlapping instances, which indicated that student teachers seemed aware of SMT. Using the researchers' instances from the overlapping instances, we conducted our analysis to determine how the student teachers were eliciting and acting on SMT in-the-moment while teaching. Our unit of analysis was an individual video instance of probing student thinking, defined as a complete interaction between a teacher and student(s). The researchers used the types of noticing framework (Teuscher et al., 2017) to identify the elicited SMT in the video instances and inferred the student teachers' interpretations of the SMT based on their response to the SMT in the video.

In the following section, we provide illustrative examples from our data set to describe these different types of noticing. Video instance 1 is the transcript for one probing student thinking instance that occurred near the end of a high school mathematics class. The high school students spent the class period learning about graphing quadratic inequalities and using the graphs to find the solutions to the quadratic inequalities.

Student Teacher: So, what did we notice the difference between these two answers [one answer was $x<5$ or $x>11$ and the other answer was $-5<x<1$]? The one from our previous problem and this one? What's the difference? Student 1?
Student 1: Um, it's not like infinity on it so it doesn't go on forever, it stops.
Student Teacher: Yeah, and what did we notice about the equations at the top of number nine and ten? How are they different in terms of the signs? Yeah, Student 2?
Student 2: One [function] is showing like one is less than zero and one [function] is greater than zero so that changes when it's outside or inside.
Student Teacher: And when do we know if it's going outside or inside?
Student 3: If it's greater or less than zero. Wait, what?
Student Teacher: Okay, say, what happens when it's greater than zero?
Student 3: Then the arrows on the outside go inside.
Student Teacher: Um, is it, let's see, I think in this case we also had our, both our parabolas, which way are they opening?
Students: Up.
Student Teacher: Yeah, so we want to make sure and graph and make sure they were opening up, because if it was opening down we might have a different answer.

We identified video instance 1 as a *General Observation* and *General Interpretation*. The general observation is because we could not infer the SMT. We have some idea that students are discussing whether a quadratic function is greater than zero or lesson than zero, but we were unable to determine what students meant when they said, "*that changes when it's outside or inside*" (Student 2) or "*then the arrows on the outside go inside*" (Student 3). The general interpretation was based on the student teacher's response to Students 2 and 3 because she seemed to carry the discussion on without seeking clarification of what students meant by "*that changes when it's outside or inside*" (Student 2) or "*then the arrows on the outside go inside*" (Student 3).

Video instance 2 is the transcript for another probing student thinking instance that occurred at the beginning of a middle school mathematics class. Students were learning about unit rates, constant growth rates, and linear equations. Students were shown a graph of a linear function (number of hands as a function of number of people) and asked to answer the following three questions: (1) What is the unit rate and what does it represent? (2) If there are 6 hands, how many people are present? (3) How many hands are there if there are 52 people? The transcript is from the class discussion about the first question.

Student 1: I was looking at this one right here [points to the point] this dot right here (1, 2), and since it is the lowest one that is not (0, 0) that is the unit rate because all you need to do is multiply it by two and it will keep going on forever.
Student Teacher: Multiple what by two?
Student 1: Multiply people and hands by two.
Student Teacher: People and hands? I am not sure I understand what you mean.
Student 1: One person times two is two people, well (pause). You add one person here then you add two hands. Whenever you go up one dot it goes add one person then it goes add two hands.
Student Teacher: Ok, so you are saying…
Student 2: There is a constant growth pattern.
Student Teacher: [revoicing] There is a constant growth pattern that you add one here (pointing to the person axis) and you add two here (pointing to the hands axis).
Student 1: Yes
Student Teacher: And then continue on?
Student 1: Yes
Student Teacher: Okay. Okay. Awesome, so your unit rate is what?
Student 1: One to two.
Student Teacher: [revoicing and writes on the board: 1 to 2], One to two, and what are your units?
Student 1: Units?
Student Teacher: What does this 1 represent [pointing to the 1 on the board]
Student 1: People. People. People to hands

We identified video instance 2 as Student Mathematical Thinking and Root Interpretation. The SMT was "I was looking at this one right here [points to the point] this dot right here (1, 2), and since it is the lowest one that is not (0, 0) that is the unit rate because all you need to do is multiply it by two and it will keep going on forever" (Student 1). In other words, the student is saying that you can use the point on the line closest to (0, 0) to determine the unit rate, which is the point (2, 1) to which he points. We inferred that the student teacher made a root interpretation – a more in-depth analysis of what the students might have meant by their utterance, or what that thinking means with respect to student understanding – because the teacher was unsure what Student 1 referred to when he states, "multiple it by 2." Therefore, the student teacher asks clarifying questions to which the student responds with "One person times two is two people, well (pause). You add one person here then you add two hands. Whenever you go up one dot it goes add one person then it goes add two hands" (Student 1). The student teacher seemed aware of the difficulty that middle school students have when beginning to work with multiplicative relationships. Following up on the statement, "you multiply it by 2" (Student 1), allowed Student

1's thinking to be made public. In responding, Student 1 begins to think about the multiplicative relationship between the number of hands and people. As he is explaining his thinking he realizes he is not correct and reverts to an additive relationship for which he is familiar.

Results

Table 1 displays the percentage of video instances based on the types of noticing. We found that merging the separate noticing skills captured the interrelatedness of attending and interpreting that reveals important and distinguishing aspects of how the student teachers acted on SMT. Of the 27 video instances the researchers coded 23 (85.2%) provide evidence of the student teachers eliciting SMT and 4 video instances (14.8%) provided evidence of the student teachers making a general observation of the SMT. However, of the 23 video instances that include evidence of SMT, 14 video instances (51.9%) include evidence of a root interpretation and 9 video instances (33.3%) include evidence of a general interpretation. Therefore, the results indicate that the student teachers were highly successful in eliciting SMT, but often did not generate a root interpretation of the elicited SMT.

Table 1: Student Teachers' Video Instances by Types of Noticing

Attending	Interpreting	Instance Count	Percent
Student Mathematical Thinking	Root Interpretation	14	51.9%
	General Interpretation	9	33.3%
General Observation	General Interpretation	4	14.8%
Total		27	100.0%

For the remainder of this report, we focus our analysis on the nine video instances where the student teachers elicited SMT but made a general interpretation. In these instances, there was no evidence that the student teachers generated a root interpretation of the elicited SMT. We were interested in identifying potential factors that may have led to the student teachers not generating a root interpretation. We share two transcripts that are representative of the SMT with general interpretation type.

Video instance 3 occurs at the beginning of a high school lesson. Students were working on a task to determine if different situations were fair or unfair to assist them in generating a mathematical definition of fair. The following transcript provides the conversation between the student teacher and a student.

Student: I think it is fair, but I am trying to think how it might not be fair?
Student Teacher: What is your definition of fair?
Student: It would be more fair if everyone got a prize or something, but this isn't the type of thing where everyone could get, I don't know, I'm thinking realistic.
Student Teacher: So, are you reconsidering the definition then of fair?
Student: Kind of, literally fair is everyone gets it.
Student Teacher: Gotcha, so like equality. Like everyone would get one?
Student: But this scenario is confusing me; it wouldn't be fair if they said that the tallest person gets the prize if they are short.
Student Teacher: Gotcha, so then that would be bias against the short people, right?
Student: Yeah, so this is, I don't know, this is like everyone has the same opportunity.
Student Teacher: (revoicing) Okay, so everyone has the same opportunity. So, does this one fit that definition of fair, this scenario?

Student: Yeah, everyone got a ticket and everyone had the, like, gets the opportunity to be picked, it's just not everyone gets picked.
Student Teacher: Right so we all have, so you and I might be in the drawing and we might not both get picked, but we have equal chances?
Student: Yeah
Student Teacher: Which is what you were saying? As long as you explain I am ok with whatever you come up with.

Our analysis of video instance 3 found that the student teacher attended to SMT multiple times. The student teacher asked the student if she was reconsidering her definition of fair. The student suggested that "*fair means everyone gets a prize,"* which is a common definition of fair but not the mathematical definition. Then the student seems confused because she thinks "*fair means everyone has the same opportunity*." While the student teacher seemed to identify that the student had two definitions of fair, how the student teacher acted on this SMT was revealing. The student teacher indicates to the student that it does not matter which way she thinks about it as long as she can explain her thinking. In other words, both of the student's definitions were acceptable. Throughout the lesson multiple students continued to bring up and discuss these two definitions of fair and the student teacher never distinguished the difference between the definitions. In concluding the lesson, the student teacher stated, "as long as we can explain why whatever method we use was fair then it should be fair, right?" We inferred that the student teacher's mathematical meaning for fair (Byerley &Thompson, 2017) may have resulted in her interpreting the SMT at a general level.

Video instance 4 occurs in a high school lesson where students were learning about probability. The students were given the following problem to work on in groups.

> Two students, Lee and Rory, find a box containing 100 baseball cards. To determine who should get the cards, they decide to play a game with the following rules:
> - One of the students repeatedly flips a coin.
> - When the coin lands heads up, Lee gets a point.
> - When the coin lands tails up, Rory gets a point.
> - The first student to reach 20 points wins the game and gets the baseball cards.
>
> As Lee and Rory are playing the game they are interrupted and are unable to continue. How should the 100 baseball cards be divided between the students given that the game was interrupted at the described moment? When they are interrupted Lee has 19 points and Rory has 17 points.

A student (Bill) shares with the class that Rory should get 17/36 of the cards and Lee should get 19/36 of the cards. Other students in the class respond with "*what?*" and "*where did the 36 come from?*" The following transcript captures the ensuing conversation between the student teacher and the students in the class.

Student Teacher: Okay, [student 1] has a question about where the 36 came from?
Bill: You take the 19+17 to get the 36.
Student Teacher: So how many cards do you give each person than?
Bill: Um, still trying to figure that out.
Student Teacher: (Writes $\frac{17}{36} * \frac{x}{100} =$on the board) and how many cards do they each have?
Student 2: The first one is 52
Student Teacher: (revoices) 52 for Rory

Student 3: 52 for the other one 47 for that one
Student Teacher: (writes on the board x=52)
Student 4: 52.7 and 47.2
Student Teacher: (revoices) 52.7 and 47.2 and writes them on the board.
Student 3: That should actually be 0.8.
Student Teacher: Which one?
Student 3: That one (points to the Rory column)
Student Teacher: (Erases the 52.7 and writes 52.8), Kay, student, what do you think we should do with the 0.8 and 0.2 of a card?

Our analysis of video instance 4 found that the student teacher attended to SMT multiple times. The student teacher asked the Bill to explain where the 36 came from in response to another student's question. Students provide the number of cards that they calculated Rory and Lee should receive. The student teacher seems to identify that Bill has based the number of cards that Rory and Lee should receive on their respective theoretical probabilities of winning. The student teacher accepts Bill's strategy and immediately moves to asking the class what they think they "*should do with the 0.2 and 0.8 of a card,*" assuming the rest of the students, those who initially did not understand Bill's reasoning, now understood his thinking. We inferred that the student teacher's not decentering (Piaget, 1955; Teuscher, Moore, & Carlson, 2016) may have resulted in her interpreting the other students' mathematical thinking at a general level.

Table 2 displays the three categories for the nine video instances where student teachers elicited SMT but made a general interpretation of the elicited SMT. The majority (66.7%) of video instances fell in the category of not decentering. As in video instance 4, the student teacher only seemed concerned with making sure that everyone had the correct answer, rather than helping students understand how Bill (the student) had come up with the answer and why that made sense. In two video instances (22.2%) we determined that the general interpretation was appropriate. This was because the student teacher was launching an activity where students later explored the ideas that they had shared. The goal during a launch of a task is to make student thinking public so it can be discussed; therefore, we felt that at that point in the lesson the general interpretation was appropriate. The last category was the influence of the student teacher's mathematical meaning as described in video instance 3.

Table 2: Possible Reasons Secondary Student Teachers' May Not Generate a Root Interpretation

Inferences for why student teachers make a general interpretation	Count	Percent
Not Decentering	6	66.7%
Appropriate	2	22.2%
Mathematical Meaning	1	11.1%

Implications

The purpose of this paper was to describe secondary mathematics student teachers' types of noticing while teaching. We demonstrated the importance of the interrelatedness of the attending and interpreting noticing skills because the types of noticing revealed important and distinguishing aspects of how the student teachers were acting on SMT. We found that our student teachers were highly effective with eliciting SMT in-the-moment of teaching. However, we found that our student teachers were less successful in interpreting the elicited SMT in-the-moment of teaching with a root interpretation. While there were two video instances where it was appropriate for the student teachers to interpret at the general level, most video instances were student teachers interpreting at the general level that were because the student teachers were not decentering.

While our analysis is a small subset of video instances from eight student teachers, we believe that future research can focus on identifying differences among student teachers to identify what practices PTs need to focus on during their course work that will prepare them to attend to and interpret SMT in such a way that will build on all students mathematical thinking and improve student learning in their classrooms. We recommend that teacher educators need to assist PTs in learning how to interpret SMT from the perspective of the students (e.g., decentering). While we would agree that this is a challenging skill for PTs to develop, we had student teachers who identify a root interpretation of the SMT in-the-moment while teaching, which allowed the student teacher to orchestrate a productive discussion in their mathematics classroom with all students.

REIMAGINING DEFINITIONS OF TEACHING MATHEMATICS FOR SOCIAL JUSTICE FOR PRESERVICE SECONDARY MATHEMATICS TEACHERS

Gabriela E. Vargas
University of Illinois at Urbana-Champaign
gvargas2@illinois.edu

Rochelle Gutiérrez
University of Illinois at Urbana-Champaign
rg1@illinous.edu

We investigate definitions and approaches that preservice secondary mathematics teachers develop about teaching mathematics for social justice while participating in an equity-based, anti-racist professional development program. We analyzed transcripts from seminar sessions of the program where participants discussed different forms of teaching mathematics for social justice. Participants described their possible teaching with what is seen in the literature while moving beyond in formulating other possible representations of teaching mathematics for social justice. These findings suggest that it may be necessary to further theorize our understanding of teaching mathematics for social justice so that representations include everyday practices beyond representations in curriculum.

Keywords: Teacher Education, Equity and Diversity, Teacher Knowledge, Social Justice Mathematics

Mathematics education continues to attempt to address injustices in multiple ways as we look for possible solutions through teaching mathematics for social justice. Some would argue providing all students with access to rigorous mathematics is an act of social justice (Moses et al., 1989; Gregson, 2013). Critical scholars suggest we change the curriculum, using mathematics as a tool to analyze injustices in society and to propose math-based solutions (Frankenstein, 1983, Gutstein 2005). This approach has become the dominant definition of teaching mathematics for social justice (TMSJ). It allows students to develop other life skills (e.g., questioning authority) that mastering "dominant mathematics" (Gutiérrez, 2002; Valero, 2004) does not guarantee (Bartell, 2013; Felton-Koestler, 2015; Gregson, 2013; Gutstein, 2006). However, carrying out this version requires knowledges, skills, and life experiences that many teachers lack. This paper investigates how pre-service secondary mathematics teachers (PMST) are developing their definitions and approaches to what TMSJ as they become educators in the field. Our current understanding and implementation of teaching mathematics for social justice have plateaued due to neoliberal educational values (e.g., individualized learning, privatization through charter schools, increase focus on profitizing through universal curricula models), that drive mathematics education. It is safe to say that there is a need to deeper theorize social justice in mathematics education. This paper seeks to understand the range of views of TMSJ that pre-service secondary mathematics teachers embrace after being exposed to a variety of anti-racist and social justice-oriented media and individuals.

Current Understanding of Teaching Mathematics for Social Justice

Mathematics education has a persistent history where students who are Latinx, Indigenous and Black have not had access to a rigorous mathematics curriculum thereby limiting the doors and economic possibilities that they can pursue in society. Some would argue that merely providing minoritized students access to dominant mathematics and science, technology, engineering and mathematics (STEM) pipeline is a form of social justice (Brantlinger, 2013; Felton-Koestler, 2015). The Algebra Project is one prominent example of transforming algebra curricula to create an entry point for African American students (Moses et al., 1989). Through grassroots organizing, teachers, students, and parents established a pedagogy of mathematics that supported students to participate in economic and technological changes (Moses et al., 1989). Other researchers agree and have defined social justice as "empowerment, both for teachers and for their immigrant students" to succeed in dominant mathematics (Planas & Civil, 2009) and highlight the importance of students being able to navigate mathematics as a gatekeeper in the real-world (Gregson, 2013).

Definitions of social justice or critical mathematics vary depending on the populations that adopt them, the worldviews espoused, and situations at hand (Gates & Jorgenson, 2009; Stinson & Wager, 2012). For the most part, what gets counted as social justice mathematics teaching involves changing the curriculum (Bartell, 2013; Brantlinger 2007; Gregson, 2013; Gutstein, 2006) to take up examples of real-life situations (Felton, 2010) or to use mathematics to read the world and possibly write the world (Gutstein, 2006; Frankenstein, 1990; 1995). For example, Gutstein (2006) had his students survey the community on experiences with the police to calculate the likelihood that a police officer will pull over a brown or Black person, versus a white person, when driving a car in a given neighborhood, while Frankenstein (1990, 1995) had her low-income college students use mathematics to examine discrimination in costs of electrical power, home mortgage distribution, and the tax system to highlight how mathematics is sometimes used to obscure economic, political, and social issues. In fact, the inclusion of ethnomathematics lessons can be seen as a form of social justice curriculum (Borba, 1990; Powell & Frankenstein, 1997) because ethnomathematical knowledge decenters a Western and colonial view of mathematics (Gutiérrez, 2017).

Critical Perspectives to Teaching Mathematics for Social Justice

While creating access to dominant mathematics is essential for Black, Latinx, Indigenous and other minoritized students, as well as interrogating injustices that these communities may experience, some would also argue for critical representations of mathematics. Such representations move beyond using social justice mathematics as curriculum and disrupt dominant social narratives and representations of mathematics (Gutiérrez, 2017; Skovsmose, 1994). Teachers and students who participate in these types of critical representations of mathematics are participating in "tactics of resistance" (Gregson, 2013) of social and institutional inequities replicated in the classroom. Providing teachers with opportunities to envision "tactics of resistance" are limited within our current literature of TMSJ except for few. That is, students need to learn mathematics to participate in the neoliberal capitalist agenda in society while being able to critique it and "play the game/ change the game" (Gutiérrez, 2008).

Teacher Practices of Social Justice Mathematics

Beyond offering a sociopolitical context of mathematics units and lessons, it is difficult to see what other forms of social justice teachers can implement in their classrooms. Although there is a strong emphasis on changing the curriculum (e.g., adopting sociopolitical contexts for learning mathematics in particular activities or units), in fact, there is a range of practices that contribute to social justice mathematics teaching. One such form is pedagogy of questioning—a "classroom environment… co-created by students and teachers [where] students have opportunities to pose their own real, meaningful questions" (Gutstein, 2008, p. 55). Pedagogy of questioning is not necessarily curricular driven but allows students to see the importance of asking questions and challenge the notion that teacher knows all. Another practice is developing relationships with students (Planas & Civil, 2009 Gutstein, 2008) in non-stereotypical ways (Bartell, 2013) by being aware of students' realities to empower their success and participation in mathematics classrooms. Empowering students includes being able to recognize the need to address race and gender issues as institutional issues (Frankenstein, 1990; 1995). Understanding students in non-stereotypical ways are important because it pushes teachers to anticipate the types of responses that students can have in a lesson (Bartell, 2013) and support the emotions that can arise (Boylen, 2009).

While developing relationships with students and implementing pedagody of questioning are valid representations of everyday tactitcs that teachers can do on a daily basis, one has to question if they are realistic in the current mathematics classroom? Research studies that address perceptions held by teachers implementing TMSJ highlight how many can get discouraged by the difficulty of implementing such lessons (Bartell, 2013) or feel it is difficult to implement while trying to keep the rigor of higher-level mathematics (Brantlinger, 2013). The increasing demand of high stakes testing presents time constraints for implementing social justice mathematics lessons, resulting in "end of the year activities"—making it seem like it is just an add-on, or afterthought, to more crucial traditional mathematics curriculum. There are limited representations of what other practices could look like. The exception to this are representations of the pedagogy of questioning (Gutstein, 2008), creating relationships with students, and challenging one's beliefs and identities (Bartell, 2013; Boylen, 2009; Gregson, 2013 Gutstein, 2008;). These constraints limit pre-service teachers being able to become a teacher that teaches mathematics for social justice if they feel like it requires entirely or mainly changing the curriculum, something for which they may feel they have no power to do in an era of high stakes education. Furthermore, we need to ask how

Methods

Data

The data in this paper comes from an equity-based professional development program in a Midwestern University where two cohorts of undergraduate pre-service mathematics scholars (juniors and seniors) interacted. Scholars received professional development including bi-weekly seminars, mentoring sessions, a partnership with a Chicago teacher, an after-school mathematics club, and critical professional development. In seminars, scholars discussed readings/videos about issues of racism and racialization, white supremacy, gender, social justice, and mathematics; learned about mathematics in nontraditional ways; engaged with guest speakers, and interacted with alumni.

Scholars consisted of two cohorts of junior and senior scholars. Junior scholars were in the first year of the program while seniors were in their second year. Juniors consisted of six scholars, of which, three self-identify as white women, one as cis-gender Latinx man, one as Asian women and one white man. Seniors consisted of seven scholars, one self-identifies as an Asian woman, and six as white women. Two self-identify as queer. Most of the scholars originated from the suburbs of a major Midwestern City and one originated from a rural town in a Midwestern state. All scholars received a scholarship in exchange for committing to teach in a school in a community of cumulative disinvestment for four years following graduation.

We focus upon two different 3-hour seminar sessions: "Teaching Mathematics for Social Justice (part 1 and 2)." Table 1 shows the topics and participants. Before coming to the seminar, scholars wrote a letter to Gutstein, reflecting on his teaching and their stances on TMSJ, especially what was appealing or concerning for them.

Table 1

Seminar Activity Topics

Activity	Participants	Materials Covered

Day 1			
	Book Discussion Part 1	Juniors	Reading and Writing the World with Mathematics
	Study of SJM Materials	Seniors	Social Justice Math Unites created by Brian Lake
	Conversation with Scholars	All	Social Justice Math Unites created by Brian Lake
Day 2			
	Book Discussion Part 2	Juniors	Reading and Writing the World with Mathematics
	Study of SJM Materials	Seniors	Guide for Integrating Issues of Social and Economic Justice into Mathematics Classrooms and Curriculum
	Questions and Stances	All	Notes and Summaries from split sessions

Analysis of Session Audio and Materials

We placed audio recorders in multiple parts of the rooms where discussions took place. We then transcribed verbatim, focusing on the relevant conversations about social justice mathematics. We transcribed a total of 140 minutes for each of the two sessions, using codes that arose in the literature. Some of these codes include references to Social Justice Mathematics, (e.g., reading the world, writing the world, challenges, curriculum) and Classroom Norms (e.g., group work, critical thinking). Other categories such as Ethical Teacher Practices (e.g., political clarity, stance, windows/ mirrors) came from existing categories of codes that we have as a project or literature our research team has produced. During the first round of coding, we captured themes that confirmed existing trends in the literature of social justice mathematics as well as highlighted themes not captured in the literature. For example, we created the code ETP-spectrum to highlight when the scholars brought up ideas of having multiple possible stances on a sociopolitical topic represented in their classroom—a representation of teaching mathematics for social justice that Brian Lake brought up in his conversation with the scholars. During the second layer of coding, we looked for other things the scholars considered as representations of everyday social justice practices. It is important to note that the researchers never directly asked for the scholars to list their explicit definition of what they consider teaching mathematics for social justice, as we worried that they would simply tell us what they believed we wanted to hear. Instead, we looked for examples of the scholars talking about the readings or their everyday practices that reference their stances of being social justice educators who can continuously push back on dominant narratives of what happens in the classroom. We then clustered the codes into different themes that showed a representation of current definitions of teaching mathematics for social justice as well as representation of everyday practices that teachers can enact their social justice teaching stances (Emerson, Fretz, Shaw, 2011). These themes include redefining mathematics, delegating authority, and examples of teaching students to be critical participants in society. Though our scholars held definitions and stances like some found in other studies, we focus the reporting of our findings on concepts not typically or explicitly addressed in empirical studies of teachers enacting TMSJ.

Findings

TMSJ as Redefining Mathematics

One way that the scholars look at TMSJ was the way they interpreted the role of mathematics and the practices that surround mathematics. Scholars brought up multiple ways of being able to redefine mathematics. One example is making mathematics applicable across school subjects.

> *Catherine:* I think it would be more beneficial **if we actually gave them examples of how to apply it. Connect it to these types of problems that are actually happening in the**

> **world…. Like [Mathematics] wouldn't have to be a separate thing**. Schools would be better off…if we are on the same page with stuff, connect the ideas, and use what other teachers are teaching.

Catherine states that some schools and teachers treat mathematics as its own "separate thing" within the curriculum. For her, having mathematics disconnected from other subjects does not allow students to see how mathematics relates to other subjects and can be applied in solving problems in the world. TMSJ as teaching math in a holistic approach would not only benefit students but the whole school to by applying all subjects to solve problems in the world. This way of redefining mathematics would not only benefit how students learn in the classroom but also support collaboration with teachers across content areas.

For the scholars, TMSJ means redefining mathematics so that students can develop different perspectives of what is the role of mathematics in increasing opportunities for students to create and understand mathematics around them. The scholars are beginning to formulate that the role of mathematics is not only providing instrumental access to mathematics as a curriculum, but it is also teaching mathematics in a holistic approach as well as teaching students to provide a spectrum of solutions. By opening different ways of knowing mathematics and who gets to be knowers, Black, Indigenous and Latinx students can not only see themselves as having something to say but are also encouraged to develop new mathematics, a way in which students can also be authors of the world.

TMSJ as Delegating Authority

In this section our scholars talk about TMSJ as finding different ways to delegate authority in the classroom. Whether it was making decisions about curriculum or facilitating discussions, delegating authority is a way to empower students in the classroom. During the conversation of scholars one scholar brings up

> *Wendy:* I am considering **redefining the structure of the roles of students in the classroom**…how [do we] get student-led discussions, **more student-led than teacher driven**. And then have them ask the questions first. What kinds of questions are we looking at when we are examining the social justice topic?

For Wendy, redefining the structure of the roles of students in the classroom is a social justice practice in that a teacher is giving up knowing the direction of a conversation and letting students decide where it should go. In this sense, she sees students being authors of the classroom (Povey & Burton, 1999). Wendy recognizes that there are daily things a teacher can do to empower her students in the classroom that could lead to questioning other power structures and dynamics in their lives. By disrupting power structures that exist in classrooms, scholars see the connection between social justice teaching and helping students develop the skills to interact as critical participants of society.

TMSJ is capacity as critical participants in society

The scholars are not just thinking about how students can be successful in their classroom, but also what skills they can learn and carry with them that can impact students as critical participants of society. These skills include supporting perseverance; teaching students to struggle; developing opinions and being able to express them; being able to efficiently communicate given constraints of a task; and taking responsibility of their peers as a community.

Tied to students being critical thinkers, Catherine defines TMSJ as allowing students to be confident and able to communicate their opinions. she shares one of her goals is to help students develop confidence by showing students the importance of sharing their opinions.

> *Catherine:* Expression of **your beliefs** or kind of like you. The way you communicate your feelings... **you have to be able to develop an opinion, but also express it in a way that is true to yourself but respectful for other people involved with it as well**. [Students] have opinions and I feel like **being able to express them is pretty important component of social justice** and I feel like should be incorporated in the classroom as well.

Catherine recognizes that her students do have an opinion and being able to express it is important for her students to learn. Whether it is a student who is passionate about approaching a problem a certain way or an opinion in a current topic that impacts the students, Catherine acknowledges that students' opinions are not only connected to their beliefs but also to their emotions about these topics. She goes beyond to express how it is not enough for students to develop their opinions but to also "be true to yourself [and] also respectful for other people involved" in the conversation. Catherine wants students to develop skills that reflect the dignity that they would like to see beyond mathematics content. Traditional mathematics lessons tend to focus on the individual and do not necessarily focus on the well-being of others. Thus, developing an opinion that is both true to yourself as a student but also takes into consideration those around you in the conversation is a form social justice that goes beyond what can be used in mathematics classrooms and toward rehumanizing mathematics (Gutiérrez, 2018).

Pedagogical Moves for Implementing TMSJ Definitions

While some may feel like it is not an accomplishment to get pre-service teachers to talk theoretically about their definitions of social justice, we have evidence that our scholars enacted their definitions as student teachers. Some of the scholars even developed their own social justice lessons that incorporated exponential growth with issues of housing regulations. We do not analyze those social justice lessons here, as they tend to replicate the existing literature on TMSJ. Instead, we transition to examples of how these scholars are implementing pedagogical moves that would accompany their stances above.

Delegating Authority. As Wendy and Erica shared their working definitions of TMSJ as delegating authority and showing students their capacity to be critical participants of society, other scholars jumped into the conversation to share examples of everyday things they do in their student teaching classrooms.

> *Catherine:* One thing I do is I will randomly, not randomly but basically **choose a student each day and I call them my teacher assistant. It starts out with having them either pass papers out or they will help me write out the example problem on the board**, or they will help me, like, having them keep the class in check. **They get really into it and** then it gets to a point where, now, **one of my students he like loves to explain**. I am trying to look over a students work he will be like " oh I will help that student, you can go and help other students". **If you let students help with classroom management**, having one student make sure that no one is purposefully hurt, **they can help with what others may not know and that student feels special and you can put them in a situation where they feel comfortable to share with the class and build their confidence**.

Catherine shares that she delegates authority in her classroom to increase students' confidence by allowing their peers see them as an expert in class. While having students help with some task that can help her get through her daily agenda, she is also trying to communicate to the chosen student that she trusts them. Setting up a buy-in for the student then allows them to transition into building their confidence to be able to help other students, i.e., build their mathematical identities. In choosing teacher assistants, Catherine shows students that they can help her with daily tasks and also be bearers of knowledge from which other students can learn. The end goal not only helps Catherine with the daily managing in her classroom but also allows her to create impactful student leaders with positive mathematical identities.

Limitations

A limitation of our current understanding of teaching mathematics for social justice comes from theory and practice that relies on democracy (for example, Freire, 1970) which helps see mathematics as a social tool for critical consciousness (Frankenstein, 1989, Gutstein, 2005). While the current literature in social justice mathematics addresses some of the curricular dilemmas of being a social justice educator, the scholar's perceptions of TMSJ lets us with questions as to how to "play the game/ change the game" on a daily basis. Teacher educators and researchers need to consider our current definitions and understand how our current understanding of teaching mathematics for social justice has plateaued. Researchers need to look elsewhere to fields like Critical Ethnic and Gender studies to see how to examine how our current understanding of TMSJ may be reaffirming notions of anti-blackness (Martin, 2018), or not addressing modern-day civil rights of teachers and students. For example, in creating opportunities for students of color to participate in STEM fields, how might we also be asking students to simply participate in racial capitalism (Melamed, 2015), where they only count for diversity measures but not to re-imagine the field of mathematics, to show that it is not just that people need mathematics, but mathematics needs people (Gutiérrez, 2012).

Conclusion

The field of critical mathematics educators has reached the point of asking ourselves how can we better understand and theorize what it means to teach mathematics for social justice? How do we expand our current understanding of social justice beyond instrumental access and critical consciousness (Larnell, Bullock, Jett, 2016) of sociopolitical issues and a better understanding of teachers' roles in challenging systems of oppression? If we are to recognize teaching mathematics as a sliding signifier or a walking road (Cochran-Smith, 2004), how can we expand our current understanding of teaching mathematics for social justice as teachers embody their politial conocimiento (Gutiérrez, 2012)? If we were to ask scholars in Critical Ethnic and Gender studies, would they agree with our current understanding and implementation of Teaching mathematics for social justice?

If the goal of teaching mathematics is to change and dismantle what we see within the relationships that we have within society teacher educators, need to provide more representations of how community members are addressing all these topics so that they can develop Political Conocimiento(that will inform their critical stance on mathematics education. Furthermore, we need examples of studies that look at how preservice teachers who are exposed to political knowledge how they implement it in their first year and beyond. If we believe that the development of critical mathematics, include aspirations and hopes that are continuously recontextualized and reformulated and, uncertainties appear (Skovsmose, 2009), we cannot expect that teachers will be successful at teaching mathematics for social justice unless we place value on more than just curriculum.

TAKING PROOF INTO SECONDARY CLASSROOMS – SUPPORTING FUTURE MATHEMATICS TEACHERS

Orly Buchbinder
University of New Hampshire
orly.buchbinder@unh.edu

Sharon McCrone
University of New Hampshire
sharon.mccrone@unh.edu

For reasoning and proof to become a reality in mathematics classrooms, it is important to prepare teachers who have knowledge and skills to integrate reasoning and proving in their teaching. Aiming to enhance prospective secondary teachers' (PSTs) content and pedagogical knowledge related to proof, we designed and studied a capstone course Mathematical Reasoning and Proving for Secondary Teachers. This paper describes the structure of the course and illustrates how PSTs' interacted with its different components. The PSTs first strengthened their content knowledge, then developed and taught in local schools a lesson incorporating proof components. Initial data analyses show gains in PSTs' knowledge for teaching proof and dispositions towards proving, following their participation in the course.

Keywords: Reasoning and Proof, Teacher Education-Preservice, Design-Based Research

Mathematics education researchers (e.g., Hanna & deVillers, 2012) and policy documents (e.g., NGA & CCSSO, 2010) emphasize the importance of teaching mathematics in ways that promote sense making, reasoning and proving across grade levels and mathematical topics. Yet, the reality of many mathematics classrooms rarely reflect this vision; even teachers who recognize the importance of reasoning and proof, in principle, often struggle to enact them, and tend to choose skills-oriented activities over proof-oriented ones for their own classrooms (Kotelawala, 2016). Preparing teachers who are capable of implementing such teaching practices and cultivating positive attitudes towards reasoning and proving is a critical objective of teacher preparation programs (AMTE, 2017). We used a design-based-research (DBR) approach to develop and study a novel capstone course *Mathematical Reasoning and Proving for Secondary Teachers*. Our goal was to explore how PSTs' knowledge and dispositions towards the teaching and learning of proof develop as a result of participating in the course, and to identify design principles that afford PSTs' learning.

Theoretical Framework and the Course Design

Researchers have conjectured that engaging students in reasoning and proving, that is, exploring, generalizing, conjecturing and justifying, might require a special type of teacher knowledge: Mathematical Knowledge for Teaching of Proof (MKT-P) (e.g., Lesseig, 2016). Building on their work, we theorize that MKT-P consists of four interrelated types of knowledge (Buchbinder & Cook, 2018). Teachers must have robust Subject Matter Knowledge (SMK) of (a) mathematical concepts and principles (Ball, Thames & Phelps, 2008), and (b) knowledge of the logical aspects of proof, such as proof techniques, valid and invalid arguments, the functions of proof and the role of examples and counterexamples in proving (Hanna & deVillers, 2012). Teachers also need strong Pedagogical Content Knowledge (PCK) specific to proving, such as (c) knowledge of students' proof-related conceptions and misconceptions, and (d) knowledge of pedagogical strategies for supporting students' proof activities (Buchbinder & Cook, 2018). Thus, we created opportunities for PSTs to develop these four types of knowledge.

The course comprises four three-week long modules, each module addressing one proof theme: quantified statements, conditional statements, direct proof, and indirect reasoning. These themes were identified in the literature as challenging for students and PSTs (e.g., Weber, 2010). Our first goal was to help PSTs to enhance their knowledge of the four themes of the course. Figure 1 shows the structure of the course (top) and a structure of one course module (bottom).

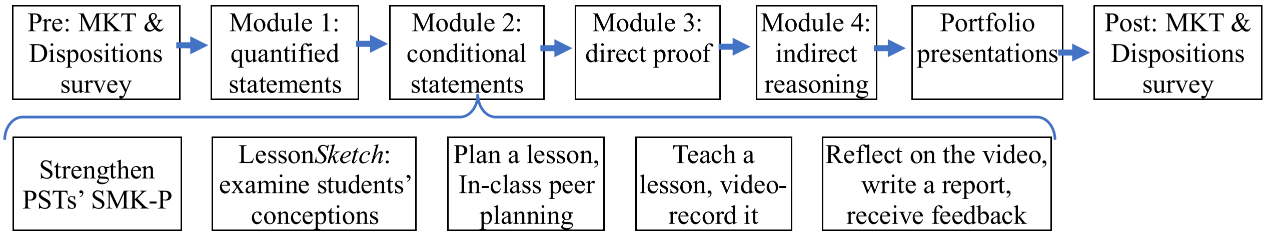

Figure 1. Design of the course *Mathematical Reasoning and Proving for Secondary Teachers*.

We designed opportunities for PSTs to enhance their proof related pedagogical knowledge, by interpreting sample student work, identifying students' conceptions of proof, and envisioning responding to students' thinking in the virtual learning platform Lesson*Sketch* (Herbst & Chazan, 2015). We also engaged PSTs in planning and implementing, in local schools, lessons that combine the proof themes with mathematical content. As PSTs enacted their lesson, they recorded it with 360° video cameras, which captured simultaneously the PSTs' teaching and the students' engagement with proof-oriented lessons. PSTs then watched and analyzed their lesson, wrote a reflection report and received feedback from the course instructor.

Methods

Participants in the first iteration of the course were 15 PSTs in their senior year (4 middle-school, and 11 high-school track; 6 males and 9 females). The PSTs had completed the majority of their extensive mathematical coursework, and two educational methods courses. Multiple measures were used to assess PSTs' learning, such as pre- and post- dispositions towards proof surveys, and an MKT-P instrument with sets of questions on the four types of MKT-P. We also collected PSTs' responses to home- and in-class assignments, video-recordings of in-class sessions, and PSTs' teaching portfolios containing four lesson plans, videos of the lessons taught, reflection reports and sample students' work. Below, we present initial results of our ongoing analysis of these data, focusing on the Conditional Statements (CS) module. The CS module comprised five activities as shown in Figure 1.

Results

The data analysis was guided by two main questions: (1) How did PSTs interact with the CS module?, and (2) What mathematical / pedagogical ideas addressed in the CS module got implemented in PSTs' lessons? In this section we present findings that respond to these questions and also describe evidence of the PSTs' learning.

PSTs' Interaction with the Conditional Statements Module

In the first activity, PSTs broke up into three groups and each group received one conditional statement, such as "A graph of an odd function, defined at zero, passes through the origin." The task was to identify its hypothesis P and conclusion Q, and use the P and Q to write statements in 11 logical forms such as: $P\ if\ Q$, $P\ only\ if\ Q$, and $If\ {\sim}P\ then\ {\sim}Q$. The PSTs were asked to differentiate between true and false statements, and to identify which statements are equivalent to $P \Rightarrow Q$. The most challenging form for PSTs to interpret was $P\ only\ if\ Q$. Some PSTs realized that it is equivalent to a contrapositive, ${\sim}Q \Longrightarrow {\sim}P$, and thus equivalent to the original statement. Other PSTs rejected this idea by arguing that P can be true "not only when Q is true." After a class discussion, all discrepancies appeared to be resolved.

The second activity utilized Lesson*Sketch*.org, a web-based platform for teacher education in which PSTs can analyze representations of classroom interactions depicted as cartoon sketches (Herbst & Chazan, 2015). The experience *Who is right?* first asked PSTs to decide whether the (false) statement: "If n is a natural number, then $n^2 + n + 17$ is prime," is true, false, sometimes true, or cannot be determined. Next, the PSTs viewed arguments of five pairs of students about the truth-value of this statement and were asked to evaluate the correctness of these arguments, identify instances of expertise and gaps in student reasoning and pose questions to advance or challenge that reasoning. The PSTs correctly identified invalid reasoning and proposed ways to acknowledge students' effort, while pointing them towards more valid modes of argumentation.

In the final activity, the PSTs analyzed current middle school and high school textbooks to identify where conditional statements appear in the secondary curriculum. PSTs also addressed students' difficulties with conditional statements and discussed ways to support student thinking.

PSTs' Implementation of a Lesson on Conditional Statements

After spending time developing lessons that involved conditional statements, PSTs implemented their lessons in the classrooms participating in the study. PSTs came up with many creative ways to integrate conditional statements in their lessons while appropriately adjusting them to the students' level. All PSTs used real-world examples, e.g., "If I do my homework, I will get good grades" to introduce the general structure of a conditional statement, and to identify their hypothesis (P) and the conclusion (Q). For example, Sam showed product advertisements, and asked students to turn them into conditional statements and analyze their structure.

The most utilized types of tasks implemented by the PSTs were True or False, and Always-Sometimes-Never, where students had to identify the hypothesis and the conclusion, determine whether the statement is true or false, and provide justifications or counterexamples. Bill had his students match hypotheses (e.g., a triangle is not equilateral) with conclusions (e.g., a triangle is isosceles), written on index cards, to produce true conditional statements. Then the students switched the order of the cards to examine how the statement and its converse compare. Overall, except for four PSTs who only minimally addressed conditional statements, the majority of PSTs successfully and creatively integrated conditional statements in their lessons.

Evidence of PSTs' Learning

To trace changes in PSTs' knowledge and dispositions following the course, we administered Dispositions Towards Proof pre- and post- surveys and a 12 items MKT-P instrument (3 question in each of the four areas of MKT-P). The analysis revealed that PSTs had relatively high initial scores on three out of four types of MKT-P. Hence instead of examining the point increase, we calculated the percentage of possible growth. E.g., although the increase in the Knowledge of Logical Aspects of Proof was only 1.15 points, it constitutes 48% of possible 2.4 points needed to obtain the maximum score. The highest gain of 66% occurred in the Knowledge of Pedagogical Practices for supporting students' learning of proof. The items measuring PSTs performance in these areas called for analyzing, interpreting and responding to students' conceptions of proof, similar to activities described above in the CS module.

The Dispositions Survey had five categories of questions: (1) notions of a proof, (2) purpose of proof, (3) confidence and comfort with proving, (4) suitability of proof in the secondary curriculum, and (5) confidence in and knowledge about teaching proof. In general, the pre- and post-test results did not show much change in categories 1, 2 and 4; a few noteworthy results occurred in categories 3 and 5. The PSTs' confidence in their ability to prove results from the school curriculum increased from 65% to 92%; the percent of PSTs recording confidence of teaching proof to students, increased from 50% to 84%. The fact that PSTs' overall growth of dispositions was relatively modest may be attributed to an initial, perhaps false, feeling of confidence due to the PSTs' prior mathematical coursework.

Discussion and Implications

We reported on the first iteration of a 3-year DBR project aimed to enhance PSTs' knowledge and dispositions for teaching proof at the secondary level. We described the overall structure of the capstone course and the theoretical underpinnings of its design. We described how PSTs interacted with the CS module through practice-based activities of analyzing students' conceptions of proof; planning and sharing lessons; classroom implementation and reflecting on it, aided by video technology. These descriptions serve as a backdrop for understanding the gains in PSTs' content and pedagogical knowledge of proof (MKT-P). The areas in which this growth was most evident are: the logical aspects of proof and pedagogical knowledge specific to proving. Although the small sample size does not allow testing statistical significance of these outcomes, we find them encouraging, since the supporting evidence goes beyond self-report.

Our data analysis is still ongoing, as we examine video of on-campus sessions and of the PSTs' teaching to create more fine-grained description of how PSTs' content and pedagogical knowledge evolved throughout the course, and to match this growth to the design principles of the course. The results of this analysis will inform future iterations of our project, and, potentially advance the field's understanding of how to support PSTs' development of MKT-P.

PORTRAITURE OF ELEMENTARY PRESERVICE TEACHERS DURING A STEM CAMP EXPERIENCE

Megan Burton

vmc0004@auburn.edu

Twenty-four preservice teachers planned, co-taught, observed peers, observed the elementary students, and participated in debriefing during a summer science, technology, engineering, and mathematics field experience. Data from lesson plans, reflections, observations of students observational noticings, and peers created a holistic view of their perspectives on teaching and learning mathematics in a diverse, authentic setting, without the challenges that often occur in traditional field-based experiences. Using the portraiture method of inquiry, the complex dynamics of this experience are captured from multiple lenses.

Keywords: Teacher Education-Preservice, Teacher Beliefs, Elementary School Education, Instructional activities and practices

Facilitating elementary preservice teachers (PSTs) cohesive understanding of teaching and learning mathematics in meaningful ways can be challenging. Experiences in mathematics field placement practice, experiences as an elementary student, and experiences in mathematics methods courses are often disconnected. One consistent complaint heard over the years is that what PSTs see in the field is often in opposition to what they are learning in their coursework (Beck & Kosnik, 2002). In addition, twelve years of classroom experiences have shaped not only their own identities, but also their beliefs about teaching and learning (Shoffher, 2008).

In this study, six PSTs observe, plan, and teach in a three-week summer Science, Technology, Engineering, Mathematics (STEM) camp. Using the narrative portraiture inquiry (Lawrence- Lightfoot, 2005) the PSTs observations, reflections, planning and teaching are analyzed to paint a portrait of the experience. These PSTs were a teaching team for 27 fourth grade students. "Teaching is not merely a cognitive or technical procedure, but a complex personal, social, and often elusive set of embedded processes and practices that concern the whole person" (Olsen, 2008, p 5). Examining the experience of PSTs from multiple perspectives supports deeper understanding of perspectives about teaching and learning mathematics.

Theoretical Framework

Research suggests that education courses linked to authentic field experiences maximize effectiveness (Weld & French, 2001). If PSTs have not experienced teaching concepts such as inquiry or project based learning, it is difficult to recreate these in mathematics classrooms or visualize what they would look like in practice (Beck & Kosnik, 2002). Teacher educators face a conundrum of how to provide opportunities for PSTs to enact and experience effective mathematics education under the guidance of mentors who also support these educational practices, when these classrooms are so rare in current K-12 settings. Finding classrooms that promote best practice, rather than ones that emulate the systemic issues of inequity and oppression that often are found in schools is a challenge.

This study is grounded in the belief that PSTs need early inquiry based field experiences with positive diverse populations, where they focus on students as mathematics learners, take teaching risks, and reflect upon the practice of teaching to meet the needs of all learners (Aguirre et al., 2013). However, it is difficult to provide these authentic placements any time in the year, but especially when coursework is in the summer. Often summer placements are in local schools that focus on remediation and drill of basic computational facts. This study centers on an alternative summer placement, which provided elementary PSTs an opportunity to reflect upon innovative mathematics teaching approaches in a positive and supportive environment. It was strategically positioned to provide PSTs experiences working with diverse populations> Instruction focused on building new knowledge and skills from the strengths and cultural competencies that each elementary student brought to the experience.

Methods, Techniques or Modes of Inquiry

Narrative portraiture (Lawrence-Lightfoot, 2005) was used to examine the perspectives and experiences of PSTs from this mathematics field placement. "Portraiture is an ethnographically oriented method of inquiry that seeks to capture and explain the ever-changing complexities of life and experience. Portraiture emerged from the desire to tell a story in such vivid detail that the event could be pictured as though it were a painting" (Lawrence-Lightfoot & Davis, 1997, p.4). In this study, a detailed, vivid portrait was created from various perspectives and then these portraits were further analyzed to develop deeper understanding of the moments. This study examined the perspectives of mathematics teaching and learning among PSTs in field placement, but the lens of each perspective was different, which created more insight and vivid portraits into the complex view of teaching and learning mathematics that preservice teachers held.

Study Context

The 23 females and one male PSTs were in their first teaching field placement in the program and came from affluent homes with many positions of privilege. Previous coursework examined lesson planning, assessment, professionalism, individual reading instruction, and culturally responsive teaching. For the semester being studied, PSTs were enrolled in mathematics, science, and reading methods coursework that were tied to the field component. The instructors of the methods courses were also the lead faculty in the summer field experience, which was a three-week Science, Technology, Engineering, and Mathematics (STEM) focused program for 97 rising third through fifth grade students. Week one focused on structures, week two focused on robotics, and week three focused on forces in motion as the unifying theme. Students explored computation through purchasing supplies in the store, which included sales. They graphed and measured experiments and explored geometric properties of shapes. Before camp began, PSTs attended mathematics methods classes to explore pedagogical concepts such as learning trajectories, assessment, technology, questioning, and project based learning within the field of mathematics. In addition, PSTs attended a 3-day workshop co-taught by the three methods faculty members. Each workshop day participants and faculty modeled and explored the content for one of the three weeks of the STEM summer experience. For example, the first day of the workshop addressed various elements they would teach, content, and projects related to structures.

This experience provided educational opportunities to elementary students from diverse backgrounds and school systems in this rural region in the southeastern United States. Sixty percent of the students were recommended for the summer experience based on financial need. A total of six systems were represented. Students from high needs schools attended alongside students from schools where resources were plentiful. Each class truly made up the diversity that public education strives to meet. The population of the camp was approximately 60% African American, 20% Asian, 15% Caucasian, and 5% other nationality representations. PSTs were able to examine their own beliefs and their practice culturally responsive teaching. PSTs were assigned a specific class for the entire summer experience. There were two third grade classrooms, one fourth grade classroom, and one fifth grade classroom. Six PSTs worked together in a classroom, but only two lead teachers per day. For the purpose of this study, the purposeful selection of a fourth-grade classroom unit was examined. Therefore, the data from the preplanning through post planning debriefing sessions for the six PSTs were the focus of this portraiture.

PSTs had five roles during the summer experience: 1) planner, 2) teacher, 3) student observer, 4) teacher observer 5) reflective, member of professional collaborative debriefing sessions. PSTs were able to plan one day and teach the next day with a teaching partner. The partner changed with each planning and teaching cycle to encourage growth and learning to work with various personalities. PSTs not teaching and planning were in the classroom observing students or observing their peer teachers. Observation instruments were used to focus on their noticings of student thinking, characteristics, and behaviors. Each day after the summer camp grade level teams would meet and debrief about the different perspectives from the day. These sessions focused on observational noticing related to teaching, students, and strategies used to make connections that informed the next day's teaching practices.

Data Sources and Evidence

PSTs reflections, lesson plans, observations of peers, field notes, and observations of elementary students were used as data sources. In order to examine data individually and for patterns about thinking of mathematics teaching and learning, there were several rounds of analysis. For each day, each data source was coded separately, as a unit, and then collectively. For example, all data (i.e. lesson plans, student observations, teacher observations, debriefing notes, and reflections) related to week one day two were examined together to note both consistencies and inconsistencies. These data sets were not only from different people, but also with different foci, but all were used to create a picture of the classroom on that day. Next data from each PSTs was analyzed as a unit to identify changes in the individual preservice teacher, as well as examining the perspective of each teacher in the various roles. Finally, the data from each role was analyzed as a unit (e.g. student observer) 15 days of student observations; 15 days of teacher observation) was examined to look for changes, patterns, and other information that helped to create a vivid image of this perspective in the classroom.

After thoroughly analyzing the data from the various perspectives, three sets of portraits were created by a team of researchers: a portrait of each individual, a portrait of each role they played in the mathematics classroom, and a portrait of how they saw mathematics teaching and learning. Researchers then analyzed the portraits for analytic themes across portraits. The themes from this analysis helped to construct a holistic visual of preservice teachers during the STEM camp experience. The portraits from the PST perspectives provide insight into their views of mathematics teaching, learning equity, and students.

Results

Findings from this study indicated that PSTs primarily noticed elements about the classroom environment and behavior, rather than focusing on the cognitive elements in the classroom. However, PSTs plans, observations and reflections were richer in focused content development as the days progressed. In addition, overall the data from each role was more focused on the perspective assigned. For example, the student observers during week 3 were more focused on students as mathematics learners, than week one which mainly focused on the teachers, despite the questions on the protocol. The portraits illustrated that each experience in the classroom provided additional insight and focus for the following experience. In addition, as PSTs gained confidence through these experiences, they were able to focus more on the mathematics and the students, rather than devoting a majority of the focus to the behavior. In addition, as time progressed, PSTs focused on strengths of individual students, rather than deficits and generalizations. It wasn't until week 2 and 3 until PSTs observing teachers and students began to notice when students could do more than they were given and that they needed more cognitive challenge. The debriefs were one space where this was highlighted by peers and discussions pivoted towards learning, which then impacted future experiences.

Scientific or scholarly significance

Examining PSTs perspectives about field experiences in diverse settings, provides insight into the connections and misconceptions they make when linking coursework, beliefs and field experiences. It provides insights into issues PSTs face and elements that are effective in deepening understanding of effective mathematics instruction. Preparing PSTs to focus on student mathematical thinking and reasoning is important in order to promote student learning (Aguirre et al., 2013). The six PSTs all looked for the positives in their students, and some recognized the role of teachers and students in the classroom dynamics, while others only focused on one of these two elements. However, the differences that each preservice teacher gained from the various perspectives provides promise into the importance of providing holistic mathematical experiences for PSTs. Studies indicate preservice teachers have the ability to develop this type of professional noticing in a teacher education program, if structures are in place (Amador et al., 2016; Fisher et al., 2014).

This study enhances research on professional noticing and teacher perspectives about mathematical teaching and learning. It provides well narratives about the mathematical teacher education identity development of PSTs in their field placements. It adds details about the nuances in the complex task of teaching and learning in elementary mathematics education.

CRITICAL MATHEMATICS TEACHER NOTICING: USING ONLINE TECHNOLOGY TO EXPLORE HOW PRE-SERVICE TEACHERS OF COLOR CONFRONT THEIR PEERS' RACIAL POSITIONINGS OF CHILDREN

Theodore Chao
The Ohio State University
chao.160@osu.edu

Melissa Adams
The Ohio State University
adams.2153@osu.edu

Mathematics teacher noticing is a construct used heavily in research around mathematics teaching and mathematics teacher education. However, just as a focus on noticing draws attention to what a teacher "sees", a focus on what a teacher does NOT "see" is equally important. In this study, we utilize an online video commenting tool to analyze what elementary pre-service teachers of color notice about the language and positioning of case study students through four-weeks of problem solving interviews. This tool served as a space for teachers of color to confront the racist ideologies present in how their peers positioned students.

Keywords: Elementary School Education, Equity and Diversity, Teacher Education-Preservice, Technology

Mathematics teacher noticing has quickly become a critical aspect of mathematics teaching and teacher preparation (Schack, Fisher, & Wilhelm, 2017), centering around the idea that effective mathematics teaching extends beyond just content knowledge, pedagogical content knowledge, or even beliefs. The physical act of "noticing" or paying attention to and being reactive to the minutiae of classroom moments is key to developing any teacher's ability to empower children mathematically. Research connecting equity with teacher noticing, however, is still largely centered around how white teachers can use noticing when working with students of color, and does not recognize the way race impacts what teacher notice. In the United States, even as the teaching force grows more diverse, most students of color continue to work only with white teachers (Ingersoll, Merrill, & Stuckey, 2014), a troubling trend due to the racial and cultural blind spots of white teachers. Moreover, teachers of color who often have experiences that can reveal these blind spots are often silenced, particularly in pre-service education (Philip, Rocha, & Olivares-Pasillas, 2017).

The construct of mathematics teacher noticing is powerful, as it has given a name to a practice that all teachers engage in. So how can mathematics teacher noticing be used to delve into a mathematics teacher education that cultivates the racial and cultural knowledge necessary to empower all students? We explore this work through the following research questions: (1) When using a technology-based video commenting platform to explore children's mathematical thinking, what do pre-service teachers of color notice in contrast to white teachers? (2) What does mathematics teacher noticing look like when connected to racial awareness?

Theoretical Framework

Mathematics teachers often hold "expert blind spots", in which they find it difficult to "see" how their students struggle mathematically (Nathan & Petrosino, 2003). These blind spots are gaping holes in a teacher's vision, in which a teacher who may not have experience being positioned as mathematically inadequate cannot understand the dilemma of their struggling students. We use this construct of blind spots to refer to how teachers who come from dominant backgrounds often view their classrooms and students through their dominant culture lenses, unaware of the extent of their blind spots (Louie, 2018).

The world that is familiar to mathematics teachers, is, of course, structured by racial ideologies in ways that operate invisibly. White supremacy creates a "racial grammar" that allows for the seemingly natural reproduction of the racial order (Bonilla-Silva, 2012). This racial grammar facilitates the construction of white stories as "universal" and creates strong perceptions about how things "are" and how people of non-white backgrounds are supposed to be (Bonilla-Silva, 2012). In mathematics education, combating this racial grammar involves taking a rehumanizing stance that recognizes and positions each and every student as not only human, but someone who holds substantial mathematical knowledge connected to their cultural and racial identities (Gutiérrez, 2018). A rehumanizing stance of mathematics teacher education also values the knowledge of teachers of color, listening to the stories they tell in order to help white teachers "see" blind spots that continue to oppress and dehumanize our children of color. Teachers of color must have space to think about, discuss, and interrogate the role of race within their classroom spaces and be empowered to share these noticings. We refer to this calling out of racial grammars and other oppressive mechanisms that operate within our field as *critical mathematics teacher noticing*.

Teacher video clubs could serve as a mechanism for engaging teachers in critical dialogue with each other surrounding their practice (Van Es & Sherin, 2008). However, while video clubs facilitate teacher dialogue around particular aspects of classroom practice, video club are also sociopolitical spaces where teachers from dominant groups hold more power and "voice". One way to hinder this silencing is through technology that creates safer communicative spaces. For instance, technology that utilizes asynchronous watching and commenting allows teachers to take their time to watch a video and comment accordingly, to reflect not only on what they notice immediately, but on what they notice after repeated watching and reflection (Chao & Murray, 2013). Bringing the conversation online, then, opens up spaces for teachers to critique the deficit perspectives of fellow teachers safely, without the silencing effect of a video club.

Methodology

The data for this study came from an elementary teacher graduate degree and licensure program at a large, state university in the Midwestern United States. We focused on a diverse master's degree cohort, where six of the 28 teachers identified as persons of color. Our analysis focused on an Elementary Mathematics Teaching Methods course instructed by the first author, in which each pre-service teacher worked one-on-one with a child in their student teaching internship. The teachers completed four interviews with a case study child: a "getting to know you interview" to begin the project, then three subsequent problem-solving interviews each week (Foote et al., 2015).

We utilized GoReact, an online video commenting tool to facilitate teacher noticing during the problem-solving interviews. Teachers individually filmed their interviews with case study students and immediately uploaded the video for their peers and instructor to watch and comment on. Then, in the three subsequent class meetings, the teachers met in person to watch the videos again, read each other's comments, and engage in discussion about what they noticed. At the end of the four interviews, the teachers produced a report on what they learned from the student through the interviews and the conversations. We utilized all of this data in our analysis: the online video, the comments, and the written reports.

Findings

Our analysis focused on instances where pre-service teachers called out dismissive or deficit language they noticed their peers using, particularly if this invoked racial grammars. We found that pre-service teachers of color's comments regularly emphasized the skills and reasoning displayed by students of color and challenged conclusions of white pre-service teachers. We believe these instances reveal what we refer to as *critical mathematics teacher noticing*, which requires an awareness of the structures and functioning of racial grammars as well as the ability to interrupt them.

Ms. Simmons, a biracial, Black pre-service teacher, was paired in online discussions with Ms. Harris, a white pre-service teacher. Ms. Harris chose Amir, a Black Somali-American second-grader, as her case-study student. Ms. Harris described Amir as struggling in mathematics and posited that "it might be because he isn't paying attention and isn't focused, and sometimes it might be due to a language barrier." In Ms. Harris's first video, she posed a problem where a boy had 13 cookies and ate six, then asked how many were left. Amir wrote the equation 13-6. Ms. Harris then asked why he subtracted, to which Amir replied that the problem said he ate and that meant he should take away. Ms. Harris commented about this interaction, "I had a very hard time getting him to explain his answers no matter how long I waited, how I rephrased the question, or what questions I asked. This was the most explaining I got him to do during the whole interview."

Ms. Simmons' responded by challenging Ms. Harris' conclusion:

> I don't know what all you asked him, but I see that he understands that "you ate" means "take away" so he chose subtraction. Maybe you could have asked him if "you ate" means you get more cookies or cookies are taken away, then you could ask if take away means you add or subtract. Maybe that would've provided more of an explanation than just asking why he chose subtraction. Sometimes students don't realize all of their steps until you point them out for them.

Ms. Simmons noticed Ms. Harris' deficit perspective, implying that there was more to Amir than what Ms. Harris saw. While Ms. Harris only noticed Amir's lack of focus or skills and refusal to explain his thinking, Ms. Simmons noticed the bigger problem of how her classmate spoke to and about Amir. Ms. Simmons also expressed a belief that students are capable of more than they can put into words and that teachers play a role in developing students' mathematical confidence.

Conclusion & Discussion

The mathematics teacher noticing work has largely focused on noticing mathematical discourse or action without specifically connecting to race or culture (Jong, 2017). Our work shows how, using critical mathematics teacher noticing, we can unpack the racial blind spots pre-service teachers hold when "noticing" the mathematical thinking of their children. We posit that the online video technology space created an immediacy for teachers to interact in dynamic ways familiar to them, and therefore, grow comfortable in couching their critique in their own social identities (i.e., as a teacher of color who has to deal with continual racial microagressions from members of their cohort).

By putting the focus specifically on racial and cultural norms within mathematics education, we draw attention to the racial "blind spots" within mathematics teacher education overall. We introduce a new term to describe this unveiling of these blind spots in mathematics teachers, in which racial grammars that have been invisibilized are brought to light: critical mathematics teacher noticing.

However, this study does have limits. First, we only analyzed data from one particular cohort when they took an elementary mathematics methods course; not measuring their prior interactions with each other. Second, the first author of this paper was also the instructor of this course, introducing bias into our interpretation of the data. And third, this is a snapshot of these teachers before they actually begin their practice. Data suggest that some of these teachers will take on racist or "othering" pedagogical stances in their first years of teaching (Chao, Hale, & Cross, 2017).

Technology can be used as a democratizing tool, an agent of change that allows various views and individual interpretations of the same media. The current research examining how we prepare mathematics teachers of color is emerging, exposing how heavily our existing structures are set up to only help white teachers without threatening their fragility (Picower, 2009). Just as we encourage our mathematics teachers to engage in classroom discussion that moves beyond the easiest and most accessible mathematical strategy, we must push our teachers to engage in conversations on equity that move beyond "safe" topics of diversity and social justice to recognize and confront white supremacy. As a field, we ask teachers to orchestrate open-ended, uncomfortable mathematical conversations in the classroom. Therefore, as mathematics educators, we must also engage in uncomfortable conversations about the blind spots our teachers and ourselves hold, especially as pertaining to perpetuating white supremacy.

OVERCOMING IMPLICIT BIAS: PERSPECTIVES FROM PRE-SERVICE MATHEMATICS TEACHERS

Karen R. Cheng
University of Tennessee, Knoxville
kcheng2@vols.utk.edu

Pre-service teacher perspectives provide important insight for teacher education and can also serve as indicators for areas of support needed in teacher preparation, especially in regards to providing training for addressing challenges in the classroom. This study examines the perspectives from pre-service mathematics teachers in an introductory mathematics education course, particularly on how challenges may be presented and addressed in the classroom based off of socially constructed implicit biases against the subject of mathematics. Participants were asked to reflect on how implicit bias may impact mathematics through two factors: 1) teacher and student challenges in the classroom and 2) addressing the concept of innumeracy. The perspectives and beliefs that these participants hold in their pre-service practice may be used to better support their clinical experiences and transition to the workforce.

Keywords: Affect, Emotion, Beliefs, and Attitudes, Teacher Beliefs, Teacher Education-Preservice

Introduction

The pre-existing perceptions and dispositions of pre-service teachers towards mathematics teaching and learning are a strong indicator of the performance and learning environment that will be established in each of these future teachers' classrooms (Franke, Kazemi, & Battey, 2007). Many factors can contribute to each pre-service teacher's development of individual perceptions and dispositions towards mathematics education, ranging from their individual backgrounds, experiences in learning mathematics, and societal influences and stereotypes on the subject area (Thompson, 1984). By examining reflections from mathematics pre-service teachers, teacher educators can establish a better understanding of how to provide professional development and teacher preparation that best supports various forms of content knowledge (curriculum-based, pedagogical, situational) needed for effective teaching (Southwell & penglase, 2005; Hill, Ball, & Schilling, 2008; Aslan-Tutak & Adams, 2015).

This study focuses on the impacts that existing social influences, which will be referred to as "implicit bias," have on pre-service mathematics teachers' perceptions of math teaching and learning. The reflections from these pre-service teachers also stem from their individual perceptions of the challenges posed by existing implicit biases towards mathematics learning. Presenting pre-service teachers with opportunities for deep self-reflection specifically on potential challenges in teaching mathematics is highly important for developing teacher accountability and better understanding of creating authentic learning opportunities in their future students (Graeber, 1999). This paper will highlight findings from this study regarding pre-service teacher perceptions on potential the implicit biases that they may encounter in their future classrooms, focusing on two main areas: 1) perceived challenges in teaching and learning mathematics, and 2) overcoming challenges presented by innumeracy.

Implicit Bias and Challenges Presented

This study is based on a framework that views perceptions and dispositions that students and pre-service teachers may have regarding mathematics teaching and learning are influenced and greatly impacted by social constructs and stereotypes (Thompson, 1984; McClain & Cobb, 2001). These pre-established societal norms about mathematics teaching and learning create challenges for teachers of all levels of expertise. For example, norms in secondary education exist regarding summer homework and readings as commonplace for English and Language Arts courses, whereas not until more recently have students and families engaged in more enrichment programs beyond the classroom for subjects such as mathematics. Additional challenges also arise from the perpetuation of negative stereotypes depicting mathematics education. For example, students (especially girls) who take a liking towards the subject area may feel outcast in their learning environments, where enjoying mathematics as regarded as "weird" by societal norms (Boaler & Greeno, 2000). Oftentimes, the statement of "I'm not a math person" may even be presented as a societal norm and something highly acceptable and perhaps even touted in commonplace (Franke et al, 2007). Through addressing these challenges outright in the classroom, teachers can set positive classroom norms for generating authentic learning opportunities that can answer the questions of "why" for learning mathematics.

Methodology

With the assumption that implicit bias in the mathematics classroom has a direct impact on teaching and learning, this study focuses on the perceptions that beginning pre-service mathematics teachers may presume prior to receiving extended mathematics education coursework and entering the teaching workforce. While this paper outlines the participants and findings of a single class, further data was collected from later cohorts as well, which would be presented in the brief research report session.

Participants and Context

This study took place in an isolated introductory mathematics education class at a public four-year university, with 11 total students. Ten of the students were mathematics majors, and one majored in statistics. All of these students were taking the introductory mathematics education course as a part of a minor program for secondary mathematics education. Each of these students had already had varying forms of clinical experiences in this teacher education minor program. It is important to note that while these students have had concurrent introductory education courses, the class in which this study was conducted was the first of their experiences with a mathematics education focus. Therefore, the responses in which these participants provided their responses regarding perceptions of implicit bias are a candid reflection of the varying levels of pedagogical content knowledge.

Data Collection and Analysis

In this study, students were asked to respond to four questions that were a part of a routine in-class survey given online through Google Forms. Identifying information (such as name, age, sex, year of study, etc.) were not recorded for this study, as this study solely examined the direct response and written perspectives of these pre-service teachers without specific association with each individual student. The intent of the survey was to generate a sampling of student responses for developing in-class discussion regarding the two factors contributing to potential implicit bias in the math classroom. Participants were allowed to provide as much or as little elaboration in their responses to the questions as they saw appropriate.

Two main factors regarding pre-service teachers' perceptions about implicit biases mathematics teaching and learning were explored in the data drawn from the survey: 1) challenges in teaching and learning mathematics (from both teacher and student perspectives) and 2) addressing the concept of innumeracy. For each of these factors, students were asked for a) their definition and understanding of each factor and b) their hypotheses and suggestions for how to approach or address each of the contributing factors.

For the first survey question, involving the participants' perceptions of challenges in teaching mathematics, keywords from participant responses were categorized as deriving from either a) limitations in a teacher's mathematics content knowledge or b) limitations in a teacher's pedagogical content knowledge. These two areas of content knowledge were chosen as the most influential indicators for effective teaching. An assumption was made that the participants may focus heavily on providing responses relating more to pedagogical content knowledge concerns due to their own identities as future mathematics educators. The second question explored participants' perspectives towards challenges faced by students in learning mathematics, and keywords from responses were categorized into two domains of either internal or external constructs. Internal constructs were defined as factors related to students' individual identity, cognition, and disposition that contribute to potential challenges in learning of mathematics. External constructs were defined as factors that were not controlled by the individual students, such as transferring of blame to a teacher or class, lack of proper curriculum or teaching, etc. The third question examined participants' perspectives towards the notion that there is a greater societal acceptance and normalization towards innumeracy (in contrast to illiteracy, which is widely disfavored by society). Participants were asked to hypothesize why this potential societal acceptance may be prevalent, and keywords from their responses were categorized into two domains: normalization of innumeracy a) developed from individual beliefs and assumptions or b) development from prior experiences or action. Factors that were classified as personal beliefs and assumptions were those such as individual perceptions on the challenge of mathematics that contributed to the formation in normalization of innumeracy. The final question asked participants to propose solutions for addressing numeracy in their own classrooms as future educators. Participant responses were categorized into two domains here as well as reflections on addressing innumeracy through a) action through change in beliefs or b) action through change in practice. In these domains, action through change in beliefs categorized suggestions from the participant responses such as generating conceptual connections for students or establishing positive environments for learning. In comparison, responses that indicated approaches for action through change in practice described keywords such as modeling, problem-based or inquiry-based learning, or implementing varied questioning in the classroom.

Findings

As predicted, participant responses greatly focused more on limitations of the pedagogical content knowledge (PCK) domain as the contributing factor to their hypotheses as to why teachers may struggle in teaching mathematics. Eight out of the eleven students noted PCK as the main contributing factor that they felt determined challenges in teaching mathematics. Responses regarding perspectives on the normalization of innumeracy likewise had a majority in favor for one of the domains than the other. Eight out of the eleven participants indicated that they perceived that the normalization of innumeracy is caused by the prior experiences or action domain. The final set of pre-service teacher perceptions showed the greatest mixture of responses. While the majority of participant responses had a distinct position or preference for one domain over the other in each survey question, there were a select few participants who did indicate keywords highlighted from their reflections for both domains.

Discussion

In addressing the first research area of pre-service teachers' perceptions of perceived challenges in teaching and learning mathematics, participant responses were highly reflective of their identities as beginning teachers. With the first question regarding challenges for teaching mathematics, the majority (eight out of eleven) participants chose to highlight pedagogical content knowledge (PCK) as the main contributing factor. As the participants mainly comprised of undergraduate students who were majoring in mathematics, an assumption exists that each of them already have a strong content background in mathematics. Therefore, this perhaps explains the lower attention and priority given to highlighting content knowledge deficits as contributing factors for creating challenges for mathematics teaching.

Although the participants were able to provide substantial responses for all four questions, there were some unclear examples of responses for these last two questions on the factor contributing to implicit bias of normalization of innumeracy. This suggests that perhaps these students did not have substantial understanding of the concept of innumeracy to adequately answer the question. They also demonstrated significantly more elaboration in their responses regarding questions that presented an actionable problem. Participants also demonstrated optimistic responses overall, particularly for the questions asking them to provide suggestions for how they might approach addressing the two factors contributing to implicit bias against mathematics teaching and learning. This further emphasizes the importance of providing opportunities for teachers (both pre-service and veteran) to engage in reflexive pedagogy where they can reflect and continue to improve on teaching.

Implications for Future Research

Future research should investigate best practices in which teachers (both pre-service teachers and veterans) can address implicit bias in their classrooms through actions such as implementing micro-affirmations for generating positive dispositions towards math as well as inclusive and reflective pedagogical methods that encourage productive mathematics learning. It is likewise important for both teachers and teacher educators to collaborate in addressing potential implicit biases that may exist in schools and school systems. Further examination of resources and other ways to support mathematics teachers in addressing these issues is also another area to explore for math teacher education research.

INDIGENIZING THE MATHEMATICS CURRICULUM WITH PRE-SERVICE TEACHERS

Sean Chorney
Simon Fraser University
sean_chorney@sfu.ca

Sandy Bakos
Simon Fraser University
sbakos@sfu.ca

In this brief research report, we examine shifts in the attitudes of pre-service teachers related to Indigenizing the mathematics curriculum through the lens of positioning theory. Written responses were examined and examples of obscuring agency, reframing of mathematics, retemporalizing and repersonalizing and more openness to rethinking attitudes emerged. By analyzing attitudes of pre-service teachers we can begin to have productive conversations.

Keywords: Indigenous Ways of Knowing, Pre-service Teacher Education, Positioning Theory.

Introduction

In recent years there has been a call to include Indigenous knowledge at all levels of schooling (BC Ministry of Education, 2015), which has proven challenging for both veteran teachers and new teachers alike. Mathematics, a discipline often associated with objectivity and abstraction, does not appear to align easily with an Indigenous approach to learning. Therefore, it is not surprising that pre-service and practicing teachers have expressed anxiety in response to British Columbia's revised curriculum, which states that mathematics teachers are to '[i]ncorporate First Peoples' worldviews and perspectives to make connections to mathematical concepts' (BC Ministry of Education, 2015). Consequently, there is a need in pre-service mathematics education to reconcile Western mathematics with Indigenous ways of knowing.

As non-Indigenous researchers, we consider teaching and learning Indigenous approaches that support holistic, personal and connected activities to be sound pedagogical practice. According to Munroe et al. (2013), 21st century learning approaches are not new ideas, but are "rooted in old ideas embedded in Indigenous knowledges" (p. 319). When the learning of mathematics includes hands-on experiences, for example, this can provide opportunities of agency, and personal relevance. In creating and in doing, mathematics becomes a discipline of practice, rather than memorizing propositional facts. The First Peoples' Principles of Learning (FPPL), created by the First Nations Education Steering Committee (FNESC) in British Columbia endeavour to reflect a respectful and holistic approach to First Peoples' values around teaching and learning. Learning is "focused on connectedness, on reciprocal relationships, and a sense of place" (FNESC, 2008). It involves generational roles and responsibilities, patience and time, an exploration of identity and recognizing the consequences of one's actions.

This research explores how a non-Indigenous instructor and teacher assistant, with a commitment to honour Indigenous values, sought to develop a respectful and culturally aware, pre-service mathematics teacher education course. This research is focused on transforming attitudes around what mathematics is and can be, while moving away from dominant ideologies and colonial practices, to more relational and respectful ways of knowing.

Theoretical Framework

We have chosen positioning theory as a way to understand the views and commitments of pre-service teachers in relation to both mathematics and to an Indigenous framing of mathematics. van Langenhove and Harré (1999) describe positioning as a stance expressed through words or actions that affects one's relation to someone else. There is an underlying moral component to the relations created during this positioning. There are three particular constructs of positioning theory: communication acts, positions and storylines. Communication acts are about the words used in an utterance, positioning is about how an interlocutor locates themselves in relation to someone else, and storyline is the underlying common narrative suggested, though not necessarily made explicit in the utterance. Each of these constructs interweave and connect with each other.

Within the teaching outlined in this study, we observed a transformation in how pre-service teachers viewed their role as teachers. Their previous experiences with mathematics learning were framed in terms of acquiring a skill set, causing them to refer to mathematics as distant and objective. However, when mathematics is more people oriented and is framed in terms of discussion, it aligns more closely with Indigenous ways of knowing. Using techniques of discourse analysis, such as voice, agency and deixis (Wagner, 2007), as well as looking at nominalization (Gerofsky, 2004) to inform positioning theory, we assess how pre-service teachers position themselves in relation to mathematics and Indigenous ways of knowing.

The goals for this research were to evaluate by the end of the course: 1) Changes in students' perceptions of the nature of mathematics; 2) Changes in students' perspectives and understandings of Indigenous ways of knowing and learning as they relate to mathematics.

Methods

Data from this study was collected from undergraduate students enrolled in a secondary mathematics methods course at a Western Canadian University in the summer of 2017. Having received some Indigenous education in previous courses, students were somewhat familiar with FPPL but had no experience connecting FPPL to mathematics. In order to ascertain student perceptions regarding the nature of mathematics and changes in perspectives of Indigenous ways of knowing, students were asked to respond in writing to the following questions at the beginning and at the end of the course: (1) What is mathematics? What does it mean to do mathematics? (2) In what ways are Indigenous ways of knowing and mathematics connected? In terms of knowing, learning and/or practicing, can you think of ways mathematics may relate to an Indigenous world view? The research team then examined all student responses to identify changes in discourse. Using a positioning theory lens, we highlight changes in student wording as a method to identify shifts in student response as well as themes that emerge.

Throughout the course, an environment was created where thinking was brought into the open to be scrutinized and re-evaluated, and notions of time, person and context were introduced into mathematical practice, rather than valuing content only. In practice, most students, are much more receptive to relational ways of engaging with mathematics because they are ‘part’ of the subject material, which aligns with Cajete (2012), who suggests ‘we’, as mathematics educators and teachers, stay away from objectification and decontextualization.

Data and Analysis

In this section we present a comparison of some of the student reflections from the beginning of the course, to those at the end. Due to the brevity of the data segments, we have combined the data and the analysis together and have categorized the data under some of the themes that emerged from our discourse analysis. All student comments are presented verbatim.

Obscuring Agency

One of the things that was noticeable was a complete lack of agency in terms of how most students described mathematics, which was indicated by the lack of an 'I' or a 'we' in their statements. However, by the end of the course, students were including not only themselves in their articulations, but others as well. In the presentation of data below (B) and (E) will represent 'beginning of course' and 'end of course' respectively.

Johanna: (B) When individuals are able to approach math problems…
(E) Mathematics is embedded in our world. It surrounds us and allows us to solve problems.

Mike: (B) Math is recognition of how patterns into an abstraction of the universe. Doing math means to discover truths.
(E) Math is a process for making sense of the patterns in the universe. To do this means to categorically recreate what we think and be able to reconstruct it for somebody else.

When a person obscures agency, they position themselves away from, or at a distance from that which they are describing (Wagner, 2007). This was also evident from the use of a common framing at the beginning of the course, that mathematics was all around them. While seemingly inclusive and holistic, this still obscures agency by not referring to a person when describing mathematics. Most students were both much more specific and present in their description of mathematics at the end of the course.

Reframing of Mathematics

Another significant change that occurred, related to how students described mathematics. The initial view that mathematics was about calculating and finding patterns had shifted to one that saw doing mathematics as involving collaborating and negotiating.

Charlotte: (B) Mathematics is a way of understanding and interpreting situations. It often involves problem solving and logical reasoning.
(E) From this course my understanding of how one does mathematics has radically changed from a more traditional, algorithmic approach to a more interactive problem based perspective where knowledge is gained through exploration, play and discussion.

Mathematics was repositioned as something that exists in activity with both people and things. This shift from understanding or interpreting something, towards ways of engaging with mathematical objects or ideas, also supports an Indigenous way of thinking that Lunney Borden (2011) calls verbification.

Retemporalizing and Repersonalizing

Jenna: (E) Math is collaborative, and every person could approach the same problem differently. We can trust that in group work, we can be inspired by other people and inspire them at the same time. Our thoughts could be broadened and completed by other people's thoughts. The discussion and collaboration may not be the most efficient way but 'learning requires time and patience'.

From this statement, it seems that group work was not simply about collaborating to find an answer, but instead spoke of inspiration, broadening perspective, and truly supporting each other in a willingness to engage with a mathematical problem and take risks while doing so.

Indigenizing the Curriculum

Although we recognize that many of the comments shared below are overgeneralized, we found that the positionality students were expressing had shifted to an openness and willingness to rethink their attitude and ways of doing mathematics.

Angel: (B) Indigenous ways of learning involves patience and time which is pertinent to mathematics education as mathematical problems are rarely solved immediately. Learning math requires dedication, practice, patience.

(E) I believe that mathematics is inherently a social endeavor, and so the process of learning and doing mathematics aligns well with Indigenous ways of knowing. I think that mathematics is a universal language that connects all of humanity.

John: (E) Learning is holistic in terms of there is a context, there is social and relational piece in it, and it is reciprocal. This is directly connected to the Indigenous belief of learning is to benefit community and the society.

These comments reflect the general attitude of many of the pre-service teachers at the end of the course and demonstrate a shift from a cultural dominant view of mathematics as a field available for study, to a more approachable discipline that engages people in supporting one another and negotiating meaning. Students have positioned themselves in a more inclusive and open space for interpretation and understanding of what it means to do mathematics.

Conclusion

This research involves attempting to change pre-service teachers' attitudes through an approach towards Indigenizing the mathematics curriculum by focusing on methods of learning mathematics and does not claim to successfully Indigenize the curriculum. Positioning theory has been used as a marker of a relationship which is relevant and informative for this course that was modeled on the relationship between people, mathematics and people, and between Indigenous ways of knowing and the pre-service teachers in this course. This research is meant to be generative of conversation, discussion and future research.

PROSPECTIVE TEACHERS' INTERPRETATIONS OF ARGUMENTATION AND CORRESPONDING TEACHING ACTIONS

We examine connections between teacher education coursework and teaching actions. In particular, we looked at one unit of instruction addressing collective argumentation in a pedagogy course and how two student teachers supported collective argumentation in their placements during the following semester. The student teachers' support for collective argumentation aligned with their interpretations of the unit on argumentation, reflecting their slightly different emphases of the role of the teacher in facilitating student participation and focusing on the goal of the argument. Our results suggest prospective teachers' interpretations of coursework can be reflected in their practice, even in student teaching.

Keywords: Classroom Discourse, Teacher Education-Preservice

Connections between teacher education coursework and teacher actions, even in student teaching, are difficult to find, and even more difficult to document. In attempting to trace teacher learning across multiple semesters, the project described in this paper begins to document how some aspects of teacher education coursework may be visible in student teachers' practice. Rather than focusing on the specific contents of the coursework, we rely on our participants' interpretations of their coursework, as inferred from various sources, and look to see how their practices reflect these interpretations. Our focus is how teachers learn to support collective argumentation in secondary mathematics classes; this paper addresses the question: How do prospective teachers' interpretations of a unit on collective argumentation (during a pedagogy class) align with their support for collective argumentation during student teaching?

Related Literature & Framework

Argumentation and proof is an integral part of mathematics. Researchers have investigated many aspects of argumentation, including student learning through argumentation (e.g., Krummheuer, 1995), and relationships between classroom argumentation and proof (e.g., Knipping, 2008). We view argumentation as attempting to convince someone of the validity of a claim and collective argumentation as people working together to determine the validity of a claim (Conner, Singletary, Smith, Francisco, & Wagner, 2014). We follow Krummheuer (1995) in using Toulmin's (1958/2003) model of an argument, adopting the vocabulary of claim, data, warrant, qualifier, and rebuttal to describe distinct parts of an argument. We attend to who contributes these parts of arguments; distinguishing between teacher, student, and joint contributions provides insight into teacher facilitation of argumentation (Conner et al., 2014).

We view learning as situated (as discussed by Lave and Wenger, 1991). That is, we follow Peressini, Borko, Romagnano, Knuth & Willis (2004) in asserting that people learn within multiple communities, and we investigate how prospective teachers may recontextualize (as used by Ensor, 2001) their on-campus learning in their student teaching practice. For instance, prospective teachers may experience collective argumentation as they learn mathematics content, and they may learn about collective argumentation in their pedagogy courses. These experiences must be recontextualized into their own practice in student teaching.

To guide our analysis of teachers' support for collective argumentation, we use the Teacher Support for Collective Argumentation (TSCA) framework (Conner et al., 2014). This framework provides three ways teachers may support collective argumentation: directly contributing argument components, asking questions that prompt components, and responding to components of arguments using other supportive actions. Each type of support has five categories, and within the categories of questions and other supportive actions, there are multiple kinds.

Methods

We report on part of a larger project following a cohort of prospective secondary teachers through their mathematics education program, into student teaching, and beyond. We purposely selected two participants as they participated in a unit on argumentation during their course work, a practicum experience, and their student teaching experience. Cathy and William (pseudonyms) were white, cisgender and in their early 20s.

Data analysis was conducted using Transana (Woods & Fassnacht, 2010). We identified episodes of argumentation (EOA) in the student teaching data. We constructed expanded Toulmin diagrams (Conner et al., 2014) for each EOA and coded teacher support based on the TSCA framework. The Toulmin diagrams provided information on the characteristics of the arguments while the TSCA framework provided analysis of the teachers' support of the arguments. We captured these thick descriptions of the participants' argumentation in memos.

The second phase of data analysis focused on the argumentation unit during the third semester pedagogy course. During the unit, participants discussed collective argumentation and Toulmin (1958/2003) diagrams and constructed diagrams for classroom arguments. For each participant, we coded his or her reflections and discussions during the unit to describe their interpretations of argumentation. We expanded each participant's memo to examine how interpretations of argumentation aligned with argumentation practices during student teaching.

Results

Cathy's Interpretation of Argumentation

Cathy saw the role of the teacher as a facilitator who asks questions, clarifies ideas, and restates contributions. She wanted students to be the main contributors to the arguments. She also wanted to make sure students pushed each other's thinking. When discussing a class reading (Choppin, 2007), Cathy said, "Your job is not to go in and argue for the student, …you have to let them work through it and possibly have other students point out and ask, like okay why did you do this?" (In-class discussion). She believed all students were capable of contributing to the conversation as long as they were comfortable within the group. Cathy wrote the following in her reflection after orchestrating a discussion in her practicum, "I wanted each of the students in my group to feel like they contributed to the discussion…If one student hadn't shared in a while, I made sure to call on that particular student." Cathy believed her role as a teacher included having students be the ones constructing and communicating the arguments.

In her written reflection, she described an effective argument as one that involved multiple students, and she labeled as ineffective an argument involving only one student. Cathy saw effective arguments as those promoting students to share their thinking. "Why would you engage students in arguments?...So they could just like—whatever math they're doing in different ways and see there is more than one way to think about it" (In-class discussion). Overall, for Cathy, student participation in the construction of arguments was a way to provide students an opportunity to learn strategies and ways of reasoning mathematically.

Cathy's Support for Argumentation

In Cathy's classroom, students directly contributed 68 claims and data/claims (out of 75) and 41 explicit warrants (out of 47). This shows Cathy was committed to having the students be the ones constructing the arguments in the classroom. Analysis of her supportive moves reinforces this result, as she revoiced the students' contributions 64 times and expanded on their contributions minimally (7 times in two days). Specific discursive actions were taken by Cathy to promote student participation. For example, Cathy made statements like the following: "Somebody raise your hand and tell me how it's not fair. I see [St 1] and [St 2]'s hands. I need a few more, guys" and "Do y'all notice anything? I'll wait until I see a few more hands." Her desire to have students participate was also evident from her lack of contributions of argument components (claim, warrant, data). During the two days, Cathy made 16 direct contributions to arguments out of the 149 explicit argument components. The remaining 133 contributions were made by students (128 contributions) or co-constructed by students and Cathy (5 contributions).

Cathy wanted many students to participate in the construction of arguments. She thought it was important for the teacher to facilitate the students' work in argumentation, and in her student teaching, we found she asked questions that pushed students to provide their reasoning and she often restated student contributions to be sure they were understood by the class.

William's Interpretation of Argumentation.

William believed that in order to facilitate argumentation effectively, the teacher should have a clear idea about the goals of argumentation. During the argumentation unit, William said:

> I feel like a huge part of the argument is knowing where you're going with it, too. … Cause I mean it is easy to facilitate an argument and not know exactly where to go and let it, so that's when you kind of can let it spiral out of control. (In-class discussion)

William viewed argumentation as a debate, and he thought it was beneficial to let students argue with each other because "Students listen to each other more than they'll listen to us" (Interview). William wanted his students to participate in collective argumentation. However, he found that having students participate and reaching his goal to cover content was a difficult balancing act. In William's written reflection, he wrote about an argument he witnessed during his field experience between two students. He found the argument to be effective "because it required both students to approach the problem in a different way then they initially did." He expanded that the argument he witnessed was effective because "mathematical concepts are being grappled with" (Reflection). For William, an effective argument not only involves multiple approaches to a problem but also provide opportunities for students to deal with mathematical concepts behind them. In contrast, William viewed an ineffective argument as one that only dealt with simple errors about a procedure or computation.

William's Support for Argumentation

Our analysis suggested that William primarily supported the argumentation in his classroom by asking questions that requested a factual answer (63 out of 137) and requested a method (31 out of 137), which aligned with his goal-directed orientation (focusing on content). There were only a few instances in which William requested an evaluation, idea, or elaboration. In terms of contributions to the arguments, William and students contributed about the same number of components (99 and 98) and contributed a few components jointly (15). This was consistent with William's desire for students to participate in arguments. However, there was a difference in who contributed claims and warrants. Students primarily contributed the claims (64) in the arguments with some claims jointly contributed with William (7). In contrast, students contributed some warrants (29) in the arguments but most of the warrants were either provided by William (46) or were implicit (40). The contributions of students and William in the EOA align with William's interpretation of the teacher's role as facilitator in reaching the goal of the argument.

Conclusion & Implications

Cathy and William developed consistent interpretations of argumentation with respect to helping students be comfortable in participating in argumentation. Their interpretations of the teacher's role in argumentation involved similar elements, with Cathy focused on the teacher as facilitator to generate student participation and William focused on the teacher as steering students toward the final claim. Our observations of their classrooms revealed consistencies in their interpretations of the teacher's role in argumentation and how they supported argumentation in their classrooms. For instance, Cathy prioritized participation and communication for students both in her student teaching and in her interpretations of the unit. Likewise, William prioritized the goal of the argumentation in his interpretations, and this priority was evident in his focused questions and contributions of components. As prospective teachers recontextualize their learning in their student teaching placements, their interpretations of this learning may take different forms. Our results suggest prospective teachers' interpretations of coursework can be reflected in their practice, even in student teaching. However, understanding their interpretations and working toward productive interpretations of coursework is even more important as seemingly subtle differences may appear much larger in practice.

This qualitative study sought to explore preservice elementary teachers' (PSETs) beliefs about the role definition plays in the learning of mathematics, as well as how an emphasis on the act of defining promotes the development of mathematical empathy. PSETs completed activities using geometry software, and collaboratively created definitions of special quadrilaterals. An assigned reading and written reflection of their experience followed. Data from these reflections were analyzed for themes and emergent categories. The coding instrument that resulted from iterative discussions by the researchers examined beliefs about the fluidity of definition and mathematical empathy (Araki, 2015). Findings suggest that including PSETs in the act of defining allowed for greater autonomy in authoring definitions, mathematical empathy, and the view that definitions are fluid in nature and dependent upon the audience.

Keywords: Geometry and Geometrical and Spatial Thinking; Instructional Activities and Practices; Teacher Education-Preservice

Introduction & Theoretical Frameworks

Though definitions are considered fundamental in mathematics, there is little agreement on what we believe to be a good definition (Wilson, 1990). There is disagreement in our field regarding whether a definition should be as minimal as possible; with some scholars insisting on a full reduction of extraneous properties and others honoring the role of context, allowing for more redundancy (Zaslavsky & Shir, 2005). Which properties and how many to include in a definition is somewhat arbitrary, and the value of a definition depends on the perspective of its author. That many different definitions can be written for the same concept is difficult for PSETs to understand (Linchevski, Vinner & Karsenty, 1992).

Few studies investigate student's conceptions of a mathematical definition (e.g., Zaslavsky & Shir, 2005). Using written responses and recordings of small group discussions, Zaslavsky and Shir (2005) investigated four students' conceptions of definitions for square and isosceles triangle, and how these conceptions were reflected in and developed through activities that elicit consideration of alternative ways to define a mathematical concept. They found that asking students to consider a variety of definitions is a powerful learning environment wherein personal concept definitions could be gradually refined along with conceptions of definition in general.

In this study, we are seeking to answer two research questions. 1) What are PSETs' beliefs about definitions and the act of defining; and 2) How does an emphasis on the act of defining mathematical terms promote the development of mathematical empathy?

Theoretical Framework 1: Fluidity of Definition

De Villiers (1998) studied what happens when we allow students to realize that different definitions of the same concept are possible with advantages and disadvantages for each. In addition to mathematical characteristics, we also wanted our PSETs to recognize that the choice of which definition to use in mathematics classrooms is also based on the pedagogical context. Keiser (2000) honored instructional context in her work with defining angle. We ask our PSETs to read Keiser (2000) to provide this exposure to student thinking and to support the development of concept imagery related to the act of defining.

From reading of the literature as well as our initial reading of the data, we have designed a *Fluidity of Definition* framework to capture four main themes that we wish to examine: *multiplicity*, *authorship*, *authority*, and *audience*. Multiplicity is the belief that definitions are not rigid and that many alternative definitions exist for a concept. Authorship indicates an ownership over a definition. Drawing on Tall & Vinner (1981), we view a definition as personal as it is based on concept imagery that we hold as individuals. Authority indicates the power to decide which language, style, and properties to include in a definition. Audience honors the pedagogical context and is the belief that a definition is influenced by who we intend to read and use it.

Theoretical Framework 2: Mathematical Empathy

When we take a view of mathematics as a humanistic discipline that is socially constructed and personal values influence our evaluation of results, then it is important for instruction to be participatory and for students to feel that they have agency and voice in the classroom. In order to develop a classroom culture where this is possible, we posit that teachers need to be aware of and able to comprehend the mathematical thinking of their students.

Araki (2015) refers to this skill as *mathematical empathy* defined as "the ability to comprehend another person's ideas and the true meaning or purpose behind them, seeking to utilize the other person's frame of reference" (p. 118). To elevate student thinking within instruction, mathematical empathy is required. Mathematical empathy is what allows us to play *the believing game* (Harkness, 2009) and find the truth in the mathematics that students share.

Methods

This study examines PSETs' beliefs about the role definition plays in the learning of mathematics, as well as how an emphasis on the act of defining promotes the development of mathematical empathy. We enacted this study in two sections of a course on Geometry for Teachers (PK -3) with 71 PSETs. The study was enacted similarly for both sections.

Prior to data collection, PSETs were exposed to dynamic figures constructed using interactive geometry software, and asked to collaboratively create a series of definitions for special quadrilaterals. Following these lessons, they were asked to reflect upon their experience. In order to help them frame their comments as both learners and future teachers of mathematics, we first asked them to individually read *The Role of Definition* (Keiser, 2000). The article was chosen as a catalyst for reflection on this experience because Keiser suggested that formal definitions can curtail thinking in middle grades classrooms and argued for more fluid definitions based on concept imagery (Tall & Vinner, 1981) that was relevant in classroom learning.

Following the reading, we prompted, "*After reading the article The Role of Definition, what new thoughts do you have about the conversations we had in class about defining quadrilaterals? How about using definitions with children?*" Once they had responded to the prompt on an electronic discussion board, they were given access to their classmates' reflections and were asked to participate in an online discussion of what had been shared. The qualitative data in this study comes from the initial posted reflections (n=71). We chose to focus on after-the-fact reflections because we were interested in our PSETs perceptions of the defining activity both as learners and as future educators.

To begin analysis, we read the 71 initial discussion posts and wrote memos about emerging themes from the data. Through discussions by the research team, using grounded theory (Strauss & Corbin, 1990) and top-down methods of Miles and Huberman (1994), we iteratively developed, applied and refined a coding instrument. The coding instrument that emerged was based on theory from research on *fluidity of definition* (de Villiers, 1998) and *mathematical* *empathy* (Araki, 2015). Once a set of initial codes was established, 14 discussion posts were randomly selected from the entire set and coded with this instrument by all three researchers.

Following this second phase of analysis, researchers met to discuss, compare, and come to a consensus for each discussion post. When there was low initial agreement about coding particular categories, discussions resulted in the refinement of code descriptions. In the Results section, we provide definitions and illustrations of what emerged from these discussions.

Results

More results and reflections will be shared during our presentation provided in a longer format to illustrate the different components of the frameworks and give a fuller sense of PSETs' beliefs and intentions. Here, we will present an overview of available findings, including subcategories within the two identified frameworks: *Fluidity of Definition* and *Mathematical Empathy*. These categories are not to be interpreted as mutually exclusive codes, but as different lenses through which to interpret a reflection.

Fluidity of Definition

Multiplicity. Multiplicity is the belief that definitions are not rigid and that many alternative definitions exist for a given concept. Some students reflected on their experience and found value in multiplicity, though this value took different forms. In her reflection, Rebecca expressed a belief that each child has a unique personal concept definition, and that in a classroom context, there is value in negotiating with others about those definitions. Trevor, however, believed that the personal concept definition is something that can be refined over time and experience; that even within one individual, definitions are multiple, fluid and changing. A third notion of multiplicity was described by Funda when she expressed frustration with textbooks that portray a single definition as straightforward and rigid. She sees this as restricting instruction unnecessarily and describes a freedom in expanding on the definitions in a local community.

Authorship. Authorship indicates an ownership over a definition. Funda's reflection also indicated a desire for authorship, but also a feeling of helplessness when using a textbook. Josie also saw purpose and value in being able to author definitions based on our classroom activity.

Autonomy. Autonomy indicates the power to decide which language, style, and properties are useful to include in a definition. When Sheena says "All of the definitions we decided were what made sense to us (and they were correct which is a big part of it as well)…we got to play around with our own wording and what we felt it was important to know about each different quadrilateral, which makes it much more personal to us and easier to understand."

Audience. Audience honors the pedagogical context and is the belief that a definition is influenced by who we intend to read and use it. In reflections on both the classroom activity and the assigned reading, it was clear that there was an impact on our PSETs' conception of audience as important in the act of defining. Here, definitions are not just mathematical tools to be internalized, but teaching tools that help convey meaning to others.

Mathematical Empathy

In efforts to code our data for evidence that our PSETs exhibited *mathematical empathy*, it became clear to us that there were (at least) two stages of empathetic work: *awareness* and *comprehension*.

Empathetic Awareness. Empathetic awareness lives in a general space where the speaker understands that there is multiplicity in mathematical perspectives. (Not to be confused with multiplicity in concept definitions.) Awareness can emerge as a belief that others see things differently or that students have different mathematical backgrounds, experiences, or understandings that are worthy of attention and understanding. However, not all statements that show awareness value multiplicity. Sometimes multiplicity indicates deviation from "standard" or inferior. When different means deviant, then awareness can be akin to feelings of what we have come to call *mathematical sympathy*, or the expression of feelings of pity or sorrow that we have understood another's ideas, but find them inferior or undesirable. As one student wrote, "I believe that if the students were just given a definition they would not have been able to explore what they thought it was and learn how their ideas were similar or different to the definition."

Empathetic Comprehension. Without a specific statement of understanding from another's perspective, awareness is not evidence of *comprehension*. In order for us to experience mathematical empathy, we must be able to comprehend from another perspective. This is akin to what Hufferd-Ackles, Fuson, and Sherin (2004) refer to as *revoicing* an idea shared by another. For example, Henry expressed mathematical empathy for a student, Dave, from the article, and went so far as to say that our discussion was lacking because this perspective was not available.

Conclusion

Coming to a consensus about how to define a special quadrilateral exposed PSETs to more than just the properties of quadrilaterals, but also the act of defining. Experiencing, albeit in a vicarious way, the difficulties faced by sixth-grade students in defining angle created space for mathematical empathy, including both awareness and comprehension. As Henry stated above, the story of Dave's confusion resonated with our students and provided an opportunity to see from someone else's perspective. When combined with their own fraught experience negotiating the properties of kites and trapezoids, the article about angle (Keiser, 2000) enabled PSETs to see far greater subjectivity in the discipline of mathematics and to consider, perhaps for the first time, that they, too, were both able and deserving of becoming authors of mathematical ideas.

PROSPECTIVE TEACHERS' CENTRAL BELIEFS ABOUT MATHEMATICAL MISTAKES

Matthew D. Duncan
Middle Tennessee State University
Matthew.Duncan@mtsu.edu

Standards-based documents suggest that mistakes should be viewed as more than dead ends and should be used as catalysts for discussion and learning. However, prospective teachers rarely experience the utility of mistakes, which influences their beliefs concerning mathematical mistakes and ultimately how they teach and treat mistakes in their future classrooms. The influence that beliefs have on teaching is well known, but the beliefs concerning mathematical mistakes are not. Research suggests that new experiences can change beliefs given time and reflection. This study explored the beliefs of two prospective teachers concerning mathematical mistakes and how those beliefs changed during their enrollment in a content course for teachers designed to align with NCTM recommendations.

Keywords: Preservice Teacher Education, Teacher Beliefs

Mathematics reform documents (e.g., Common Core State Standards Initiative [CCSSI], 2010; National Council of Teachers of Mathematics [NCTM], 2014) encourage teachers to teach in ways that focus on student learning and leverage students' experiences with mathematics content. Teaching in the spirit of these documents involves engaging students in meaningful tasks as well as encouraging student interaction and discussion centered on the students' work (NCTM, 2014). Many of these discussions focus on students' mistakes and provide opportunities for students to reflect on those mistakes (NCTM, 2014). However, the way reform documents describe teaching is in stark contrast to traditional ways of teaching that remain pervasive in today's mathematics classrooms (Philipp, 2007).

In mathematics, teachers' beliefs play a significant role in teaching and learning (Pajares, 1992; Philip, 2007). Their beliefs influence not only how they teach mathematics but what mathematics is, what it means to do mathematics, and how they envision the roles of the teacher and the students in a mathematics classroom (Cooney, Shealy, & Arvold, 1998; Thompson, 1992). This includes how prospective teachers (PTs) will treat mathematical mistakes in their future classrooms. If mathematical mistakes are to play the role that research and reform documents advocate, then teachers' beliefs concerning mistakes need to align with that role, or mathematics education's progress will remain compromised (NCTM, 2014).

When prospective teachers (PTs) enter their teacher preparation programs, their beliefs and belief structures are already well established (Cooney et al., 1998; Pajares, 1992). Their experiences include the PTs' years of being a student in primary and secondary mathematics classrooms (Philip, 2007; Thompson, 1992). Understanding the beliefs of PTs is the first step in ensuring alignment of PTs' beliefs concerning mistakes with mathematics education research and teaching documents (e.g., CCSSI, 2010; NCTM, 2014). Additionally, accounting for the context in which those beliefs are investigated is necessary. Therefore, the purpose of this study was to investigate PTs' beliefs concerning mathematical mistakes while considering the error climate of the classroom. This leads to the primary research question of the study: What beliefs do PTs' hold about mathematical mistakes, and how do those beliefs change, if at all, given the classroom error climate?

Theoretical Framework

Two theoretical constructs guided the study. The first of these was the *error climate* of the classroom (Steuer, Rosentritt-Brunn, & Dresel, 2013). Steuer et al. (2013) assumed that although learning from errors depended on individual characteristics of learners the classroom context was a precursor to those. Thus, classroom climate facilitates learning from errors and the potential to transcend individual attributes.

The second construct was Leatham's (2006) theoretical framework for viewing beliefs as a sensible system. The sensible system framework assumes that an individual, whether that person is able to articulate a belief, organizes beliefs into "organized systems that make sense to them" (p. 93). Leatham's (2006) framework consists of three dimensions that assist in visualizing an individual's belief. The first of which is the psychological strength of a belief. This is a description of the relative importance that a belief is to an individual that can vary from central to peripheral. The second dimension is the "quasi-logical relationship" (Leatham, 2006, p. 94) that exists between beliefs. The final dimension of the sensible system framework is the extent to which beliefs are clustered in isolation from other beliefs. This clustering of beliefs allowed for the contextualization of beliefs and explained why a belief in one context may not be as central in another. This framework provided guided the data collection and data analysis. Together, the error climate and beliefs as a sensible system framework provided a lens to examine what PTs' beliefs were concerning mathematical mistakes.

Methodology

In this study, I utilized an exploratory, multiple case design to investigate PTs' beliefs concerning mathematical mistakes and how those beliefs change, if at all. With a variety of criteria available from which to select the two cases (e.g., ACT score, mathematical content knowledge), I selected participants that displayed characteristics of different implicit theories (see Dweck & Leggett, 1988), but in the middle of the implicit theory continuum for data collection purposes. The decision to select participants based on implicit theory was made because of the role that implicit theory plays in persisting when making mathematical mistakes and that implicit theory transcends levels of mathematical ability (NCTM, 2014).

As beliefs are not able to be articulated directly and must be inferred by the researcher (Leatham, 2006; Pajares, 1992), a variety of opportunities were given to the participants to describe their beliefs concerning mathematical mistakes over the fall semester as they were enrolled in a mathematics content course designed for PTs that intend to teach at the elementary school level. The course was designed to ensure that PTs were routinely exposed to mathematical mistakes in group tasks, homework, and tests. Additionally, the participants were given numerous opportunities to reflect on the mistakes presented in class as well as their own mistakes during data collection. Data sources included error climate surveys, interview protocols, classroom observations followed by interviews, reflective journals, exit tickets, and in-class reflections. I analyzed the data chronologically using open coding. Codes were created based on distinct concepts and categories that originated in the data.

Results

Results from the error climate surveys, which were an indication of the participants' perceived error climate, differed noticeably for both participants from the beginning of the study to the end. The most notable differences for Cindy, a pseudonym, were her view of how mistakes are perceived by others in the class and how mistakes are used in a mathematics classroom. Although her view of her past mathematics classrooms indicated that a student can learn from mistakes, there was a shift in the emphasis of learning from mistakes by the end of the study. Additionally, evidence suggested that Cindy perceived that mistakes were more welcomed by both the teacher and students. In contrast, the most notable shift in Harley's perceived error climate was how she interpreted the teacher's reactions to mistakes. Evidence from the beginning of the study suggested that Harley believed that mistakes were not important for the teacher and that learning from mistakes was solely the responsibility of the learner, not the teacher or the class as a whole. By the end of the study, Harley perceived mistakes as something everyone could learn from and saw mathematical mistakes as both a personal learning and pedagogical tool that should be used often.

As the two participants' other qualitative data were analyzed, beliefs concerning mathematical mistakes emerged that were considered as central to each of them. These central beliefs transcended context and were influential in how the PTs made sense of specific mistakes as well as the repeated presence of mathematical mistakes in their classroom. A brief description of each participant's central beliefs concerning mathematical mistakes is presented below.

Cindy

From the onset of the study, Cindy believed in the value of mathematical mistakes. Throughout the course of the study, Cindy expressed how she learns from mistakes. She wrote:

> I don't like to make them at all. But even though I don't like to make them, mistakes are a part of life. You learn from mistakes, how to fix them, or make them better. You can be told how to do it, and sometimes pick up on it, but when I make a mistake, I learn why I made the mistake and how to fix it. Then, try again to figure it out. Mistakes will happen, but you need to be able to accept the mistake and learn from it. (Cindy, Journal entry, Dec. 4, 2017)

The value of mistakes for Cindy surfaced in many instances including when she could not reconcile what she learned from a mistake, stating "you can always learn something." This persisted throughout the study, but what she learned from a mistake shifted from learning how to fix the mistake to being able to go to "a deeper level" of knowledge as the study ended.

Cindy also believed that mathematical mistakes had the most service if "the majority of the class made that mistake." Void of the type of mistake (e.g., "minor" or "major") or when the mistake was made (e.g., class discussion, homework, or test), the number of people making the mistake was extremely important to her. This was by far the stickiest (Thompson, 1992) belief Cindy held throughout the study.

Finally, Cindy believed mathematical mistakes should be used as moments for learning for both students and for her as a prospective teacher. Mistakes that were presented during in-class activities, homework, and tests were done so in an effort for her to be able to anticipate what her future students might do, and more specifically what the majority of them might do. Additionally, and from Cindy's perspective, the mathematical mistakes that were highlighted and discussed in class helped her achieve a deeper of learning and to "know more than her [future] students."

Harley

Harley believed mathematical mistakes were instances where someone either made a mental mistake (e.g., adding incorrectly) or was an indication of a lack in understanding. At the beginning of the study, Harley believed that mistakes needed to be fixed either by someone pointing out the mental mistake or fixed by someone that did not have the same lack of understanding. Similar to Cindy, learning from this mistake was the responsibility of the person that made it, especially after being shown how to correct it.

Similar to Cindy, Harley also believed that mistakes had the most utility when a majority of the class was making the mistake, regardless of what the mistake was. This belief was pervasive for Harley and is best captured in her final interview when asked about when a mistake is useful and best used for class discussion:

> It depends on like how much time you have in that class and what mistakes are going to be more important, not more valuable, but more...cause they're all valuable to learning but just need to be said more than others. Like I said, if I'm the only one getting it wrong, that's just one person, but when the whole class is messing up, they're all going to fail if they don't get this. That one needs to be brought up, [and] then she can come back to me if there's time in the class. I think it's like that. (Harley, Final interview, Nov. 30, 2017)

Harley believed that mathematical mistakes were extremely valuable, and this belief strengthened as the study progressed. For Harley, mathematical mistakes could be used to ensure that you "*really* understand something," and to elicit different ways of thinking about the same problem, which is aligned with NCTM's view of the role that mistakes should play.

Discussion

Central beliefs were persistent and mediated how other beliefs are clustered, interpreted, and in some cases influenced in different contexts. Furthermore, these central beliefs were used when PTs make sense of situations that are in contention with their current beliefs, which emphasized the importance of understanding what those beliefs are. For teacher educators, understanding PTs' central beliefs concerning mathematical mistakes is crucial if there is going to be an effort to change them. Additionally, understanding central beliefs can inform teacher educator high-leverage practices to further support alignment of PTs' beliefs with literature on how mistakes should be used in the mathematics classroom and ultimately the PTs' classrooms. Findings suggest PTs notice how mathematical mistakes are used in their teacher preparation classes, especially if they are used differently compared to previous mathematics classrooms. Leveraging that environment and making the purpose of using mathematical mistakes explicit is a first step in aligning PTs' beliefs with literature recommendations.

CO-PLANNING WITH INTERNS: ENVISIONING NEW WAYS TO SUPPORT INTERN DEVELOPMENT OF EFFECTIVE LESSON PLANNING

We examine the potential of co-planning during the internship experience to assist interns in making the transition from being a mathematics education student to becoming a mathematics teacher. We describe six strategies to facilitate co-planning between mentor teachers and interns. We report data from interns and mentors about their comfort level with particular strategies, their use of the strategies, and the benefits and challenges of co-planning in the internship setting.

Keywords: Teacher Education-Preservice, Instructional Activities and Practices, High School Education, Middle School Education

Crucial to both a successful mentor/intern relationship and to the development of the intern as a teacher is the co-planning process. We have found that mentor teachers often struggle with how to scaffold interns' involvement in the lesson-planning process. Within our program, and in conjunction with universities across the country, we have been working to develop and study strategies to help mentors and interns plan together more effectively.

Theoretical Framework

Our work with co-teaching and co-planning during pre-service teachers' internship experiences is grounded in Lave's (1991) apprenticeship model of learning. Lave defines learning as "first and principally the identity-making life projects of participants in communities of practice" (p. 157). The work of interns is not simply to build a more refined and abstract knowledge of teaching but to work towards becoming "a respected, practicing participant" (p. 157) in the classroom. In such an endeavor the working relationship between intern and mentor teacher is a major determining factor in the intern's ability to participate productively and collaboratively in the practice of classroom teaching. The mentor teacher serves as both collaborator and mentor for the intern. We envision this mentorship as what Feiman-Nemser and Beasley (1997) termed "mentoring as assisted performance." The mentor's role is not just that of a supportive presence or critic of a performance, but as a real-time coach helping interns navigate the world of the classroom. Our strategies for engaging in co-planning provide guidance on ways in which mentors can interact to scaffold interns as they learn to plan and ways in which mentors and interns can collaborate on planning.

Project Background

This project began with a realization of how powerful the co-teaching strategies (Friend, Reising, & Cook, 1993; Bacharach, Heck, & Dahlberg, 2010) were for our interns and mentors. The co-teaching strategies provided strategies for how mentors and interns could share classroom responsibility and language for them to talk about their shared work. Despite the usefulness of the co-teaching strategies, we found that many intern-mentor pairs were not taking full advantage of co-teaching because they not effectively co-planning. Much of the literature on co-planning envisions co-planning as two teachers sitting together in the same place, at the same time, going from a general topic to a full lesson plan. Schwille (2008) provides one teacher's description: "We'd be sitting at our table and we'd have our plan books. We'd have all of the books and materials and stuff around us. We'd just be sitting at this table talking, basically." (p. 153). Just as the co-teaching strategies expanded the vision of co-teaching beyond the Team Teaching model, we sought to envision other ways that teachers could engage in co-planning.

Development of the Co-Planning Strategies

The first stage of our work was the development of a set of potential co-planning strategies. Because the success of the co-teaching strategies, we used these as inspiration for developing six co-planning strategies. We defined each approach, described how a planning session might go, and identified potential benefits and concerns for each approach. In 2015, we piloted our training with interns, mentors, and university supervisors at two universities. Based on feedback from participants, we refined the descriptions of the strategies and the training. In 2016 we used feedback from eight secondary mathematics intern/mentor pairs and 83 pairs across other grade levels and subjects to further refine our descriptions and training.

Co-Planning Strategies

These co-planning strategies are not progressive or hierarchical. However, in working with our interns, we have found that some co-planning strategies are more productively used early in the internship while others might be more appropriate later. We present them (see Table 1) in an order in which they might first be encountered in an internship setting.

Table 1: Co-Planning Strategies (adapted from Cayton, et al., 2017)

Strategy	Definition
One Plans, One Assists	Each co-teacher brings a portion of the lesson, although one clearly has the main responsibility. The team works jointly on final planning.
Partner Planning	Co-teachers take responsibility for about half of the components of the lesson plan. Then they complete the plan collaboratively.
One Reflects, One Plans	Mentor thinks aloud about the main parts of the lesson and the intern writes the plan.
One Plans, One Reacts	One co-teacher plans and the other makes suggestions for improvement.
Parallel Planning	Each member of the co-teaching team develops a lesson plan, and the two bring them together for discussion and integration.
Team Planning	Both teachers actively plan at the same time and in the same space with no clear distinction of who takes leadership.

The Current Study

In this study, we address three research questions: Which co-planning strategies are mentor teachers and interns using and are most comfortable using? What do mentor teachers and interns perceive as the benefits and challenges of co-planning? How valuable do mentor teachers and interns perceive co-planning and co-teaching to be?

Data for this study is from 11 secondary mathematics intern/mentor pairs and include pre- and post- surveys from both interns and mentors and weekly journals from interns. The interns in this study began learning about and practicing co-planning strategies during their mathematics methods course in their junior year. Interns and mentors participated in two 2-hour co-planning/co-teaching workshops and one math-specific 1-hour co-planning workshop.

Findings

Interns' usage of strategies and comfort level with strategies is summarized in Table 2.

Table 2: Usage of Co-Planning Strategies & Intern Comfort Level

Usage of Co-Planning Strategies	Interns' "Most Comfortable" Strategies	Mentors' "Most Comfortable" Strategies
One Plans, One Assists(128)	One Plans, One Assists (6 of 11)	One Plans, One Assists (4 of 9)
One Plans, One Reacts (82)	One Plans, One Reacts (6 of 11)	One Plans, One Reacts (2 of 9)
One Reflects, One Plans (51)	Team Planning (3 of 11)	Team Planning (4 of 9)
Partner Planning (41)	One Reflects, One Plans (1 of 11)	One Reflects, One Plans (0 of 9)
Team Planning (26)	Partner Planning (0 of 11)	Partner Planning (4 of 9)
Parallel Planning (5)	Parallel Planning (0 of 11)	Parallel Planning (2 of 9)

In their journals interns reported strategies used during each class period. The most used co-planning strategies were *One Plans, One Assists* (128) and *One Plans, One Reacts* (82). Three strategies: *One Reflects, One Plans* (51), *Partner Planning* (41), and *Team Planning* (26) were used moderately, while *Parallel Planning* (5) was rarely utilized. All co-planning strategies were used at least once, but only one intern used all six strategies.

The strategies interns reported as most comfortable were *One Plans, One Assists* and *One Plans, One Reacts.* No interns reported comfort with *Partner Planning* or *Parallel Planning.* Mentor teachers mentioned a broader set of strategies as comfortable with no single strategy mentioned by more than half of the mentor teachers. There was often a difference between what the interns reported and what the mentors reported as most comfortable.

We found that mentor teachers expressed more benefits than challenges on both the pre- and post-survey. There were four themes in the reported benefits: benefits for interns, benefits for mentors, benefits for high school students, and benefits for both teachers. (See Table 3).

Table 3: Benefits of Co-Planning

Benefits	Mentor Pre	Mentor Post	Intern Pre	Intern Post
For interns	6	3	8	10
For mentors	3	6	0	0
For lesson plan/students	3	3	2	1
For both teachers	2	5	3	0

Of the challenges raised by the mentors, only time for planning and allowing interns independence, were mentioned both pre and post by the same mentor. In the pre-survey, the 11 mentors identified 14 benefits and only 5 challenges. In the post-survey the nine mentors who completed the survey identified 17 benefits and 5 challenges. Interns expressed more benefits than challenges on both the pre- and post-survey. There were two main themes: benefits for interns and benefits for high school students. Compared to the mentors, interns reported more of a balance between benefits and challenges. In both the pre- and post-surveys, interns identified benefits focused primarily on themselves. In the post-survey the number of interns noting benefits for themselves increased slightly, while the number mentioning benefits for quality of lesson plans/student instruction decreased slightly.

On the post-survey interns and mentors were asked to rank "How valuable was co-teaching/co-planning in your clinical experience?" on a scale of 1 to 5. Ten interns responded; seven rated it as valuable or extremely valuable. Three were neutral. Nine mentors responded; eight rated it as valuable or extremely valuable with the ninth neutral. The high value ranking from the interns and mentors was supported by quotes from the data:

- Intern: "I really enjoyed co-planning. I would think of ideas and talk it over."
- CT: "I think that it is the best way to grow an intern and to grow as a clinical teacher. Co-Planning has to be some of my favorite times with my intern, because I learn as much as they do…"

Discussion and Implications

Participants in this study used a variety of the co-planning strategies. They felt that co-planning was beneficial for helping interns improve their planning skills and that use of the co-planning strategies helped to avoid frustration and wasted time. The strategies helped to facilitate good communication between mentors and interns. Interns reported feeling empowered to contribute to the planning process, even before they were ready to plan complete lessons.

The literature and our pre-survey results indicate concerns about the challenge of finding time for co-planning, however, one result from our study is that the co-planning strategies may help with time concerns. Many of the strategies involve a combination of face-to-face planning and individual work time so mentors and interns need less common planning time. In addition, the use of the co-planning strategies resulted in less time wasted by interns creating plans that did not meet mentors' expectations.

Although we use the co-planning strategies in co-teaching settings, they are useful in a wide variety of settings. Interns in more traditional internship models still need help learning to plan and must still share the planning with their mentor teacher. We have seen these strategies used by two or more licensed teachers and by pairs of interns. We have used these strategies ourselves as we plan our university courses or plan presentations together. While these co-planning strategies grew out of our experiences with co-teaching, they appear to be much more broadly applicable.

ASSESSING PRESERVICE SECONDARY TEACHERS' PRACTICE WITH 'STANDARDIZED STUDENT INTERVIEWS'

Allyson Hallman-Thrasher
Ohio University
hallman@ohio.edu

This study used a standardized, practice-based assessment of 13 preservice secondary math teachers to determine how they responded to a common student algebraic error. Data included a video-recorded interview with a researcher who played the role of a ninth-grade algebra student demonstrating a common student error about squaring a binomial. Data were analyzed using mathematical task analysis guide and features of a math-talk community. Findings indicate participants were able to elicit student thinking but were not able to respond in meaningful ways that supported conceptual understanding. Symbolic manipulation, rather than connecting representations, was the primary method for addressing misconceptions.

Keywords: Algebra and Algebraic Thinking, Instructional Activities and Practices, Teacher Education-Preservice

Practice-based teacher education requires teacher educators to identify high-leverage practices (Ball & Bass, 2000; Sleep & Boerst, 2012) and deliberately design and embed in teacher education programs opportunities to develop skill with those practices. With an increased emphasis on teaching *practice* (Hiebert & Morris, 2012) comes a need to assess the developing practice of preservice teachers. This paper shares an example of a practice-based assessment for preservice secondary teachers (PSTs) focused on eliciting and responding to student thinking. Research questions address (1) what mathematical and pedagogical approaches were used, (2) the level of cognitive demand, and (3) quality of mathematical discussion established when PSTs responded to a common algebraic error.

Background

Though authentic field experiences are critical components of teacher preparation, they are problematic in several ways that indicate 'practice-based' should not be conflated with more time in the field. In K-12 classrooms, PSTs are limited to the context of a specific lesson and set of students. Classroom demands and established norms may limit PSTs opportunities to enact some practices (Campbell & Elliott, 2015). The complexity of managing a class of learners makes it difficult for a novice to isolate and target a particular practice. Competing goals of the university and K-12 school complicate which practices PSTs are encouraged to learn to enact and adopt in classrooms (Feiman-Nemser, 2001). Supporting field experiences with structured and repeated opportunities for novices to practice the work of teaching is critical to a robust practice-based teacher education program (Ball & Bass, 2000).

Using high-leverage practices to frame secondary math teacher education supports a practice-based approach and can make the complexity of teaching accessible to novices. Teacher preparation programs have designed experiences where prospective teachers can try out and develop proficiency with enacting high-leverage practices (Forzani, 2014). Coached rehearsals (Lampert et al., 2013), instructional routines (Lampert & Graziani, 2009), and collaborative teaching cycles (Hallman-Thrasher, 2017) have been shown to support preservice teachers at developing *skilled practice* (Grossman & McDonald, 2008). Analysis of video (e.g., van Es & Sherin, 2010) and creating and analyzing representations of practice (e.g., Crespo, Oslund, &

Parks, 2011) have improved preservice teachers' attention to student mathematical thinking. Only recently have researchers extended this work to the secondary level (e.g., Campbell & Elliott, 2015; Ghousseini & Herbst, 2016).

The standardized student interview used in this study is example of an *approximation of practice* (Grossman, Hammerness, & McDonald, 2009) in that it engages novices in work that is proximal to that of a practicing teacher: eliciting student thinking, recognizing a student's misconception, and responding to the misconception in ways that foster conceptual understanding. Based on 'standardized patients' used in medical training (Barrows, 1993), in the interview a researcher plays the part of student who holds a particular misconception and a preservice teacher plays the role of a teacher tasked with diagnosing the misconception. The researcher's responses, language, and actions are guided by a protocol to ensure a standard experience across PSTs. Standardized students in simulations of teaching practice have been used with preservice elementary teachers to elicit student thinking around a correct, non-standard algorithm, interpret that student's thinking, and describe that thinking to an observer (Boerst, Sleep, Shaughnessy, & Ball, 2012). This study goes a step further by assessing preservice secondary teachers' abilities to both elicit *and* respond to student thinking and to do so in the context of a common student error.

Methods

Participants were 13 preservice (grade 7-12) mathematics teachers (PSTs) enrolled in a large university's undergraduate secondary mathematics teacher education program and completing their only mathematics methods course. PSTs were given a copy of the problem "$(x+3)^2 = x^2 + 9$" along with paper, pens, graph paper, algebra tiles, and a graphing calculator. PSTs were instructed to use any of the tools available to facilitate a discussion to help the student identify the error, revise the work, and understand why the original answer was incorrect. The interview was video recorded and all written work made during the interview was collected.

Each video was coded to determine what pedagogical moves the PST made in responding to the standardized student (e.g., proposed similar problem, suggested a counterexample, asked student to explain or justify work) and what mathematical approaches were taken: numeric (comparing with squaring a constant or plugging in numbers to find a counterexample), algebraic (using properties of algebra to simplify expressions), geometric (using an area model or algebra tiles), or graphic (comparing graphs of $y = x^2 + 9$ and $y = (x + 3)^2$ or using knowledge of transformations on functions). Each video was assigned a level for cognitive demand from the mathematics task analysis guide (Stein, Smith, Henningsen, & Silver, 2000) and a level (0, 0.5, 1, 1.5) for each component of the revised math-talk framework: questioning, explaining mathematical thinking, source of ideas, and responsibility for learning (see, Hallman-Thrasher, 2011; Hufferd-Ackles, Fuson, & Sherin, 2004).

Results

Results of the study address the level of cognitive demand and quality of mathematical discussion established and the mathematical and pedagogical approaches used when PSTs responded to a common algebraic error that indicated an underlying misconception. Of the 13 PSTs, 5 elevated the cognitive demand to *procedures with connections*, 6 maintained it at *procedures without connections*, and 2 lowered it to *memorization*. The quality of the PSTs discussion as assessed by the revised math-talk framework was clumped into four categories. Three PSTs who rated the lowest level in all components of math-talk were *tellers*, consistently lowering the cognitive demand by telling the student how to correct the work or correcting the work for the student. Five PSTs were *delayed tellers* who elicited thinking before telling the student a strategy; they rated a level 1 in questioning and explaining, but level 0 in source of ideas and responsibility for learning. Three PSTs were *non-tellers;* they posed many questions and did not draw conclusions for the student, but their questioning failed to address the key mathematical concepts. They rated a level 0.5 or 1 in all math-talk components. Two PSTs were *connecters* who raised the cognitive demand by asking the student to justify work, pressing for complete explanations, and connecting to other representations or the underlying concept of distributing twice, *and* requiring the student draw conclusions or judge validity of ideas. These PSTs rated high (level 1 or 1.5) in all components of math-talk.

In terms of mathematical approaches, all 13 PSTs initially performed algebraic manipulation or guided the standardized student to do so. Many focused on interpreting symbols by asking the student, "What does squaring mean?" or, "What do parentheses mean?" Only 3 PSTs eventually used or helped the student use a different strategy or connect to a different representation (1 geometric and 2 comparing graphs). Five PSTs explicitly asked about the pneumonic device 'FOIL' and when the standardized student claimed not to know this term, 4 went on to describe how to use it to multiply two binomials. Seven others asked the standardized student how to solve a different problem and drew comparisons between squaring a binomial and multiplying two distinct binomials. Two PSTs helped the student identify the error by asking the student to notice what happened to the equation $(x + 3)^2 = x^2 + 9$ when a number was substituted for x.

The initial pedagogical move for 10 PSTs was to pose a question, whereas 2 PSTs immediately pointed out the student's error and 1 explained a correct procedure. Of those who began the interaction with questioning, 2 prompted the student towards a particular approach, "How do you expand this to look like multiplication?", and 8 elicited student thinking with some form of "How did you get the answer?" PSTs' follow-ups to their initial question varied from revoicing to clarify student explanation, pressing for justification by asking "How do you know that's the answer?", and pressing the student to further explain concepts and terms. Three PSTs who initially elicited thinking, then suggested strategies that were unrelated to the student's way of thinking. Similarly, 1 participant who initially prompted a strategy, then elicited student thinking about that strategy, and leveraged it to connect to a graphical representation.

Findings showed that there was room for improvement in PSTs' ability to maintain high cognitive demand and connect across representations in response to a student's incorrect solution. Even when PSTs raised the cognitive demand, they did not keep the responsibility for generating ideas and judging validity of approaches on the student. The PSTs persisted in suggesting new ideas for the student to execute and evaluating the correctness of the student's work. This indicates that posing questions and eliciting explanations may be more accessible to novices than shifting mathematical authority from teacher to student or supporting students in generating new ideas. Further, though most PSTs knew to start their interaction with questioning, not all questioning was mathematically productive. Eliciting student thinking was not consistently associated with high cognitive demand or high math-talk ratings, and prompting a strategy was not consistently associated with low cognitive demand and low math-talk ratings; how PSTs followed their initial inquiry mattered.

Conclusion

Though PSTs were frequently adept at asking questions, leveraging student thinking to respond in ways that build conceptual understanding was challenging. Most PSTs did not distinguish between the standardized student making an error and having no meaning for the mathematical objects. PSTs need guidance on how to interpret and what to do with student thinking once they have elicited it and they need opportunities to practice that skill. These findings may point to the need to decompose the high-leverage practice of eliciting and responding to student thinking into practices of a smaller grain-size. One such smaller practice could be the use of questioning as a formative assessment of conceptual understanding or as means of shifting authority to the student. With smaller practices identified teacher educators can develop specialized experiences that support preservice teachers in learning these practices. Findings can inform the creation of an instructional activity (Lampert et al., 2010) for responding to an incorrect student solution in ways that allow a teacher to diagnose a misconception and leverage student thinking to respond in ways that build conceptual understanding.

ONLINE LEARNING EXPERIENCES AND IMPACT ON STATISTICS EDUCATION PERSPECTIVES

Taylor Harrison	Christina Azmy	Hollylynne Lee
NC State University	NC State University	NC State University
trharri2@ncsu.edu	cazmy@ncsu.edu	hollylynne@ncsu.edu

In this qualitative study, we used discussion forums and lesson plans from an online course on teaching mathematics and statistics with technology in order to examine participants' statistics education perspectives. Participants' perspectives included the nature of statistics, features of a good statistical task, learning statistics, teaching statistics, and role of technology. Some expressed perspectives were also reflected in participants' lesson plans, but others were missing.

Keywords: Teacher Beliefs, Data Analysis and Statistics, Technology

Background

Although we know the importance of developing statistically literate students in a data-driven world (Kwasny, 2015), and guidelines have been endorsed by the American Statistical Association for K-12 students' learning (Franklin et al., 2007) and mathematics teacher preparation in statistics (Franklin et al., 2015), many preservice mathematics teachers are not well-prepared to teach statistics (Lovett & Lee, 2017). The purpose of this study is to examine how online materials specifically designed to provide rich experiences in teaching and learning statistics may impact the statistics education perspectives of preservice and inservice teachers.

Teachers of statistics enter a classroom with already-developed perspectives of statistics education based on their previous experiences as learners of statistics, in and out of school, or based on their belief that statistics and mathematics are the same (Gal, Ginsburg, & Schau, 1997). There is a large body of evidence that using technology to teach and learn statistics allows teachers to create data visualizations to aid in analysis, link multiple representations, and augment graphs with statistical measures (e.g., Lee et al., 2014). We hypothesized that participants' use of such technology would impact their statistics education perspectives. Teacher preparation is increasingly being offered online, with some evidence that it is effective with a supportive learning environment, higher levels of motivation of learners, contexts that encourage instructor and peer interaction, and opportunities to practice material (Noesgaard & Ørngreen, 2015). Lee, Lovett and Mojica (2017) found that experiences in an online professional development course impacted participants' perspectives about statistics teaching related to: 1) statistics being more than computations and procedures, 2) using dynamic technology, 3) using real, messy data, and 4) increasing students' levels of statistical understanding. The current study examines the question: *When teachers engage in online modules, what perspectives about teaching and learning statistics do they express, and later enact in planning to teach statistics?*

Methods

The context for this study was a mostly asynchronous required online class on teaching mathematics with technology at a large southeastern university. The course focused on teaching statistics and geometry, with weekly modules that contained articles, videos, quizzes, data investigations using technology, and forum discussions. The instructor also held synchronous class sessions approximately every other week. There were six week-long statistics modules, covering content on the nature of statistics, statistical habits of mind, levels of understanding, measures of center and variability, and inference. Participants include eight preservice (PST, 4 undergraduate, 4 graduate) and three inservice teachers (IST, graduate-level).

Data sources included posts from four discussion forums in the first two modules (of 6) on teaching statistics with technology and statistics, and nine lesson plans (some worked in pairs) on teaching a topic in statistics participants submitted after all six modules. Based on an initial reading of all (approximately 100) posts, a set of data-driven codes, which were also informed by literature, were used to code the posts. A checklist derived from these codes was then applied to lesson plans. For example, since participants discussed concerns that their own students would need time to learn technology tools; that idea became something that was coded for in lesson plans. Once lesson plans were coded, frequencies were calculated, and trends identified.

Findings

Analysis of discussion forums and lesson plans resulted in five salient areas of participants' perspectives: the nature of statistics, features of a good statistical task, learning statistics, the practice of teaching statistics, and role of technology in statistics education.

Perspectives on the Nature of Statistics

When asked to reflect on what they had learned after Week 1, over half the participants (n=6) explicitly commented on the differences between mathematics and statistics, pointing out differences such as uncertainty in answers, the level of focus on computations and procedures, the role of context and data, the role of measurement, issues of sampling, and the role of interpretation. For example, a response to the prompt included:

> …statistical thinking is very different from "standard" math thinking. "Standard" math involves a lot of procedural thinking and there is always some form of right answer. In statistics, procedure is important, but context, interpretation, and analysis is heavily involved in the process. (PST, undergraduate student)

Three participants also expressed the belief that because of these differences, statistics is, by its nature, more engaging for students than typical mathematics.

Features of a Good Statistical Task

When asked to reflect on a task they participated in, and to analyze some example tasks, their responses included descriptions of what they believe constitutes a good statistical task. The majority of participants (n=8) expressed that a good statistical task is interactive or "hands-on". For many participants, this meant students should be exploring data, looking for relationships, and creating (with technology) their own data displays. This perspective was enacted in their lesson plans, as all (n=9) planned tasks seemed to be hands-on and interactive.

Many participants (n=8) explicitly mentioned issues regarding data when assessing quality of a statistical task, with the most common sentiments being that data should be interesting to students (n=8), real (n=4), and relatively large (n=2). These perspectives were also evident in lesson plans, where all (n=9) tasks used real data, most (n=7) used data likely to be interesting to students, and most (n=5) used large data sets, often with hundreds of cases and over 10 variables.

When describing a good statistical task, most participants (n=9) referred to at least one phase of the statistical cycle (pose->collect->analyze->interpret), and five participants mentioned that a task should include all four parts. It is interesting to note that, while most lesson plans had tasks with students analyzing (n=9) and interpreting (n=8) data, only one task had students posing their own questions to investigate, and only two tasks had students collecting their own data.

Other features mentioned by multiple participants include having students share their findings with the class (n=2), including questions that require students to justify answers (n=2), and including a clear learning objective for students (n=2). These features showed up in lesson plans 7 times, 8 times, and 1 time, respectively. With each task feature, at least one participant who had expressed that perspective did not create a task that reflected that perspective.

Perspectives on Learning Statistics

Though not specifically asked about it, some participants gave their perspectives on how students learn statistics. Some participants (n=3) expressed the need for students to have time to get acquainted with data before beginning analysis. After watching a video, one PST reflected:

> [In this video], connecting students with the data before they start analyzing was emphasized. This means allowing students to know what was going on when and where the data was taken.[…] I did not use this method while I was learning statistics in high school, but I do plan on using it when teaching statistics.

Five lesson plans allotted time or specifically included questions in the task intended to help students become familiar with data before analysis began. Other participants (n=3) reflected on how technology can become a tool that can affect how a student interacts with a statistical task, or on the diversity of students' expected statistical skill levels.

Perspectives on the Practice of Teaching Statistics

Across all four discussion forums, participants expressed their perspective about the practice of teaching statistics. Three participants expressed the necessity for teachers to ask good questions during a lesson, as one IST expressed her concerns about her ability to do so:

> I am also concerned about being able to effectively direct my students with the right questions so that the task is successful. […] If I am not able to direct the task effectively we would not reach our outcome goals or be able to help the students develop along the statistical thinking chart.

Six participants stated a need for teachers to ensure their students were engaged. These participants were confident they could do so, having seen some examples in the modules. Seven lesson plans (including all six created by participants valuing engagement) included a launch phase or activities intended to get students engaged in the content of the lesson. Other perspectives included the benefit of grouping students (n=3), though all nine lesson plans included grouping students. Three participants indicated the importance of statistics in K-12, and two participants believed statistics lessons were an opportunity for cross-curricular content.

Perspectives on the Role of Technology

Perspectives on the role of technology tools generally fell into two categories: how tools can impact statistical learning, and methods for implementing tools. Six participants mentioned that quickly producing accurate graphical displays and calculations makes data easier to analyze and interpret. In addition, most (n=7) participants mentioned that being able to simultaneously see multiple linked representations would allow students to better analyze and interpret data, as well as help keep the context of data foregrounded. Two participants expressed that whether or not a tool was easy to use would have an impact on how much a student would learn while using it.

Three participants expressed concerns that statistical technology tools would be difficult for students to use. Similarly, four participants believed that students would need adequate time with the technology in order to learn how it effectively. This was also reflected in the plans, where most (n=6) lessons either included time for students to interact with the technology before the task started, or indicated students would be familiar with the tool due to their work in prior tasks. Over half (n=6) of participants stressed the importance of sufficient guidance from the teacher in order for technology to be effective learning tools. However, only two lesson plans allotted any time for such guidance to be given, anticipated any student struggles with technology, or gave any suggestions on how to address those struggles. Finally, some participants believed that whether a piece of technology was an effective statistical learning tool depended on factors such as students' age or statistical skill level, and the learning objective to be taught in the curriculum.

Discussion

Our study found the online learning environment to be effective in impacting some of the participants' perspectives on statistics education, adding to the body of literature that says that online learning is effective (Noesgaard & Ørngreen, 2015). "Effectiveness" can be measured in different ways, but for our purposes, we were solely interested in evidence of perspectives that could influence the design of lesson plans. The perspectives we observed built on those seen in previous online contexts (e.g., Lovett & Lee, 2017) but also included other perspectives such as ideas about curricular considerations and features of a good statistical task.

In general, participants were not specifically asked about their perspectives on specific topics, but were rather responding to open-ended discussion prompts or to other participants. For this reason, one cannot infer that because a participant did not express a particular perspective in discussion forums, that the participant does not hold that perspective. A prime example of this is the issue of grouping students—only two participants expressed the opinion that students should be grouped, and yet, every lesson plan included grouping students. One interesting finding is that for perspectives expressed by participants, there was often a lack of evidence of that perspective in their lesson plans. There are three clear examples of this: students posing their own statistical questions to investigate, students collecting their own data, and students needing guidance on how to use technology. It is unknown why these discrepancies existed. Perhaps they were due to the perceived constraints of the classroom (e.g. time), or perhaps participants had trouble fully assuming the role of a teacher, particularly for those with no prior teaching experience.

PRESERVICE SECONDARY TEACHERS' OPPORTUNITIES TO LEARN HOW TO TEACH REASONING AND PROOF

Jia He
Augusta University

Tuyin An
Georgia Southern University
tan@georgiasouthern.edu

This study investigated future secondary teachers' opportunities to learn how to teach reasoning and proof reported by instructors of required courses in three secondary mathematics teacher education programs. We examined not only what future teachers learned but also how they learned to teach reasoning and proof. We found limited opportunities and noticed variations in the amount and types of the opportunities provided by each university. We noticed that important issues such as modifying or enacting reasoning and proof tasks and using manipulative and technology were not discussed in two of the universities. We also found that instructors reported limited types of instructional activities they had used to engage future teachers in learning to teach reasoning and proof. Implications of the research were discussed at the end of this paper.

Key words: Reasoning and Proof, Teacher Education-Preservice

Reasoning and proof (R&P) play an important role in school mathematics curriculum. The field of mathematics education recommends that R&P should be integrated into students' mathematical experiences across all grades and across a breadth of content areas (Common Core State Standards Initiative, 2010; NCTM, 2000). However, many secondary students have difficulty in writing valid proofs (e.g., Knuth, Choppin, & Bieda, 2009). Studies also show that teachers' conceptions, knowledge, and prior learning experiences of R&P can have significant impact on their teaching of R&P and thus affect their students' understanding and achievement in learning R&P (Oehrtman & Lawson, 2008). However, substantial amount of literature focused on how R&P was taught and learned in secondary classrooms (e.g., Ball, Hoyles, Jahnke, & Movshovitz-Hadar, 2002). There was a lack of investigation particularly on preservice secondary teachers' (PSTs) opportunities to learn how to teach R&P in their college mathematics or mathematics education courses, which is the main focus of our on-going study.

Theoretical Perspectives

Teachers' teaching practices of proofs have been studied within various curriculum contexts and educational settings (e.g., Herbst, 2002). The majority of the research has focused on factors and strategies that might aid teachers' in effectively teaching R&P. For example, Oehrtman and Lawson (2008) suggested effective proof teaching approaches, such as asking students to reflect on their procedures and reasoning patterns, identifying successful procedures and reasoning patterns, and challenging students to further reflect on their reasoning in new context. A noticeable theme of suggestions of effective teaching of R&P focuses on the teaching philosophy that emphasizes the nature of proofs rather than their external form or routine, and how the nature of proofs interacts with the instructional contexts as an organic whole. For example, Herbst (2006) suggested that, "customary, sometimes ritualistic, practices of proving in high school geometry classrooms stand in the way of engaging students in more authentic mathematical activity," and, "it seems important thus to develop customs of doing mathematical work that make students accountable for tasks that require reasoning deductively even if the product is not yet fully written as a mathematical proof" (p. 344). These suggestions guided us in the analysis of some of the initial categories of the data. We will elaborate them in our findings.

Methods

As a part of the larger NSF funded study, we examined required mathematics and mathematics education courses at three contextually different universities A (Master's degree-granting institution), B (Ph. D – granting institution with a five-year undergraduate program), and C (Ph. D – granting institution with a four-year undergraduate program). We analyzed 15 instructors' responses to the interview question "What opportunities are there to talk about activities or strategies for teaching secondary students to engage in reasoning or proof?" Interview data were analyzed using the *inductive* and *deductive* analysis methods alternately (Patton, 2002). The initial categories of data consisted of categories suggested by literature. The breath and depths of these initial categories kept evolving as the data analysis was going until we resolved all discrepancies and reached a set of categories that can capture all relevant ideas from data. After coding was done, we counted the number of instructors who mentioned a particular category of knowledge or activities at each university and reported the counts in Table 1.

Findings

As recommended by *Principles and Standards for School Mathematics* (NCTM, 2000), we considered not only *what* teachers learn but also *how* they learn to teach R&P. We report these two aspects in the following two sections.

Knowledge that may affect PSTs' future teaching of R&P

Table 1 presents opportunities for PSTs to learn to teach R&P reported by instructors as the efforts they had made to support PSTs' learning of teaching R&P. We found that these opportunities were all from mathematics education courses. All three universities reported providing PSTs opportunities to learn the importance of R&P in secondary schools, the difference between conceptions of proof in secondary school setting and college setting, and how to ask questions to support secondary students' R&P. For instance, Instructor of Secondary Math Methods 1 at University C mentioned that:

> We just talk about what can count as proofs, and I try to really encourage them to have a broader definition of proofs, what does it mean to prove something? Why do we have to write it in two columns? What happens if kids just write out a really good argument in a paragraph and they don't have all the steps in the right order, but they are able to justify it.

Instructor of Middle School Math Method at University C reported having a discussion with PSTs about asking questions:

> The idea of being able to justify anything you're saying or asking students to explain more, when I show them any kinds of videos of teaching we're focusing on the questioning. What question is she asking to draw out their understanding of what is happening? How to ask questions that get students to not just give you the answer but to explain their reasoning.

For each of the other three categories, including modifying or enacting R&P tasks, using manipulative and technology, and multiple ways to present a deduced result, we only found one instance mentioned by one university. For example, Instructor of Secondary Mathematics Methods 3 at University B mentioned discussing with his student's about "thinking about ways in which teachers can mobilize different tools from physical manipulatives to representations that they use" to promote students' understanding of R&P. In summary, we found that University A and C seemed to heavily focus on questioning and conceptions of R&P in school setting. In addition, University B also addressed important issues such as adapting proof tasks and adopting tools and technology in teaching R&P.

Table 1: Opportunities for PSTs to Learn to Teach R&P at Three Universities

Categories	A	B	C	Total
Knowledge that may affect PSTs' future teaching of R&P	**5**	**5**	**5**	**15**
Importance of R&P in secondary school	1	1	1	3
Conception of proof in school setting	2	1	1	4
How to ask questions to support secondary students' learning of R&P	1	1	3	5
Modify or enact R&P tasks	0	1	0	1
Use manipulative and technology to teach R&P	0	1	0	1
Use multiple ways to present a deduced result	1	0	0	1
Activities used to engage PSTs in learning to teach R&P	**2**	**5**	**1**	**8**
Evaluate secondary students' proof writing	1	1	0	2
Examine secondary textbooks	1	1	0	2
Watch video of teaching practices in secondary classrooms	0	0	1	1
Study research based materials	0	1	0	1
Modify existing proof tasks	0	1	0	1
Field experience with secondary students	0	1	0	1

Activities mathematics educators used to engage PSTs in learning to teach R&P

As seen in Table 1, we found interesting variations across the activities mathematics educators used to engage PSTs in learning to teach R&P. Instructors at University B used a variety of ways to engage PSTs. In contrast, instructors at University A only reported a couple of activities. Evaluating secondary students' proof writing and examining secondary textbooks were two types of activities reported by both Universities A and B. For example, Instructor of Secondary Math Methods at University A mentioned that "It may come up with looking at work students have actually produced and trying to make judgments about whether the argument that students have made in answering a problem is clear, concise, and accurate." Instructor of Secondary Math Methods 3 at University B discussed using research based materials in his teaching method course:

> We have been using the cases of R&P in secondary mathematics materials that are being developed under an NSF grant. There are case-based materials designed to increase teachers' knowledge of what is meant by R&P and how to teach R&P tasks.

The same instructor reported providing PSTs opportunities to "modify tasks from their curriculum that may not be strong in R&P to enhance the R&P potential." The only instructional activity reported by instructors at University A was to have PSTs watch and analyze videos of teaching R&P in secondary classrooms.

Discussion and Conclusions

Overall, we found limited opportunities for PSTs to learn how to teach R&P across the three teacher education programs. We also noticed variations in the amount and types of the opportunities provided by each university. University B reported the highest amount of instances with the widest range compared to the other two universities. University B reported an emphasis on discussing how to modify or enact proof tasks, which is an important component in preparing PSTs in teaching R&P due to the important role tasks play in teaching mathematics (Lin, Yang, Lee, Tabach, & Stylianides, 2012). Another reason why PSTs need opportunities to learn modifying or enacting a proof task was pointed out by Instructor of Secondary Math Methods 3 at University B. He said "since we know that there are not a wealth of really strong R&P tasks in even the better textbooks that we have in middle and high schools right now." University B also reported stressing PST' reflection on using tools and technology in teaching R&P. This aspect was not mentioned in the instructors' reports in Universities A and C. Nowadays, as technology is getting used more and more widely in K-12 classrooms to support student explorative learning, there is a need to have a discussion on how technology could possibly support or hinder secondary students' learning of R&P. In fact, many studies have reported both the positive and negative impact of the use of technology in secondary classrooms on student learning and understanding of mathematical proofs (Sinclair et al., 2016). The lack of reported instances in Universities A and C regarding the use of technology raises a question on if PSTs were well prepared to incorporate technology properly in their future teaching of R&P.

Though we aimed to report how teachers were prepared in teaching R&P, our research is not meant to be evaluative but informative. We expect that our findings will support other teacher education programs as they are reflecting on their teacher training programs in terms of promoting their future teachers' ability to teach R&P. Some of the instructional activities used by mathematics educators such as having PSTs read research based materials on R&P could be incorporated into all teaching method courses and benefit other teacher education programs.

We admit that due to the lack of classroom observation data, we were unable to capture real moments when PSTs were learning to teach R&P. However, instructors' self-reported data are mostly likely to reflect instructors' focuses of the course and thus may have considerable level of impact on PSTs' learning. In this paper, we focused on PSTs' opportunities to learn how to teach R&P as teachers. We see the possibility that opportunities for PSTs to engage in R&P as learners could also affect their future teaching practices. We will report those findings in another paper.

EXPLORING AREA AND PERIMETER: A LOOK AT THE MATHEMATICS KNOWLEDGE OF TEACHER EDUCATION CANDIDATES

Jennifer Holm
Wilfrid Laurier University
jholm@wlu.ca

This research report explores the mathematical conceptions that teacher education candidates (TECs) bring into a teaching program, specifically the (mis)understandings about area and perimeter of rectangles. A thematic analysis was performed on the incorrect solutions in order to gain an understanding of where teacher education candidates were making mistakes. This report discusses the themes that were discovered and how some of the information provided was mathematically correct but missed the bigger connections within the questions. The information provided supports the need to consider what misconceptions are being brought to teacher education programs and how to address them within the program.

Keywords: teacher education, mathematics knowledge for teaching, measurement, misconceptions

Studies have linked mathematics knowledge for teaching to increased student achievement (e.g., Baumert et al., 2010). In Ontario, the teacher education program is a two-year degree after a bachelor's degree in another area. Since it is an after degree program, there is no way to guarantee if any mathematics courses or earlier teacher preparation courses have been taken. As such, there is a strong emphasis on ensuring that the knowledge developed during the program supports teacher development in mathematics knowledge for teaching. This study looks at the content strand of measurement, particularly area and perimeter of rectangles, in order to draw some conclusions about the understandings that are brought to a teacher education program.

Literature

Developing a deep understanding of mathematics not only influences teachers' own mathematical conceptions, but also may support better classroom teaching (Stipek, Givvin, Salmon, & MacGyvers, 2001). Teachers' mathematical conceptions, ideologies and development subsequently influence their students' mathematical development (e.g., Schommer-Atkins, Duell, & Hutter, 2005) and thus are of critical importance.

Teachers need knowledge of mathematics that is specialised for teaching (e.g., Silverman & Thompson, 2008). Knowledge of mathematical content for teaching goes beyond simply being able to solve mathematical problems. Teachers need to deeply understand concepts, see connections among mathematical ideas, have knowledge of the potential connections to mathematical pedagogy, and be able to break down all the concepts with students in order to support student learning (Ma, 1999).

As a framework for the study, the work of Ball and Bass (2000) was used to guide the exploration of the samples. Ball and Bass discuss how constructing knowledge in mathematics mirrors what mathematicians do and focus on students providing mathematical reasoning for their knowledge claims. This was used as a starting point of looking at the reasoning of the TECs in supporting their discussions around area and perimeter.

This study looks specifically at area and perimeter of rectangles. In order to put this into context, I look at where in their school the TECs had potentially encountered this information. In Ontario, students by the end of the end of grade 4 will have "determin[ed] area and perimeter relationships for rectangles" (Ontario Ministry of Education, 2005, p. 64). Perimeter is first introduced in grade 2, and concepts related to area are first introduced in grade 1 within the Ontario curriculum. According to the Common Core in the US (2010), area and perimeter are first mentioned in grade 3, and specifically look at "exhibiting rectangles with the same perimeter and different areas or with the same area and different perimeters" (Measurement).

Mode of Inquiry

The research reported in this summary is a small portion of a larger study involving teacher education candidates and their knowledge and beliefs related to teaching and learning mathematics. The data set in this study comes from a modified version of the Perceptions of mathematics survey (see Kajander, 2010). Specifically the data comes from two questions on the survey: (1) *For the rectangle below, calculate the perimeter and the area*; (2) *Is it true that as the perimeter of a rectangle increases, so does the area? Explain.* The participants in the research study were TECs from two different years of a teacher education program in Canada. The survey was given on the first day of a teacher education course related to teaching mathematics (also known as a "math methods" course). The two years were combined since there was no control over who entered into the program or their past experiences. The purpose of the study within the larger program of research was simply to explore the mathematics knowledge for teaching that participants bring to a teacher education program related to an understanding of area and perimeter of rectangles. A total of 147 TECs were included in the total data set for analysis in this research report.

Initially quantitative analysis was performed on both of the questions in order to determine the success rate for the participants with the content of the two questions. Following this, a thematic analysis (Braun & Clarke, 2006) was conducted on the 125 incorrect responses to the second question in the data set in order to determine the specific misconceptions of the TECs. Using the process outlined by Braun and Clarke (2006), the data was initially read for initial codes, and then themes were created based on the codes. The themes were then reviewed to ensure all data points were included and then named for the current research report. This research study used an "inductive approach" where the themes were tied to the data as a unit instead of existing literature (Braun & Clarke, 2006, p. 83).

Results

Quantitative Analysis

The initial results come from a quantitative analysis on the two questions in the data set. As can be seen in Table 1, the majority of the TECs in the study were able to correctly identify the area and perimeter of the 3cm by 5cm rectangle given in question 1. Interestingly, the most common incorrect answer for calculating the perimeter was 225cm (3×3×5×5).

Table 1: Results for question 1

Both area and perimeter correct	Area only correct	Perimeter only correct	Both area and perimeter incorrect
88.4% (130)	4.8% (7)	4.8% (7)	2% (3)

Note. Percentages are listed based on the percentage of total participants (N=147). The number in brackets is the total number of participants who were identified in each category.

The results for the second question were slanted in the opposite direction, as can be seen in Table 2. Less than 10% of the entire data set were able to correctly answer question 2, by indicating that just because the perimeter increased, it does not mean that the area does as well. Of that 10%

though, 2 of the participants did identify that it was not a true statement; however, were unable to explain why it was not. For the remaining portion of the research report, we look at only the TECs who gave an incorrect response to the question (n=125).

Table 2: Results for question 2

Correct with explanation	Correct with no explanation	Incorrect response	Unsure	No response/ irrelevant
8.1% (12)	1.3% (2)	85% (125)	1.3% (2)	4% (6)

Note. Percentages are listed based on the percentage of total participants (N=147). The number in brackets is the total number of participants who were identified in each category.

Thematic Analysis

In examining the quantitative data, it would be easy to conclude that the participants have limited knowledge of the question that was asked. What became clear in examining the responses for themes was the participants had strong misconceptions about the question; however, some of their responses were definitely mathematically accurate just missed the bigger concept of the question.

A total of 125 data points were used in order to conduct the thematic analysis. From this starting point, a total of 32 codes were created in order to describe each of the data points; however, some of the participants' responses included more than one code. Table 3 lists the themes that were created in order to describe all of the codes with a sample participant response to help define one instance of the category. For space, only a few of these themes will be described in more detail in this paper to add to the description.

Table 3: Themes from the thematic analysis of the data set

Theme	Sample participant response
Statement of fact	"Yes, the area increases as the perimeter of the rectangle does." Or "Larger perimeter = more area"
Relationship to multiplication / formula	"True because the area is calculated based on the length and the width."
Focus on definition of area or perimeter	"Yes this would be true because the area of a rectangle is what is inside the perimeter so therefore if the perimeter were to increase the area would as well."
Focus on increasing side lengths	"If the side lengths (perimeter) increase so would the values to find the area."
Real-life example	"Yes because the space increases. If a wall in a room increases then the space inside will as well."
Using examples to prove the incorrect conjecture	6+4+6+4=20 7+4+7+4=22 6×4=24 7×4=28
Using algebra	"Since perimeter is a linear function, while area is an essentially geometric (curved) function, no matter the values of l and w, area will tend to increase faster up to ∞."
Concepts that are not related to area/perimeter of rectangles	"This assumption isn't valid if the shape isn't symmetrical."
No response/don't know	"I don't know why."

Focus on definition of area or perimeter. In some cases, the participants looked at the definition of area or perimeter (or both) and used these to justify the conclusion that when perimeter increases that so would the area. Generally these responses did not really prove anything except that the participants knew what area and perimeter meant.

Focus on increasing side lengths. Participants whose solutions fell into this theme were focused only on the impacting that increasing either a single or both sides lengths would impact the perimeter and the area. It was notable that the statements made by these participants were mathematically correct (i.e., increasing a single side length would always increase both the area and perimeter). This, however, did not correctly answer the question since there are times when the perimeter would increase and the area would not by other manipulations.

Using examples to prove the incorrect conjecture. Examples were used by many of the participants in order to "prove" that when perimeter increases, so does the area. In some cases only a single example was included to compare to the rectangle in the previous question. The data showed up to four examples being used in order to "prove" the conclusion drawn. In one case, the participant included examples that actually proved that this was not a correct statement; however, the participant was unable to make the determination that increasing the perimeter does not always increase the area.

Conclusion and Discussion

What was interesting in the thematic analysis of the solutions was that there were elements that were mathematically correct; however, missed the bigger picture of the question. The use of examples to "prove" the statement or looking at only "increasing" side lengths showed that the TECs had applied their knowledge of area, perimeter, and multiplication correctly to the question. Some of the statements were flawed, such as indicating a direct relationship between area and perimeter of rectangles: "Perimeter and area are positively correlated –as one goes up, so does the other." As Van de Walle et al. (2014) notes, area and perimeter are a source of difficulty for elementary students, and this study points to these ideas persisting into a teacher education program. The solutions of the participants in this study provided interesting examples to discuss where the misconceptions came from and to encourage a stronger understanding of area and perimeter in rectangles during experiences within the methods course.

REHEARSALS OF AMBITIOUS TEACHING IN IMMERSIVE CLASSROOM SIMULATION ACTIVITIES

Carrie W. Lee
East Carolina University
Leecarr16@ecu.edu

Pedagogies for engaging PTs in ambitious teaching often involve rehearsals integrated into iterative cycles and this can be difficult to imbed within large teacher preparation programs. Innovative technologies utilizing immersive classroom simulation activities (ICSA) allow PTs to rehearse instructional activities with student avatars. This study found that ICSAs provide opportunities to engage aspects of ambitious teaching such eliciting and responding to student thinking and afford PTs with unique opportunities to position students as competent. The affordances and constraints are discussed

Keywords: Teacher Education, Pre-service, Instructional activities and practices, Elementary School Education

Introduction and Purpose

As we reflect over the past forty years in mathematics education one focus of research and practice has been ambitious teaching that prioritizes the learning of all students regardless of ethnicity, race, class, or gender (Grossman, Hammerness, & McDonald, 2009). More recent research has focused on tools and structures within teacher education to successfully engage preservice teachers (PTs) in the intricacies of ambitious teaching (Thompson, Windschitl, & Braaten, 2013; Kazemi, Franke, & Lampert, 2009). Within this work pedagogies of teacher education have been examined (Lampert & Graziani, 2009; Ghousseni & Herbst, 2016) and structures such as *Cycles of Enactment and Investigation* (Lampert et al., 2013) have been designed to engage PTs in opportunities to deliberately practice specific teaching episodes and enact those episodes in classroom settings. As we look forward to the next forty years in mathematics education, it is vital we actualize this reconceptualization of teacher education at scale and utilize innovative technologies to support our work. The human resources needed to employ an iterative, practice-based process within teacher preparation are often unavailable at institutions with large programs. One innovative technology is virtual simulation software, such as that available from Mursion® (developed as TLE TeachLivE™), that provides immersive, interactive learning through practice-based teacher development (Dieker, et al., 2014). During the immersive classroom simulation activity (ICSA), pre-service teachers can engage with a classroom of five student avatars on a large computer screen. A simulation specialist operates the avatars and uses a simulation scenario to guide the interactions. This exploratory study extends research on cycles of enactment to examine 1) What opportunities are afforded with embedded prompts in rehearsals of ambitious teaching within an ICSA? and 2) How do PTs respond to embedded prompts within an ISCA?

Perspectives

Work by Grossman et al. (2009) defines three essential pedagogies of teacher preparation that enable novice teachers to learn through engagement in the teaching process. These pedagogies are the representation of practice, decompositions of practice, and approximation of practice, and all are needed to develop ambitious teaching. Lampert at al. (2013) has integrated these pedagogies of practice into an iterative cycle that utilizes rehearsal and classroom-teaching episodes, titled Cycles of Enactment and Investigation (CEI). The work presented here utilizes this framework and seeks to explore the affordances and constraints of situating approximations of practice within immersive classroom simulation activities (ICSA). Within the ICSA a scenario is created to target key aspects of instruction, scripting certain student responses to provide a vast array of opportunities with the lesson. Essentially the ICSA parallels a rehearsal within the CEI, yet does not allow the same coaching.

Methods

Larger Context

This report shares preliminary findings from a study situated within a longitudinal, comparative study designed to compare the effectiveness of ICSA and peer rehearsals in the development of PTs' ambitious teaching. PTs engage in a CEI with two number talks as the instructional activity (2 ICSA/peer rehearsals and 1 classroom enactment). The number talks are two-digit multiplication number strings. A scenario was created for the ICSA and a trained simulation specialists uses to the scenario to "act" the part of five student avatars. The PTs facilitate the number talk with the group of five student avatars (referred to as students for the remainder of the report) or with 3 peers and the teacher educator.

Participants, Data, and Data Analysis

Within this study three participants were randomly selected as case studies from the larger context. Participants were enrolled in an elementary mathematics methods course focused on grades 3-6 and had previously completed an elementary mathematics course focused on grades K-2. The data used in this study are three video-recorded ICSA sessions, one per participant. The sessions ranged from 8 minutes to 11 minutes. During the ICSA the participant lead a number talk with the problem "12x24." This problem came third in a number string.

The use of GoReact©, a video analysis tool, allowed for detailed coding of each teacher and student interaction within the video-recorded ICSA. GoReact is a secure online video analysis tool that connects comments or codes directly to the segment of video for which they address. Each video was examined multiple times and each teacher and student interaction was coded using a set of a priori codes adapted from Lampert et al. (2013) that defined elements of ambitious instruction. In addition to the a priori codes unique interactions were noted in comments and these were interpreted to develop additional codes pertaining to positioning of students as competent. The goal of analyzing the videos was to identify aspects of ambitious teaching that arose within the ISCA (exemplars and missed opportunities) and illustrate unique features of the ISCA.

Results

Analysis of the three cases resulted in exemplars of each of the elements of ambitious teaching that were strategically coded, as well as examples of missed opportunities. In the following sections the exemplars and missed opportunities are discussed in the context of the ICSA to illustrate the affordances and constraints of the ICSA.

Eliciting and Responding to Student Thinking

One of the main reasons a number talk was selected as the instructional activity is the inherit requirement to elicit students' mental strategies for solving a problem. Across the three cases the students volunteered responses, and this was a function of the classroom norms designed in the scenario. Each PT elicited strategies from three of the five students and at least one student was probed for further explanation. PTs responded to students' decomposition strategies (i.e., (20 x 12) + (4 x 12)) by probing for additional clarification about the factors. However, these follow-up questions elicited different student responses based on the open-ended or literal nature of the question. For example, one PT asked “Where did this 20 come from” for which Carlos answered “the 24” while another PT asks Carlos “Why did you break into 12 x 20 and 12 x 4?” This more open-ended question elicited a more lengthy explanation of wanting to multiply by groups of 10 to make the multiplication easier to do.

In addition to differentiating responses based on question type, the ICSA was designed for one of the student to explain that they “multiplied 12 by 2 and then added a zero to get 240” when multiplying 12 x 20. The PTs did not attend to this particular student response and did not ask for further explanation to deconstruct the mathematics

Representation of Mathematical Ideas

Overall, student strategies were recorded accurately on the board except for one instance. As the PTs represented the students’ strategies on the board, each PT recorded the decomposition strategies by placing the parts of the decomposed factor second in the set of equations they listed (ie., 12 x 20 = 240 and 12 x 4 = 48). This was due to the way the strategies were verbally shared by the students that were scripted in the scenario. This could be modified to allow for more complexity in how relationship of the factors is recorded.

There were two instances where the PT revoices the student’s strategy to ensure that she has recorded the students’ thinking. In one of these cases the PT was inaccurate in her representation of 12 x 25 = 300 -12 =288. The scenario script could address this misconception by triggering a student to ask a question about the equality of a statement, such as “Does 12 x 25 = 300 -12?” This would result in the PT having to grapple with this.

Orienting Students to One Another

Throughout the number talks, PTs did not utilize strategies, such as turn and talk, for that would allow students to orient to one another. This may have been due to the fact that certain students, Carlos and Mina, were quick to volunteer and scenarios can be modified to include longer time before raising hands. Furthermore, PTs focused on moving to the next strategy and not using moves that would ensure students were listening to one another. There was one response from a PT that directed, “Carlos please explain to your classmates how you broke apart the 24.” In doing so, Carlos turned and spoke to his classmates instead of directly to the teacher.

Building on Reasoning

The scenario was designed to have two students share strategies to solve 12x24 by using the distributive property and either decomposing 12 or 24. This design element was intended to elicit questions from the PTs to address the similarities, differences, and application of the property. Interestingly, only one PT directed attention to these two strategies and asked, “How are these ways different from each other?” When Emily responds quickly that different numbers were broken down, they PT praises Emily and solicits another strategy. This missed opportunity to make the connection to the distributive property shows an area for attention.

Students as Competent

The students expressed frustration with the problem when it was initially posed and Will shared that he did not arrive at an answer to the problem. From these student responses arose the need to code the interactions for instances of how the PTs positioned the students as competent or not. This coding revealed that PTs send mixed messages to students about mathematics and ability. At the beginning students cry out “This is crazy, we can’t do this in our heads” and ““How come these keep getting harder? I wish they used smaller numbers.” One PT responded, “You can do it. You are smart.” While she was trying to encourage students, the message she is sending them is that if you cannot do it then you are not smart. Another PT prefaces the problem with claims that it will be hard stating “This on is going to be harder…if you can’t figure it out it is ok because I had a hard time figuring it out and I had paper." This response assumes students will struggle and devalues the use of mental strategies.

When Will shares that he was not able to solve the problem, all three PTs attempt to engage Will to understand his confusion; however, they prematurely abandon their efforts. One PT tries to decipher Will's starting point when he shares, "The first thing that clicked for me was that both have twos and I thought I could do something with the two that might make it easier. But then I just got confused." In response this PT praises Will stating, "That's good that you were able to start thinking and you didn't give up when you saw the problem," and then immediately calls on another student. Will's interactions force PTs to grapple with how to address students' needs and guide them to an understanding of the problem.

Lastly, Carlos and Mina are called on first in two of the cases due to volunteering. They are also called upon for further explanation in all cases. This emerging trend highlights the positioning of certain students as competent and valued while others are expected to be passive participants in the class.

Conclusion

Analysis of recorded ICSAs indicated that certain elements of ambitious teaching were evident and afforded due to the strategic development of the scenario used within the ICSA. PTs were engaged with eliciting and responding to student thinking, representing ideas, and building on reasoning, yet they were not engaged in orienting students to one another. The missed opportunities highlight the need for additional scaffolds built into the scenario and specific feedback from teacher educators to build PTs engagement in these teaching practices. Also, the ICSA provided a unique opportunity for PTs to navigate student misconceptions and frustrations with mathematics. The authentic expressions from the students are unique to this technology and not present in peer rehearsals. This affordance within the ICSA and the standardization of the scenario make this innovative tool a plausible solution to utilizing CEI at scale. Although conducting numerous peer rehearsals may not be feasible for a teacher educator, rehearsals within an ICSA will allow for strategic scenarios to be replicated without additional work. The larger research project will provide valuable insights into the comparison of ICSA and peer rehearsals and inform the ongoing reconceptualization of practice.

PRE-SERVICE TEACHERS' PERCEPTIONS OF THE USE OF REPRESENTATIONS AND SUGGESTIONS FOR STUDENTS' INCORRECT USE

Mi Yeon Lee
Arizona State University
mlee115@asu.edu

Ji-Eun Lee
Oakland University
lee2345@oakland.edu

We investigated how elementary pre-service teachers (PSTs) perceive using representations in teaching mathematics and what representations they suggest to guide students' use of representations in teaching fractions. A written questionnaire was administrated to 151 PSTs and an inductive content analysis approach was used to analyze the data. Findings suggested that fraction-related topics were the PSTs' main choice for using representations, but PSTs tended to use models procedurally and predominantly depended on circular area models in guiding students who use representations incorrectly. Implications for designing mathematics methods courses in terms of effective use of representations are discussed.

Keywords: Representations, Fraction Models, Manipulatives, Preservice teachers, and Teacher Preparation

Introduction

The ability to execute a wide range of instructional practices that are deeply rooted in profound mathematical knowledge for teaching is integral to effective mathematics teaching (Hill, Ball, & Schilling, 2008). In this study, we examine PSTs' ability to analyze students' work, to choose and use appropriate mathematical representations in explanations, and to evaluate the instructional advantages and disadvantages of representations. In the hope that this study has implications for teacher preparation, which in turn will have impact on PSTs' future practices, we investigated the following research questions:

(1) How do pre-service teachers perceive using representations (e.g., manipulatives or models) in teaching mathematics?
(2) What fractional representations (e.g., manipulatives or models) do pre-service teachers suggest to guide students' incorrect use of representations in learning fractions?

Theoretical Perspectives

Knowledge of Representation

As noted, use of various representations is commonly considered necessary in mathematics instruction because of the abstract nature of mathematics and mathematical discourse. Accordingly, teachers' and students' competence in using representations has long been emphasized in mathematics education. Educators refer to this competence using varied terms such as representational flexibility, representational fluency, representational thinking, and representational competence (Greer, 2009).

While using representations is recognized as important to supporting students' sense-making process, the literature also documents that limited uses or misuses of representations, often due to teachers' limited content knowledge, can negatively affect teaching and learning (Izsák, 2008; Lee, Brown, & Orrill, 2011). However, while adequacy of teachers' content knowledge is a necessary condition for effective use of representation, that alone is not sufficient. Teachers need to be fluent in using not only their own solution representations but also pedagogical representations (Cai, 2005).

Fraction Models

Given the importance of representations in teaching and learning mathematics we further examine three major types of pedagogical representations in fractions: area, length, and set models. The area models (e.g., circular pie pieces, rectangular regions, geoboard, drawings on grids or dot paper, pattern blocks, etc.) subdivide a whole area into equal parts. The area model elucidates the part-whole concept of fractions and the meaning of the relative size of a part to the whole (van de Walle, Karp, & Bay-Williams, 2013).

Another major fraction model is the length model (e.g., fraction strips, Cuisenaire rods, number lines, etc.), in which measurements of lengths are compared rather than measurements of areas. Linear models allow students to integrate their knowledge of fractions and whole numbers in a continuous model (Siegler, Thompson, & Schneider, 2011). Some research has suggested that with the linear model it is difficult for students to develop an accurate visualization of the value of a given fraction (Behr & Post, 1992). However, another strand in the literature emphasizes the utility of linear models in that they help students understand fractions that are greater than one more easily due to their continuity, in contrast to the discrete wholes used in the area models (Lee, 2017; Siegler et al., 2011). Set models (e.g., two-color counters, objects, tallies etc.) utilize discrete collections within sets of countable objects. Literature offers mixed results and suggestions regarding the effectiveness of the set model. While many researchers recognize the importance of set models due to the applicability of students' prior knowledge of whole number strategies and the connections with many real-world uses of fractions (Behr & Post, 1992), others recommend introducing set models later than other models because it may require some understanding of ratio or the concept of fraction multiplication (van de Walle et al., 2013).

While the forms of models differ, the methods of representing a whole and its parts can be varied. Watanabe (2002) explains two distinct methods for representing fractions, depending on how the relationships between the whole and fractional parts are shown: (1) the part-whole method in which the fractional part is embedded in the whole and (2) the comparison method in which the whole and part are constructed separately. Watanabe (2002) asserts that children may benefit from more explicit treatment of the different ways that fractions can be represented.

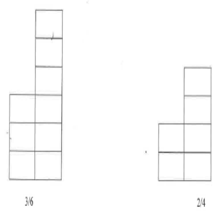
Methods

One hundred fifty one elementary PSTs at a large Southwestern university in the U.S. participated in this study. All were enrolled in an elementary mathematics content course. They had taken a course that dealt with number and operations, in which they learned about fractions and fraction operations along with manipulatives or pictorial representations such as set, length, and area models. The participating PSTs completed a written questionnaire. For this study, we focused on one open-ended question and two tasks (see Figure 1). The first and third questions below were created by the authors and the second question comes from prior research conducted by other researchers and the first author (Cross, Lee, Zeybek, & Adefope, 2015).

The written questionnaire was administered to all PSTs for one hour. To analyze the data, we used an inductive content analysis approach that included both qualitative and quantitative analyses (Grbich, 2007). First, to analyze the open-ended question, we read all PSTs' responses and identified common themes among them. Then we developed a coding scheme and used it to analyze the responses. When there were discrepancies between the two researchers' codes, we discussed them until we reached 100% agreement on the coding. Finally, to find patterns, we calculated the frequency of codes in the PSTs' responses.

To analyze the PSTs' responses to students' fractional models, we first identified the correctness of the responses and categorized the models that PSTs provided in terms of two aspects: (1) the types of models such as length model, area model, set model, and a drawing based on algorithm to find the common denominator; and (2) whether the same sized whole was used for both fractions. Then we developed a coding scheme for fractional models and used it to code all data. Finally we interpreted the data quantitatively and qualitatively.

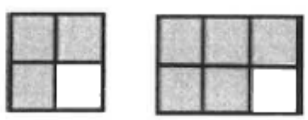
1. (1) What topics would be the most effective for elementary kids to learn mathematics with manipulatives or models? Describe the topics and explain how to teach the topics using manipulatives or models.
   (2) What do you think is the most important in teaching a math lesson to elementary kids using manipulatives or models?
2. **Task 1**: Susan is given the following question: Which is larger 2/4 or 3/6? How do you know?



Susan created the following models with the multi-link cubes to represent the fractions and help her with comparing the fractions.

(1) Do you think Susan's models will help her to compare the fractions?
(2) If you don't think Susan's models will help her, please create a model that you think would be useful for comparing 2/4 and 3/6.

3. **Task 2**: You asked a 3rd grade student, Lisa to make a drawing to compare ¾ and 5/6. She draws the following picture and claims that "3/4 and 5/6 are the same amount."



(1) Do you think Lisa's models are correct?
(2) If so, explain. If not, create a model that you think would be useful for comparing ¾ and 5/6 and explain why your model would be helpful.

Figure 1. Problems used for this study

Findings

PSTs' Perception of Using Manipulatives or Models in Teaching Mathematics

In the first part of the questionnaire, when PSTs were asked to suggest topics in which manipulatives or models can be used effectively, the most popular responses were topics involving the part-whole fraction concept, equivalent fractions, and fraction comparisons (35%), followed by whole number operations (25%), geometry (8%) and place value (7%). If we consider fraction operations (e.g., fraction addition, subtraction, multiplication, division) and other fractional numbers (e.g., decimals and percents), the topics related to fractions account for 40% of the responses. However, with regard to the topic of fractions, most PSTs pointed out the basic part-whole concept of fractions and very few (3 out of 108 responses) mentioned that manipulatives could be used to compare fractions, which is related to the focus of our study.

In addition, when the PSTs were asked what they considered to be most important in teaching mathematics with manipulatives or models, 25% of their responses indicated *understanding and reasoning*. The second most frequently mentioned aspect (16%) was providing students with *hands-on experience or opportunities to use visuals* as effective tools for solving difficult problems when they are unsure how to proceed. Almost as many responses (15%) indicated the importance of *controlled and focused management* by helping students understand how to use the manipulatives and models accurately, demonstrating their use, and establishing consistent rules for using them purposefully rather than as toys.

Identifying Correctness of Using Manipulatives for Comparing Two Fractions

Approximately two thirds of the PSTs recognized the incorrect use of models in both tasks (66% and 63% respectively), but not all of them identified valid reasons. When asked to propose models to guide students, the majority of PSTs illustrated both the invariance of the whole and equal partitioning. However, 20% of responses to Task 1 and 12% to Task 2 failed to show the invariance of the whole and/or equal partitioning in their representations. It is worthwhile to note that the most common models were area (especially circular wedges) and length/linear models (especially rectangular strips rather than a number line). Also, it was noted that even though the methods of representation used in the two tasks differ (i.e., Task 1's comparison method vs. Task 2's part-whole method), the PSTs tended to guide students using the methods familiar to themselves such as a part-whole method.

Implications

Considering that the PSTs' work in this study reflects their perceptions prior to taking a methods course, the results provide some insights into how to design a methods course. First, mathematics educators need to explicitly cover the *comparison method* as well as the *part-whole method*. Many PSTs in this study demonstrated unfamiliarity with the comparison method. Second, mathematics educators need to address *number line models* in more depth when considered that the PSTs in our study made very limited use of number line models. Third, mathematics educators need to help PSTs implement effective *pedagogical representations* as distinguished from solution representations. Finally, mathematics educators need to engage PSTs in *drawing models* by focusing on the principles of invariant wholes and equal partitioning in comparing fractions when considering that many PSTs appeared unaware of the importance of the principles.

BRIDGING BELIEFS, VALUES AND PAST EXPERINCES WITH INSTRUCTIONAL PRACTICE

Kayce L. Mastrup
University of California, Davis
klmastrup@ucdavis.edu

Research has established the challenges that novice math teachers face as they move from teacher preparation programs into their first year of teaching (Drake, 2006; Gainsburg, 2012; Millsaps, 2000; Thompson, 1992). Specifically, math teachers are found to have problems with implementing instructional practices that promote conceptual understanding. This research places direct emphasis on understanding in detail the connections between teachers' mathematical life stories and specific instructional sense making. More specifically, how do preservice teachers inform the development and implementation of their instructional practice over the course of their credential year and into the first two years of practice? What are the factors that influence this informing and what combinations of factors attribute to their development and implementation of instructional practice?

Keywords: Teacher Education-Preservice, Teacher Beliefs, Instructional Practice

Introduction

Prospective teachers come to formal teacher preparation programs with ideas and ways of thinking that influence what they learn from courses and experiences (Ball, 1988; Silva & Roddick, 2001). During teacher preparatory programs, preservice teachers face the challenge of balancing their prior mathematical experiences, what they believe mathematics learning environments should be, with what they are taught about teaching mathematics (Gainsburg, 2012; Lampert, 1988; Thompson, 1984). Scholars have been analyzing the connection between teacher belief and practice for years (Thompson, 1992) and researchers continue to find that teacher's beliefs are reflective of the nature of the instruction the teacher provides to students. While prior research centered on the topic of preservice mathematics teachers' belief structures (Ball, 1988; Cooney, Shealy, & Arvold, 1998; Harkness, D'ambrosio & Morrone, 2007; Drake, 2006; Millsaps, 2000), little of this research places direct emphasis on understanding in detail the connections between teachers' mathematics life stories and specific instructional sense making. Furthermore, while the need to study the mental processes of teachers has increased over the past decade, research in this area has largely concentrated on what teacher candidates understand about mathematics as they enter teacher preparatory programs (Ball, 1990; Thompson, 1984, 1992). This research aims to understand why new teachers do or don't use the practices emphasized during their credential programs by examining their instructional practices in light of their prior mathematical experiences. The following questions are guiding this research: How do preservice teachers inform the development and implementation of their instructional practice over the course of their credential year and into the first two years of practice? What are the factors that influence this informing and what combinations of factors attribute to their development and implementation of instructional practice?

Theoretical Framework

Ricoeur's (1992) concept of narrative identity, which is based on one's understandings of oneself across time that are accomplished by organizing and clarifying one's experience through narrative and Sfard and Prusak's (2005) definition of identity: collections of stories individuals hear and tell about themselves, frame this study. Autobiographies, whether written or verbal, provide individuals the opportunity to see influences and experiences that have affected their view at different points in time. Narratives provide individuals space to express to not only themselves, but others, who they are now, how they came to be, and where they think their lives may be going in the future. Rather than looking for conflicts between belief and practice, this work focuses on uncovering the interplay between community, belief/identity and practice. This research will focus on the key factors provided in Table 1, which have been associated with belief, mathematical identity and instructional practice in some manner. The aspects of what builds the foundational knowledge of instructional practice for preservice and in-service educators are rooted in their K-16 mathematics apprenticeship of observation and their mathematical identity. During the first year of a teacher preparatory program additional factors are added on: cohort mentor teacher(s), cohort member(s), program coursework, program instructors, edTPA and student teaching. All of these factors inform preservice teachers' instructional practice in varying ways. Results presented in this paper focus solely on the various relationships, connections and changes related to instructional practice upon entrance into teacher preparation through the preservice year.

Research Design

This small-scale study is taking place at a university in Northern California and began fall of 2016, with data collection anticipated to conclude spring of 2020. Currently, I have data from eight participants, three males and five females. Five of the participants have completed the first year of a two-year master's in education credential program and are teaching full time as the teacher of record in secondary mathematics classrooms. The remaining three participants are in the middle of the first year of the same master's in education credential program and are completing coursework and student teaching. My intent is to follow participants for three years, beginning with the teacher preparatory program and through their second year of teaching. I collected and analyzed four main categories of data for this study: a screener survey, observations of participants during methods class, coursework and interviews.

Data Analysis

Data were analyzed in a number of ways. First, each individual interview was transcribed and then coded according to constructs identified in the literature and natural emerging themes. These codes were then applied across the multiple data sources and finally a comparison across multiple participants was completed. The following excerpts are from one participant's data that was collected during year one of the teacher preparatory program.

Ophelia is currently teaching eighth grade math and she is on track to earning her Master of Art in education spring 2018. The different data sources include preliminary thematic analysis that begin to illuminate the connection between the factors of influence on Ophelia's instructional practice.

At the start of the program, Ophelia was asked to write a mathematics autobiography, which was shortly followed by a second paper on the topic of how Ophelia thought students learn math and how she defines math. In these papers, Ophelia shares her own personal struggles with learning mathematics and how these experiences have shaped her mathematical identity.

> The only aspect I didn't like about learning math was when the only way to solve a problem was by using an equation and the teacher wouldn't provide any explanation beyond just plugging the numbers into an equation. I would feel frustrated in not understanding why that worked or where the equation came from. Luckily, not all my teachers were like that, many would find a way to give us an explanation as to why we could use a certain equation.

Ophelia's apprenticeship of observation consisted of educators that created learning environments where students were able to approach problems in a variety of ways, as well as very didactic and teacher centered environments. The frustration expressed in the previous excerpt, is tied to Ophelia's mathematical understanding and how she viewed and situated herself as a mathematics learner different types of learning environments. In a later assignment, Ophelia re-emphasizes the struggles she faced learning mathematics during her adolescence. Learning environments where knowledge production was rooted in procedural understanding and memorization over those that focused on developing conceptual understanding did not provide her the opportunities she needed to achieve the mathematical understanding and confidence she desired.

> I was a student that used memorizing as my primary tool until I discovered I couldn't do that anymore for certain topics. I then had to find new ways to learn and deepen my understanding. I do believe new knowledge is constructed based on past knowledge that we have acquired.

During the interview Ophelia shared a variety of mathematical experiences, starting when she was a little girl practicing flash cards with her sister, up through college where she completed coursework and earned a Bachelor of Science in mathematics. When asked to share a positive experience about mathematics Ophelia shared stories centered around one specific teacher. When probed further about why this was such an important memory she elaborated:

> I think it was the topic and the teacher. He made it really exciting to learn. We would do a lot of neat projects, that we would do learning on our own and then bring it back to the class to share. And I think that was the first time I started struggling with math specifically, but I also, I was ok with the struggle – my teacher made that, something you didn't necessarily

> have to get the answer as long as you started working on the process that is what he was looking for and so I think that gave me a really good foundation and I realized it was ok to be wrong and struggle with math.

Ophelia then dives even deeper and provides additional evidence of the connection between mathematical identity, apprenticeship of observation and instructional practice. The following is from one of her weekly reflections:

> I am working on taking different approaches with them [students] and finding ways to improve. I noticed how if a student gave an incorrect answer, I wouldn't respond as well as I would have liked. I am still trying to find the balance of how to do it. I have tried supporting the student to try the problem again and I have said how the student's answer was an interesting answer and opened the question back up to the class to see if anyone got anything different. Each week I find a way to push myself more. I think I will see if my [mentor] teacher would be up for changing the warm-up format to not be as traditional and rather elicit students' prior knowledge.

As Ophelia discusses and reflects upon the struggles her and her students faced, she draws upon her apprenticeship of observation when indicating the type of instruction, she wants to enact in her classroom. Her mathematical identity is tightly linked to this apprenticeship, as she was exposed to learning environments where mathematical mistakes were not only valued but encouraged and utilized. Ophelia recognizes the danger of teaching students just procedural understanding and fact memorization. Her instructional practice is heavily influenced by her prior experiences. While Ophelia is trying to apply various ideas learned during her methods coursework, at this stage of the program Ophelia's mathematical identity, and apprenticeship of observation have greater influence on her instructional practice.

Conclusion

Preservice teachers need to reflect upon their past math experiences while active in the teacher preparatory program in order to make connections between how their experiences have shaped their conceptions of math and teaching. This research on the role of prior beliefs and experiences with mathematics and teaching might produce indicators for which candidates align with the underlying principles and educational philosophies of the program they are applying for. Knowing more about the mathematical history of credential candidates could inform teacher educators about the potential hurdles their preservice teachers might face when learning how to become effective teachers that are grounded in practices that foster high levels of conceptual understandings and promote equitable access to mathematical knowledge for their students.

PRE-SERVICE TEACHER DESIGN OF ACTIVITIES THROUGH COLLABORATION AND AUTHENTIC ENACTMENT

Michael S Meagher	Michael Todd Edwards	Asli Ozgun-Koca
Brooklyn College – CUNY	Miami University of Ohio	Wayne State University
mmeagher@brooklyn.cuny.edu	edwardm2@muohio.edu	aokoca@wayne.edu

Pre-service mathematics teachers collaborated with a Master Teacher in the authentic implementation of lesson plans in high school classrooms. The pre-service teachers made small strides in their own ability to design activities. There were indications that the pre-service teachers experienced growth in recognizing the value of collaboration and revision. There were limits to their ability to enact lesson learned about cognitive demand in their own activity design.

Keywords: Teacher Education - Preservice, Instructional Activities and Practices, Teacher Beliefs, Teacher Knowledge

Introduction

Much of the work of preservice teacher candidates is learning how to design rich activities that will engage students in inquiry-based mathematics and be accessible to all students. An extra layer in this challenge is that typically lesson plans and tasks designed in pre-service contexts, prior to student teaching, are never taught in classrooms meaning there is no feedback loop for the design beyond feedback from an instructor or peers. Our approach to this challenge was to design the CRAFTeD cycle (Meagher, Edwards & Ozgun-Koca, 2011b), inspired, in part, by Lesson Study research, to give teacher candidates the opportunity to see tasks that they designed implemented in classrooms and, therefore, promote growth in their individual task design.

The cycle emerged from our previous work (Meagher, Ozgun-Koca & Edwards, 2011a) where the decisive influence of the field placement in terms of the mentorship/exemplars students experienced became apparent.

The CRAFTeD cycle: (i) A class of preservice high school teachers design an activity; (ii) an experienced inservice teacher reviews the activity and gives feedback; (iii) the inservice teachers teach the revised activity, observed by the preservice teachers; (iv) the preservice and inservice teachers meet together to reflect on and redesign the activity.

We report the results of a small-scale intervention study designed to measure growth in teacher candidates' ability to design tasks for mathematics classrooms that require "higher level demands" (Stein & Smith, 1998) with the intervention of CRAFTeD cycles as well as to examine the influence of the CRAFTeD cycle on their growth as preservice teacher candidates.

Literature review and relationship to research

Pre-service teachers early in their program develop lesson plans - typically in isolation - that are never taught in a classroom, creating a disconnect between planning, implementation, and assessment of student learning (Allsopp et al. 2006; Meagher, Ozgun-Koca & Edwards, 2011a). While university methods instructors laud the merits of student-led inquiry, exploration, and discovery-based teaching methods, secondary mathematics teachers in too many schools favor instruction directly focused on student preparation for high-stakes, multiple choice state tests (Seeley, 2006). Developing communities of practice (Wenger, 1999) and lesson study groups (Fernandez, 2002) can help candidates and practicing teachers adopt a more research-based focus in their lesson planning and develop a shared repertoire of communal resources which transcend individual contributions. Providing candidates with opportunities to experience their lessons taught by Master Teachers in authentic classroom settings increases motivation for lesson writing. Preservice teachers demonstrate a trajectory of learning about lesson plans in a cycle of designing a lesson to be taught by a Master Teacher and reflecting critically on the implementation of that lesson (Meagher, Edwards & Ozgun-Koca, 2011b).

Methods and Methodologies

Methods and Methodologies

Participants in the study were students in the second semester of a two-semester sequence of methods classes both involving field experiences and both prior to student teaching.

Early in the semester teacher candidates designed a lesson length activity on composition of functions. Teacher candidates then participated in a CRAFTeD cycle on a different topic. At the end of the semester teacher candidates revised the original lessons on composition of functions.

For quantitative analysis both versions of the activities were scored by all members of the research team using a rubric based on Stein & Smith (1998) with a "definitive" score agreed on. For qualitative analysis the constant comparative method (Glaser & Strauss, 1967) was used to establish trends in the data.

Results

Quantitative Data:

Each component of the task was given a score: Memorization: 1pt; Procedures without Connections: 2 pts; Procedures with Connections (3 pts); Doing Mathematics (4 pts) (Stein & Smith, 1998). The scores were averaged for the entire task to get an overall score for each task.

Table 1: Researcher mean scores from Version 1 and Version 2 of the tasks

	1	2	3	4	5	6	7	8	9	10	11	12		
Vers 1	2.67	2.67	2.50	1.63	2.50	3.00	2.50	2.55	2.08	2.40	2.00	2.32	Mean	2.40
Vers 2	2.27	2.67	2.70	1.64	2.60	3.13	2.55	2.73	2.60	2.17	1.80	2.76		2.47

There was, on average, a slight improvement over the course of the semester (the class average increased from 2.40 to 2.47) toward "higher order demands" (Stein and Smith, 1998). In four of the eleven activities, the cognitive demand was reduced. This reflects a decision that some components were so open-ended as to be difficult for the students to engage with and, in revision, the cognitive demand was lowered.

Table 2: Researcher Scores vs Student Scores for Version 1 of the tasks

	1	2	3	4	5	6	7	8	9	10	11	12		
Researcher	2.67	2.67	2.50	1.63	2.50	3.00	2.50	2.55	2.08	2.40	2.00	2.32	Mean	2.40
Version 1	2.88	2.58	2.80	1.73	2.70	2.43	2.70	2.73	3.00	2.00	3.00	2.05		2.55

The numbers in the table above represent a comparison between the researchers' assessment of the average component score for the original activities and the students' own assessment of the average component score. As can be seen, the researchers assessed the components of the activities to have, on average, a slightly lower cognitive demand than in the students' assessment. This is, perhaps, to be expected with researchers who are experienced in working with pre-service teachers likely to have a more rigorous standard for cognitive demand. It is notable, however, that there is not a great deal of difference with the pre-service teachers exhibiting a good understanding of the levels of cognitive demand. This can, in large part, be ascribed to the fact that the students had to use Stein and Smith's (1998) cognitive demand framework as part of the assignment when the developed the original activities.

Qualitative Data:

CRAFTeD Cycle. At the end of the CRAFTeD cycle the teacher candidates wrote a reflective essay on the process. The following significant trends emerged in the data:

(i) a recognition of the need to give high school students an opportunity to struggle with mathematics and to discuss mathematics

Seeing a lesson that they had designed actually implemented in a class was an eye-opening and rich experience for the students. The Master Teacher with whom they collaborated stressed that student struggle is important but it was a surprise to the preservice candidates to see it in action in terms of the amount of time the Master Teacher allowed students to work on a task with which they were having difficulty and how he then handled the discussion. The preservice candidates observed the Master Teacher allow the students to struggle enough to make the subsequent discussion of the task as rich as possible. "He checked students answer and asked where they struggled with, then I heard the best conversation I have ever heard in the high school classroom." (TC 9). Another teacher candidate noted that the students, at the end of the warm up activity, "seemed to be having a difficult time connecting their observations with a kind of "main idea" but that "Once the students had a chance to discuss this out loud with [Master Teacher's] guidance the students developed a much clearer understanding. She remarked that "the class discussion is where students made the most progress." (TC 7).

(ii) an expectation that the work should be challenging and appropriate for high school students

Related to the teacher candidates' recognition of the importance of giving students an opportunity to struggle was their discomfort with that notion and the consequent initial design of tasks that were not challenging to the students either in their level or construction. The students were taken aback by the Master Teacher's rejection of their initial offerings. "A concern that [the Master Teacher] had early on in our lesson development was that our lesson was not at the high school level." (TC 3) and "[the Master Teacher] felt as though our [first idea] was too juvenile for his students" (TC 4). However, this feedback forced to both consider the level but also to consider the mind set of their approach. One teacher candidate remarked "After the presentation of our first ideas of the lessons, [the Master Teacher] made it clear to us that, when we first began this process, we were stuck in the ideas that we were taught and were not doing a great job of looking at the content as a teacher rather than a student." (TC 7).

Revision of tasks on composite functions. At the end of the semester the teacher candidates were given the task of revising their activities on composite functions and to write an essay to explain the changes they made. The following significant trends emerged in the data:

(i) appreciating continuous reflection and improvement

One of the affordances of the CRAFTeD cycle is that there is authentic feedback on the lessons that teacher candidates write. The teacher candidates are often surprised to see the different ways students interpret questions, how students may not look at a graph and see what is obvious to the teacher candidates, how the timing can be so different than what they imagined when it meets reality. This effect is heightened because of the huge amount of collaborative effort that goes into making the lessons. One result of the study is that, despite the challenge and effort the teacher candidates came to value the multiple iterations of revisions from first presenting their ideas to the Master Teacher, to negotiating within the teams about priorities for the revisions, to seeing how what they feel is a very solid lesson has many flaws when given to real students. “I learned how to listen to the reactions and feedback of students to eventually improve the lesson in any way possible. Through this project, I strengthened my ability of discussion with my fellow classmates by learning to work together to make our lesson unified and seamless. During this project, there were many hiccups and setbacks, but after each one my group came together and reflected on how we could make the lesson better.” (TC 8).

(ii) a focus in changes on fixing instructions and small details rather than elevating the cognitive demand of the task.

One of the affordances of teacher candidates seeing a lesson they designed themselves actually taught is the heightened attention paid to how the students interact with the task. One result of this was that the teacher candidates were very concerned when the students had difficulty in following instructions written on the worksheet. “When students got a hold of our lessons that we had created, they often expressed that there was a lot of writing or confusing instructions. There is no reason to confuse students with wording when the goal is mathematical.” (TC 8) and “I want students to focus on the mathematical content, and to not get caught up in instructions.” This is a valid concern but had the effect in the revisions of the lessons that a large number of the changes and justifications for changes were simply to do with wording of instructions, precision of notation etc. with a dearth of attention paid to the overall cognitive demand of the task.

Conclusion

This small-scale intervention study was designed to provide pre-service mathematics teachers with experiences in designing activities with high levels of cognitive demand and to experience some of those activities being authentically implemented in high school classrooms. The pre/post structure of one pair of activities showed the teacher candidates teachers making small strides in their activity design. There were notable limitations in their ability to craft effective open-ended questions, focus activities on key mathematical ideas and maintain cognitive demand although Stein and Smith’s (1998) proved to be a useful tool in developing their thinking about cognitive demand. The teacher candidates made larger strides in their openness to the importance of student struggle and student collaboration in mathematical work. The teacher candidates also exhibited growth in valuing collaboration and cycles of revision in lesson planning.

scannon5@gsu.edu

This paper is a reflection on a co-teaching experience during the first mathematics methods course of a teacher preparation program, where a community of teachers (teacher educators and pre-service teachers) could reflect on tensions (with teacher beliefs, with practice, and with mathematics). Cognitively Guided Instruction (CGI) was a central tenet to the course material and required learnings, opening up opportunities to (re)negotiate those tensions with beliefs, practice, and mathematics. We employ poststructural theories, attending to the documents that participants produced as well as the thinking and reading happening simultaneously, using writing as a method of inquiry.

Keywords: teacher education – preservice, teacher beliefs, elementary school education

This paper is a reflection, of sorts, on a co-teaching experience during the first mathematics methods course of a teacher preparation program. This course brought together a safe space and community for *teachers*—teacher educators and pre-service teachers—to reflect on *tensions*—tensions with teacher beliefs, with practice, and with mathematics. Cognitively Guided Instruction (CGI; Carpenter, Fennema, Franke, Levi, & Empson, 2014) was a central tenet to the course material and required learnings, and that consistent focus opened up opportunities to (re)negotiate those tensions with beliefs, practice, and mathematics. As our pre-service teachers were navigating the often-overwhelming requirements of the preparation program, they were confronted by their beliefs about what mathematics is, who can do mathematics, as well as how mathematics ought to be taught and learned; meanwhile, we (as teacher educators, doctoral students, and novice scholars) were navigating the always difficult world of academia, dissertation-writing, and reading in theory. Kayla, for instance, is writing her dissertation on mathematics teacher beliefs reconceptualized as an entanglement that is not stable; and yet, she recognizes her beliefs about teaching and learning mathematics, names them, feels them, teaches them. Susan wonders how post- theories might help us navigate those tensions, or perhaps present more tensions, by providing us the space to explore them, question them, trouble them.

In the current educational context that privileges conformity and compliance by teachers (McDermott, 2013), pre-service teachers need strategies to help them exercise professional autonomy. Teachers often experience a disconnect between the identities cultivated in their university classrooms and those currently privileged in schools, which leaves them feeling like they do not have the freedom to act, feel, and think in the ways they desire (Labaree, 2010). Furthermore, teacher educators are also engaged in negotiating and renegotiating tensions between theory and practice. Consequently, forming a teaching identity becomes a complex task that involves negotiating often contradictory ideas about teachers and teaching (Britzman, 2003). Teacher education, however, often focuses on helping teachers develop a stable identity rather than negotiating the shifting identities with which teachers must contend. This study aims to reconceptualize teacher beliefs as teacher educators (re)negotiate tensions and entanglements with/in teaching frameworks, and to write stories of those tensions. We take up posthuman and poststructural theories of subjectivity and methodology to consider pre-service teachers and teacher educators as subjects (selves) whose beliefs about teaching and learning mathematics are *always-already* entangled, impossible to think as pre-existing or separate (Derrida, 1967/1974).

This study is informed by poststructural theories (e.g., Foucault, 1981/2000), the purpose of which is to describe the linkages of language, power, and identity that impact how individuals interact with and produce the social world (Davies, 2003). In adopting this perspective, we attend to the documents that participants produced (e.g., reflective writings about readings, assignments about mathematics teacher beliefs, etc.) both inside and outside of class. The goal was not to collect or understand any individual participant's thinking but to explore what it is possible to learn as teacher educators in our (re)negotiating of tensions as we connect theory with practice as well as what possibilities exist and can exist for pre-service teachers to act, think, and feel as mathematics teachers.

Imagining reflection as in-constellation (Myers, Bridges-Rhoads, & Cannon, 2017) has given us the space before to question the taken for granted practice of reflection and think about it as a relation, as reimagining, as meddling in the middle (McWilliam, 2008), all to de-stabilize the too-familiar practices we ask of pre-service teachers. In co-teaching this class and in writing this paper, we again trouble the stability and familiarity of reflection alongside teacher beliefs in mathematics teaching and learning.

Methodology

The participants in this study include 20 pre-service teachers enrolled in the first of two math methods courses during their early childhood and elementary education teacher preparation program during an undergraduate Bachelor of Science in Education degree at a large, urban university in the southeastern United States. This teacher preparation program is four semesters in duration, where pre-service teachers are enrolled in coursework as well as part-time field placements during the first three semesters, and full-time field placement (student teaching) occurs during the fourth and final semester. This first course, which takes place during their second semester of the program, was intended to focus on the primary grades and designed to introduce CGI as an instructional framework.

The following documents were produced and shared over the course of the semester: reading journals (completed weekly and outside of class), beliefs statements (written in class at the end of the semester), and course evaluations. Documents were then analyzed using a collaborative process of writing as a method of inquiry (Kvale & Brinkmann, 2009; Richardson & St. Pierre, 2005) that involved the two of us sitting together and separately to read theoretical texts and study documents while writing and talking about how they interact. In this way, we write stories about our constant (re)negotiation of teacher beliefs and instructional practices as well as theoretical paradigms and neoliberal pressures in order to illustrate how various truths about teachers and teacher educators are continuously produced as language is organized into ways of thinking, speaking, and acting. Broadly speaking, our process of writing as a method of inquiry uses writing as a way of knowing, thinking, and creating; thinking and rethinking, reading and rereading of data alongside theoretical texts, writing and rewriting as a generative and cyclical process where stories and themes are welcome to come about on the page (Jackson & Mazzei, 2012; Koro-Ljungberg, 2015; Richardson, 1997).

Here we present some of these stories of pre-service teachers negotiating their beliefs while we as teacher educators are negotiating our own. These "findings" are preliminary, not fixed or final but rather coming about in the midst of different stories and writing and thinking. We draw on class conversations, course assignments, reading journals, course evaluations, and our anecdotal notes, to begin to tell this story of tensions in beliefs, teaching, and mathematics.

The Story (Begins…)

> *Due to the way I was taught mathematics during schooling, I have never had a positive relationship with the subject. Before, I imagined math as a left-brain concept, but now, I can view it as a creative process. Math is not something to be dreaded, but teachers can and should use math to create a space where experimenting, trying, failing, and succeeding are always implied and welcome. Math is not a teacher standing in front of a chalk board, barking out orders for equation solutions, but rather, communication between students, collaboration in the classroom, and a space where creativity to solving the proposed problem is encouraged and celebrated. Over the past 15 weeks, I have had the opportunity to learn what true mathematics looks like in the elementary classroom. By learning about it in the university classroom and implementing it in the field, my entire perspective on methods of teaching mathematics and learning math has completely changed. In August, my belief was that math was taught to you. It was an art of rote memorization, and one that, quite frankly, I was no good at. However, as we learned about CGI, my perspective on the teaching and learning process regarding math completely changed.*

Beliefs were claimed to have changed in this course experience, for one reason or another, but this requires a conceptualization of beliefs as measurable or distinguishable. As the course instructors, we hope that these pre-service teachers will learn something from us, and many of them come to this course with negative and harmful past experiences in mathematics, so this new learning and outlook is subjectively good… but what happens when these pre-service teachers are confronted by all of the other aspects of teaching? What happens when it is time to enact those beliefs amidst the mandates and curricula and relationships and mathematics (and, and, and…)?

> *This type of environment can be difficult to create and even more difficult to maintain. However, I think that this system on learning is so much more beneficial to students overall than rote memorization. By refusing to "take the easy route" and just give out solutions, teachers should strive year round to make the classroom climate one that promotes the success of students and their learning processes, even if that can sometimes be difficult. But, as much as I'd love to have an environment where everything is student centered, key terms are avoided, and I allow them to find strategies rather than teach them; we must think about testing. As much as I hate it, standardized tests play a huge role in our students' academic success. And teachers are assessed based on how well our students do. I want my students to be successful and on a timed test, they do not have an ample amount of time to come up with strategies and take a deep look into every question. Therefore, I would teach tricks. However, I would only introduce tricks if the students already mastered the concept.*

The connection to practice is overwhelming. Overwhelming for us as former teachers (re)negotiating those beliefs while trying to prepare these pre-service teachers for their future classrooms (and everything that comes with them), and overwhelming for them as students in the field, getting a small dose of reality but also engaging in conversations about those negotiations, navigating the tensions and finding ways to enact with pride and confidence and responsibility. Their reading journals brought concerns to the group; questions about application and reality, ways to make teaching work for themselves and their future students.

Initial Implications

As we have begun to think with this data and witness the tensions in both our becoming researchers in mathematics education and in the students' evolving views of themselves as future educators in elementary mathematics classrooms, important questions are beginning to surface. What does/should mathematics look like? Who can do mathematics and how do we make a mathematics that is accessible to more students? (Martin, 2015; Stinson, 2013). In what ways do these new beliefs and plans for instruction change the way we think about mathematics?

> *I wholeheartedly believe that the stigma of "math is hard," "some people just aren't good at math," and "there's only one way to solve the question" are just excuses that teachers give because that's how they were taught. But if we switched those stigmas into norms- that math is easy, everyone is good at math, there are infinite ways to solve the question- then we are believing in math for what it truly can be- and believing in the students to succeed as well.*

There is opportunity and possibility in rethinking ourselves and mathematics. It changes how we do mathematics teaching. It is our hope that in further delving into and around this data, questions and moments will arise that will push us to think differently. It is in difference, not in repetition that we can make spaces for more students and pre-service teachers to find success in mathematics, and to see themselves as mathematicians.

CONSTRUCTING A FRAMEWORK ACKNOWLEDGING THE SOCIOCULTURAL, CRITICAL, SPATIAL, AND QUANTITATIVE WAYS OF KNOWING THE WORLD

Lisa Poling
Appalachian State University
polingll@appstate.edu

Travis Weiland
Appalachian State University
weilandtj@appstate.edu

In this paper we discuss an epistemological framework rooted in a dialectic ontology of social, historical, and spatial dimensions. The framework is designed to make explicit the intersecting sociocultural, critical, quantitative, and spatial ways of knowing the world, which are inherent in mathematics education and quantitative learning environments more broadly. The intersection of these ways of knowing the world are discussed and then considered in relation to teacher education. We posit this framework could be powerful for both designing learning experiences for pre-service mathematics teachers and for making explicit to pre-service teachers a lens for making sense of their own future classroom environments to enact a more just and comprehensive mathematics curriculum.

Keywords: Teacher Education-Preservice, Teacher Knowledge

Introduction

The social and historical dimensions of reality have long been considered important when considering the teaching and learning of mathematics (Lerman, 2000), and more recently political dimensions have become highlighted (Gutiérrez, 2013), however a dimension that has been somewhat neglected is that of spatial justice. For the purpose of our research we define spatial justice as the critical examination of how geography and access impact opportunity. A recent push in that direction has been spearheaded by Dr. Laurie Rubel and her team in their work on conceptualizing *Teaching Mathematics for Spatial Justice* (Rubel, Hall-Wieckert, & Lim, 2017, 2016; Rubel, Lim, Hall-Wieckert, & Sullivan, 2016). In their work, they developed and implemented lessons involving spatial justice themes that intersected with critical pedagogy. Their work was situated in a mathematics courses for social justice in high school and undergraduate classes serving predominantly underserved students in New York City (Rubel, Lim, et al., 2016). This work shows the potential that considering spatial justice in relation to mathematics education can provide some tools and design heuristics to implement such learning opportunities in mathematics classrooms. In our work, we are drawing from the seminal work done by Rubel and company (Rubel et al., 2017; Rubel, Hall-Wieckert, et al., 2016; Rubel, Lim, et al., 2016) but are incorporating the notion of spatial justice in two fundamentally different ways. One way is by developing an epistemological framework that explicitly acknowledges sociocultural, critical, quantitative, and spatial ways of knowing the world drawing from the triple dialectic ontological perspective that Soja (2010) discusses. The second way is by investigating how such an epistemological framework could be used in constructing curriculum for pre-service mathematics teachers and also made explicit to pre-service teachers for making sense of their own future classroom environments. In this paper, we outline our epistemological framework, beginning with its ontological foundations, and then briefly discussing possible uses for it in teacher education settings.

Ontology

At the ontological level, in other words the characteristics of humans' reality, we are aligning our framework to include the commonly considered social and historic dimensions as well as the spatial (Soja, 2010). From this perspective spatial reality is not just viewed as a physical container for human social and historical realities, but instead as something that forms a triple dialectic ontological relationship with both the social and historical dimensions of reality (Soja, 2010). For example, geography or peoples' ways of knowing and interacting with their physical surroundings are shaped by their social interaction. We can also see this through the formation of political boundaries of nation states, which leads to the shaping of our spatial understanding of sociocultural interactions and the history of place. At the same time, spatial elements shape social structures. For example, rivers or mountains have often formed natural boundaries that then became social or political boundaries. This also goes beyond natural phenomenon. For example, scientists recently announced the beginning of a new geological era the Anthropocene dominated by humans reshaping of the earth (Crutzen & Stoermer, 2000). The structures that humans build both physically in terms of buildings, roads, and dams, as well as socially, such as voting boundaries, school districts, environmental laws, or norms over our interactions with the natural world have a profound effect on the spatial.

The spatial dimension also forms a dialectic relationship with the historical dimension. Natural forces work over time changing the earth, this is something that scientists have recognized over decades, but the same holds for our believed or imagined spaces and our understanding of the nature of the earth. For example, this can be seen in terms of a shift from the dominant view of the earth as flat to that of it as round and also in the methods we use to display the earth in term of cartography, and our understanding of how we can occupy space and what spaces we can occupy. We will not elaborate on the social historical dialectic, which is very well described elsewhere in mathematics education. Instead, we now shift to discussing our epistemological framework which builds off this ontological perspective.

Ways of Knowing in Quantitative Learning Environments

Our framework is based on the notion that there are many different ways of knowing or coming to know the world in which we exist. Some ways of knowing are privileged in society and by institutions whereas others are often marginalized, silenced or discredited. In the case of the ways of knowing, quantitative understanding is often privileged in dominant discourse. However, localized ways of knowing or certain cultural perspectives on the world are at times disadvantaged or marginalized particularly in the context of the mathematics classroom which is commonly seen as neutral (d'Ambrosio, 1985; Frankenstein, 1994; Gutiérrez, 2013). The framework we present here is by no means exhaustive of the ways of knowing the world. Instead what we are attempting to do is make explicit four important ways of knowing in quantitative learning environments which have been considered and investigated in various combinations by scholars in the past (d'Ambrosio, 1985; Frankenstein, 2009; Gutstein, 2006; Lerman, 2000; Rubel, Hall-Wieckert, et al., 2016; Skovsmose, 1994). Our work differs from past work in that we seek to consider and foreground all four aspects interwoven and inseparable in guiding the creation of quantitative learning experiences for pre-service students. Furthermore, we have also designed the framework to be made explicit to pre-service teachers such that the framework itself becomes part of the attunement process in making sense of quantitative problems and the world more broadly, with the hope that they will be able to transfer such ways of knowing or at least be open to different ways of knowing in other contexts. The main practices we are drawing from these ways of knowing are summarized in Table 1.

Table 1: Way of Knowing Framework

Ways of Knowing	Quantitative	Socio-cultural	Critical	Spatial
Key Practices	• Measurement • Collecting data • Modeling the world through quantification • Shaping the world through quantification • Problem solving through quantification and abstraction	• Using funds of knowledge of communities to make sense of the world • Considering the ways different communities of practice come to know the world	• Reading and writing the world • Making sense of social structures • Transforming social structures • Problematizing structural causes of (in)justice	• Considering how space and social structures shape and are shaped by one another • Understanding that spatial/social structures are historical

Implications and Future Work in Teacher Education

Rubel, Hall, and Lim (2017) discuss their Teaching Mathematics for the Spatial Justice (TMSpJ) design heuristic, applying it to two systems the lottery and alternative financial institutions. Looking back and extending the work of Rubel, Hall and Lim, we, because of our focus on working with pre-service teachers, shift from external foci such as the lottery, to looking ahead and grounding this work in spaces that remain central to the day-to-day notions of teaching. The main structure we are working to explore is that of the rural education system, and what are the opportunities students have based upon location and available resources. Teaching is a precarious profession, individuals want the best outcomes for their students but how many of the student outcomes are influenced by socio-cultural or historical decisions that challenge overall success? Soja (2010) talks about the "multiscalar view of a city", we believe that this idea is not limited to only cities (p. 32). In our study we want to challenge the notion that multiscalarity does not only occur in cities but extending this work to include issues that are found in rural settings. Although the number of influences in a city is exponential, we believe that pre-service teachers must see and validate the multitude of ways of knowing that change the opportunities for students living in areas that are rural.

Another system that is important for pre-service teachers to reflect on includes the structures related to public access and the availability of resources such as food, water, shelter, transportation etc. that ultimately become influences on opportunities for success. Children living in rural areas face similar challenges to those living in cities, but the ways of knowing do not look the same, therefore using critical pedagogies and quantitative measures a more complete understanding of equity and justice come to light.

Education and access to opportunities often determine trajectories established for students, especially in mathematics. In using the proposed framework to work with pre-service teachers, individuals will gain insight into multiple ways of knowing that will help them to better understand and support their future students. The lens in which they see and understand the world becomes inclusive, allowing their ways of knowing to look at the social, critical, and spatial challenges. When considering how the uneven development of geography impacts the opportunities of students in rural communities, it is essential to equip pre-service teachers to critically examine and validate those practices that fail to provide equal opportunity.

HALF THE BASE OR HALF THE HEIGHT? PSTS' EVALUATION OF A TRIANGLE AREA STRATEGY

Cristina Runnalls
University of Iowa
cristina-runnalls@uiowa.edu

Dae S. Hong
University of Iowa
dae-hong@uiowa.edu

The purpose of this study was to explore how elementary pre-service teachers responded to a novel strategy for justifying the triangle area formula. We conducted interviews with 24 pre-service teachers. Findings highlighted concerns when assessing the mathematical content of the strategy, as well as differences in pedagogical responses depending on content knowledge. In many cases, pre-service teachers leveraged their understanding towards productive responses, while also grappling with generalization. Recommendations for supporting pre-service teachers in navigating the intersection between content and pedagogical knowledge are discussed.

Keywords: Mathematical Knowledge for Teaching, Measurement, Teacher Education-Preservice

Eliciting, interpreting, and responding to student thinking are essential tasks for mathematics educators, and a key component of effective mathematics instruction (NCTM, 2014). In the classroom, this practice includes seeking clues of understanding in what students say, write, or draw, and connecting to students' unexpected strategies. Given the importance of this skill, it is important to encourage development of this ability early in teacher education programs.

Successful application of this practice requires different types of knowledge, including knowledge about student thinking and how to connect to and build upon novel approaches. One area where this knowledge may be of concern is area measurement. Studies have shown that students often demonstrate procedural understanding of area, using the formula *length x width* incorrectly and without understanding (Zacharos 2006). While pre-service teachers (PSTs) have sometimes exhibited similar misunderstandings (Murphy 2012), they have also shown valuable knowledge, including understanding area as two-dimensional space and concrete measure (Baturo and Nason 1996). While perhaps not an ideal conceptual understanding of area, this knowledge represents a key starting point in mathematics education courses.

For students, utilizing formulas without understanding their development is likely to lead to incorrect usage and ineffective learning. For PSTs, lacking understanding of area may also lead to difficulties when interpreting and responding to student work. Exploring how PSTs leverage existing knowledge towards their instructional responses may help teacher educators understand how to encourage development of effective teaching practices early on. The purpose of this study was to explore how PSTs responded to a novel strategy for explaining triangle area, within the context of their existing content knowledge. The research questions for the study were: *(1) How do elementary pre-service teachers evaluate a novel strategy for justifying the triangle area formula? (2) What instructional strategies do PSTs use when responding to the novel strategy?*

Related Literature

Area measurement is a vital part of elementary school mathematics, offering connections between mathematics and the physical world, marking a shift into two-dimensional mathematics, and providing opportunities to estimate, manipulate, and visualize. However, studies have shown that students often demonstrate a more procedural understanding of area. They may use the formula *length x width* incorrectly (Zacharos 2006), or misunderstand the role of unit squares

(Kamii & Kysh, 2006). While PSTs have exhibited similar struggles (e.g. Murphy, 2012), they have also exhibited valuable knowledge about area (Baturo & Nason, 1996).

One approach for understanding how PSTs may interpret and respond to student thinking is to analyze their responses to hypothetical student work. Examining student work allows PSTs time for reflection and offers a low-risk setting for exploring response strategies. Responding to student work is a central component of teaching, and practicing this skill offers opportunities to develop effective instructional practices. Analyzing student work has helped in understanding how PSTs respond to student-invented strategies in past research (e.g. Son 2016), providing insight into how they develop responses and what may be done to support this development.

This work is further grounded in the theory of mathematical knowledge for teaching, where knowledge required for effective mathematics instruction is composed of multiple components, among them common and specialized content knowledge, knowledge of content and students, and knowledge of content and teaching (Ball et al., 2008). We were interested in exploring our PSTs' existing common and specialized content knowledge, and specifically how this knowledge informed their knowledge of students, knowledge of teaching, and instructional practices.

Methodology

Twenty-four elementary PSTs enrolled in a geometry/measurement course volunteered to participate. The participants were all female, with a range of mathematical backgrounds.

Data Sources and Collection

Data sources included both a pre-assessment and interview. The pre-assessment consisted of questions assessing both common and specialized content knowledge, as well as knowledge of content and students. Assessment tasks were adopted from prior studies (e.g. Zacharos, 2006).

The first author then conducted semi-structured interviews with all participants. In this study, we report on responses to one interview task, where participants were asked to study and respond to the diagram in Figure 1. Participants were told that the figure represented a student's attempt to explain the area formula *½ bh* via cutting and rearranging pieces of the figure. They were then asked to evaluate the strategy for mathematical accuracy, to describe their assessment of the knowledge exhibited by the student, and to offer possible instructional responses.

Pre-assessment data was collected immediately prior to the course measurement unit, with interviews were conducted in the following four weeks. While participants had been exposed to similar material prior to the interviews (both in their own education and in the course), none of the participants were previously familiar with the justification of the triangle area formula that comprised the primary data source for the present work.

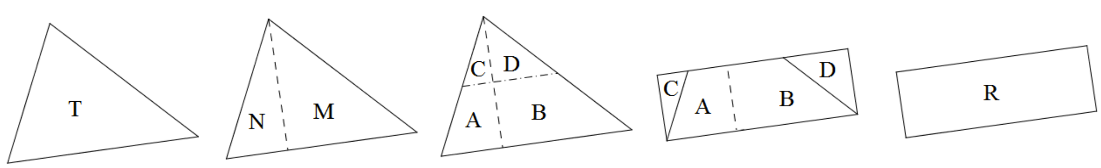

Figure 1. Interview question diagram. Novel strategy to verify area formula for a triangle.

Data Analysis

Interviews and reflective memos were qualitatively analyzed for content and instructional responses. The two authors coded interviews independently for content knowledge (see Table 1) as well as instructional response strategies (see Table 2). After initial coding, the authors met to discuss themes, resolve discrepancies between codes, and identify key findings.

Findings

PSTs' Content Concerns

The majority of PSTs (22 out of 24) grappled with evaluating the mathematical accuracy of the diagram, noting concerns regarding the fit of the pieces, connections to the triangle area formula, and generalizability to other triangles. Frequent responses are provided in Table 1.

Table 1: PSTs' Most Frequent Content-Related Responses

Description	Example
Doubt about the "fit" of pieces C and D when forming a rectangle (6 out of 24)	"You can't even know that this is correct because you don't have side lengths… just simply saying that this goes there and that goes there is not really valid" (Participant 14)
Difficulty connecting area formula for a triangle with area formula for a rectangle (10 out of 24)	"If you have one half base times height, that is not equal to base times height… You can't have the same amount of area be base times height and half of base times height at the same time" (Participant 20)
Confusion linking bisected *height* in Figure 1 with the formula indicating a bisected *base, **1/2bh*** (6 out of 24)	"I can see where the one half the height comes from, but I don't know…I get kind of confused when it comes to the base because you don't want to split the base in half because it didn't get divided and it's just not how I see it" (Participant 01)

Many PSTs' concerns were mathematically valid, engaging with pieces of specialized content knowledge and indicating critical thinking about the steps necessary to justify a formula. They sought clarity in the "fit" of the diagram, and understanding of how to connect diagram to formula. Most PSTs recognized that the strategy may not be generalizable, but struggled to fill in the details themselves. As a result, half rejected the strategy (12 out of 24) or stated the diagram was valid without verifying details (7 out of 24). Accepting without understanding or rejecting the method could lead to issues in a real teaching situation, leading either to the acceptance of incorrect strategies or the halting a productive discussion. Given that the sequence in Figure 1 is a viable strategy, our PSTs' responses indicated that struggles with understanding of the content may lead to struggles in responding to student thinking in future instructional moments.

PSTs' Instructional Responses

Our PSTs provided a variety of instructional responses, with some leveraging their content knowledge to inform their pedagogy. Frequent responses are described in Table 2.

Table 2: PSTs' Most Frequent Instructional Responses

Description	Example
Focuses on an alternate method for justifying area of a triangle (6 out of 24)	"[If] you made an exact copy [of the triangle] and flipped it on its axis… it would sort of look like a parallelogram. Then… you can do length times width or base times height and you are multiplying by point five to get half of it" (Participant 19)
Looks for additional examples or explanations (12 out of 24)	"This is very interesting! Can you show me? How do you know its correct?" (Participant 02).
Guides the student away from the strategy (9 out of 24)	"I would go over the formula again. I would bring up not to use this because it won't work every time" (Participant 12).

Twelve participants provided student-centered responses, asking the student to look for more examples or provide further explanation. Three PSTs went further and suggested the entire class investigate the strategy, so that other students could engage as well. These PSTs indicated a desire to elicit student thinking, bring about mathematical discussion, and provide room for the entire class to engage in new ideas. Although content knowledge may be concern for follow-up, these responses represented a good starting point for addressing unfamiliar strategies.

At the same time, other responses provided by PSTs were more teacher-centered. Nineteen PSTs provided procedural recommendations, such as giving area practice problems or asking the student to focus on use of the formula. Such responses indicated a higher value on procedural fluency, and frequently stemmed from prior difficulty with understanding the strategy. While testing empirical examples is a useful strategy for exploring generalization, it was unclear if the PSTs would have been able to follow up on those examples for this purpose.

Discussion and Conclusions

Our PSTs showed that it may be challenging, but certainly possible, for them to practice effective instructional practices. While struggles with content hindered some instructional responses, half of our PSTs placed the student at the center of discussion, a positive point from which to develop knowledge about teaching. They indicated a desire to learn from their students, and sought to merge the student's understanding with their own. For these PSTs, it would be helpful to discuss techniques for follow-ups to probing questions, with a focus on the specialized knowledge required to assess novel strategies. This knowledge should be explored not only to learn content, but also to see how these ideas may arise in day-to-day teaching practices.

Participants who struggled with their own justifications were less willing to explore new or unfamiliar ideas. As noted previously, eliciting and interpreting student thought is an important component of effective teaching, but may be especially difficult for those PSTs who continue to struggle with their own justifications. For these PSTs, it may be wise to focus on developing the ability to ask probing questions, eliciting students' understanding and giving themselves time for processing. Modeling how to address such challenges with probing questions, continuing dialogue, and scaffolding may help develop these key questioning skills. By integrating content knowledge with hands-on experience responding to student work, PSTs can begin realize for themselves where they may be missing understanding, and how this may impact their teaching practices in the future.

HOW DO PRESERVICE TEACHERS ELICIT THE THINKING OF A STUDENT WHO HAS MADE A MISTAKE?

We report on a study of novice teachers' eliciting performances in a scenario in which a student has made a mistake and, if sufficiently probed, is able to recognize the mistake and revise their work. Our findings reveal the skills and capabilities of one group of preservice teachers at the start of a teacher education program.

Keywords: Teacher Education-Preservice; Instructional Activities and Practices

In mathematics teaching, a regular problem of practice is that a student does something "unexpected" when solving a mathematics problem such as using an invented approach or making a "mistake" when carrying out a known process. Interactions around "unexpected" student responses can be powerful sites of learning for both teachers and students (Hiebert et al, 1997). For example, when an answer is incorrect, the joint sense-making required to interpret student thinking goes beyond the identification and correction of mistakes or errors into the conceptual analysis of why the mistake or error was made (Borasi, 1994; Kazemi & Stipek, 2001). The information that teachers can uncover through elicitation can then guide their pedagogical response. While the importance of interacting with students around mistakes is well-documented, far less is known about the ways in which preservice teachers (PSTs) elicit student thinking when a student has made a mistake in their arithmetic process. In this study, we set out to explore the eliciting skills and capabilities of PSTs in a context in which a student has made a mistake in their arithmetic process and will recognize the mistake if asked specific questions about their reasoning. We use the term *mistake* to mean isolated and unrepresentative mis-executions of an algorithm (i.e. "careless mistakes") (Radatz, 1980). We studied the skills of PSTs at the beginning of a teacher education program in order to find out about the skills that they bring to teacher education.

The Practice of Eliciting Student Thinking

In teaching, "teachers pose questions or tasks that provoke or allow students to share their thinking about specific academic content in order to evaluate student understanding, guide instructional decisions, and surface ideas that will benefit other students" (TeachingWorks, 2011). Our decomposition of the work of eliciting student thinking includes bringing out the student's process and probing key aspects of what the student says and does to uncover the student's understanding (Shaughnessy & Boerst, 2018b). We use "skill with eliciting student thinking" to refer to the degree to which PSTs are able to engage in these areas of work.

Using a Teaching Simulation to Assess Skills with Eliciting Student Thinking

Since 2011, we have been using teaching simulations to study PSTs' skill with eliciting student thinking (Shaughnessy & Boerst, 2018a Shaughnessy, Boerst, & Farmer, 2018). In these simulations, a PST interacts with a "standardized student" (a teacher educator taking on the role of a student using a well-defined set of rules for responding) around a specific piece of written work. We design teaching simulations to have a consistent three-part format (Shaughnessy & Boerst, 2018b). First, PSTs are provided with student work on a problem and given 10 minutes to prepare for an interaction. Second, PSTs have five minutes to interact with the standardized student, eliciting and probing the "student's" thinking to understand the steps they took, why they performed particular steps, and their understanding of the key mathematical ideas involved. Third, PSTs are interviewed about their interpretations of the student's thinking.

We designed this simulation to be one in which a student makes a mistake that is evident in their original written work. This student uses an alternative algorithm for solving multi-digit subtraction problems (see Figure 1). The process involves writing the value of the minuend and subtrahend in expanded form and making any necessary trades. When used correctly, the user would then subtract the numbers place-by-place in expanded form. This student correctly applies the expanding and trading process, but mistakenly adds values by place instead of subtracting. This student has conceptual understanding of expanded form, the meanings of addition and subtraction, and when, how, and why to make trades. In this particular instance, however, the student accidentally loses sight of the fact that they are solving a subtraction problem due to the addition symbols in expanded form. During the interaction, the student will realize their mistake when pressed to: make and evaluate an estimate for the original problem, represent their process with a picture, talk about the meaning of the operation, explain why trades were made, solve another multi-digit subtraction problem, or re-solve the original problem. The teacher educators carrying out the "student" role were trained to only reveal the mistake or revise the process if pressed by the PST on one or more of these specific points.

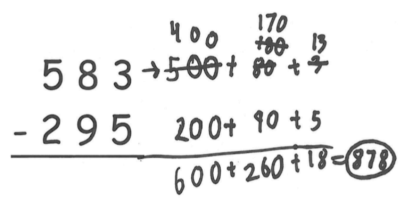

Figure 1. Student work. The student makes a mistake.

Methods

Thirty PSTs enrolled in a university-based teacher education program in the United States participated during the first week of the teacher education program. The teaching simulations were video-recorded. In this paper, we focus on three core components that we assessed: (a) eliciting the student's original process, (b) probing the student's understanding of key mathematical ideas, (c) eliciting and probing the student's mistake, including the reason for the mistake and the revised process and solution. For each of these components, we identified specific "moves" and tracked their presence or absence in each performance. We used the software package Studiocode© to parse the video into talk turns. Then, we identified "instances," which contain a question posed by a PST and the student's response to that question. Two independent coders applied all of the relevant codes to each instance. Disagreements were resolved through discussion and by referencing a code book.

Findings

Eliciting the Student's Original Process

The student's process had five steps: expanding both the minuend and subtrahend, comparing the numbers in each place, trading, adding (rather than subtracting) numbers by place, and adding the partial sums to arrive at the answer. The highest rates of eliciting occurred around the expansion (70%), the comparison of the numbers in each place (90%), and the trading steps (80%). In fact, 65% of PSTs elicited all three of these steps and 90% of the PSTs elicited two or more. However, only 53% of the PSTs elicited the step where the student made the mistake. The smallest percentage of eliciting occurred around the adding of the partial sums (10%). Because this step took place after the mistake, it may not have seemed important to PSTs who had elicited the mistake. Given that these PSTs elicited some, but not all, of the student's steps, we concluded that they brought skills relevant to eliciting a student's process that may be leveraged in the teacher education program to work towards more thorough elicitation.

Probing the Student's Understanding of the Original Process

We coded whether PSTs probed the student's understanding of six mathematical ideas underlying the process. The highest percentages of probing occurred around the operation in the problem (27%), why the student expanded (37%), and why the student traded (27%). The lowest percentages of probing occurred around the equivalence of expanded form and the "original" number (7%), the reasonableness of the answer (7%) and what trading means (0%). This suggests that limited probing of mathematical ideas occurred. However, when we looked across the set of ideas, we found that 67% of PSTs probed the student's understanding of one or more idea. Thus, we concluded that this 67% of PSTs brought skills relevant to probing the student's understanding in this scenario, but note that their probing was not focused on particular ideas.

Eliciting and Probing the Student's Mistake and Revised Process

We coded the extent to which the PSTs elicited and probed the student's mistake of adding numbers by place instead of subtracting. We found three patterns in PST' performances: eliciting that the student had made a mistake (47% of PSTs), pointing out the mistake and getting the student to agree without first eliciting the mistake from the student (20% of PSTs), and only asking questions that were not focused on the mistake (33% of PSTs). In other words, 67% of the PSTs uncovered the mistake either by eliciting it or asking the student to confirm that they made a mistake; 33% percent did not learn about the mistake.

We further examined the performances of the 47% of PSTs who elicited the mistake from the student. These 14 PSTs elicited the mistake in different ways. Eleven of the 14 asked about the operation involved in the problem and then pressed on how that operation (subtraction) related to what that the student had done (addition). Another two PSTs posed another problem for the student to solve or asked the student to redo the original problem. A third approach, used by one PST, was to ask why the student had made the trades (to get enough to subtract).

To explore what PSTs did after learning the student had made a mistake, we considered the 20 cases in which PSTs uncovered the student's mistake either by eliciting or pointing out the mistake. Three of the 20 PSTs asked questions to learn about how and/or why the mistake was made. For example, in response to the student's comment, "I think I made a mistake," one PSTs asked, "How did you make a mistake?" Five of the 20 PSTs made statements based on their own inferences about how and/or why the student made the mistake and got the student to agree. The other 12 PSTs did not ask follow-up questions about how or why the mistake was made. For example, one PST elicited the mistake, then immediately shifted focus to the revised process. Of the 20 PSTs, 15 elicited some or all of the revised process from the student. Sometimes this included asking about all of the steps in the process again, but other times it focused on redoing the step where the student had made the mistake. In 10 of the 20 cases, the student revised their final answer. These findings suggest that this group of PSTs bring skills relevant for eliciting a student's mistake but may need to learn reasons and strategies for probing how and why a mistake was made.

Discussion

Understanding the skills with teaching practices that novices bring to teacher education is key to designing experiences that are responsive to the needs of PSTs (Shaughnessy & Boerst, 2018a). This study examined the ways in which PSTs at the beginning of a teacher preparation program elicited the thinking of a student who made a mistake when using an alternative algorithm to solve a subtraction problem. Learning about the reason for a mistake is important for teachers to accurately assess and respond to student thinking. For example, a student who was genuinely unsure of the meaning of expanded form would need different instruction than a student who has made a mistake when carrying out a well-understood process. However, at the start of their teacher education program, these PSTs focused more on eliciting the revised method and/or solution than asking about why the mistake was made. The data suggest several directions for continuing research. First, the PSTs in this study were in their first week of a teacher education program. In what ways do their skills with eliciting student thinking develop over time? Second, what course activities might effectively cultivate an inclination to probe how and why students make mistakes? Third, the assessment itself involved a mistake where the student was using a "non-standard" approach to solve the problem. Anecdotally, we have reason to think that some PSTs were discounting the student's reasoning because they believed that the student should be using a different method to solve the subtraction problem. A future study could compare skills in eliciting around a mistake with a "standard" and an "alternative" algorithm.

FROM BATCHES TO PARTS: PROSPECTIVE TEACHERS' REPRESENTATIONS FOR PROPORTIONAL RELATIONSHIPS

Eric Siy
University of Georgia
ericsiy@uga.edu

In this report, I describe how using representations facilitated a shift in reasoning about proportional relationships in a content course for prospective middle school teachers. The prospective teachers initially approached proportional relationships and created representations from a multiple batches perspective. After some support, the teachers reasoned with a variable parts perspective and modified their representations accordingly.

Keywords: Teacher Education-Preservice, Middle School Education, Number Concepts and Operations

Researchers have stressed the importance of representations in mathematical thinking (Cuoco, 2001; Janvier, 1987). Additionally, representations are a critical feature of effective mathematics teaching. In *Principles to Action,* (National Council of Teachers of Mathematics, 2014), the authors explicitly identified teaching with representations as principle for high quality mathematics teaching practice. Using and connecting mathematical representations "[engage] students in making connections among mathematical representations to deepen understanding of mathematics concepts and procedures and as tools for problem solving" (p. 10). However, teachers' conceptions of representations are sometimes framed as not "real" mathematics (Stylianou, 2010) and prefer to prioritize abstract, procedural rules (Eisenhart et al., 1993). One viable avenue is to provide prospective teachers with opportunities to learn with representations which influences both teachers' knowledge and use of representations (Jacobson & Izsák, 2015). In this report, I characterize such an opportunity for prospective middle school teachers to reason about proportions using representations. Specifically, I describe two ways prospective teachers reasoned about proportions and how they were supported in transitioning from one to the other.

Theoretical Framework

Definition of Representations

In this study, I frame representations as culturally and historically rooted artifacts whose meanings grow out of how communities have interacted with an inscription over time. Saxe's account (2012) of cultural forms and functions describe how historically rooted artifacts change over historical time. Forms are socially rooted artifacts perceivable by the community such as the base-27 system of the Oksapmin peoples (Saxe, 2012) or a number line (Saxe, de Kirby, Le, Sitabkhan, & Kang, 2015). Functions are how forms are used by the community. Over time, the community may preserve historical forms but may also change them in order to serve new functions. For example, as students use a number line form in earlier grades, the form shifts to accommodate rational numbers while preserving whole numbers. In this report, I focus on strip diagrams as representations although others were found in the data (e.g., equations).

Definition of Multiplication and Proportional Relationships

The class analyzed in this study used a multiplier-multiplicand definition for multiplication notated by equation $N \cdot M = P$ (Beckmann & Izsák, 2015). In this equation, the value N denotes the number of bases units in one group (the multiplicand), the value M denotes the number of groups (the multiplier), and the value of P denotes the number of units in M groups.

Additionally, a proportional relationship is the collection of the set of values *x* and *y* satisfying the equations of the form $N \cdot x = y$ or $x \cdot M = y$. Using this definition of multiplication, Beckmann and Izsák called the first relationship a multiple batches perspective wherein the amount in one group is preserved i.e., for a certain amount of the first quantity, there are a corresponding amount of the second quantity. They name the second relationship a variable parts perspective wherein the number of groups is preserved i.e., for a certain number of groups of equal size of the first quantity, there are a corresponding number of groups of the same size of the second quantity. They also claim the variable parts perspective has mostly been overlooked in the literature but can be used to think about secondary topics such as geometric similarity and slopes of lines. The results of this report show the accessibility of the variable parts perspective and describe features of students' representations help them reason with this perspective.

Data and Analysis

I analyzed four lessons from a mathematics content course for prospective middle school teachers (PSMTs). The lessons were on proportional reasoning based on the ideas in Beckmann and Izsák (2015). The 13 PSMTs in the course were predominantly white women. In class, PSMTs were expected to use the multiplier-multiplicand definition of multiplication and explain their thinking with drawings rather than memorized algorithms or symbol pushing. I also acted as a participant-observer and sat at one of the tables asking questions to support, extend, and connect PSMTs ideas. I analyzed two introductory lessons on proportional relationships and two lessons marking the transition from using multiple batches to variable parts. I analyzed video recordings of class. One stationary camera captured the whole class and another camera followed the teacher during small group work. Each table had an iPad where PSMTs can write notes and present their drawings. The primary analytical techniques were modified from Saxe et al., 2015 and focused on identifying forms and functions of the representations. To identify a form, I characterized the geometric inscription or object the PSMT used to explain their reasoning such as a bead, strip, or partition of a strip. I identified functions by using the PSMTs verbal explanations and annotations to explain what each form represented.

Results

Initially, the PSMTs' ways of reasoning using a multiple batches perspective where a ratio represented a composite unit. With support, the PSMTs reasoned using a variable parts perspective by assigning different values to the partition of a strip and collapsing batches of strips into one. I present two students' shifts in reasoning modelling other PSMTs in the course.

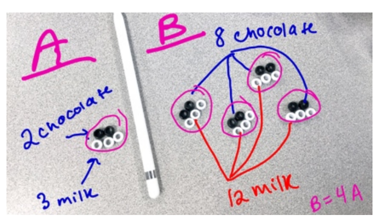

Figure 1. An Exemplar of a PSMT's Initial Arrangement

In the first lesson, the PSMTs were given a set of black and white beads and the hot cocoa problem. They were asked to determine if a hot cocoa mixture with two drops of chocolate and three drops of milk had the same flavor as a mixture with eight drops of chocolate and 12 drops of milk (see Noelting, 1980). PSMTs initially described rearranging the set of eight black beads and 12 white beads in four groups with two black beads and three white beads to show the new mixture had the same flavor (see Figure 1). This indicated a multiple batches way of reasoning i.e., $(3 + 2) \cdot x = y$ where x is the number of batches and y is the total ounces of hot cocoa.

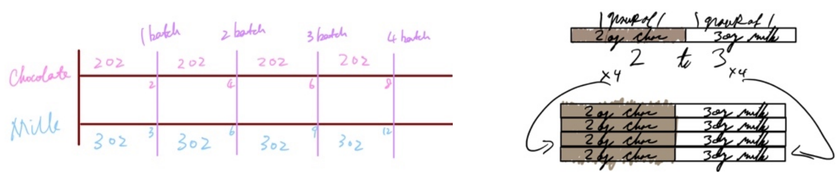

Figure 2. (a) Double Number Line and (b) Strip Diagram for the Hot Cocoa Problem

The following day, PSMTs were asked to make double number lines (DNLs) and strip diagrams (SDs) of the hot cocoa problem that captures multiple mixtures. The PSMTs found creating and explaining DNLs to be generally unproblematic. Most PSMTs created DNLs with increments of two ounces of chocolate and three ounces of milk similar to Figure 2a to show multiple mixtures of the hot cocoa. When making SDs, they created drawings resembling the DNL where strips represented a batch of two ounces of chocolate and three ounces of milk (Figure 2b). In other words, although the form of representation changed, its function remained similar in that it explicitly showed batches. At the table where I was seated, the PSMTs expressed difficulty in creating SDs that capture multiple mixtures. I pressed them to think of larger quantities of hot cocoa and how they would draw it. Molly then created the drawing in Figure 3a. During whole class discussion, she explained she initially drew one cup (the first row) of hot cocoa with five equal sized parts, two parts chocolate (blue parts) and three parts milk (pink parts). She explained that 1,000 cups of hot cocoa would also have two parts chocolate and three parts milk and stacked multiple strips to show 1,000 cups. She divided 1,000 cups into five parts to get 200 cups in one part. Describing the difference between one cup and 1,000 cups, she gestured towards the first column in her drawing, "so instead of having one-fifth in that one tiny box, [this column] is worth 200 cups." This indicated Molly was beginning to consider partitions of the strip diagram as a part with a variable amount in it i.e., either 1/5 of a cup or 200 cups.

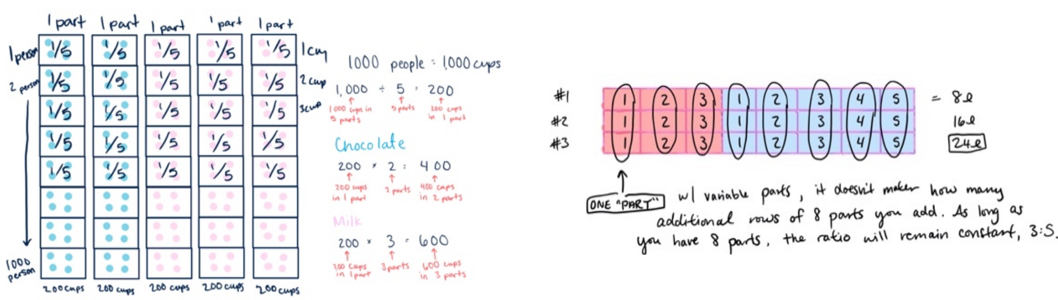

Figure 3. (a) Molly's Hot Cocoa Strip Diagram (b) Christina's Punch Strip Diagram

In the lessons transitioning from using multiple batches to variable parts, the class worked on the problem, "If you mix juice and bubbly water in a three to five ratio to make punch, how many liters of juice and how many liters of water would you need to make 24 liters of punch?" Once again, some PSMTs initially created SDs showing multiple batches. Christina's transition in reasoning during small-group discussion was similar to Molly's. Using her drawing (Figure 3b), she initially showed three batches by iterating a horizontal strip representing a batch containing three liters of juice and five liters of water. She iterated the strip three times to get 24 liters of punch. However, she was still confused about drawing a SD highlighting three and five parts instead of two parts with three liters and five liters. After talking with Molly, Christina

Hodges, T.E., Roy, G. J., & Tyminski, A. M. (Eds.). (2018). *Proceedings of the 40th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Greenville, SC: University of South Carolina & Clemson University.

explained she would change her drawing by collapsing multiple partitions into one partition, "I guess it would be different…I was trying to show the variable parts. It doesn't matter if [the drawing] keeps on going down, the ratio is going to be the same, so it might be clearer if this was just one big part [gestures to the first column] and not split into three because it looks like batches." Similar to Molly, Christina was flexible with the amount in a partition i.e., one partition could be one or three liters. She noted that a ratio could refer to the number of parts of same amounts i.e., $x \cdot (3 + 5) = y$ where x is the amount in a part and y is the total liters of punch.

Discussion

When initially approaching proportion problems, PSMTs used a multiple batches perspective way of reasoning. This could indicate PSMTs experience in their own education may have primarily supported a multiple batches perspective and can be leveraged to develop variable parts perspective. When prompted to think about the situation in different ways i.e., using larger numbers or focusing on the ratio as a number of parts, the PSMTs were able to successfully consider a variable parts perspective. Additionally, the partitions in strip diagrams shifted functions supporting a variable parts perspective when they "collapsed" the iterated strips and generalized that a partition could be any amount. This study demonstrates the viability of PSMTs capacity to reason with variable parts, an unnoticed perspective in the literature. Additionally, the results suggest teachers and teacher educators to support their students to reason flexibly with the mathematical functions of representations such as the strip diagram.

THE INFLUENCE OF MATHEMATICAL KNOWLEDGE FOR TEACHING AND BELIEFS ON PRESERIVCE TEACHERS' NOTICING

Lisa Skultety
University of Illinois at Urbana-Champaign
Dobson2@illinois.edu

A preservice teachers' (PSTs') ability to notice students' mathematical thinking can play an important role in their ability to respond to students' ideas and orchestrate productive discourse. Consequently, the topic of teacher noticing has been of interest recently, but little is known about why PSTs notice what they do. This report describes the initial analysis of a project investigating how Mathematical Knowledge for Teaching (MKT) and beliefs about the role of students' thinking in the math classroom influence elementary PSTs' noticing within the context of fractions. Regression analysis indicates that neither MKT or beliefs had a statistically significant impact on PSTs' noticing. Being in a course section that "practiced" noticing through several activities throughout the semester was the only statically significant predictor of noticing scores at the end of the semester.

Keywords: Teacher Education-Preservice, Teacher Beliefs, Mathematical Knowledge for Teaching

What teachers see or fail to see in a classroom is tightly linked to the decisions that teachers make, which makes teacher noticing critical to all aspects of teaching. Using students' thinking in instruction is essential for high quality instruction, but this can only be done if the teacher first notices students' mathematical thinking, which can be challenging, especially for novice teachers. Little is known about why teachers notice what they do, therefore leaving many unknowns about how to best improve teachers' ability to notice students' thinking and consequent capacity to make instructional decisions based on students' thinking. This study investigates how elementary PSTs' beliefs and Mathematical Knowledge for Teaching (MKT) are related to their ability to notice students' mathematical thinking.

Theoretical Framework

According to Jacobs, Lamb, and Philipp (2010), noticing of students' mathematical thinking includes: (a) attending to children's strategies while working on mathematics, (b) interpreting and making sense of children's mathematical understandings, and (c) deciding how to respond because of these interpretations. Noticing as a skill can be taught, improved, and refined (Schack et al., 2013; Schoenfeld, 2011), and it should be cultivated with PSTs. By practicing noticing with PSTs and scaffolding the complexities of noticing students' mathematical thinking, PSTs are better prepared to notice students' mathematical thinking and enact high quality math instruction in their future classrooms

Research on PSTs' noticing of student's mathematical thinking while watching videos has overwhelmingly focused on the *what* of noticing. Studies have investigated what classroom features PSTs tend to notice and in what ways their noticing of these features may change over time (Sherin & van Es, 2005; Star & Strickland, 2008). While these studies have yielded a deeper understanding of PSTs' noticing, there are still important questions left unanswered. Several authors have alluded to knowledge and beliefs impacting PSTs' noticing (Schoenfeld, 2011; Star & Strickland, 2008). However, there are not many studies that investigate the impact of beliefs or knowledge on noticing, and even fewer studies investigating these factors together.

Consequently, the relative contribution of each of these factors is unknown. Studies that have investigated beliefs and noticing have measured beliefs about mathematics in general, including PSTs' math attitudes (Fisher et al., 2014). It may be more appropriate to specifically investigate beliefs about the importance of using student thinking in instruction, as these beliefs may be more tightly connected to a teachers' noticing. Additionally, past studies that have investigated MKT in relation to noticing, cite a theoretical connection, but have been unable to find a statistically significant connection (Thomas, Jong, Fisher, & Schack, 2017). The lack of expected findings may indicate that the instruments were not well aligned.

This study is designed to build and improve on prior studies by combining attention to PSTs' knowledge, beliefs about the importance of using student thinking in classroom instruction, and their noticing. This study examines whether changes in PSTs' knowledge and beliefs correspond with changes in their noticing of students' mathematics thinking.

Methods

Participants

The study was conducted in the Fall of 2017 with 97 elementary PSTs during their first of two math methods courses. The PSTs were divided amongst four sections of the same course. Course instructors met on a weekly basis to collaboratively plan the activities and assignments each week. Three of the sections served as a comparison section to the focal section. The focal section participated in an additional two noticing activities and a video observation assignment.

Data Sources

Noticing of students' thinking about fractions. The PSTs' noticing of students' thinking is measured by a noticing activity where they watch a short video and then respond to four prompts via an online survey. The intention of the video is to simulate what a teacher would experience while listening to students collaboratively working on a task. The video showed two second graders working on a fraction subtraction problem using pattern blocks, while one of the students explained her reasoning at a conceptual level by detailing her thought process for her partner while using pattern blocks to visually represent her thinking. This clip was chosen since videos that demonstrate students' reasoning at a conceptual level result in more substantive considerations of students' mathematical thinking (Sherin, Linsenmeier, & van Es, 2009).

Following the work of Jacobs et al. (2010) and Fisher et al. (2014), the journaling prompts consist of three categories that correspond with the three components of noticing of students' mathematical thinking: attending, understanding, and responding. The prompts are: (1) *Describe what the student did in response to the problem presented.* (2) *Describe what you learned about the student's understanding of mathematics from their response.* (3) *If the student were in your classroom, what question(s) might you pose next? What would you hope to accomplish by asking these questions?*

Mathematical Knowledge for Teaching. This study uses a subset of the Learning Mathematics for Teaching (LMT) instrument to measure PSTs' MKT (Hill, Schilling & Ball, 2004). Items in the LMT address common and specialized content knowledge, asking teachers to solve mathematical problems, evaluate student solutions, and represent content to students. Since the study focuses on fractions, I created an instrument of 23 items by selecting questions that specifically require the use of fractions from both forms of the LMT rational number modules.

Beliefs Likert Scale. The survey given to PSTs' at the start and end of the semester to measure their beliefs about the role of students' thinking in math teaching combined 16 items from Beswick (2005) and 18 items from the Mathematics Beliefs Scale (Fennema, Carpenter, & Loef, 1990). Through factors analysis, the 34-item scale was pared down to 18 items ($\alpha = .83$)

that consist of five factors: what teachers should tell students, the role of student thinking in math teaching, the role of productive struggle, the importance of understanding students' errors, and the role of student justification in the math classroom. The mean of the items within each factor was used as each PSTs' score for that factor.

Analysis

PSTs' noticing was analyzed according to the three components of noticing. All coding was binary, with a 1 indicating that the response connected to the mathematical thinking of the student in the video and a 0 indicating that the PST did not connect their answer to the student's thinking. The responding score considered both the question posed by the PSTs and their reasoning for asking that question. The score from the three components were summed to create an overall noticing score.

The measures were administered at the beginning and end of the semester. Using SPSS, I performed linear regression analysis to determine how the change in predictors (LMT, beliefs, and section) related to PSTs' noticing score at the end of the semester. Given the results of the regression analysis, an independent samples T-Test was conducted to investigate how the focal and comparison sections differed.

Results

The linear regression model contains the following predictors: the change in LMT scores, the change in each of the five factors, noticing score at the start of the semester, and if the PST was in the focal section or not. Of all predictors, the only statistically significant factor is if the PST was in the focal section or not ($p = .011$). In order to amplify if there was any predictive power of the predictor variable to the final noticing score the regression was run six times with the following three predictors: if the PST was in the focal section or not, noticing score at the start of the semester (as a control), and the predictor of interest. The results of these regressions are in Table 1, demonstrating that none of the factors are statistically significant. In each individual model run in Table 1, the focal section predictor continues to be significant (with a $p < .005$), while the noticing score from the start of the semester is never significant.

Table 1: Regression Models Run with Focal Section as Control

Model	Variable	Std. Beta	t	Sig.
1	Change in LMT Score	.05	.503	.616
2	Change in Mean: *What Teachers Should Tell Students*	.109	1.052	.296
3	Change in Mean: *Role of Student Thinking in Math Teaching*	-.047	-.474	.637
4	Change in Mean: *Role of Productive Struggle*	.112	1.105	.272
5	Change in Mean: *Importance of Understanding Students' Errors*	.016	.158	.875
6	Change in Mean: *Role of Student Justification in Math Classrooms*	.002	.015	.988

An independent samples T-Test was run with all predictors to investigate how the two groups compared. Table 2 shows the only significant result when equal variances are assumed between the two groups is for the noticing score at the end of the semester and the change in noticing score over the semester. In regard to the PSTs' MKT and beliefs, the two groups are statistically similar.

Table 2: T-Test Results with Focal and Comparison Sections

Predictor	Focal Mean	Comp. Mean	Focal Std. Dev.	Comp. Std. Dev.	Focal Std. Error Mean	Comp. Std. Error Mean
Change in Noticing**	1.26	.4	.964	1.175	.201	.138
Post Noticing***	1.91	1.15	.848	.892	.177	.104
*Note: ** p < .01, ***p < .001*						

Discussion

The results from the regression analysis demonstrate that the only statistically significant predictor of the PSTs' noticing score at the end of the semester was if they were in the focal section or not. The predictors for knowledge and beliefs did not yield statically significant results. This does not mean that knowledge and beliefs had no impact on noticing, but the statistical analyses did not indicate a strong enough impact to yield statically significant results. The focal and comparison sections differed in two ways: the PSTs in the focal section participated in a noticing activity three additional times throughout the semester. They watched and discussed two additional video clips (different from the clip shown at the start and end of the semester) and conducted a video observation. All of these activities contained the same question prompts as those used to measure PSTs' noticing at the start and end of the semester. The results indicate that activities within the methods course that used real classroom video to "practice" noticing students' mathematical thinking impacted PSTs' noticing in a significant way.

PROSPECTIVE TEACHERS' USE OF CHIP MODEL

Nicole M. Wessman-Enzinger
George Fox University
nenzinger@georgefox.edu

Eileen Murray
Montclair State University
murrayei@mail.montclair.edu

Ten elementary and middle school prospective teachers (PTs) participated in clinical interviews where they modeled integer addition and subtraction number sentences with two-colored chips. The PTs constructed various models using the two-colored chips that both matched and did not match the number sentences presented to them. Although the prospective teachers sometimes created models that did not match the integer addition and subtraction number sentences, some recognized these inconsistencies. The results highlight spaces of PTs' accomplishments and struggles with using two-colored chips for certain integer number sentences. Implications of this study support facilitating PTs' construction of models and leveraging their thinking and uses of models in instruction.

Keywords: Teacher Education-Preservice, Number Concepts and Operations, Cognition

Understanding the ways that prospective teachers (PTs) reason is important so that we can leverage discourse and instructional experiences in teacher education. PTs use various manipulatives, such as the two-colored chips, as they engage in activities around the teaching and learning of integers. Yet, we know little about the ways PTs construct models for integer operations with two-colored chips. This research report highlights the results of an investigation that sought to make sense of the following research question:

> In what ways to elementary and middle school PTs use two-color chips to model integer addition and subtraction?

Conceptual Framework

The minus symbol has multiple meanings (i.e. unary, binary, opposite) that are often confounded (Bofferding, 2014; Vlassis, 2004, 2008). In fact, students often operate with the negative integers by simply omitting or "ignoring" the minus symbol and adding it later (e.g., Ayres, 2000; Bell, O'Brien, Shiu, 1980). Confounding the meaning of the symbol or omitting it all together will interfere with the ways that integer addition and subtraction is modeled with the chips.

Subtraction can be interpreted in two different ways, with take-away or distance (Selter, Prediger, Nührenbörger & Hußmann, 2012). The take-away interpretation of subtraction aligns best with chip models, as discrete objects are used and may be removed; and distance interpretations align with other models, such as number lines. The use of a subtraction model does not automatically insure success; knowing how the model is connected to the mathematics is what is needed to develop conceptual understanding (e.g., Kamii, Lewis, & Kirkland, 2001).

In this study, we focus on a subset of models (Van Den Heuvel-Panhuizen, 2003), *manipulatives*, and specifically the use of a two-colored chips. The use of two-colored chips is often referenced as the chip model, but these manipulatives can be used in differing ways (e.g., Murray, in press). Thus, there are many chip models, and we explore the various different models that PTs may construct in this study.

Using two-colored chips to model integer addition and subtraction has both affordances and constraints, or places where the model breaks down (Murray, in press). No model is vigourous enough to support all problem types (Vig, Murray, & Star, 2014). Integer number sentences like 3 – 5 = ▢, for example, presents a constraint in using two-colored chips. If one starts with 3 chips of one color, representing the positive 3, and tries to remove five chips of the same color, this does not work. Consequently, the model needs to be adapted—such as adding in "zero pairs" to the model (i.e., representing 1 + -1 with two different colored chips).

Consistency refers to how things like contextual situations match number sentences (Wessman-Enzinger, in press). Similarly, consistency can also refer to how a model matches a number sentence. The use of discrete objects for 2 + 3 may not necessarily match 2 – -3. Attention to PTs' consistency as they use two-colored chips to model integer addition and subtraction will highlight potential affordances and hindrances of models (Vig et al., 2014).

Methods

Ten elementary and middle school PTs volunteered to participate in structured, task-based interviews (Goldin, 2000). The PTs participated in the study as freshmen, during their first mathematics content course for teaching elementary and middle school mathematics, prior to using two-colored chips in their university coursework.

The PTs worked in pairs within the interviews to better elicit natural discourse about tasks. Although in pairs, each PT received the number sentence on a single sheet of paper, with colored markers, and two-colored chips (i.e., two-sided red and yellow chips). The following number sentences were given to the PTs: -5 + 9 = ▢, 1 – 5 = ▢, 7 + -2 = ▢, -5 – 4 = ▢, 2 – -3 = ▢, -8 – -3 = ▢, -5 – -7 = ▢. The PTs solved each integer addition or subtraction number sentence any way they wanted, modeled the number sentence with a number line, and then modeled the number sentence with two-colored chips. This research brief focuses on the ways PTs used the two-colored chip models for integer addition and subtraction.

Results

The results are described in two parts: (a) ways that PTs used two-colored chip models that are *consistent* with the number sentences and (b) ways that PTs used two-colored chip models that are *inconsistent* with the number sentences.

Consistent Uses of Two-Colored Chips

Zero pairs. Half of the PTs consistently used zero pairs with the two-colored chips for the number sentences -5 + 9 = ▢ and 7 + -2 = ▢ in this study. Brooke and Sayoni, a pair of PTs, matched up two sets of chips. Brooke used 9 red chips and 5 yellow chips for -5 + 9 = ▢; Sayoni used 9 yellow chips and 5 red chips for -5 + 9 = ▢. Although they represented the -5 flexibly with either red or yellow chips, they paired the chips up similarly. Brooke stated, "I know these cancel out," pointing to the pairs of chips. And, Sayoni highlighted the solution, "I have these 4 left" after the canceled pairs.

Comparing two sets. PTs compared two sets of chips with -5 – -7 = ▢ only twice. Kaye compared two sets of chips for -5 – -7 = ▢. She constructed two rows, placing five red chips to represent -5 in one row and seven red chips to represents -7 in another row. Kaye reflected:

> I do not know how to show this in a way that universally makes sense … Since you are subtracting, this equal zero somehow (pulls away five pairs of red/red chips)...They are not negative, they are positive (points at the remaining two red chips), that's the part that I am stuck on.

As Kaye compared the two sets, she confounded zero pairs (1 + -1 = 0) with her reflection on how -1 – -1 = 0, which presented a challenge in determining how the solution she knew (-5 – -7 = 2) matched the remaining two red chips in her model. Although she confounded zero pairs, her comparison aligned to the number sentence.

Taking away from one set. The only consistent use of chip model with a take-away interpreation of subtraction included taking chips away from one set of chips for the number sentence -8 – -3 = ▢. Rochelle started with eight red chips and took away three red chips:

> You have the 8 negative chips. You are subtracting the negative three, so you are taking away three of the negatives (pulls away 3 red chips). And that leaves you with negative five.

Inconsistent Uses of Two-Colored Chips

Zero pairs. Each of the PTs used zero pairs, combining two different colored chips to represent additive inverses (i.e., 1 + -1 = 0). However, in doing so the PTs often changed the number sentences (e.g., changing 1 – 5 = ▢ to 1 + -5 = ▢). Crystal, for example, modeled 1 – 5 = ▢ with one yellow chip representing +1 and five red chips representing -5. She combined the chips, paired a red and yellow chip together, pulled the pair off to the side, and pointed to the four remaining red chips as the solution. Crystal, although she constructed this model for 1 – 5 = ▢, recognized that this model did not fit the original addition number sentence well: "one minus five is hard to do with the chip model because you are taking away from a smaller number."

Joining. Joining two sets of chips was a common strategy when PTs solved the number sentences -5 – 4 = ▢ and 2 – -3 = ▢. However, the PTs often changed these number sentences before modelling the chips with joining. In particular, the PTs changed -5 – 4 = ▢ to -5 + -4 = ▢ and 2 – -3 = ▢ to 2 + 3 = ▢. Kacee, for instance, modeled 2 – -3 = ▢ by using 2 red chips and 3 red chips. She joined these two chips, illustrating a solution of 5. Kacee, without prompting, shared: "If I did not already know it was five, I think it would be a lot harder to figure out what I am supposed to do with them [reference to the chips]." Although she recognized that that she did not think this was the best model to use with the chips, she did not provide an alternative model.

Taking away from one set. Starting with a set of chips of a singular color, the PTs modeled integer number sentences by taking away chips. For 1 – 5 = ▢, Jakob started with five red chips and took away one red chip—illustrating 5 – 1 = ▢ rather than 1 – 5 = ▢. Jakob referenced this take-away strategy while recognizing that his model did not incorporate subtraction. Even so, he did not offer an alternative model.

Flipping chips. PTs occasionally flipped chips as they used them. At times, this method occured as the PTs employed another strategy, and other times it stood alone. Kaye, flipped chips as a stand alone method for 2 – -3 = ▢: "If you were to add these, it would be negative. But since you are subtracting it, they're all like (and flips chips over to yellow)." Kaye started with 2 yellow chips and 3 red chips. She flipped the red chips to yellow. In some ways this matches 2 – -3 = ▢ in the sense that, her model matched the relationship between subtraction and adding the opposite (e.g., 2 – -3 = 2 + 3).

Concluding Remarks

Although the PTs' focus on procedures interfered with their ability to use models consistently (e.g., changing 2 – -3 = ▢ to 2 + 3 = ▢), the PTs often expressed unprompted recognition that their model did not match the number sentences. These types of observations have potential to be spaces where mathematics teacher educators can build on PTs' thinking, facilitating discussion about models and issues of consistency.

It is important for PTs to be consistent with number sentences and models; they need to connect the mathematics with the model (Kamii et al., 2001). Even so, when PTs provide an inconsistent model, mathematics teacher educators can leverage this as a way to encourage discussion. Given the challenges for children transitioning to models from whole number to integers, it seems likely these may be spaces that PTs will need to have discussions in their own classrooms in the future.

Letter-writing activities, in which pre-service teachers exchange written correspondence with K-12 students, have a rich history in mathematics education. The purpose of this research was to explore the affordances of letter-writing exchanges in the development of preservice K-8 teachers' understanding of mathematics and mathematical feedback processes. Analyzing formative feedback regarding a mathematical task at the level of the task, the processes used to analyze the task, and the self-regulatory mechanisms involved in these processes yielded interesting results. Among these were that exposure to different ways of thinking about a task were sufficient to elicit new thinking in participants, that a metacognitive awareness of the feedback cycle could prompt change in the manner that feedback was perceived, and that improving mathematical understanding is an incremental process that is not easily measured.

Keywords: Algebra and Algebraic Thinking, Instructional Activities and Practices, Mathematical Knowledge for Teaching, Teacher Education-Preservice,

Introduction and Purpose

Letter-writing activities, in which pre-service teachers (PSTs) exchange correspondence with K-12 students, have a rich and diverse history in mathematics education. In their earliest iterations, these projects served as diagnostic tools and pedagogical aids, providing PSTs the opportunity to examine K-12 students' mathematical thinking and evaluate their skills and attitudes towards the subject (Fennell, 1991; Phillips & Crespo, 1996). Later letter writing-projects shifted the focus to examine PSTs' learning, and provided a firm theoretical framing for these activities within the realm of the knowledge and beliefs needed for teaching mathematics (Crespo, 1998, 2003). More recent projects further developed this framework by considering the type of problems and cognitive demand of the tasks PSTs explored with the students (Crespo, 2003; Norton & Kastberg, 2012) and the nature of the feedback processes involved in these exchanges (Kastberg, Lischka, & Hillman, 2016). It is from this fertile heritage that we implemented a letter-writing project in which PSTs from four U.S. universities exchanged correspondence with one another around a shared, high-cognitive-demand task in order to evaluate the development of their mathematical understanding of the task and their ability to provide productive feedback.

The purpose of this research was to explore the affordances of this letter-writing exchange in the development of the PSTs' understanding of mathematics and mathematical feedback processes. Project participants across the four universities engaged in a shared mathematical task focused on algebraic reasoning and exchanged solutions with a partner from another university in the form of written letters. Upon receiving feedback from their partners, participants revised their written solutions, composed new letters, and engaged in a second feedback cycle. The artifacts of these exchanges, including participants' written descriptions of their formative thinking, feedback, responses to feedback, reflections on the feedback cycle, and summative analysis of the initial task supported the researchers in examining the relationships between participants' understanding of the mathematical task and the feedback cycle.

Research Perspective

Earlier letter-writing research provided four types of practical and theoretical perspective for our project. First, the research suggested a variety of pedagogical benefits for PSTs that justified the substantial time they committed to participate in the project. These benefits included practice with the assessment of mathematical thinking (Fennell, 1991), engagement in the feedback cycle (Kastberg, Lischka, & Hillman, 2016), and enjoyment of the activity as it offered them opportunities to test out their mathematical ideas, exposed them to new perspectives and ways of thinking regarding mathematics, and challenged their notions of the nature of productive mathematical exchanges (Crespo, 2003). Second, the research base highlighted shifts in PSTs' metacognitive thinking that could occur with appropriate implementation of the project. These shifts included a transition from directed, unproductive questions and commentary to responses that would examine and challenge their partners' unique ways of thinking based upon analysis of the work presented for the task (Crespo, 2003; Norton & Kastberg, 2012). Third, prior studies elaborated on the potential pitfalls of projects of this type and informed the design of our project. As forewarned in the literature, we encountered instances of participants blaming their peer's lack of effort for their own inability to engage in the feedback process, redirecting the peer's thinking to align with their own rather than building on the ideas presented in the writing, and a failure to offer actionable feedback regarding incorrect thinking for the task (Kastberg, Lischka, & Hillman, 2016; Norton & Kastberg, 2012). From these precedents, we were able to address these concerns both implicitly, in the form of prompts offered for our participants' written reflections regarding the feedback process, and explicitly via classroom instruction. These interventions helped to mitigate the negative impact of these factors to some degree. Finally, and most significantly, past research directed our attention to the importance of the nature of the formative feedback offered in letter-writing exchanges (Kastberg, Lischka, & Hillman, 2016) and the participant's reflections on these processes (Norton & Kastberg, 2012).

This focus on formative feedback and reflection established the theoretical framing for the current study. Hattie and Timperley's (2007) model of feedback as a means of reducing "discrepancies between current understandings and performance and a goal" (p. 86) comprised the central definition for evaluation of our participants' work, and the four levels of focus for feedback established in this model guided the initial thematic analysis of our participants' feedback and reflections. These levels include feedback focused on the project's mathematical task, the processes used to understand and record one's thinking about the task, the self-regulatory processes needed to engage with the task successfully, and evaluations of the individual completing the task. We worked under the assumption that feedback along the first three of these levels would offer opportunities for increased mathematical understanding of the task by shifting participant's attention to the productive aspects of their work (Kluger & DeNisi, 1996) while the final level would provide affective and emotional reinforcement for engaging with the task.

Methodology

The research was conducted across four universities with a mathematics teacher educator (MTE) at each institution supervising the process; the 187 participants in the study were K-8 preservice teachers in mathematics education courses. There were two classes of juniors from

University A (n = 56), a class of juniors and seniors from University B (n=16), three classes, primarily constituted of freshman, from University C (n = 81), and one class juniors and seniors at University D (n=34). All participants were given the same task: discover and explicitly describe patterns across the stages of a growing tile pattern (Foreman & Bennett, 1996).

Participants from different universities were paired with one another. For example, participant 1 from University A was paired with participant 2 from University B, with these participants completing the first draft of the task at the same time in the form of a letter to another unknown participant. These letters were collected by each MTE and shared with the other MTEs in a google drive folder so all four had access to participant responses. The MTEs then provided participant 1's letter to participant 2 and participant 2's letter to participant 1. The participants read each other's solution and provided feedback to help shape the mathematical precision and accuracy of the presented solution. Participants were provided with a rubric to focus their feedback on specific components of the solution. This feedback was shared with the original participant, following a similar exchange process facilitated by the MTEs to maintain anonymity among the participants, who had time to implement feedback and make revisions to their original solution. Feedback from the peer was elicited a second time, and participants had another chance to make changes in light of the feedback before submitting a final analysis of the task to their respective MTE. Throughout the exchanges, and again after the final task analysis, participants were asked to reflect on the processes of giving and receiving feedback in relation to the task. Critical cases were selected from each participating university, and thematically coded via the framework introduced earlier.

Results

These findings include preliminary results from student work at University B. The majority of participants at University B had rather thorough and mathematically appropriate initial drafts, and their work improved nominally throughout the process. A few participants produced initial drafts that needed much improvement, but after analyzing their first and final work along with the feedback, either there was limited improvement or no improvement could be linked directly to the feedback provided. While such results seem to indicate that the peer feedback process had limited impact, a closer look at the data sheds light on more nuanced ways the exchange contributed to participants' understanding. The exchanges of three participants are described below to highlight some of the impact of the letter writing activities.

Participant A's initial work was strong and the feedback she received was focused on aspects of both the task and the process used to solve it. Additionally, the correspondence introduced a new way of thinking about the pattern that considered the change in the number of tiles between each stage. Participant A reflected on this approach and made a connection to the first derivative of the explicit formula they had originally developed, even though this way of thinking was not provided in the exchange. This case demonstrated that exposure to different ways of thinking can promote a deepened reflection regarding the mathematics of the task.

Participant B's initial work involved a recursive pattern, which proved to be an ineffective approach to analyzing the task. However, the feedback she received was superficial and process based, without providing any concrete suggestions for improvement or description of the problem. Participant B, who had been seeking task-based feedback, realized before writing her second draft that the recursive nature of her approach was unproductive and chose a completely different path for the second draft. Although Participant B's reflection indicated that the feedback received in this peer exchanges was ineffectual in improving her mathematical understanding, she noted that the iterative nature of the feedback processes prompted her to think about the nature of feedback itself. More specifically, her reflections on the process indicated that she had identified characteristics of helpful feedback that would benefit her in the future.

Participant C's initial work consisted of a systematic and quantitative approach, but the relationships observed were not made in terms of the stage number of the pattern. Consequently, the participant was unable to write an explicit formula. The feedback she received targeted all three levels of the framework: task, process, and self-regulation, and was highly detailed. This prompted Participant C to see new features of the pattern that were better aligned with an explicit representation, however she was still unable to write a formula which captured these relationships. Nonetheless, she noted how the feedback was helpful in allowing her to describe this new way of thinking. Additionally, she commented on her need to state her thinking in a different way, perhaps one that would be "simpler for students to follow." Although the feedback process appeared to help this participant in understanding the nature of the task, only incremental gains were seen in her final task analysis. This incremental growth was not easily measured and could be entirely masked by examining her mathematical results in isolation.

Discussion

One benefit of peer feedback exchanged between participants from different universities is the honest nature of the feedback from an anonymous peer with similar professional goals. Without the pressure of direct relationships, participants who understood the need for it were better able to provide critical feedback. Additionally, participants from another university would often provide different perspectives on the task that spurred new ways of thinking. Our initial results identified two areas in which participants benefit from this intervention: 1) deepening their mathematical knowledge by looking at strategies they may not have initially considered, and 2) self-reported improvement in their self-efficacy regarding the task, their motivation to engage with the task, and their confidence in their results. Additionally, many participants commented on the need for increased precision when explaining their thinking or giving feedback, as both could be interpreted in unintended ways. Future analysis will seek to generalize the results noted here across the full sample and to identify other critical cases of the affordances of letter-writing exchanges for the development of preservice K-8 mathematics teachers' understanding of mathematics and mathematical feedback processes.

EXCHANGING DEFICIT FOR AFFORDANCE: DEVELOPING PRESERVICE TEACHERS' CAPACITY TO SEE EMERGENT BILINGUAL STUDENTS' RESOURCES

We present a Scholarship of Teaching and Learning (SoTL) research project study aimed at helping pre-service teachers to grasp the importance of their emergent bilingual students' bilingualism and cultural backgrounds as resources to serve them in apprehending mathematics instruction and explaining their mathematics to others.

Keywords: Teacher Education-Preservice, Teacher Knowledge, Equity and Diversity, Instructional Activities and Practices

Suppose that a teacher asked his elementary-aged students the simple question, "What is ten plus four?" How should the teacher evaluate the response of a student who claimed that "10 + 4 = 2"? There seems to be an error, and we might expect teachers to make the same assessment of the students' work at face value; the student was incorrect and needs remediation. But might she be correct? It is more difficult to see evidence of correctness. How might our evaluation change if, when asked about this solution, the student had explained that she had found this solution by looking at the clock? Withholding judgment and listening to the student leads us to perceive advanced mathematical reasoning (employing modular arithmetic) at play, where superficial assessment would fail to capture the understandings as well as resources that she had drawn upon to solve it.

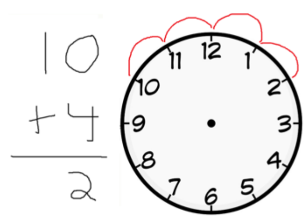

Figure 1. Ten plus four is two (mod 12)

This instance serves as an analogy for mathematics education research that has focused on issues of cultural and linguistic complexity: mathematics teachers and researchers may have been more prone to see inaccuracies than accuracies, and deficits than affordances, when considering students in the context of linguistic and cultural diversity. The research has sufficiently described educational achievement gaps with respect to language minority students (see Gutiérrez, 2008; and Moschkovich, 2002, for discussions), but only more recently has been moving away from investigating issues of equity in education through deficit lenses toward seeing students through affordance lenses, which movement may be made more difficult because of habitually negative evaluative mindsets in mathematics teaching. This paper reports brief findings from a Scholarship of Teaching and Learning (SoTL; Bishop-Clark & Dietz-Uhler, 2012) research project aimed at understanding how PSTs can be helped to perceive emergent bilingual students' learning of mathematics on the line between deficit and affordance perspectives, and in enabling them to see "difference not deficit" (Lewis, 2014) in emergent bilingual students.

Diversity Growth in US Classrooms and Theoretical Framework

Teachers in US schools are seeing an enrichment in racial and ethnic diversity in their classrooms (*Musu-Gillette et al., 2016*) and students' first languages are increasingly found to be other than English. For instance, in the last decade the percentage of students participating in English Language Learner (ELL) programs has steadily increased from 9.1 to 9.4 percent of all students (NCES, 2016) – a total of about 4.6 million students in the US. (The terms ELLs, English Learners (ELs), and, more recently, emergent bilinguals (EBs) have variously been used with respect to students whose first and often stronger languages are other than English. Although varying in connotations, they are used here synonymously.) In this paper we study an effort to help PSTs to be "well-prepared beginning teachers of mathematics", as the recent AMTE Standards for Preparing Teachers of Mathematics (2017) define them, by improving their ability to "recognize the difference between access to and advancement in mathematics learning and work to provide access and advancement for every student" (p. 21), especially in culturally and linguistically diverse environments. This study contributes to the recent work by others who have attended to the need of preparing PSTs for teaching diverse students (see for example, Gallivan, 2017; White et al., 2016; and Meskill, 2005), and also to the complexity of accounting for EBs in measures of educator effectiveness (Jones et al., 2013; Turkan et al., 2014).

The present study used Wilson's (2016) model of *pedagogical content knowledge for teaching mathematics to ELLs* (PCK-MELL) as a theoretical framework for the type of knowledge that we aimed to develop in our PSTs. This model posits knowledge for teaching mathematics to EBs as a subset of pedagogical content knowledge related to knowledge of students and knowledge of teaching within Ball, Thames, and Phelps's (2008) *mathematical knowledge for teaching* (MKT) model. We chose this framework, which was used in studies concerned with mathematics teachers' knowledge in relation to issues of linguistic diversity (Sorto et al., 2018), because it addresses not only the obstacles that emergent bilinguals can face in the classroom, but also the resources that such students draw upon as a result of their emerging bilingualism and non-dominant cultural backgrounds.

Method and Participants

The research method used for this SoTL study was an instructional intervention which we call the Teaching Emergent Bilinguals (TEB) Project that was based on the PCK-MELL framework. The intervention employed *challenge-based instruction* (CBI; Crown et al., 2012) by positioning PSTs as test-writers tasked with developing multiple-choice teacher licensure exam questions that could be used to ascertain whether aspiring teachers possessed a sufficient understanding of resources that emergent bilinguals bring to the learning of mathematics. A research question that guides this analysis is the following: within the constraints of the multiple-choice test-writing task, what resources do PSTs identify that EBs draw upon in specific mathematics classroom work and how do they operationalize these resources? The 52 participants in this study came from a large Hispanic Serving Institution (HSI) in the southwestern United States and greater than 90% of participants in this study were Latino/as, mostly female (>90%), all of whom were enrolled in mathematics courses as part of degree plans leading to teacher certification. PSTs in this study worked in groups of 2 or 3 students (25 groups in all), across two different class sections, and submitted their items and accompanying explanation documents via email to the course instructor.

Findings

As indicated above, the TEB project required PSTs to reason about the experiences of emergent bilingual students in the classroom, what linguistic and cultural (or other) resources they draw upon in English-taught mathematics classrooms, and to operationalize these resources in the form of multiple-choice teacher licensure exam items. Analysis of their items involved carefully reading their items, as well as supplemental explanations they had provided, and then forming categories of resources identified by students across all of their items and explanations. In this brief report, we present summary findings and also one example test item, selected because it exemplifies both one of the resources identified by PSTs as well as the way in which many students in this sample applied their own past experience to the task. Resources identified in PSTs' test items included the following:

- Bilingualism –general communicative ability in both languages with full or partially fluency
- Specific Spanish-English cognates: words with similar appearances and meanings in both languages
- Prior mathematical knowledge: familiarity with the mathematical topic or object
- Bilingual teachers
- Parents, friends, relatives that understand English
- Pictures and other visual displays as substitutes for words

An example item is the following.

Marilyn and Karina didn't know what to wear the following day to school. They both had the same number of possible combinations.

Pants/Shorts	Shirts
Blue Pants	Pink
Blue Pants	Red
Blue Pants	Yellow
Black Pants	Pink
Black Pants	Red
Black Pants	Yellow
Khaki Shorts	Pink
Khaki Shorts	Red
Khaki Shorts	Yellow

Marilyn: "Que me voy a poner?"

Karina: "Pos you can wear pantalones con una shirt de cualquier color que quieras."

Marilyn: "Pero esta haciendo calor afuera."

Karina: "Bueno you can also think of the posabilidad of wearing chores."

Marilyn: "Bueno, I have 2 pairs of pantalones, 1 short and 3 different colored shirts."

Karina: "Okay, entonces tenemos que hacer una table to show our possibilities."

Count the objects and use pictures to find the possible combinations.

Make a chart with all the possible combinations.

3 shirts
yellow, pink, red

2 pants
black, blue

What helped the EL's to figure out how to solve the problem?

A) Mathematical Terms

B) Their use of Bilingualism and peer work

C) Talking to the teacher about the problems they encountered

D) Looking for information in their math books.

Figure 2. An item indicating PSTs' observation of bilingualism as a resource to EBs

In this item the darker inserted box should represent the problem upon which the emergent bilingual students are working and the table should represent their written mathematical work.

Discussion

Figure 2 shows how one group of PSTs operationalized bilingualism as a resource for EBs. However, participants frequently experienced a considerable challenge in the task of identifying resources that emergent bilinguals use in the classroom, often asking us, "What are we supposed to do for the Resources part? We just can't think anything." On one hand, writing test items about teaching mathematics and not merely about mathematics was a challenging task for them. But when asked about obstacles that EBs might face, we observed that they could more readily generate lists of things that might cause difficulty for EBs than of EBs' resources. One explanation may be that, similar to the analogy that begins this paper, PSTs may be more prone to envision disability rather than capability when thinking about EB students. This paper has presented brief findings suggesting that the TEB intervention may promote PSTs' perceptions of the affordances of the bilingualism of their EB students in their future mathematics classrooms.

PROMOTING KNOWLEDGE INTEGRATION IN TEACHER PREPARATION

Matthew S. Winsor
Illinois State University
mwinsor@ilstu.edu

David D. Barker
Illinois State University
dbarker@ilstu.edu

J. Vince Kirwan
Kennesaw State University
jkirwan@kennesaw.edu

In this study, we investigated the opportunities secondary pre-service teachers (PSTs) had to integrate their knowledge of mathematics, learners, and pedagogy in a methods and content course taught in tandem. In particular, we describe and report on the instructional moves associated with this potential knowledge integration. Implications for pre-service teacher education and directions for further research will be provided.

Keywords: Teacher Knowledge, Teacher Education-Preservice

Secondary mathematics teachers must develop a thorough and connected understanding of mathematics (M), pedagogy (P), and learners (L) in order to plan effective lessons, implement mathematical tasks, and interpret student thinking. Unfortunately, pre-service secondary mathematics teachers (PSTs) may not have the opportunity to connect their knowledge of mathematics, pedagogy, and learners. The traditional structure of teacher preparation programs often delivers pedagogy and content in different departments on campus, leaving it up to PSTs to integrate their fragmented knowledge (Ball, 2000).

To address the challenge of promoting connections between PSTs' knowledge of content, pedagogy, and learners, we investigated the opportunities for knowledge integration in a methods and a content course for secondary pre-service teachers (PSTs) taught in tandem. This paper will describe some preliminary findings for the following research questions: What instructional moves appeared to promote knowledge integration in a methods and content course for secondary PSTs?

Theoretical Foundation

For this study, we define *knowledge integration* as the coordinated use of multiple knowledge types in order to reflect on, or make, instructional decisions. Bishop and Whitefield (1972) proposed that teacher decisions are made using a framework or schema. The main operation of a schema is to store knowledge through a network of connected pieces of knowledge called "elements" (Marshall, 1995, p. 43). The more connections that exist within a schema, the more useful the schema will be. Hence, the process of knowledge integration leads to the development of a more robust schema, resulting in the potential for more informed instructional decisions. The knowledge types used in this study are defined as follows:

Knowledge of Mathematics (M): knowledge regarding the mathematical concept(s) related to the content under investigation. Includes the connections and relationships among ideas, the way(s) and mean(s) of justifying and proving these ideas, and conversations focused on mathematics and reasoning about the mathematical topic.

Knowledge of Pedagogy (P): knowledge regarding the tasks, curriculum, instructional goal(s), or questions used to further the lesson. Includes comments centered on the lesson implementation or decision-making regarding the flow of the lesson.

Knowledge of Learners (L): knowledge regarding student thinking. Includes observed as well as anticipated student thinking, conversations about student characteristics, habits, or misunderstandings.

Our definitions of knowledge of mathematics, learners, and pedagogy are related to other models of teacher knowledge, such as mathematical knowledge for teaching (MKT) (Hill, Ball, & Shilling, 2008) or pedagogical content knowledge (Shulman, 1987). However, the definitions in this study are broader in scope, as we are focused more on the *interactions* among these knowledge sets (i.e. knowledge integration). Our study seeks to uncover instructional actions that promote knowledge integration among PSTs.

Methods

To answer our research question, field notes were collected for every session of a senior-level secondary methods and capstone content course at a teacher preparation program in the Midwest. The content and methods courses were taught in tandem, with the same set of students. The field notes were initially read to identify individual episodes—sections of the transcript centered on a single idea. Following the identification of episodes, the above definitions were then applied to code all episodes. If multiple forms of knowledge were used during a single episode, we defined this to be an example of potential knowledge integration. For instance, if an episode contained both M and L statements, we identified this as an opportunity for PSTs to integrate their knowledge of M and L. We note that evidence of multiple knowledge types does not ensure knowledge integration, only that the potential of knowledge integration was present. Our next step in analysis was to investigate the instructional moves that appeared to promote this potential knowledge integration. We applied open coding to develop categories for these different instructional moves. Discrepancies in coding were discussed by the research team, and definitions and categories adjusted, until all disagreements were resolved.

Findings

From the field notes, we identified 405 different episodes in the content course and 273 episodes in the methods course. Table 1 displays the number of episodes that contained evidence of the different knowledge combinations. For instance, the 26 in the last column for the content course indicates there were 26 episodes in the content course where the knowledge of mathematics, learners, and pedagogy were exhibited.

Table 1: Combinations of Knowledge Used in Episodes From Both Courses

Course	M	L	P	M-L	M-P	L-P	M-L-P
Content	265	4	18	41	32	19	26
Methods	4	10	92	1	17	135	14

Table 2 provides the definitions for several of the categories of instructional moves identified through our open coding process. This list includes the most common instructional strategies used in episodes with the potential for knowledge integration.

Table 2: Definitions of Categories

Reflecting on Instruction: The teacher educator reflects, has the PSTs reflect, or PSTs organically reflect on the instruction in a course. The conversation is focused on the pedagogical moves, or their justification, associated with this observed teaching experience.
Reflecting on a Shared Learning Experience: PSTs reflect on how a set of tasks or activities affected them from the perspective of the learner. The teacher educator or the PSTs can initiate this reflection.

Development of a Pedagogical Product: The teacher educator asks the PSTs to develop or modify a pedagogical product. (e.g., excerpt of lesson plan, assessment, task, lesson objective, classroom norms or rules), or PSTs discuss the process of developing a pedagogical product.
Evaluation/Critique of Pedagogical Products: The teacher educator has PSTs evaluate/critique a provided pedagogical product (e.g., excerpt of lesson plan, assessment, task, etc.). PSTs do not create the pedagogical product being evaluated.
Focus on High School Student Thinking: The teacher educator considers, has the PSTs to consider, or PSTs organically consider how a ***high school student*** would think about a particular mathematics topic.
Discussion of a Daily Topic: The teacher educator has the PSTs discuss a reading or daily topic in a course.

Table 3 provides the distribution of instructional moves for each knowledge combination in both the content and methods course. For example, the 14 in the first row indicates there were 14 episodes in the content course where reflecting on instruction resulted in the coordinated use of mathematics and pedagogy.

Table 3: Distribution of Instructional Moves

	Content				Methods			
Category	ML	MP	LP	MLP	ML	MP	LP	MLP
Reflecting on Instruction	0	14	3	6	0	1	45	2
Reflecting on a Shared Learning Experience	10	0	0	2	0	1	4	4
Development of a Pedagogical Product	0	2	2	9	0	7	11	4
Evaluation/Critique of Pedagogical Products	0	0	1	1	0	2	7	3
Focus on High School Student Thinking	12	1	2	6	0	0	0	2
Discussion of a Daily Topic	2	0	5	0	1	0	55	0

We note that the instructional moves identified above may not be the only moves that promote integration, these were the instructional moves used by these particular instructors that promoted potential integration.

The development of a pedagogical product appeared to stimulate the widest variety of knowledge integration, independent of the course. Moreover, episodes within this category possessed the largest frequency of knowledge integration involving all three knowledge types. When a teacher develops a pedagogical product, there is a need to draw upon mathematics, and to consider the effect on learners, when making these important decisions. It is interesting to note that we had three categories related to pedagogical products—development, enactment, and evaluation/critique. Of these three categories the development of a pedagogical product resulted in the most knowledge integration, enactment of a pedagogical product resulted in the least.

Before conducting this research, one of the main tools employed in the methods course was to provide PSTs with readings to be discussed during the next class. These discussions focused on how PSTs believed the ideas in the articles related to their teaching and future students. We identified 55 episodes in the methods course where potential LP integration took place as a result of discussing a daily topic. Unfortunately, episodes that include integration with M were not present, with the exception of a single ML episode. This finding has led to the realization that we need to provide opportunities for our PSTs to apply these pedagogical ideas to specific mathematical contexts, which could be done using instructional moves such as development of a pedagogical product. This finding aligns with Steele and Hillen's (2012) design principles for a content-focused methods course.

Reflecting on instruction promoted knowledge integration in both the content and methods course. In the content course the main type of potential integration was MP and in the methods course it was LP. Taking the time to reflect on and process experiences obtained while observing others teach (the instructor in the content course and clinical teachers in the methods course) appeared to help PSTs integrate their knowledge.

Discussion and Implications

Examining one's own practice is exciting and terrifying at the same time. We often believe that the activities and tools used in teaching methods and content courses are tried and true and lead to expert teachers leaving our universities to share mathematics with the youth of the world. Analyzing our teacher preparation practice through the lens of knowledge integration has led to some surprising results that will have an impact on our program in years to come. So far, the data in our study point to a mixed review of effectiveness in promoting knowledge integration. On the one hand, having students create pedagogical objects (e.g., lesson plans, tasks, effective questions, etc.) seems to be quite effective at promoting knowledge integration. On the other hand, having students read and respond to articles, without additional activities to apply the concepts, seems to do little to promote knowledge integration in PSTs. As we continue to analyze the data we will continue to refine our list of effective teaching actions that secondary mathematics teacher educators can use to promote knowledge integration. Our next step will be to further incorporate these strategies into our program, and hopefully programs at other universities, to continue to push towards our goal of promoting knowledge integration.

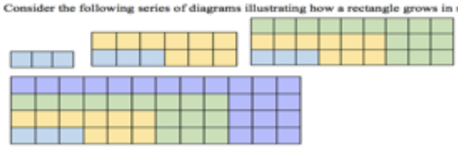
PRESERVICE TEACHERS' USE AND CONNECTIONS OF REPRESENTATIONS OF QUADRATIC FUNCTION IN SOLVING AND PLANNING TO TEACH

<u>Nigar Altindis</u>
Syracuse University
naltindi@syr.edu

<u>Nicole L. Fonger</u>
Syracuse University
nfonger@syr.edu

This research was conducted in response to an enduring challenge of supporting preservice teachers (PT) to learn about teaching mathematics from a conceptually oriented approach. We situate this work as an inquiry into how PTs use representations in learning and planning to teach. In prior work, numerical, graphical, tabular and verbal representations strengthened students' sense-making through creating and flexibly moving among representations (Doorman et al., 2012; Lobato, et al., 2012). Less is known about how such understandings influence teachers' plans for instruction. The research questions guiding our inquiry are: How do PT use and connect representations to reason about rate of change of quadratic functions?; and What trace is observed from PT representational activity to their planning for teaching? Participants were five high school PT in the final semester of their program. We conducted a 60-min. audio-recorded task-based interview with each PT. We curated four quadratic function tasks set in a rate of change context (e.g., see Figure 1). We asked PT to pick one task to solve, and to solve it in more than one way. We prompted PT to think aloud and clarify meanings (e.g. "Did the graph help you to answer the question?"). Both researchers debriefed after each interview on what we noticed and wondered. We share initial results from analyses of each interview.

Consider the following series of diagrams illustrating how a rectangle grows in several iterations.



This remote-controlled car is continually speeding up. The table shows the total distance the car has traveled after different amounts of time.

How far will the car have traveled after 14 minutes? Is the car accelerating? What is the acceleration?

Total Time (minutes)	**Total Distance Traveled** (feet)
0	0
2	2
4	8
6	18
8	32

Figure 1. Rate of change of quadratic function tasks (from Ellis (2011); Lobato et al. (2012)).

Initial analysis revealed PT were explicit about the nature of the growth in the dependent quantity (e.g., length or speed), and independent quantity (e.g, area or time) and were able to identify constant rate of rate of change in tables, but less explicit in graphical representations. We observed little evidence of PT using representations to connect to meanings of quadratic function as modeling constant rate of rate of change in linked quantities (as advocated by Ellis, 2011). We also found a strong trace from PT use of representations for their own problem solving to their planning for instruction. For example, Claire said "So if my students are like me, I'm a definitely need to see colors … 'cause it was hard to see the groups of three with just all this gray". Next steps will focus on elaborating an empirically based theoretical framework to understand observed trace from PT own problem solving to their plans for instruction.

PRACTICING TEACHERS PERCEPTIONS OF CONNECTIONS TO KNOWLEDGE AND SKILLS LEARNED IN THEIR TEACHER PREPARATION PROGRAM

Brian Bowen
West Chester University
bbowen@wcupa.edu

Keywords: Teacher Education-Preservice, Teacher Knowledge

Research on the preparation of mathematics teachers has provided insight into issues such as specialized content knowledge for teaching (Hill, Schilling, & Ball, 2004), understanding of ways in which students learn (Ball & Forzani, 2011) and social aspects of classroom culture (Gutiérrez, 2013). AMTE has integrated this research into their publication *The Standards for Preparing Mathematics Teachers* (AMTE, 2017). The publication of this document serves as an impetus for teacher educators to reflect on the ways in which their own teacher preparation programs can grow to better serve their students.

Previous research has examined the effectiveness of teacher preparation programs through comparisons of outcomes such as student test scores and professional licensure exams (Boyd et.al., 2009). More recent efforts have focused on examining the connections between the knowledge gained by pre-service teachers in their preparation program and the application of this knowledge after becoming practicing teachers (Morris & Hiebert, 2017). Results of their work suggests that mathematics teacher educators must carefully choose the "small sets of knowledge and skills that matter most for beginning teachers" (Morris & Hiebert, p.555).

The purpose of this study was to better understand the knowledge and skills related to teaching of mathematics in-service teachers perceive as important for beginning teachers and what knowledge from their pre-service preparation they were able to apply in their instruction. Data was collected from practicing elementary and middle grades teachers (n=101) who received their undergraduate preparation within the past eight years from a university in the Northeastern United States. Participants completed a questionnaire that included Likert and short answer questions. Results suggested that there were specific content (e.g., fractions and geometry) and learning experiences (exploring multiple approaches to solving problems) that participants associated with supporting their current teaching practice. However, responses also suggested a pattern in which participants perceived a lack of preparation (knowledge of curriculums). Participants provided suggestions on learning experiences related to knowledge and skills needed to teach mathematics effectively that would benefit future pre-service teachers.

ELEMENTARY PRESERVICE TEACHERS BELIEFS RELATED TO MATHEMATICS

Jennifer Cribbs
Oklahoma State University
jennifer.cribbs@okstate.edu

John Weaver
Oklahoma State University
john.weaver@okstate.edu

Adrienne Sanogo
Oklahoma State University
adrienne.redmond@okstate.edu

Introduction

The purpose of this study is to understand the relationship between mathematics related affective measures, including professional mathematics identity, mathematics identity, mathematics mindset, mathematics anxiety, teaching self-efficacy, and beliefs about teaching and learning mathematics. In addition, this study explored the impact of two different field experience implementation techniques to determine whether either resulted in a change in beliefs over the course of a semester. The following research questions were used to guide this study: 1) are elementary preservice teachers' self-perceptions and beliefs about mathematics and teaching correlated and 2) do elementary preservice teachers self-perceptions and beliefs about mathematics and teaching differ based on different field experience models as part of their mathematics methods course?

Methods

Data were collected using a pre- and post-survey of elementary preservice teachers (EPT) in the fall of 2017 at one university in the Mid-west region of the United States. A total of 70 EPTs in four different sections of an intermediate mathematics methods course participated in the study. In addition to demographic information, the survey included items to measure professional (teacher) mathematics identity, mathematics identity, mathematics mindset, mathematics anxiety and teacher self-efficacy. Additionally, EPTs were asked to complete an online self-assessment to determine where EPTs' beliefs fell in terms of a student-centered versus teacher-centered educational philosophy.

Results

Using Pearson's correlation test, each of the mathematics constructs were found to be significantly correlated with each other except teacher self-efficacy with mathematics identity and mathematics anxiety. In order to address research question 2, a series of t-tests were conducted with the post-survey data, finding that no significant differences existed between the immersive and traditional field-based groups of EPTs.

Discussion

Results from this study indicate that many of the mathematics-related constructs are significantly correlated with one another. However, some of the variables are more highly correlated than others, such as professional mathematics identity with mathematics identity as well as professional mathematics identity and mathematics identity with mathematics anxiety. Conversely, teaching self-efficacy was either weakly correlated or not correlated with the constructs measured. Additionally, mathematics teaching philosophy was only weakly correlated with mathematics mindset. When addressing the second research question, no significant differences were found between the groups. If the goal is to assist students in developing more positive beliefs related to mathematics and teaching mathematics, the immersive versus traditional program investigated in this study did not result in significant change. While much is gained by participating in methods courses and field experiences, longer exposure to these, or similar experiences, may be needed to significantly affect beliefs and self-perceptions.

ELEMENTARY PRESERVICE TEACHERS WHOLE-CLASS INSTRUCTIONAL DECISION MAKING

Lara K. Dick
Bucknell University
lara.dick@bucknell.edu

Melissa M. Soto
San Diego State University
melissa.soto@sdsu.edu

Mollie H. Appelgate
Iowa State University
mollie@iastate.edu

Dittika Gupta
Midwestern State University
dittika.gupta@mwsu.edu

The purpose of this research study is to understand how PST's analysis of individual student written work relates to PSTs' whole class instructional decision making (Jacobs et al., 2010). For this study, PSTs at four different institutions in four different states, participated in a multi-digit multiplication module designed with a goal of developing PSTs' skill of making whole class instructional decisions based on analysis of a set of individual students' written work taken as representative of a whole class. The research question for this study is: How does PSTs' professional noticing of individual student work samples relate to their whole class instructional decision making?

Keywords: Professional Noticing, Student Work Analysis, Instructional Decision Making

Methodology

Participants were 68 elementary PSTs enrolled in a mathematics methods or content course at four different institutions in the U.S.; class sizes ranged from 10 to 30 students. PSTs were either enrolled in a four-year elementary education program or in a post-baccalaureate elementary credential program. In each course, participants were taught a professional noticing module focused on children's solution strategies for multiplication. For this study, we report on a portion of the module in which PSTs professionally noticed five individual student work samples and synthesized their noticing to make whole class instructional decisions.

PST responses were scored using a 4-point scale analytical rubric that was developed by the researchers and reliability was verified using the *Flesis Kappa* statistical measure (Landis & Koch, 1977). We then determined the Kendall's tau coefficient to measure the ordinal association between the two mean scores.

Preliminary Results and Implications

We are in the midst of scoring all PST noticing rubrics, thus our analysis is of a preliminary nature. Current results show that the more robust the PSTs' professional noticing of individual student work, more robust their whole class instructional next steps. Since making instructional decisions based on students' mathematical thinking is a difficult skill to develop, providing PSTs with opportunities to analyze sets of student work samples that can be considered representative of a whole class, and thus support all students, is recommended.

A RESEARCH EXPERIENCES FOR UNDERGRADUATES PROGRAM: PREPARING FUTURE RESEARCHERS IN STEM EDUCATION

Molly H. Fisher
University of Kentucky
molly.fisher@uky.edu

Jennifer Wilhelm
University of Kentucky
jennifer.wilhelm@uky.edu

Introduction and Research Questions

Our Research Experiences for Undergraduates (REU) project has exposed pre-service K-12 teachers to timely problems involving STEM teaching and learning through original research conducted with eight STEM Education faculty mentors. At this time, 23 undergraduate Fellows have fully completed the academic-year program. Previous research has shown that undergraduate research programs can allow students to make a more educated decision regarding the pursuit of a graduate degree (Willis, Krueger, & Kendrick, 2013). Our REU project's main objective for pre-service teachers was to instill an appreciation of the interplay between society, education, and research. This study aimed to answer the following questions: (1) To what extent can undergraduate STEM Fellows' knowledge and confidence in STEM Education research change through participation in an intensive nine-month research program? and (2) What research products and career trajectories will result from REU Fellows' participation in our REU program?

Design, Analysis, and Findings

This research employed a mixed methods approach (Creswell & Plano Clark, 2007). Quantitative data included administering a pre/post survey (Kardash, 2000) concerning undergraduate research to determine Fellows' research expectations, familiarity with research literature, and ability to conduct statistical analyses. Qualitative data was comprised of Fellows' pre-, mid-, and post-evaluation interviews and their final research papers and presentations. Using a two-tailed t-test to analyze the results of the survey, we discovered significant growth in the Fellows' ($n = 22$) confidence levels in studying, conducting, and analyzing research ($t(21) = -4.488, p < .001$). This significant growth was also echoed in their interviews with the program evaluator. Further, our findings showed Fellows entered the program with confidence in analyzing literature, but still needed improvement in the areas of designing their own research projects and performing statistical analyses of their data. Fellows believed this program would greatly increase their abilities to conduct research and write manuscripts for publication. At the end of their nine-month research experiences, Fellows stated they felt they had gained expertise in coding and analyzing data, conducting clinical interviews, using technology, writing, and presenting, but most frequently noted their increase of interpersonal skills and collaborating with peers. Additionally, most of the Fellows still planned to work as a teacher at the K-12 level, but the experience had helped them gain deep pedagogical knowledge and strategies that could be integrated into their future teaching.

ELEMENTARY PRE-SERVICE TEACHERS' USE OF RESOURCES TO MAKE SENSE OF CURRICULAR PRESENTATIONS OF PROOF

Taren Going
Michigan State University
goingtar@msu.edu

Keywords: Reasoning and Proof, Teacher Education – Preservice, Curriculum

Because of the important role that proof plays in mathematical learning and sense-making (Yackel & Hanna, 2003), mathematical reform documents have called for proof to be central to all levels of schooling (e.g. NGA & CCSSO, 2010). Considering this at the elementary level, what teachers know about proof and how they have experience the process of proving will affect how they promote (or don't promote) proof in their classrooms (Stylianides & Ball, 2008). As such the nature of learning opportunities around proof and proving for elementary pre-service teachers (EPSTs) are important to consider. Some of the only such opportunities take place in mathematics content courses for EPSTs and the associated textbooks. In these texts EPSTs are dominantly given the opportunity to examine others' completed proofs, but there are many instances where informal or exploratory resources are connected to a completed proof (McCrory & Stylianides, 2014), which can offer increased insight into why the proof is true (Weber, 2005).

My research is guided by the questions: 1) *How do EPSTs use resources from in-text explorations of the proving process as they make sense of written proofs?* and 2) *To what extent are there connections between how EPSTs interpret particular resources as they read proofs and how they use those resources as they prove?* This poster will present findings from analysis grounded in data from interviews and written work of EPSTs as they engaged in making sense of two curricular presentations of proof.

EPSTs' proof understandings have been an "enduring challenge" in the field, yet few studies examine the process of proving and understanding proofs rather than simply the product. To better understand this process, my finding report on the types of in-text resources (e.g. definitions, diagrams, written descriptions of proof approach) EPSTs utilize as they make sense of written proofs and how EPSTs connect exploratory resources to written proofs. My findings also address parallels between the processes of reading proofs and proving. Through these parallels, this work has implications to better understand EPSTs' current learning opportunities around proof and enrich them through informing curriculum work and teaching experiments.

PRESERVICE TEACHERS' RESPONSIVENESS TO STUDENT MATHEMATICAL THINKING IN REHEARSALS OF INSTRUCTIONAL PRACTICES

Duane Graysay
Syracuse University
dtgraysa@syr.edu

Benjamin L. Freeburn
University of Kentucky
byf5045@gmail.com

Rationale

A current trend in mathematics teacher education is to support preservice teachers (PTs) to develop complex mathematics teaching practice by identifying core practices and by creating opportunities for PTs to enact, to reflect, and to investigate those practices (Grossman, Hammerness, & McDonald, 2009). Research-supported core practices for mathematics teaching include *posing purposeful questions* and *eliciting and using evidence of student thinking* (NCTM, 2014). An approach to developing PTs' practices is to rehearse core practices within interactions that approximate classroom instruction. It is important to attend to the extent to which PTs coordinate these practices. We investigate the question: How do PTs respond to student thinking while rehearsing the practice of posing purposeful questions?

Method

We analyzed video of 12 secondary mathematics PTs' engagement in three rehearsals of the practice of posing purposeful questions. In Rehearsal 1, PTs worked in pairs in interaction with one simulated student. In Rehearsal 2, PTs worked individually to interact with a pair of simulated students. In Rehearsal 3, PTs worked individually with a small group of peers. Using the Teacher Response Coding Scheme (TRC, Peterson et al., 2017), we coded each PT response to student thinking for the Actor who is invited to consider an instance, the Move represented by the response, the extent to which students' actions are explicitly referenced, the extent to which student ideas are central to the response, and the extent to which the response connects to a related mathematical point (Peterson et al., 2017). We searched for patterns among the nature of the communication moves, for the extent to which the moves incorporated student thinking, and for whether the moves yielded explicit statements of student thinking.

Results

Our ongoing analysis suggests that posing questions that elicited evidence of student thinking and that built on student thinking were challenging for PTs. Student statements were not always explicit, and PTs' questioning did not necessarily help to draw out clarifying information. Further, relationships between the teacher's response and the student's thinking were often implicit or could not be easily inferred based on the teacher statement. An implication is that the development of questioning as a routine must be further supported by helping PTs to attend to the quality of the information that is elicited and to the clarity and directness of their responses.

INSTRUCTIONAL STRATGIES USED TO TEACH REASONING AND PROOF IN SECONDARY TEACHER EDUCATION PROGRAMS

Jia He
Augusta University
jhe@augusta.edu

Tuyin An
Georgia Southern University
tan@georgiasouthern.edu

Keywords: Reasoning and Proof, Teacher Education-Preservice

Despite the importance of proof, a considerable body of research suggests that many secondary school students face challenges in constructing or understanding proofs (e.g., Knuth, Choppin, & Bieda, 2009). Some pre-service secondary school teachers are confused about the process of constructing, evaluating, or understanding mathematical proofs (Knuth, 2002). Teacher preparation program accreditation agencies such as the Conference Board of the Mathematical Sciences (2012) recommend that preservice teachers engage in different types of proof related reasoning. This raises the question: "What opportunities do pre-service secondary teachers have to develop their knowledge of reasoning and proof?" Yackel & Cobb (1996) suggests the importance of the way in which mathematical ideas and process are conveyed during the instruction. Thus, in this study, we are interested in "What teaching strategies do instructors use to support pre-service secondary teachers' learning of mathematical ideas and processes related to proof?"

The study was conducted at secondary mathematics teacher preparation programs in three contextually different universities. Data include instructor interviews of five required mathematics or mathematics education courses at each university. Each interview was audio-recorded and transcribed. Three researchers iteratively coded the data and resolved discrepancy.

We developed a framework to capture instructional strategies. Our framework includes proof specific teaching strategies and general teaching strategies. We found variations in terms of the strategies used among three universities. We also found that a majority of instances of proof specifics strategies involve engaging students. However, half of the instances of general teaching strategies were instructors' sole efforts without engaging students. We also noticed that more instructional strategies, both proof specific teaching strategies and general teaching strategies, were reported in mathematics courses than in mathematics education courses.

This work has implications for the current learning opportunities for future teachers. It offers insights on detailed differences between teacher education programs. It informs changes that need to happen in teacher education programs.

TRANSFORMING LEARNING THEORY: A LENS TO LOOK AT MATHEMATICS COURSES FOR PREPARING FUTURE TEACHERS

Kim Johnson
West Chester University of Pennsylvania
kjohnson2@wcupa.edu

Dana Olanoff
Widener University
dolanoff@widener.edu

Keywords: Learning Theory, Teacher Education-Preservice, Metacognition

Research has shown that prospective teachers (PTs) enter their mathematics content courses with procedural understandings of mathematics (e.g. Thanheiser et al., 2014). However, in their work as teachers, they will be required to know and understand more than just *how* to solve mathematics problems (AMTE, 2017). Teachers should possess a “robust knowledge of the mathematical and statistical concepts that underlie what they encounter in teaching.”(AMTE, 2017, p. 6).

Additionally, PTs often believe that they already know the elementary mathematics that they will need to teach (Thanheiser, 2018). Therefore, it is the job of mathematics teacher educators (MTEs) to help PTs see the need for, and develop the specialized mathematics content knowledge that they will need to use in their work as teachers. We suggest that transformative learning theory (TLT; Mezirow, 1991) provides a model through which MTEs can help PTs move from shallow procedural understandings to conceptual understanding with deeper procedural understandings as a base.

We present a 4-step cycle based on TLT: Disorienting Dilemma; Critical Reflection; Rational Dialogue; Action. A disorienting dilemma involves a task where PTs’ preconceived understandings are challenged or where the procedures that they already know are not enough to solve the problem. In the critical reflection phase, PTs are asked to work through the dilemma independently while reflecting on their previous assumptions. The rational dialogue phase focuses on PTs justifying and explaining their thinking to peers in order to reach an equilibrium between their prior assumptions and the disorientation presented by the task. The fourth and final step, the action phase is the most important because it involves making connections between the PTs’ procedural fluency and the conceptual understanding, helping PTs to see how the procedures they learned (their prior assumptions) are related to the knowledge needed to teach mathematics (their transformed understanding).

RIGHTS OF THE LEARNER AND ROUGH DRAFT THINKING: TWO COMMITMENTS FOR HUMANIZING MATHEMATICS TEACHER EDUCATION

Crystal Kalinec-Craig
University of Texas at San Antonio
Crystal.Kalinec-Craig@utsa.edu

Amanda Jansen
University of Delaware
Jansen@udel.edu

Keywords: Teacher Education-Preservice; Equity and Diversity; Classroom Discourse

The purpose of this paper is to illustrate two commitments to humanizing mathematics education in the context of teacher education: Rights of the Learner (RotL) and Rough Draft Thinking (RDT). Based on the vision of Olga Torres, a mathematics teacher and teacher educator, the Rights of the Learner (RotL) situate students' ideas as valuable contributions to the process of learning mathematics. Students should have the right to: be confused; claim a mistake; speak, listen and be heard; and write, do and represent what makes sense to them (Kalinec, 2017). The RotL align with divergent formative assessment (Pryor & Crossouard, 2008), which encourages teachers to learn *what* students know rather than only *if* they know something, which encourages differing approaches and leverages the collective strengths of a group as they solve a task (Lotan, 2003). Rough Draft Thinking (RDT) is the process of sharing unfinished, in-progress ideas and remain open to revising those ideas. This commitment is inspired by the concept of "exploratory talk," forwarded by Douglas Barnes, which is using talk to "work on understanding" or talking to learn (Barnes, 2008, p. 3). Rough draft talk sounds like false starts, expressions of uncertainty, and incomplete or imperfect sentences (Jansen, Cooper, Vascellaro, & Wandless, 2016). Articulating one's own thinking as a draft that can be revised honors the continual process of making sense of a new idea. During rough draft thinking, learners are focused on sorting out their thoughts rather than performing for an audience (Barnes, 2008). Promoting RDT can be seen as a part of promoting mastery goals (oriented to engage in school in order to learn and understand) over performance goals (oriented to engage in school in order to perform well or to avoid performing poorly) (Ames, 1992). This poster theorizes about how pre-service teachers can learn about RotL and RDT in order to resituate their perspectives on teaching and learning mathematics. By leveraging asset-based mathematics practices that foreground what students already know and can do (and thereby resist a deficit perspective of students' thinking is something that always needs to be immediately corrected or changed), the authors define the theoretical underpinnings of the RotL and RDT before giving examples in practice. The poster includes examples from practice in teacher education.

THE DEVELOPMENT OF DISCOURSE FACILITATION AMONG PRESERVICE ELEMENTARY TEACHERS: A LONGITUDINAL INVESTIGATION

Amanda Gosek
North Carolina State University
ajgosek@ncsu.edu

Temple A. Walkowiak
North Carolina State University
tawalkow@ncsu.edu

Carrie W. Lee
East Carolina University
leecarr16@ecu.edu

Keywords: elementary, discourse, preservice, teacher development

The recently released Standards for Preparing Teachers of Mathematics (AMTE, 2017) point to the need to *develop* preservice teachers (PSTs) in discourse facilitation. However, facilitating high-quality discourse in a way that impacts learning is difficult (Michaels & O'Connor, 2015), particularly for PSTs (Neergard & Smith, 2012). Therefore, understanding *how* they develop in their facilitation of mathematical discourse, the very focus of this study, seems particularly important for the work of mathematics teacher educators. Specifically, this study investigated how PSTs in an undergraduate elementary teacher preparation program (TPP) developed in facilitation of discourse (herein referred to as "math talk") over four semesters.

Four participants were purposefully selected from a group of 16 who were studied in depth during their TPP and first year of teaching. The four participants were selected because they demonstrated the most "success" (Brinkerhoff, 2003), in comparison to the larger group, in facilitating math talk during the first year of teaching, as measured by an observational protocol (Walkowiak, Berry, Meyer, Rimm-Kaufman, & Ottmar, 2014). We used the Mathematics Discourse Matrix (Sztajn, Heck, & Malzahn, 2013) to code each five-minute segment of four previously video-recorded lessons, one per semester, as to which discourse type on the matrix was primarily represented. We created graphical representations of the codes to make sense of development during the TPP.

Findings indicate two of the participants showed progress over time in how they were facilitating math talk while the other two participants' lessons remained relatively similar. This study can spark discussion in our field about how we measure, make sense, and generate developmental trajectories for mathematics pedagogy. Furthermore, the findings point to the importance of understanding factors that influence variation in teacher development.

QUALITY RESEARCH OF MATH WORD PROBLEM SOLVING INTERVENTION FOR ELEMENTARY STUDENTS WITH LEARNING DISABILITIES

Bingyu Liu
Purdue University
liu1972@purdue.edu

Mandy Rispoli
Purdue University
mrispoli@purdue.edu

Keywords: Math word problem solving, Elementary students, Students with learning disabilities, Quality indicators,

Theoretical Perspective

Special educators have formulated guidelines, Council of Exceptional Children's new set, for identifying evidence-based practices in special education (Cook et al. 2015). However, recently there is limited research that evaluated the body of work using Council of Exceptional Children (CEC) quality indicators. The purpose of this review is to identify the quality of previous investigations of empirical single subject design studies on mathematics word problems intervention of elementary students with learning disabilities. The very recently studies of effective intervention represent an attempt to improving the skills of mathematics performance.

Research Questions and Design

This review will address the following research question: what is the quality of the research on math word problem solving interventions for students with learning disability?

Data Collection Techniques and Analysis

This literature review was conducted for studies which provided intervention. Online databases were scanned to locate math word problem solving intervention studies for elementary students with math learning disabilities. Relevant studies were reviewed based on title, key words, abstract and method to check if the studies involved word problem solving. The Council of Exceptional Children's (CEC, 2014) new set of standards were used for identifying evidence-based practices in special education. The articles were evaluated by CEC quality indicator for single-subject study by reviewing method, result and discussion sections of the articles.

Summary of Findings

The finding indicated that not all studies met CEC quality indicator for single-subject study. Researchers need to continue to apply the quality indicator into their studies. The studies involved interventions that require special training, but the authors didn't describe any training of interventionists and didn't note that no training were required. Future researchers could use CEC quality indicator to evaluate their studies and publish more high quality studies that meet all the quality indicators.

The importance of student struggle in learning is well documented in the literature (e.g., Piaget, 1960; Hiebert & Grouws, 2007). In mathematics education, more students are being encouraged to engage in productive struggle to learn mathematics at a deeper, more conceptual level (NCTM, 2014; Warshauer, 2015). Hiebert and Grouws classify productive struggle as the effort by students "to make sense of mathematics, to figure something out that is not immediately apparent" (p. 387). The goal of this exploratory study was to identify and characterize the nature of prospective teachers' struggles as they engaged in a non-routine mathematical task in a mathematics content course. The researchers sought to determine 1) how prospective elementary, middle, and secondary teachers engage in productive struggle as they complete non-routine mathematical tasks and 2) how prospective teachers perceive and characterize their struggle during non-routine mathematical tasks.

Thirty-two prospective elementary, middle, and secondary teachers from three different mathematics content courses engaged in a non-routine mathematical task. Researchers observed each class and students completed exit tickets where they discussed the struggles encountered while completing the task. The exit tickets and observation notes from each of the three content courses were coded using Warshauer's (2015) list of four types of student struggles. We will describe the method used to code the data where four additional themes emerged from what Warshauer's team identified. In addition, we will share the analysis of exit tickets and researchers' observation notes that revealed that prospective teachers 1) attempted to describe their own struggles while they focused on getting the correct answer and making sense of their work; 2) identified positive and negative types of struggles; and 3) the responses in the elementary course were notably different than those from the other two courses. The poster will also highlight examples of each type of struggle that were identified as well as a discussion of the results and the possible implications on teaching prospective mathematics teachers and future research.

USING SELF-DIRECTED LEARNING TO PROMOTE MATHEMATICAL ENGAGEMENT AMONG PRESERVICE TEACHERS

Susanna Molitoris Miller
Kennesaw State University
SMolitor@kennesaw.edu

Kevin Currie-Knight
East Carolina State University
kevincurrieknight@gmail.com

Keywords: Learning Theory, Informal Education, Instructional Activities and Practices, Teacher Education-Preservice

Many Pre-Service Teachers (PSTs) enter professional development programs without "meaningful understandings of mathematical content, appreciation of what mathematics entails, or confidence in their own ability to do and to learn mathematics,"(Ball, 1990, p. 5). However, many students experience college learning in a similarly disengaged way (Blum, 2017). It has been suggested that meaningful learning occurs when students have an opportunity to engage with the topic in a way that includes space for pausing in mastery and enjoyment (Handa, 2003).

Self-directed learning (SDL) is a pedagogical "process in which individuals take the initiative" in elements of their learning, from diagnosing learning needs to deciding how to demonstrate mastery (Knowles, 1975, p. 18). This poster presents a conceptual argument for using SDL to promote student engagement in mathematics teacher education, supported by the experience of two teacher educators who have used SDL in their classrooms.

Many studies show that SDL increases learner engagement. SDL in marketing and business courses led to increased curiosity and interest in the studied areas (Boyer, Edmondson, Artis, & Fleming, 2013). College students who report studying a topic/subject for autonomous reasons (like having an interest for the topic) showed more motivation and perseverance toward, and performed better on, tasks than their extrinsically-motivated peers (Black & Deci, 2000). Self-directed learning among in-service teachers on the job tends to be more emotionally impactful than formal learning on the learners (affecting their identities as teachers); formal learning is often "seen as a bureaucratic requirement" (McNally, Blake, & Reid, 2009, p. 259).

This is in line with our own experiences using SDL in our respective college classrooms. Our evidence of engagement includes a record of the personalized projects students have constructed tailoring math to their own interests and teacher journals documenting observed instances of student engagement.

Keywords: Teacher Education-Preservice, Number Concepts and Operations

Research (e.g., Smith, 2017) suggests that it is important to focus on models of multiplication beyond equal groups. From our experience teaching mathematics content courses for prospective elementary teachers (PTs), we have found that our students sometimes struggle with understanding the array or area model of multiplication.

In order to address these issues, we designed a sequence of mathematical tasks whose overarching goal is to help PTs develop a better understanding of the array model of multiplication. We designed these tasks by engaging in a previously developed task design cycle (Tobias et al., 2014) that focuses on modifying a task designed for children into a task for PTs.

The initial task begins with a 29x23 rectangular array. We ask PTs to come up with three ways to determine the number of 1x1 unit squares in the array by breaking the picture into regions. Subsequent tasks focus on using base-10 blocks to model the array and exploring how the model relates to the partial products algorithm for multiplication. Our goals for these tasks are for PTs to connect the number of 1x1 unit squares in the array with the product 29 x 23. Specifically, our goals for the tasks are for PTs to 1) recognize that a product can be found by summing, or combining, partial products, and that this procedure can be modeled by decomposing a rectangular array into different regions and 2) use a rectangular array model to make sense of the distributive property of multiplication over addition as a driving force behind the partial products (by place value) and the standard algorithms.

Preliminary data analysis indicates that we were somewhat successful in achieving our goals. However, many PTs still focused only on the total number of squares in an array, rather than on the components that made up the multiplication problem. In our poster, we will share the task sequence and examples of student work. We will also discuss how we have begun to modify the tasks in order to help us better achieve our goals.

ELICITING PERSONIFICATION TO STUDY PRE-SERVICE TEACHERS BELIEFS

Robert Sigley
Texas State University
Sigley@txstate.edu

Muteb Alqahtani
SUNY Cortland
muteb.alqahtani@cortland.edu

Keywords: Teacher Beliefs, Teacher Education-Preservice

The recently released Association of Mathematics Teacher Educations Standards for Teacher Preparation claims that “All teachers, including well-prepared beginners, must hold positive dispositions about mathematics and mathematics learning, such as the notions that mathematics can and must be understood, and that each and every student can develop mathematical proficiency” (p 2.7, AMTE, 2017). A goal for mathematics classes for PSTs should be to try and align the students’ beliefs that align with those positive dispositions about mathematics and mathematics learning. Studies (e.g., Philippou & Christou, 1998) have shown that teachers tend to come into these courses with negative dispositions about mathematics. In this study, we used the method of eliciting personification (Zazkis, 2015) to see what is revealed about PSTs beliefs that other methods (e.g., surveys, journaling) fail to capture.

Sixty-eight sophomore PSTs participated in the study using an assignment to elicit their personification by describing a character called Math and writing a dialogue between them and their math character. The assignment was given during the beginning of the semester. After completing the course, the students were asked to describe the character Math from the course and compare this Math to the one they described at the beginning of the semester. Additionally, they were asked to read their first assignment and respond to their previous assignment by creating a dialogue between their current selves and themselves as the start of the class.

The assignments were analyzed by the authors using a thematic analysis (Braun & Clarke, 2006) approach to open-code and develop themes related to beliefs about mathematics. At the beginning of the semester the PSTs that engaged in the task viewed mathematics as an activity that occurred only schools. They first met math when they entered school and all their described interactions, both positive and negative, occurred in a school setting or by engaging in tasks related to schooling (e.g., homework). They described a volatile relationship where math was alternating between a positive relationship and one that was out to hurt them. In their end of class write-ups their focus was on a more approachable mathematics that wants to help the students understand. Instead of blaming themselves for not working hard enough, they instead realized that they could ask questions of others to help understand the content and that math was kind and wanted the best for them. Going forward, research is needed to focus on how to leverage activities such as this to help build positive identities and dispositions towards mathematics.

Looking back into the recent past, research has shown that emphasizing the importance of effort for learning mathematics can have positive effects on students' achievement, engagement, and sense of competence (Dweck, 2010; Middleton & Jansen, 2011). To adopt this focus, teachers must embrace the belief that success (or being "good at math") is attributable to effort (i.e., growth mindset) rather than inherent ability (i.e., fixed mindset). To support this goal, teacher educators must address related issues with prospective teachers in their teacher preparation programs. As a result of their own experiences as learners of mathematics, many prospective elementary teachers (PETs) have fixed mindsets and negative ideas about their own mathematical abilities and what it means to be successful in mathematics (e.g. Stoehr, 2017).

Looking ahead to the future of this issue, we developed and piloted a suite of instruments designed to elicit PETs' beliefs related to success in mathematics. This suite of tools included three complementary elements: (a) a personification of mathematics task (adapted from Zazkis, 2015), (b) a drawing protocol imaging someone who is "good at math," and (c) a semantic differential. In the personification task, PETs write a description of mathematics as a person, draw a picture of mathematics, and script a conversation they would have with mathematics. For the drawing protocol, PETs reflect on the characteristics of someone who is "good at math" and create an image of this person. Finally, the semantic differential presents 20 sets of paired words (e.g., fast/accurate or ease/effort) and asks participants to make a selection along a continuum as to which of these words more appropriately describes someone who is "good at math."

As a trio, these instruments provide a rich description of PETs' views of what it means to be "good at math," and allow us to consider these ideas through a conceptual framework examining attitudes towards mathematics along three interconnected dimensions: *vision of mathematics, perceived competence, and emotional disposition* (Di Martino & Zan, 2010). One's vision of mathematics includes beliefs about what it means to be successful in mathematics, while perceived competence positions one's own competence within this constructed reality. These factors are regulated by emotional dispositions that account for the positive and negative affective characteristics that PETs express in relation to mathematics. Our suite of instruments and preliminary data from our pilot study provide snapshots of PETs' dispositions related to teaching and learning mathematics, which we hope can inform mathematics teacher educators who support these emerging teachers.

PROSPECTIVE ELEMENTARY TEACHERS' NOTICING: INTRODUCING A TRAJECTORY OF CHILDREN'S MULTIPLICATIVE THINKING IN A CONTENT COURSE

Andrew M. Tyminski

Keywords: Learning Trajectories; Teacher Education – Preservice; Teacher Knowledge

Effective teaching involves understanding children's mathematical thinking, interpreting their thinking to assess current understanding, and deciding where children need to go next in order to advance their learning (Heritage, 2010). Researchers refer to this set of skills as the professional noticing of children's mathematical thinking (Jacobs, Lamb & Philipp, 2010). We argue prospective teachers (PTs) need to learn to effectively notice children's mathematical thinking and further, need multiple opportunities in their preparation program to develop their skill at noticing. It is important thus to orient PTs to the work of teaching early in their program, long before they take a methods course. In this study, we designed and enacted an intervention to support PTs development of noticing children's thinking in a first semester content course and examined the following research questions: (1) How does the OGAP framework support PTs' noticing of children's multiplicative thinking; and (2) How does the OGAP framework support PTs' development of knowledge of children's multiplicative thinking?

Drawing from research on learning trajectory-based professional development, we designed an intervention using the Ongoing Assessment Project (OGAP) framework (Petit, 2013) that scaffolded PTs' noticing according to a trajectory of children's multiplicative reasoning. We designed a series of four, 50-minute class sessions which utilized number talks and video clips to introduce PTs to the five levels of Children's Multiplication Strategies (Petit, 2013): early-additive, additive, early-transitional, transitional, and multiplicative.

This poster reports on some of the results of a pre-post survey created by the authors which was used to measure PTs ability to attend to and interpret four samples of children's multiplicative strategies in a variety of ways. Four multiplication problems and associated sample of student work were used as a context for PTs to answer a set of identical questions. One question asked PTs to anticipate children's multiplicative thinking for the given task, a second asked PTs to describe the provided sample of student work, and a third asked PTs to posit the next step in a progression of children's multiplicative thinking. We utilized the OGAP framework as a lens analyze PTs responses to these questions.

The results shared indicate that PTs made improvements in their noticing and knowledge of children's multiplicative thinking from pre- to post-survey. For example, PTs' responses included specific language from the OGAP framework to describe children's thinking; as exemplified by Toni's response on the post-survey, "A child might solve this problem using the transitional strategy, displaying an area model that considers both dimensions but not every individual unit".

PRESERVICE ELEMENTARY TEACHERS USE OF JOURNALS AS A MEANS OF REFLECTING ON PROFESSIONAL VISIONS OF MATHEMATICS INSTRUCTION

Ashley N. Whitehead
Appalachian State University
whiteheadan@appstate.edu

Keywords: Teacher Education-Preservice; Teacher Beliefs

Before entering their teacher preparation program, future preservice teachers develop preconceived notions of what good teaching looks like based upon their time as students of mathematics (Masingila & Doerr, 2002). However, once they become a preservice teacher of mathematics, these ideals, or visions to which they strive (Hammerness, 2003), often do not align with the standards-based practices of their teacher preparation program. Nevertheless, teacher preparation programs can help to refine preservice teachers' visions of instruction. One way in which teacher preparation programs can help preservice teachers to refine their visions is through writing prompts (Duffy, 2002). The hope is that through reflection, preservice teachers are able "to develop a clearer sense of their purposes for teaching and of their commitment to the profession" (Hammerness, 2003, p. 55). Therefore, two main questions guided this study:

1. How do preservice elementary teachers' visions of mathematics instruction evolve throughout an elementary mathematics methods course?
2. What impacts their vision of mathematics instruction throughout the methods course

Participants & Data Collection

Thirty-two preservice elementary teachers volunteered to participate in the study that took place during their second mathematics methods course, during their senior year. Throughout the course, participants were exposed to a variety of tasks, readings, and discussions to enrich their content and pedagogical knowledge. In addition to the course assignments, the participants were asked to complete six journals throughout the course which specifically asked them to reflect on their visions of mathematics instruction.

Results & Discussion

Preliminary results of this study show the impact of Jo Boaler's *Mathematical Mindsets* text used throughout the mathematics methods course. Many participants described their vision as changed after reading and discussing growth versus fixed mindsets during the course. They also attributed their experience in the course, where the instructor modeled a growth mindset and made the environment safe for sharing mistakes, to their changing vision. This change shows the importance of teacher educators modeling reform-oriented practices in methods courses and how specific readings and discussions attribute to the change of preservice teachers visions of effective mathematics teaching.

MIDDLE AND SECONDARY TEACHERS' INFORMAL INFERENTIAL REASONING

Christopher Engledowl
New Mexico State University
chriseng@nmsu.edu

James E. Tarr
University of Missouri
TarrJ@missouri.edu

This study examined middle and secondary mathematics teachers' knowledge structures and informal inferential reasoning (IIR). Using task-based clinical interviews (Goldin, 1997) and cross-case analysis, nine teachers responded to four LOCUS assessment tasks (Jacobbe, 2016). Responses were used to construct knowledge structure maps for measures of center, spread, and shape (Groth & Bergner, 2013). Teachers' IIR was analyzed for the appropriateness of responses (Means & Voss, 1996) and key components of IIR were identified. Teachers with more connected knowledge structures and fewer undesirable knowledge elements exhibited more acceptable forms of IIR. Although teachers engaged in the inference and data components of IIR (Makar & Rubin, 2009), they rarely referenced uncertainty. Implications for teacher education and future research are discussed.

Keywords: Data Analysis & Statistics, Teacher Knowledge, Cognition

Globally, there has been an increased recognition of the need for statistical literacy. This is particularly evident in the U.S. from the increased number of statistics standards included in the Common Core State Standards for Mathematics (CCSSM) and from other standards reform documents (e.g., Franklin et al., 2007). This push is due, in part, to consistent findings that tertiary students struggle to improve in their statistical reasoning abilities throughout introductory courses (e.g., delMas, Garfield, Ooms, & Chance, 2007). Not surprising, the majority of K-12 mathematics teachers in the U.S. feel unprepared to teach statistics content, despite completing at least one college level statistics course (Banilower et al., 2013) and despite the consistent calls for mathematics teacher education reform over the past twenty years (Conference Board of the Mathematical Sciences, 2001, 2012; Franklin et al., 2015). More importantly, standards reform documents, such as the CCSSM, require teachers to engage their students in informal ways of reasoning, which is not typically found in tertiary courses (Garfield, DelMas, & Zieffler, 2012), thereby leaving many teachers unable to draw on experience to support such teaching. Several studies have found great success in engaging students in informal inferential reasoning (IIR) as a way to promote students' statistical literacy across middle and secondary grades (see for example, Makar & Ben-Zvi, 2011, special issue in *Mathematical Thinking and Learning*; Pratt & Ainley, 2008, special issue in *Statistics Education Research Journal*). However, there has not been an associated level of research into teachers' engagement in IIR, leading to recent claims that research connecting teachers' content knowledge and IIR is a "critical area for future research" (Langrall, Makar, Nilsson, & Shaughnessy, 2017, p. 517). This study examined teachers' knowledge structures for measures of center, spread, and shape as it related to their engagement in tasks designed to elicit IIR. The goal was to understand the ways in which teachers' knowledge structures may be constructed, and how they support the ways teachers engage in IIR, in the context of task-based clinical interviews. This work adds to research base on teachers' IIR—a relatively thin area compared to research on students.

Theoretical Framework

This study draws on the work of Zieffler and colleagues (2008), who defined informal inferential reasoning (IIR) as "the way in which students use their statistical knowledge to make arguments to support inferences about unknown populations based on observed samples" (p. 44). Their framework for IIR describes three essential components—making claims about populations from samples, utilizing prior knowledge, and using evidence-based arguments to support claims about populations (Zieffler et al., 2008, p. 45). We further expanded this framework, drawing upon Rossman (2008), to include inferences made about causality between variables in addition to claims about populations from samples.

In considering the role of knowledge in this IIR framework, we took the stance of Franklin and colleagues (2007) who assumed that knowledge and informal reasoning develop alongside one another. Furthermore, in Zieffler and colleagues' literature review, they found that informal reasoning did not improve with "maturation, education, or life experience" (2008, p. 44). Therefore, we theorized that IIR occurs at the intersection of statistical knowledge and informal reasoning, and neither knowledge nor reasoning are required for the development of the other.

Research Questions

This study addressed the following two research questions: What knowledge structures do middle level and secondary mathematics teachers have regarding center, spread, and shape of distributions (RQ1)? How do teachers' knowledge structures support IIR (RQ2)?

Method

Setting and Participants

A stratified purposeful sample (Patton, 2002) of nine practicing middle and secondary mathematics teachers each participated in two task-based clinical interviews. Teachers were required to have taught statistics content that included data analysis explicitly using measures of center, spread, and shape of distributions. Teachers were also chosen in order to obtain four strata: 1) statistics taught as a unit within middle level mathematics ($N = 3$), 2) statistics taught as a unit within secondary mathematics ($N = 2$), 3) Non-Advanced Placement (AP) Statistics ($N = 2$), and AP Statistics ($N = 2$). There was wide variability in teachers' backgrounds that was not concentrated in any one strata, all teachers had Master's degrees in education-related fields, and all had completed at least one tertiary course in statistics.

Data and Analysis

Task-based clinical interviews were conducted with each teacher, using two tasks for each of two 60–90 minute video recorded interviews. The four tasks were selected from released items from the *Levels of Conceptual Understanding of Statistics* (LOCUS) assessment (Jacobbe, 2016) in order to align with Huey and Jackson's IIR task framework (2015) to maximize the potential for observing IIR engagement. Due to space limitations, the tasks are not included, but they were: New Year's Day Race, Tomatoes and Fertilizer, Extended School Day, and Jumping Distances. Teachers' written and verbal responses aided in answering both research questions. Interview protocols were developed, following the suggestions of Ginsburg (1981) that questions should require reflection, determine the seriousness of responses, confirm that participants understood the question, and evaluate the strength of belief of responses by challenging them. Moreover, we followed suggestions from Goldin (1997) that follow-up questions be non-directive and that the protocol anticipate as many contingencies as possible. Contingencies were more completely anticipated by using LOCUS tasks because a range of student responses are included along with each released task. Due to space limitations, instruments and tasks will not be shown here but will be provided during the presentation.

Data analysis first involved transcribing each interview and coding teachers' responses for constructed knowledge elements related to center, spread, and shape of distributions (RQ1).

Connections between knowledge elements were then also hypothesized through open-coding across all tasks. Node-link diagrams were used in order to visually represent each teacher's knowledge structure. We followed a similar method to that of Groth and Bergner (2013) that involved mapping Partially-Correct Constructions for each participant. Thus, teachers' responses were further classified as either *desirable* or *undesirable*. A *desirable* constructed knowledge element is one that has been identified in the literature as having the potential for supporting the development of other knowledge elements or more complex depictions of that knowledge element. An *undesirable* element is one that may support the development of inconsistent or disconnected knowledge elements, or not allow for a *desirable* element to be constructed from it. *Desirable* elements were visually represented by blue rectangles, and *undesirable* elements with yellow rectangles with rounded vertices. These value laden terms should not be misconstrued as a teacher's lack of expertise because an *undesirable* element does not necessarily imply that it is inherently incorrect. Observed connections between knowledge elements were depicted with a double-headed arrow. After all knowledge maps had been constructed, a within-case analysis was carried out to confirm each knowledge structure, and then a cross-case analysis was carried out to identify common themes across structures to categorize types of structures.

To address RQ2, we drew upon the work of Means and Voss (1996) to first identify teachers' arguments—their claims and reasons for them—and if they were supported by *acceptable* or *unacceptable* evidence. Next, we employed Makar and Rubin's informal statistical inference framework (2009) to identify which of the three components, evidence of IIR, were observed in teachers' arguments—generalization beyond the data, data as evidence, and probabilistic language. A cross-case analysis (Creswell, 2013) was carried out to identify categories of types of IIR. Lastly, types of IIR were compared with types of knowledge structures to characterize how teachers' knowledge structures may support their IIR.

Findings

Knowledge Structures for Center, Spread and Shape

After a cross-case analysis, 3 basic types of knowledge structures were identified (see Figure 1): *desirable-connected* ($N = 3$), *undesirable-connected* ($N = 4$), and *undesirable-disconnected* ($N = 2$). *Desirable-connected* structures included almost no *undesirable* knowledge elements and knowledge elements were highly connected, with connections observed both *within* and *between* knowledge types (center, spread, shape), as can be seen in the case of Rosalynn's knowledge structure as a case of a *desirable-connected* structure in Figure 1. This knowledge structure category was highly consistent across teachers—salient features were observed across all cases. On the other end of the spectrum, *undesirable-disconnected* knowledge structures contained multiple *undesirable* knowledge elements that were observed to be largely disconnected, with no connections observed between center and shape knowledge types. These characteristics were consistent across the two cases of *undesirable-disconnected* structures, as can be seen in the case of Amalia's knowledge structure in Figure 1. Knowledge structures described as *undesirable-connected* also contained multiple *undesirable* knowledge elements, but knowledge elements were highly connected—thus integrating *undesirable* knowledge elements into the overall structure, as can be seen in Ellie's knowledge structure in Figure 1. Knowledge structures in this category were more varied than the other types. For instance, not all structures included direct connections *between* all knowledge types (center, spread, shape), but all included direct connections *between* at least two of the three types. Moreover, the majority of knowledge elements were connected to at least one other knowledge element—reflecting the highly integrated nature of teachers' knowledge. It is of note that in all cases of both *undesirable-*

connected and *undesirable-disconnected* structures, at least one direct path connecting two elements of center, spread, and shape included at least one *undesirable* knowledge element.

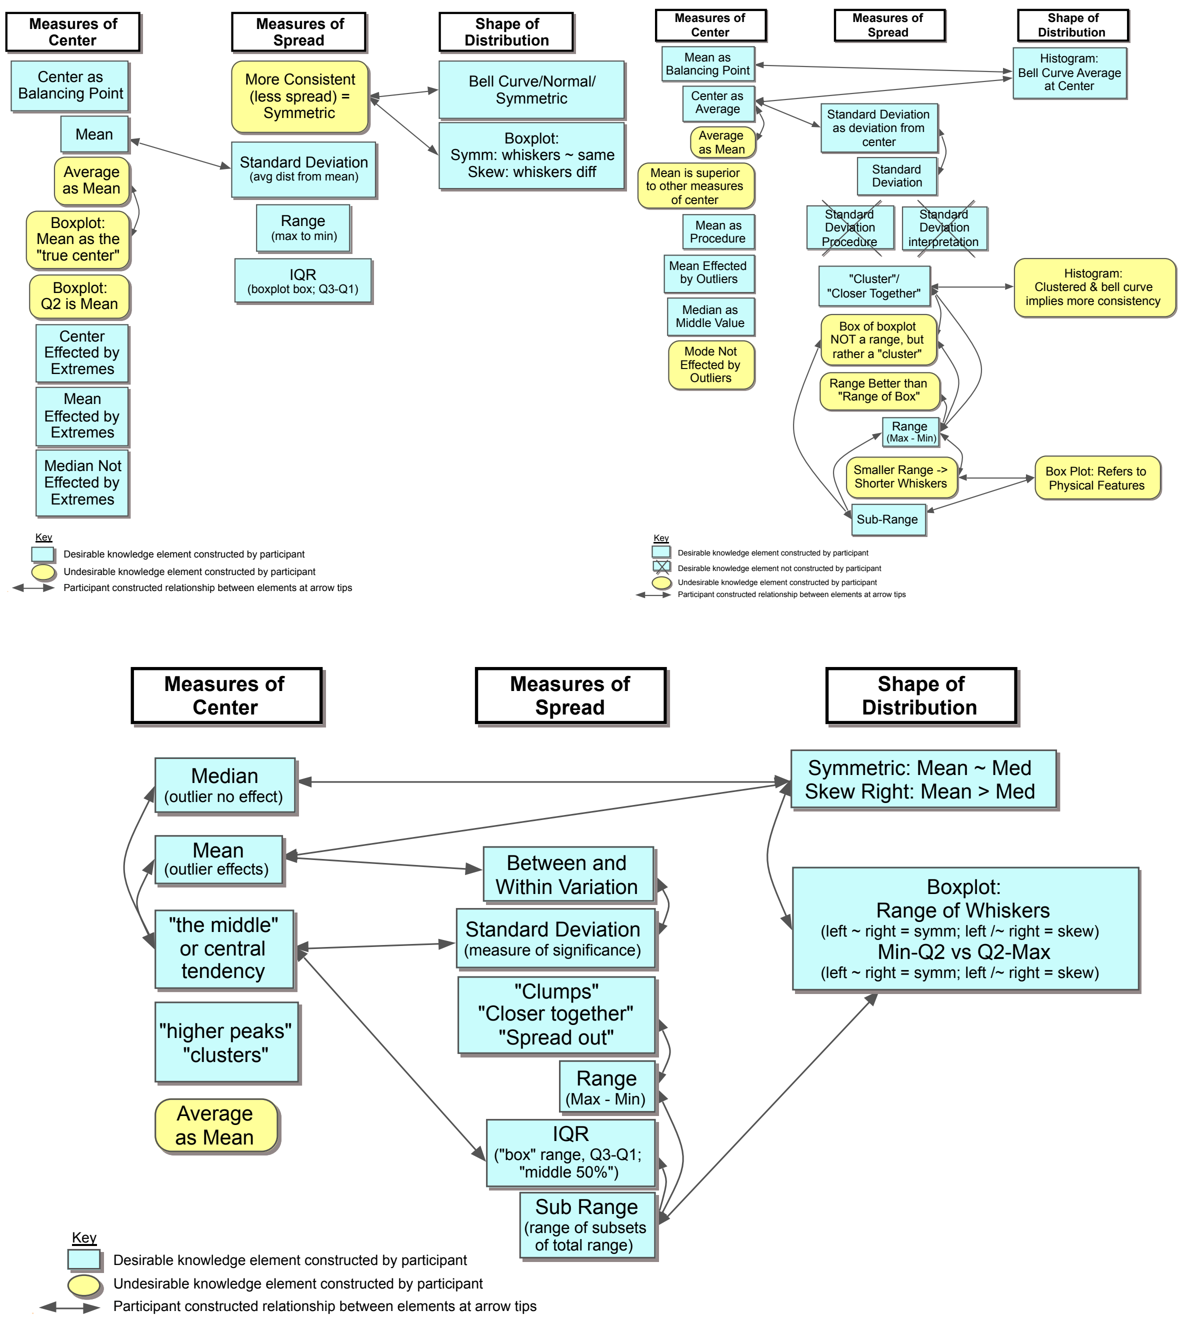

Figure 1. Representative cases of the three types of knowledge structures

Knowledge Structures and Support for IIR

Tasks that did not require engagement in IIR explicitly (e.g., asking only about characteristics of samples) produced different findings than those that did. In particular, teachers more frequently exhibited *acceptable* supports in their arguments when reasoning in these non-

IIR contexts than in those tasks that demanded IIR (see Table 1). For example, five teachers were observed to reason using *acceptable* supports (i.e., drawing on *desirable* knowledge elements) for at least 75% of their responses (note that teachers were encouraged to offer multiple responses per task per the interview protocol) and two of those (Rosalynn and Tim) reasoned in this way for 100% of their responses. In contrast, within IIR contexts, none of the teachers were observed to reason using *acceptable* supports for at least 75% of their responses. Although teachers' reasoning in IIR contexts largely made use of *unacceptable* supports in their arguments, when the task only required drawing upon center, spread or shape, 8 of the 9 teachers were able to offer at least one response coded as *acceptable*. However, 5 of these 8 teachers simultaneously offered responses coded as *unacceptable*, indicating wider variation in responses for IIR contexts than non-IIR contexts.

Table 1: Comparing Reasoning Types and Knowledge Structures

Non-IIR Reasoning	Teacher	Knowledge Structure	IIR Reasoning
Mostly Unacceptable	Kathy	Undesirable-Disconnected	Mostly Unacceptable IIR
Mixed	Amalia	Undesirable-Disconnected	Mostly Unacceptable IIR
Mixed	Ellie	Undesirable-Connected	Mostly Unacceptable IIR
Mixed	Ruby	Undesirable-Connected	Mostly Unacceptable IIR
Mostly Acceptable	Michaela	Undesirable-Connected	More Unacceptable IIR
Mostly Acceptable	Harrison	Undesirable-Connected	More Unacceptable IIR
Mostly Acceptable	Mike	Desirable-Connected	More Unacceptable IIR
Mostly Acceptable	Rosalynn	Desirable-Connected	Mostly Acceptable IIR
Mostly Acceptable	Tim	Desirable-Connected	Mostly Acceptable IIR

Tasks that required IIR were also coded according to the three components of informal statistical inference described by Makar and Rubin (2009). Two teachers utilized all three components (generalization/causation, data as evidence, probabilistic language) for one response each and 8 of the 9 teachers incorporated both a generalization and data as evidence when their reasoning was coded as *acceptable*. The use of probabilistic language was exceedingly rare, observed in only the two cases where all three components were included, indicating that teachers largely did not consider the deterministic nature of their inferential statements.

Comparing reasoning types to knowledge types, the greatest observable pattern is that teachers with mostly *desirable* elements that were highly integrated also reasoned in *acceptable* forms for the majority of their responses, while teachers with many *undesirable* elements that were largely *disconnected* tended to reason in *unacceptable* forms for the majority of their responses. A second salient pattern is that those who reasoned in more *acceptable* forms across both contexts (non-IIR and IIR) tended to have more connected knowledge structures. Moreover, the relationship between reasoning types and knowledge structures appeared most evident at opposite ends of the spectrum. To illustrate this, on the Jumping Distances task, participants were asked to compare center, spread and shape of the distances a sample of students jumped by examining a pair of boxplots—one boxplot representing jumping distances for a subset who was provided with a target to jump towards, the other not having a target to jump towards (see Figure 2). The following responses come from Amalia and Rosalynn as they respond to this item:

> *Amalia*: The no target looks to be more symmetric. This one [target plot] is close to be symmetric, but it is slightly skewed. […] The whiskers make me think [the no target plot is] not skewed because they look almost the same length. Whereas this one [target plot] is a little longer on the left [gesturing to both whiskers of target plot] […] But yeah, I was just looking

at the whiskers, and just the fact that the target group, there is a bigger difference between the largest and the shortest jump, versus here [no target], there's not as much of a difference. (lines 10 and 21)

Rosalynn: The shape of the distribution […] Since you do have a longer whisker on the left, you're looking at a slight left skew for the target group versus a more symmetric distribution for the no target group. […] The left part [gesturing to distance from minimum to median] is more spread out for this one [target] than the right part. (lines 6 and 9)

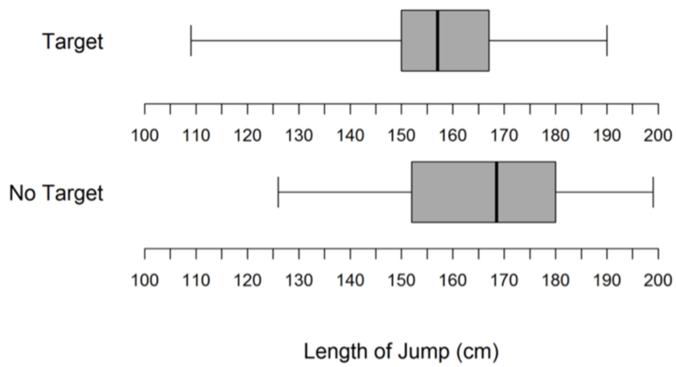

Figure 2. Boxplots provided on Jumping Distances task.

Within these excerpts, you can see that Amalia first begins to describe the distribution's shape using *desirable* knowledge elements—referring to the respective lengths of the whiskers for each plot to hypothesize about the shape. However, she then creates a second argument that draws on an *undesirable* knowledge element—that the smaller range of the no target plot implies more symmetry. Thus, without making contradictory claims, she simultaneously argued in ways coded as both *acceptable* and *unacceptable*. This perspective of spread as being connected to shape in an *undesirable* way led to her *unacceptable* form of reasoning. Amalia's knowledge structure was categorized *undesirable-disconnected* (see Figure 1), and her reasoning was impacted by the integration of *undesirable* elements, thus resulting in more responses coded as *unacceptable*. In contrast, Rosalynn's responses remained in comparison to whether things appeared more evenly spread to the left and right of center, drawing on *desirable* knowledge elements for each response. Therefore, Rosalynn's knowledge structure, categorized as *desirable-connected* (see Figure 1), supported her reasoning in ways that led to more *acceptable* forms of reasoning. Teachers whose knowledge was more integrated yet contained multiple *undesirable* elements, were observed offering both *acceptable* and *unacceptable* forms of reasoning simultaneously—leading to the characterization of having a more mixed form of reasoning.

Discussion

A major finding of this study is that middle and secondary teachers' knowledge structures for center, spread and shape of distributions fell into three categories—*desirable-connected*, *undesirable-connected*, and *undesirable-disconnected*. Looking across these categories, 7 of the 9 teachers were found to have highly interconnected knowledge structures that all made connections among the three knowledge types (center, spread, shape), and some made connections across all three. Moreover, despite many teachers having *undesirable* elements integrated into their knowledge structures, most were observed to have at least one connection between *desirable* elements of center and spread. Although there is evidence that teachers' knowledge structures were highly interconnected, teachers struggled to integrate their knowledge of center, spread and shape. For instance, teachers in this study were largely observed to recognize that connections existed between knowledge element types (less so between center and shape), yet they did not utilize these connections and draw upon multiple knowledge types simultaneously, as prior research has found for students and pre-service teachers (Doerr & Jacob, 2011; Groth & Bergner, 2006; Noll & Shaughnessy, 2012). Moreover, these studies also found that hierarchically higher levels of reasoning required the integration of multiple knowledge elements simultaneously—such as describing a measure of spread in relation to a measure of center—thus, supporting the notion that *desirable-connected* knowledge structures are associated with more *acceptable* forms of reasoning.

Although the theoretical framework for this study does not assume that there is any particular prior knowledge necessary for engaging in IIR—and that knowledge and informal reasoning work together during engagement in IIR—the teachers who engaged in IIR in *mostly acceptable* forms were those with *desirable-connected* knowledge structures. This finding aligns with Makar and colleagues' (2011) claim that statistical knowledge is an important support for IIR. Moreover, as found by Huey (2011) and Watson (2003), teachers in this study tended to focus only on measures of center unless explicitly prompted otherwise.

These results promote the need for statistics teacher education to include explicit opportunities, embedded within tasks, for teachers and preservice teachers to grapple with connections both *within* knowledge types and *between* them. For instance, some teachers in this study believed that outliers were either *always* or *never* ignorable, that the term average *always* implied the arithmetic mean, or that the mean was *always* or *never* a better measure than the median. Situations that confront teachers with these dichotomies will allow them to consider a more nuanced understanding and more flexible knowledge structure. Moreover, teachers in this study largely drew on ideas of center to support inferences, even when tasks did not restrict them in this way. Consequently, tasks designed to engage teachers in IIR should also encourage attention to all of center, spread, and shape—not isolating one type.

More research is needed in these areas in order to explore the kinds of task features that are more likely to encourage integration of all three knowledge types, thus supporting teachers in strengthening their knowledge structures and reasoning. One possible fruitful area of research is to provoke teachers into weighing the evidence of their inferential statements through requiring the construction of multiple inferential statements and responding to multiple inferential statements to explore their validity. This will allow engagement in the statistics practice described in the *Statistical Education of Teachers* report as being able "to compare the plausibility of alternative conclusions and distinguish correct statistical reasoning from that which is flawed" (Franklin et al., 2015, p. 14).

A final needed area of research is in explicitly engaging teachers in, and drawing attention to, the use of probabilistic language. A profound lack of attention to this component of IIR was observed in this study. Unlike mathematics, where deterministic statements are the norm, inferences in statistics are predictions and therefore come with a degree of uncertainty.

AN ANALYSIS OF HIGH SCHOOL STUDENTS TAKING STATISTICS USING THE HSLS:09 DATASET

Travis Weiland
Appalachian State University
weilandtj@appstate.edu

In this study I report results of an quantitative analysis using a large scale public dataset (HSLS:09) to investigate which students are taking statistics courses in high school to begin to understand the access students have to opportunities to learn statistics concepts and practices in high schools in the United States. The main result of this study is that predominantly the top academically performing high school students are earning credit for taking statistics. This is concerning as all students should have experiences learning concepts and practices from statistics to be prepared to engage in and play active roles in today's data centric societies. In line with the conference theme of looking forward, implications for future research and policy are discussed.

Keywords: Data Analysis and Statistics, Equity and Diversity, High School Education

Background and Statement of Problem

Society today is drenched in data (Steen, 2001). Individuals are surrounded by data aimed at influencing their decisions about what school policies to implement, politician to vote for, or medicine to use. Statistics, the science of data, is becoming an increasingly important discipline for people to be familiar with the key concepts and practices of, because of society's reliance on data (Ben-Zvi & Garfield, 2008). As Franklin et al. (2007) states, "every high school graduate should be able to use sound statistical reasoning to intelligently cope with the requirements of citizenship" (p.1). For students to develop sound statistical reasoning it is important that a goal of public K-12 education is to provide students with opportunities to have rich learning experiences with concepts and practices of statistics if they are going to be critical citizens in today's data-driven societies.

Teaching statistics in the K-12 setting is firmly rooted in the mathematics curriculum and access and opportunities to learn are crucial equity issues to consider in mathematics education (Gutiérrez, 2009; Schmidt & McKnight, 2012). In the United States, students' opportunities to learn mathematics have been found to vary greatly due to the decentralized nature of education in the U.S. (Schmidt & McKnight, 2012). The implementation of the Common Core State Standards for Mathematics (CCSSM; National Governor's Association Center for Best Practices (NGA Center) & Council of Chief State School Officers (CCSSO), 2010) was meant to serve as a unifying force to reduce some of the variation in the mathematics content covered across states in the U.S. However, not all states have signed on to adopt the standards, and other states have begun to modify the standards to be implemented in an attempt to distance themselves from some of the controversy and politics around the standards (Orrill, 2016). In the CCSSM, data analysis and statistics have gained emphasis in grades 6-12 compared to most previous state standards. However, there has also been the loss of much of the statistics and probability content at the K-5 level, which could have serious ramifications in the future (Lubienski, 2015).

It is important to point out that standards are not the only factor influencing curriculum as classroom teachers and local contexts have a direct influence on the enacted curriculum students experience in the classroom (Remillard & Heck, 2014). However, this is a unique issue in the case of statistics because although the instruction of statistics is firmly rooted in the mathematics curriculum at the K-12 level, statistics is a distinct discipline with concepts and practices that are non-mathematical (Cobb & Moore, 1997; Groth, 2013). This can cause problems because many K-12 mathematics teachers have often had little to no prior coursework in statistics (Franklin et al., 2015; Shaughnessy, 2007), which could have very serious repercussions for the opportunities students have to learn statistics in school. Since the enactment of mathematics curriculum varies greatly from classroom to classroom based on a number of factors (Remillard & Heck, 2014; Schmidt & McKnight, 2012), it is very difficult to study what opportunities students have to learn statistics concepts and practices on any kind of large scale.

In this study, I used the National Center for Educational Statistics' (NCES) High School Longitudinal Study of 2009 (HSLS:09) public access dataset to begin to investigate which students are earning statistics credit in high school in an effort to better understand high school students access to opportunities to learn statistics concepts and practices. More specifically, I investigated the following research questions:

1. What relationship is there between demographic characteristics (i.e. sex, race, and SES) of students who earned at least one credit of statistics and those that did not?
2. What relationship is there between the academic performance of students who earned at least one credit of statistics and those that did not?
3. What relationship is there between the beliefs/attitudes of students who earned at least one credit of statistics and those that did not?

Conceptual Framework

This study is framed in a larger equity framework, specifically investigating issues around achievement and access, which are dimensions of what Rochelle Gutiérrez (2009) refers to as the dominant axis of equity. Gutiérrez (2002) states a basic definition of equity as being the, "erasure of the ability to predict students' mathematics achievement and participation based solely on characteristics such as race, class, ethnicity, sex, beliefs and creeds, and proficiency in the dominant language" (p.153). Drawing upon this definition this study is focused on the characteristics of race, class, sex, and beliefs and whether or not there is a relationship between students' statistics course taking and such characteristics, in an effort to begin to investigate the equity in student's participation in opportunities to learn statistics concepts and practices. To consider the issue of achievement in this study, students' mathematics achievement in terms of algebraic reasoning as well as their achievement in terms of their GPAs was considered in relation to whether or not they earned at least one credit in statistics or not.

Mode of Inquiry

Data source

The public access dataset from the HSLS:09 was the data source for this study. The goal of the HSLS:09 is to provide data to "better understand the impact of earlier educational experiences (starting at 9th grade) on high school performance and the impact of these experiences on the transitions that students make from high school to adult roles" (Ingels et al., 2015, p. 6). As such, the HSLS:09 was designed to gather data on a sample that is nationally representative of students entering 9th grade in 2009 (n=23503). One of the goals of the HSLS:09 is to provide data to investigate, "the nature of the paths into and out of STEM (science, technology, engineering, and mathematics) curricula" (Ingels et al., 2015, p. 6). At this point data is available for the base year (Fall 2009), first follow-up (Spring 2012), post-secondary status update (Summer/Fall 2013), and high school transcript report (2013-2014).

Methods

For this study, quantitative methods were employed to investigate variables related to students' demographics, mathematics course taking, academic performance, and beliefs/attitudes towards math and science. Students' mathematics course taking was considered in terms of whether or not they earned at least one credit in statistics/probability in high school and what was the highest level mathematics course students took in high school. As a note, AP Statistics course taking was not included in this analysis, because that data is only available in the restricted use data file. The HSLS:09 has a number of different academic performance variables, which include students' performance on a mathematics assessment designed to assess students' algebraic reasoning. In this analysis, I chose to use students' theta score for their performance on the mathematics assessment, which provides a norm-referenced measurement of achievement, for the base year assessment and the first follow-up assessment. Students' mathematics, STEM, and all academic course GPAs were also used as performance variables. Finally students' identity, self-efficacy, utility of and interest beliefs/attitudes towards mathematics and science, which were measured as normalized scale variables during the base year and the first follow-up, were considered. A complete listing of the variables and their description that were used in the analysis can be found in Table 1.

An initial exploratory data analysis (Tukey, 1977) was conducted and important descriptive statistics are reported in the results. An inferential analysis of the data was then done to address the research questions to investigate the relationship between students' demographics, academic performance and beliefs/attitudes and whether they earned credit for taking a statistics course of not. The inferential statistics used included two-sample t-tests for scale variables, which included variables for students' academic performance, beliefs/attitudes towards math and science, and SES, grouped based on whether or not they had at least one credit of statistics. In other words, the specific relationship that was investigated was whether or not there were differences in the variables considered, between the two groups. For categorical demographic variables, chi-square tests were used to determine if there were associations between the variables and the two groups considered. Standardized residuals were also employed in the case of statistically significant results of the chi-squared tests to get a better idea of which categories were significantly different from what was expected. Design effects normalized analytic weights were used for all inferential statistics. Effects sizes are reported for the quantitative variables by converting the t-test statistics to r and then using the commonly used cutoff's of r=.1 for small, r=.3 for medium, and r=.5 for large effect sizes (Field, 2013). Effect sizes for the categorical variable χ^2-test statistics are reported using Cramer V and the same cutoffs of .1, .3, and .5.

The method of focusing on transcript data to investigate students' course taking is not new. The transcript studies conducted periodically as part of the National Assessment of Educational Progress (NAEP) have been a source of such information over the past few decades. Based on such information, it was recently reported that, statistics/probability course taking in high school increased from 1% of high school graduates in 1990 to 11% in 2009 (NCES, 2016). Unfortunately, the NAEP transcript data is also limited in the information it collects on students, as it is focused mostly on transcript data of course taking and is only linked to students' performance on the NAEP assessment in 12th grade in some cases. The HSLS:09 public access dataset includes significantly more variables related to students' course taking, academic performance, demographics, and beliefs/attitudes towards mathematics and science, making it useful to investigate factors related to who the students are that are taking statistics courses.

Table 1: List of variable names and the descriptions from the HSLS:09 codebook (Ingels et al., 2015) for the variables analyzed in this study.

Variable Name	Description of Variable
X3T1CREDSTAT	Indicates at least one Carnegie unit in Statistics/Probability, does not include AP Statistics
X3THIMATH	Highest Mathematics course
X3TWHENALG1	Indicates the grade level the student took Algebra I.
X1TXMTH & X2TXMTH	The mathematics theta score represents the student's ability level on a continuous scale. The theta score provides a norm-referenced measurement of achievement, that is, an estimate of achievement relative to the population (fall 2009 9th graders) as a whole. It provides information on status compared to peers.
X1MTHID & X2MTHID	This variable is a scale of the sample member's math identity. Sample members who tend to agree with the statements "You see yourself as a math person" or "Others see me as a math person" will have higher values.
X1MTHUTI & X2MTHUTI	This variable is a scale of the sample member's perception of the utility of mathematics; higher values represent perceptions of greater mathematics utility.
X1MTHEFF & X2MTHEFF	This variable is a scale of the sample member's math self-efficacy; higher values represent higher math self-efficacy.
X1MTHINT	This variable is a scale of the sample member's interest in his or her base-year math course; higher values represent greater interest in the base-year math course.
X1SCIID & X2SCIID	This variable is a scale of the sample member's science identity. Sample members who tend to agree with the statements "You see yourself as a science person" or "Others see me as a science person" will have higher values for X2SCIID.
X1SCIUTI & X2SCIUTI	This variable is a scale of the sample member's perception of the utility of science; higher values represent perceptions of greater science utility.
X1SCIEFF & X1SCIEFF	This variable is a scale of the sample member's science self-efficacy; higher X2SCIEFF values represent higher science self-efficacy.
X1SCIINT	This variable is a scale of the sample member's interest in his or her base-year science course; higher values represent greater interest in the base-year science course.
X3TGPAMAT	GPA in Mathematics.
X3TGPASTEM	GPA in STEM courses.
X3TGPAACAD	GPA in Academic courses.
X1SEX	Student's sex
X1RACE	Student's race/ethnicity-composite
X1SES	Socio-economic status composite for base year
X2SES	Socio-economic status composite for first follow-up year

Results

Of the sample of students, there was not transcript data available for 1575 (6.7%) of the students. 19748 (84%) students did not earn any credit in statistics/probability, and 2180 (9.3%) students earned at least one credit in statistics/probability, which in looking back is slightly lower than the 11% of students reported in 2009 NAEP transcript study (NCES, 2016).

Demographic Characteristics

In considering the relationship between students' demographic characteristics and whether or not they earned at least one credit in statistics, the characteristics of sex, race, and SES were investigated. In comparing sex to earning statistics credit, there was no significant association (χ^2=0.538, df=1, p=0.463). The association between race and earning statistics credit was statistically significant (χ^2=17.923, df=7, p=0.012). However, the effect size was small (Cramer V=.083). In looking at the standardized residuals of the observed and expected cell counts the only significant residual (those $\geq\pm1.96$) was for Asian students earning a credit in statistics with z=2.8, meaning there were significantly more Asian students who earned at least one credit in statistics than expected. A further caution is that three of the expected counts where less than five, though that only constitutes 18.8% of the cells, which is below the 20% cutoff that is generally considered acceptable (Field, 2013). Finally, in considering the relationship between SES and earning statistics credit there were statistically significant differences between the groups in both the base and first follow-up years, the results of which can be seen in Table 2. The group differences in SES also had small effect size.

Table 2: Difference in scale variables between students who did not earn any credits in statistics/probability versus those who earned at least one credit in statistics/probability.

Beliefs/Attitudes

Looking at the belief/attitude scale score variables (see Table 2); during the base year students who earned at least one credit in statistics/probability had significantly stronger mathematics and science identities, mathematics and science self-efficacy beliefs, and interest in their 9th grade mathematics course than students who did not. This pattern continued for the identity and self-efficacy variables in the first follow-up of the study. There was no difference in the mathematics or the science utility scale scores during the base year of the study. However, at the time of the first follow-up, students who earned at least one credit in statistics/probability had significantly higher mathematics and science utility scale scores than students who did not. It seems that over the course of three years of high school education the population of students who earned at least one credit in statistics/probability by the end of high school, were students who began to view mathematics as more useful on average than students who did not, whose average scale score changed minimally from the base year to the first follow-up year. The same cannot be said in the case of science where the scale score for both populations decreased on average from the base year to the first follow-up year. It is important to acknowledge that there is no way of knowing when students earned at least one credit in statistics, so no inferences should be made that temporal shifts in beliefs and attitudes might be influenced by statistics course taking. It is also important to note that even though a number of the belief/attitude variables differed significantly between the groups, none of the differences had more than small effect sizes, and quite a few were below the r=.1 cutoff for small effect sizes.

Academic Performance

In looking at the mathematics course taking of those students who earned at least one credit in statistics/probability, a striking trend emerges that students taking statistics are largely the top mathematics students. Nearly half (n=1053) of the students earning statistics/probability credit in high school completed Algebra I in 8th grade, just over a quarter took statistics as their most advanced mathematics course in high school, and in fact over a quarter of students took calculus in high school (see Table 3). This trend is also supported by the mathematics performance of students who earned a statistics/probability credit versus those who did not (see Table 2). Students who earned at least one credit in statistics/probability had significantly higher theta scores on the algebraic reasoning assessment on average in both the base year and the first follow-up than students who did not earn a statistics/probability credit. This same trend can be seen in the GPA of students' mathematics courses taken in high school, and in their GPA for STEM courses, and all academic courses (see Table 2). Furthermore, the differences had small to moderate effect sizes. These results seem to indicate that the students who earned at least one credit in statistics/probability may include more than just top performing mathematics students, but perhaps even the top performing students in general.

Table 3: Frequency of students' highest level mathematics course taken for students who earned at least one credit in statistics/probability

X3 Highest level mathematics course taken/pipeline	Frequency of students who earned at least one credit in statistics/probability
No Math	0
Basic math	0
Other math	0
Pre-algebra	0
Algebra I	0

Algebra II	0
Trigonometry	0
Other advanced math	0
Probability and statistics	697
Other AP/IB math	260
Precalculus	596
Calculus	144
AP/IB Calculus	483
Total	2180

Discussion and Scholarly Significance

Considering the results as a whole the two most significant factors that differed between the group of students who earned at least one credit in statistics and the group of students that did not were academic performance and SES. Though there are other factors that differed with statistical significance between the two groups, they were all of small or less effect sizes and given the large sample size should be considered with caution as only small differences are needed for statistical significance, which may not be significant in a practical sense. One possible reason, for predominantly top academically performing students earning at least one credit in statistics is that they have more time in their schedule to take additional mathematics courses like statistics.

Most states require at least three years of mathematics, which generally includes an Algebra I, Geometry, Algebra II trajectory or a more integrated Math I, Math II, Math III trajectory where the various strands of mathematics are taught together over three years. That means that students who take the typical 9th grade mathematics course of Algebra I or Math I in 8th grade have more time to take statistics as an elective course in their junior or senior year.

The cohort of students in the HSLS:09 were in high school during the very beginning of the influence of the CCSSM (NGA Center & CCSSO, 2010), which does recommend that statistics concepts be included in all students' high school mathematics education. However, the enacted curriculum that students experience is generally carried out by the classroom teacher who mediates the influence that official curriculum, such as the CCSSM, have on the enacted curriculum (Remillard & Heck, 2014) and as I discussed earlier, statistics has a unique position in this regard as many mathematics teachers have often had little to no prior experience with learning statistics (Shaughnessy, 2007). Though the results here do not show that all students do not have access to opportunities to learn statistics, they do point out that there may, at the very least, be an issue in how statistics courses are offered or advertised to students, or perhaps in students' perceptions of the usefulness of statistics, or who should take it. The results do show that the majority of students are not earning any credits in statistics/probability, which means if they are not experiencing statistics in their other mathematics courses, they are not having any experiences with statistics in high school. It is important that more research is done around students' opportunities to learn statistics at the K-12 level especially in the context of the enacted curriculum that students experience and how students are provided access to opportunities to learn statistics at the school level.

A limitation in this analysis is that using the HSLS:09 data it is only possible to determine which students earned at least one credit of statistics/probability in high school. It does not provide information on specific course performance, when the student took the course, or identify those students who were enrolled in a statistics/probability course but did not earn credit, which limits the results reported. Furthermore, it is not possible to determine the quality of the students' instruction or whether or not they had any opportunities to learn statistics in any of their other courses. However, given the current dearth of empirical research looking at the teaching or learning of statistics on any kind of large scale, these results help to give some idea of patterns in statistics course taking, which have implications for further research and for policy. Another limitation is not having transcript data on who earned credit for AP Statistics. However, given that AP courses are advanced courses the inclusion of such data would have likely only amplified the results as the students often taking AP courses are generally high performing and of a higher SES. However, it is still important that future analyses include such data.

Related to the equity framework used in this study, the results reported here are significant in that if the goal of education is democratic equality, preparing students to participate as critical citizen's in society where statistical reasoning is crucial, than there is a serious issue in that it appears that predominantly only the top performing students in high school are earning credits in statistics/probability. It is promising that students' sex was found to have no association with their taking of statistics. However, race does appear to have a weak association and there are significant differences in the academic performance and SES of those who earned credit in statistics and those who did not, which points to inequity in students' access to statistics. Going back to Gutiérrez's (2009) equity framework, it is also important to point out that using this data, equity can only be considered through the dominant axis, which means there is still the issue of the critical axis of equity, namely identity and power, to consider in future work. Though the variables of math and science identity were considered in the HSLS:09, they are different than the identity construct that Gutiérrez (2009) discusses. The identity variables in the HSLS:09 consider an individual's identity relative to its alignment with the discipline, whereas Gutiérrez (2009) is looking at identity from the perspective of the individual and how they see themselves in relation to the discipline and curriculum. It is crucial, that if we are to achieve the promise of equal educational opportunity, that all students should have experiences learning statistics concepts and practices, and that they have experiences in seeing themselves in the curriculum and considering how to read and write the world with statistics (Weiland, 2017).

PROBABILITY AND INDEPENDENCE: A COMPARISON OF UNDERGRADUATES

Karen Zwanch
Virginia Tech
kzwanch@vt.edu

Probability and independence are difficult concepts, as they require the coordination of multiple ideas. This qualitative research study used clinical interviews to understand how three undergraduate students conceptualize probability and probabilistic independence within the theoretical framework of APOS theory. One student's reasoning was consistent with a process conception, one student with at least an object conception, and one with a schema conception of probability and independence. Differences in students' thinking are analyzed, with a specific focus on intuition and simultaneously occurring events.

Keywords: Probability; Post-secondary Education

Review of Literature

"Students have difficulty just sorting out the mathematics of whether events are statistically dependent or independent in probability problems" (Shaughnessy, 2003, p. 221). The sentiment of this quotation resounds throughout the literature on probabilistic independence, and it has been well documented for students at varying ages. Considering the definition of independence, for two events A and B, $P(A) = P(A|B)$, there is a clear relationship between conditional probability and independence which students must come to understand. In recognition of the need for students to coordinate these concepts, Tarr and Jones (1997) constructed a framework for understanding how middle school students conceptualize independence and conditional probability. When students' understanding of these two concepts were analyzed within the four levels of this framework, it was determined that students' levels of reasoning regarding conditional probability and independence tend to be the same; this finding advances the apparent connection between conditional probability and independence, and furthermore, implies that students may construct these concepts in tandem.

Undergraduate students' struggles with probabilistic independence have been well documented. Kelly and Zwiers (1988) delineated three common misconceptions undergraduates have with independence: determining whether events are (in)dependent, understanding that dependence does not imply cause, and understanding that (in)dependence is not reliant upon time. Plaxco's (2011) findings support this third struggle. In interviews with undergraduates, Plaxco found that all students alluded to a temporal conception of independence and two of the three students included an element of time in their definition of independence. Students' inabilities to separate an element of time from their understanding of independence is clearly problematic, as the conditioning event may occur at the same time as or after the second event. In response to some of the difficulties students experience in conceptualizing independence, Keeler and Steinhorst (2001) call for the improvement of instruction in undergraduate probability courses, and specifically call instructors to capitalize on students' intuitions. They posit that an inquiry-based learning environment facilitates students' understanding of probability by building upon students' intuitions. Abrahamson (2014) also encourages probability instruction that "guide[s] students to appropriate the cultural resource as a means of supporting and empowering their tacit inference" (p. 250). His findings indicate that students' tacit inferences are a powerful instructional tool that instructors can leverage by linking it to formal mathematics. These researchers build upon the work of Fischbein (1987), who defines students' intuitions as primary or secondary. Primary intuitions are those students develop prior to instruction, whereas secondary intuitions are developed through formal mathematical experience. Secondary intuitions are not right and primary intuitions wrong; rather, secondary intuitions replace primary intuitions in situations where primary intuitions fail. Thus, for both Keeler and Steinhorst, and for Abrahamson, it seems that helping students construct secondary intuitions to complement primary intuitions regarding independence may be a powerful instructional approach.

On the other hand, Ollerton (2015) found that although undergraduate students have an intuitive understanding of independence, they struggle to conceptualize independence in a mathematically appropriate manner. Thus, it remains to be seen to what extent students' intuitions of probabilistic independence are beneficial in a mathematical context. Therefore, the purpose of this qualitative research study is to construct a more comprehensive understanding of how undergraduate students conceptualize both conditional probability and probabilistic independence, including how students use intuition to understand probabilistic independence.

Theoretical Framework

APOS theory (Dubinsky, 1991) utilizes reflective abstraction as the mechanism for learning mathematics, and specifically delineates the process by which individuals mentally construct mathematical schemas by progressing through action (A), process (P), and object (O) conceptions of mathematical concepts. These progressions ultimately formulate a schema (S), which is a "person's own cognitive framework which connects in some way all of the ideas that the individual either consciously or subconsciously views as related to the piece of mathematics" (Mathews & Clark, 2003, p. 3).

An *action* conception is the most rudimentary, in that mathematical tasks are completely external (Mathews & Clark, 2003); therefore, it is necessary for the student to carry out the actions of solving. Once an individual has interiorized the mathematical actions, they are able to act with a *process* conception (Dubinsky, 1991), enabling the individual to perform processes internally and to "reflect on, describe, or even reverse the steps of transformation" (Mathews & Clark, 2003, p. 2). As one's mental constructions become more powerful, processes can be encapsulated into *objects* (Arnon et al., 2014), which are static entities in and of themselves to which actions can be applied (Arnon et al., 2014). Ultimately, a *schema* conception, or a collection of thematized mathematical objects (Mathews & Clark, 2003), is the most powerful, and allows for the coordination of objects either within or between mathematical concepts.

Probability and Independence

The following is a preliminary genetic decomposition (Arnon et al., 2014) used to facilitate the analysis of students' reasoning. Within APOS, students operating with an action conception of probability are likely to calculate probabilities by applying a formula, or by relying upon physical manipulatives or a drawn sample space. As a process, students are able to anticipate the result of a probability problem without physical manipulations, and can therefore compare and reverse probabilities without actions. Once probability is encapsulated into an object, students are able to conceptualize compound and conditional probabilities because simple probability is now a static entity that can be combined (compound) and nested (conditional). As a schema, students can coordinate encapsulated objects within probability, including coordinating multiple representations of compound and conditional probability.

Probabilistic independence is a component of probability, and thus, its construction will be linked with that of probability (Tarr & Jones, 1997). With an action conception of probability and independence, determining independence will be reliant upon a formula with no justification of its use. Anticipation of the results of probability, indicative of a process conception, may allow students to develop an intuition for independence, without explicit calculations. As probability is encapsulated into an object, students begin to conceptualize conditional probability, which facilitates reasoning with regard to the definition of probabilistic independence. Finally, as a schema, multiple representations of probability and independence can be coordinated; this includes contingency tables, formulas, and definitions, to name a few.

Methods and Analysis

The participants in this qualitative study include three undergraduate students at a large, research university in the southeastern United States. The participants were recruited because they were at least 18 years of age and had taken a probability course. All participants were individually interviewed once, for approximately 40 minutes, and were assigned a pseudonym. Interviews were video recorded for the purposes of retrospective analysis. During the interview, each student completed nine questions meant to elicit their understandings of conditional probability and probabilistic independence. Questions six and seven are adapted from Manage and Scariano (2010; Appendix A) and question nine is from the research of Tversky and Kahneman (1980; Appendix A). Additional questions are described in the results section.

The data were analyzed using APOS theory. Accordingly, students' responses to each task were compared to the preliminary genetic decomposition described above. Note that it is possible for responses of students who have constructed more sophisticated conceptions of a mathematical concept to align with the reasoning of a less sophisticated conception. However, students with a less sophisticated conception cannot act in a manner consistent with a more sophisticated conception. For example, a student with an object conception of independence may write out all of the steps to completing a task because they believe they are supposed to show work. To an observer, this may seem to indicate independence is external, or an action, for the student; however, it is not a counter-indication of a process or an object conception. Conversely, a student with only an action conception cannot act in a manner consistent with an object. Thus, student responses throughout the interview were taken as a whole, and the most sophisticated conception of probability and independence observed was attributed to the student.

Results

John

The first participant, John, was a sophomore electrical engineering major who had completed a probability course in the previous semester. When asked to find the probability of rolling a six on a six-sided die given the result is even, John answered two related, albeit incorrect, probability problems: What is the probability of rolling a six? And, what is the probability of rolling an even? With some prompting he realized "Ohhh, oh, oh. *Given* that it's even." On its own, this could be interpreted as a misunderstanding, however, John treated conditional probability problems as two related problems, instead of as one problem with a conditioning event, three out of four times throughout the interview. In question nine he went as far as to say, "So this is, like, two parts." I interpret these responses as John's inability to recognize the need to adjust the sample space of the problem as a result of the conditioning event; and therefore interpret this an indicator that John has not encapsulated probability into an object because he does not nest two probabilities.

In the instances when John did solve conditional probability problems correctly, he relied heavily on a formula. On one question in particular, he applied a formula for conditional probability and when asked to justify its use, said, "so you find (laughs)… I don't know how to explain this… it's just…" An explanation never followed. Later, in response to question nine, John tried to find a relationship between the formulas he had inappropriately applied and the contingency table provided in the problem. He explained:

> I'm thinking this is definitely true (points to his written formula), but I'm thinking maybe some of those (pointing to numbers in the contingency table) could actually give me the answer. … doesn't (as he checks one number in the contingency table against his formula), doesn't (checks a second number), doesn't (checks a third). No, it doesn't.

John's conclusion is that the numbers in the contingency table were unrelated to the formula. This speaks to his inability to conceive of the relationship between the two events within the task, which is a counter-indication of constructing an object conception of probability and independence because he does not justify the nesting of two probabilities. This is also a counter-indication of a schema conception because he does not relate multiple representations of conditional probability.

Although John relied heavily on formulas to reason about conditional probability, when reasoning about independence, he used formulas to justify his responses, not the other way around. In a question about the probability of being dealt two different sets of cards, he indicated that all cards dealt were independent of one another, and later used calculations to explain this. John went as far as to say, "just by intuition, they're the same," meaning the two hands are equally likely to be dealt. What John termed intuition, I consider to be his anticipation of the result, and therefore, evidence of at least a process conception of probability and independence. An area in which John continued to struggle with respect to independence was when two events were occurring simultaneously. In question seven, events C and D occur on a single roll of one die. John intuited these to be dependent events (incorrect), however, in justifying this response with a formula, he found them to be independent (correct). This was the only question regarding independence on which John's intuition led him astray. This was also the only question in which one event could not be interpreted to occur before the other event. Ultimately, John explained, "I believe in the formula. The results of the formula, they can't be false. … [but] if you just read it, not thinking about the formula, it would seem like they're kind of dependent." In this situation John struggled to discern independence from dependence as a seeming result of temporal reasoning; this limitation indicates that John has not coordinated conditional probability with independence in situations involving simultaneous events.

I attribute to John a process conception of probability and independence; that is to say, he has not yet encapsulated probability into an object upon which he can perform actions. John was able to apply formulas for probabilistic independence as a justification for his reasoning, not as a substitution for his reasoning. This is evidence of a process conception. However, John did not consistently adjust the sample space to account for the nesting of probabilities in conditional probability problems, which is a counter-indication of him having constructed an object conception. Furthermore, he did not demonstrate an understanding of the relationships between contingency tables and conditional probability, nor could he coordinate conditional probability with independence when events occurred simultaneously. These limitations are counter-indications of John having constructed a schema conception of probability and independence.

Dan

The second participant, Dan, was also a sophomore electrical engineering major, and was in the final three weeks of his probability course. In all conditional probability questions, Dan immediately recognized the need to adjust the sample space to account for the conditioning event. When asked to find the probability of rolling a six given the result is even, Dan explained, "If it's even it's going to be one-third because there's one possibility and there are three times it can be even – two, four, six. You want it to be six, so the number is one over three." This cogent justification implies that for Dan the probabilities of rolling a six and rolling an even are static objects that he acts upon by nesting them; this indicates at least an object conception of probability and independence.

He also coordinated his understanding of conditional probability with contingency tables. In question nine, for instance, he visually demonstrated this apparent coordination when he circled one column on the contingency table and said, "So it's gonna be this right there." He proceeded to verbalize the relationship between the table and the formula for conditional probability. This is evidence that Dan has constructed a schema conception of probability because of the coordination between multiple representations within the mathematical concept.

With regard to probabilistic independence, Dan relied upon his intuitions to anticipate the results of events within a set without performing calculations. In response to question six, he said, "I mean, there's only three possible outcomes. I'm just thinking about it … so that's the same for all of these … they can't be independent." When asked if he was comparing the probabilities of each event occurring, Dan repeated that he was "just thinking about it." This is evidence of his use of intuition, rather than mental calculations, which reinforces the indication of at least a process conception of probability and independence.

Dan's anticipation of probabilistic independence failed him, however, when responding to question seven. His intuition led him to believe that the simultaneous events occurring on a single die should be dependent, but upon calculation, he determined them to be independent. Reflecting on his calculations, he said, "It doesn't make sense. I'm just trying to picture this as a single event. It's not like you're saying this happened after the other event. … I just feel like it shouldn't be independent because they're happening at the same time." Dan spent several minutes trying to think of and explain other situations of independence as a means of eliminating his cognitive conflict, but was unsuccessful; he remained perturbed by the idea of independent events resulting from the roll of a single die. This is evidence of Dan not having coordinated objects of independence and probability in the case of simultaneous events, which is a limitation of his conception, and a counter-indication of him having thematized these objects into a schema. Considering probability tasks alone, it is possible to attribute to Dan a schema conception. However, when considering in tandem his reasoning with regard to probabilistic independence, it seems inappropriate to attribute to him the same conception. Based on this evidence, it is appropriate to attribute to Dan at least an object conception of probability and independence.

Aaron

The third student, Aaron, was a sophomore mathematics and economics major; he had completed AP Statistics in high school and received college credit for the course. Aaron calculated conditional probabilities correctly on all appropriate tasks, and did so largely mentally. In each of these questions he adjusted the sample space correctly in response to the conditioning event. In question nine, for instance, he explained that the sample space was changing from 1,000 taxis to 290 taxis by saying, "You add up how many times he actually says blue, which is the 290, and then of those times it's actually blue only 120. … That's (points to 120/290) the probability that the cab is blue given that he said blue." This excerpt exemplifies Aaron's ability to operate on one probability nested within another. When asked to explain his response to question nine, Aaron also constructed a tree diagram, and stated it was better organized than the table. He also clarified, "This is just what the table was telling me." As a whole, this is evidence that Aaron can coordinate formulas, contingency tables, and tree diagrams in reasoning about conditional probability.

In response to an independence task in which a set of people's behaviors and socio-economic statuses were given in a contingency table, Aaron calculated P(A|B) in determining whether event A depends on event B. When asked a follow-up probe (is event B dependent upon event A), he said "Maybe that's something where it's always if it goes one way [A depends on B] then it goes the other [B depends on A]. No, that isn't right." When asked how he arrived at this conclusion, he did not describe performing any calculations; instead, he described reasoning that P(A|B) is not equivalent to P(B|A), which is evidence of using a mental structure to anticipate the results of conditional probability. Aaron's ability to fluently solve conditional probability problems, to compare and reverse the conditioning events, and to reason using multiple representations, are all indicators of at least an object conception of probability. Moreover, his ability to compare and reverse conditioning events indicates he is likely operating on probabilities as static entities in their own right; for this reason, it seems likely that Aaron has constructed a schema conception of probability.

To further examine the schema attribution, it is important to consider his means of operating with regard to probabilistic independence. Aaron began the interview by explaining that probabilistic independence "means that the knowledge of one of them [events] happening shouldn't affect the likelihood of the other one happening." His metaphor of "dependence as knowing" was recurrent; I interpret his use of this metaphor as a mental structure that Aaron engaged to anticipate the independence of events. He used this metaphor again in question six: "you know that if you win, you don't lose and so the information of winning would help you figure out whether or not you lose. … they are dependent." Here, his metaphor of dependence as knowing includes the idea that "information" about winning provides knowledge, and therefore, implies dependence. Aaron's metaphor of dependence as knowing facilitates the coordination of independence with conditional probability, as demonstrated on question seven:

> If you know you rolled C [1 or 3], it doesn't actually help me know how likely it is that you rolled D [1 or 4], it just lets me know that it's more likely that you rolled a one… that means these would be independent… And then it goes the other way. If I knew about event D I wouldn't know any more about event C happening.

Aaron reasons about independence by explaining that knowing event C occurred doesn't give him more knowledge about whether event D occurred. Aaron does not struggle with the idea of events C and D occurring simultaneously because he coordinates conditional probability with probabilistic independence by applying his metaphor; this is evidence of a schema conception.

Discussion

John, Dan, and Aaron demonstrated different levels of reasoning; John's being consistent with a process, Dan's with at least an object, and Aaron's with a schema. A major difference between John's and Dan's conceptions is that Dan had encapsulated probability into an object upon which he could act, making it possible for him to appropriately interpret conditional probability. Dan understands the conditioning event to require an adjustment of the sample space, and justifies the use of probability formulas in his reasoning. John could not nest probabilities. Fischbein and Gazit (1984) found that difficulty reconstructing sample space in conditional probability is widespread, and this was experienced by John. Fischbein and Gazit's findings may be explained through the lens of APOS, as it appears that students must objectify probability to appropriately reconstruct sample space. This is an area for future research.

The main difference between Dan’s and Aaron’s reasoning was regarding independence. Aaron was able to coordinate probabilistic events as static entities and act upon these events to determine independence regardless of a temporal connection. The task on which this difference was the most apparent was task seven, in which two dice are rolled simultaneously. On this task, Dan’s object conception did not allow him to coordinate multiple objects (probabilities) occurring simultaneously, whereas Aaron’s schema conception did. It is possible that Dan was relying on primary intuitions (Fischbein, 1987) in this situation, whereas Aaron had constructed secondary intuitions that allowed him to intuit results in the situation of simultaneously occurring events. However, the role of simultaneously occurring events in students’ constructions of independence requires further empirical consideration; specifically, why this difficulty limits students’ coordinations of probability and independence, and how a perturbation, such as Dan’s, can be exploited in instruction to engender the construction of more sophisticated conceptions. Abrahamson (2014) indicates that probability instruction should link students’ intuitions to analytic reasoning and empirical activities with regard to probability. Perhaps by helping students construct these links, they will be engendered to construct secondary intuitions to supplement their primary intuitions; without secondary intuitions, it seems as though students may be restricted to thinking about independence as reliant upon time.

Interestingly, Aaron had the most sophisticated conception of probability and independence among this group of students, and was the only student to rely on a metaphor for determining probabilistic independence. Sfard (1994) argues that “reification is, in fact, the birth of a metaphor which brings a mathematical object into existence and thereby deepens our understanding” (p. 54). With this understanding, it stands to reason that Aaron’s metaphor of dependence as knowing was born out of his thematization of probability and independence into a schema, thereby allowing him to more meaningfully intuit independence. Aaron’s use of metaphor was an unexpected result in this research study, and it remains to be seen whether reasoning with metaphor with regard to probabilistic independence advantages students’ reasoning in some way over the intuitive reasoning engaged by the other two students.

Conclusions

As is frequently noted in the literature, students’ abilities to determine the independence of probabilistic events is problematic. Although these undergraduates were all STEM majors with formal instruction in probability and independence, each demonstrated a different conception. With a process conception, John was significantly limited; moreover, his intuitions regarding independence were primary (Fischbein, 1987). Similarly, Dan relied on primary intuitions in the situation of simultaneous events. Although Dan had constructed at least an object conception of probability, he had not constructed secondary intuitions regarding independence involving simultaneous events. John’s and Dan’s intuitions advantaged their reasoning in different ways, demonstrating that not all intuitions are equally beneficial. Future research should examine the conception of probability and independence that supports students’ constructions of secondary intuitions, specifically with regard to temporal reasoning.

The preliminary genetic decomposition utilized in this research is preliminary in that it requires refinement, and the varying reasoning of these students can direct these revisions. First, intuition was included as an indicator for the construction of a mental structure for independence, and thus, a process. While this was appropriate for John, Dan’s intuitions were more sophisticated. As a result, intuition needs to be more thoroughly examined within the APOS framework. Furthermore, these results indicate that even primary intuitions can be beneficial to students’ reasoning, which supports leveraging students’ intuitions in instruction. By capitalizing on primary intuitions, perhaps researchers can identify the mental constructs that support the construction of secondary intuitions and schemas, and instructors can begin to engender these constructions in their classrooms.

Appendix A

6) Assume a competitive game can end for team A in a win (P(win) = 0.4), loss (P(loss) = 0.5), or tie (P(tie) = 0.1). Are these events pairwise independent or dependent?

7) Roll a single, fair, four-sided die once and observe its upper face. Define two events: "C: Rolling either a 1 or a 3" and "D: Rolling either a 1 or a 4." Are these events independent or dependent?

9) A cab was involved in a hit and run accident at night. There are two cab companies that operate in the city, a Blue Cab company and a Green Cab company. It is known that 85% of the cabs in the city are Green and 15% are Blue. A witness at the scene identified the cab involved in the accident as a Blue cab. The witness was tested under similar visibility conditions and made the correct color identification in 80% of the trial instances. What is the probability that the cab involved in the accident was a Blue Cab rather than a Green one?

**note that a contingency table was also provided to participants for question 9.*

POSITIVE INTERDEPENDENCE THROUGH DATA MODELING

This paper describes work to integrate statistics and data modeling deeply into weekly routines of classroom instruction, and to use data modeling practices to support positive interdependence at small-group and whole-class levels. This research pursued a local problem of practice identified by a collaborating teacher: how to promote her students' individual and collective agency in respect to their achievement. Our hypothesis was that designing, creating, interpreting, and revisiting anonymized data representations of aggregated assessment information could offer a context for classroom groups to formulate, guide, and monitor various efforts to improve. Here, we report preliminary findings from work to foster relations among data, representations, conceptual structures, and collective agency in these classes. We also discuss implications of these early findings for researchers in data science education.

Keywords: Data Modeling, Positive Interdependence, Classroom Assessment, Representations

How can students in mathematics classes develop a culture of positive interdependence? Although research has shown that shared action and responsibility in classrooms can be powerful in supporting students to learn (Deutsch, 1962; Johnson & Johnson, 1989), we also know that mathematics classes create individualism and competition (Johnson & Johnson, 1999). Here we explore how learners' creation, negotiation, and use of aggregate representations of *classroom assessment data* can drive effective individual and collective action to improve their learning. This follows a line of work that leverages student-generated mathematical objects in aggregate representations to support participation in discourse and reasoning within the classroom community (Wilensky & Stroup, 1999; Abrahamson & Wilensky, 2004; Brady, White, Davis & Hegedus, 2013). We seek to build more visible relations between the social structures in the classroom that support or undermine positive interdependence and the conceptual structures that underpin the data generated by assessment tools during regular classroom routines. Relations among students' collective and individual perceptions as learners are deeply connected to the ways their learning is measured and represented, and how these data are used for interpretation. Yet we know that there are significant conceptual barriers for students when reasoning about data in aggregate. For example, students need deliberate support to move from case-based thinking about data to seeing aggregate "collective" data shape (Petrosino, Lehrer & Schauble, 2003). With this research in mind, we sought to capitalize on these strategies as resources for collective learning. In this paper we describe initial findings about design conjectures guiding our work, and identify opportunities that we are discovering and refining in ongoing work to map the *mathematical structures* behind assessment data and *social structures* in the class onto one another to promote interpretive discussion (cf., Stroup, Ares, & Hurford, 2005). Given the importance in data science of flexibly connecting information and interpretations about individuals and aggregates, we believe such tools are particularly powerful here.

Study Design and Data Collection

The data for this analysis have been generated in an ongoing year-long design-based research study (Cobb, Confrey, diSessa, Lehrer, & Schauble, 2003) conducted in collaboration with a 6th grade teacher in a racially and economically diverse urban public school in the Southeastern US. This teacher had been participating in a larger professional development project to improve middle-grades statistics instruction, and this study emerged to address a problem of practice that she identified: supporting her students in making sense of weekly quiz data. This teacher has been teaching for less than 5 years with a master's degree in education, and she is highly motivated with a strong commitment to supporting her students. Our collaboration has led us to focus on designing tools and routines to help students (a) see their grades as products of a coherent system; and (b) better navigate data aggregations at multiple levels: responses to quiz questions, individual quiz scores, individual report card scores, classroom aggregates of quiz scores, and classroom aggregates of quiz item responses.

We collected data from each of this teacher's three classes. The school has labeled two of the classes as *regular* 6th grade math classes and one as *advanced*. Many of the students in the classes had historically experienced little success in school mathematics, but the teacher is committed to supporting them to experience success in her class. The school's assessment routine requires students to evaluate assessment scores weekly, to create learning plans to improve, and then to "re-take" comparable assessments.

Over the Fall, we integrated ourselves into the classroom community, with the goal of becoming familiar resources for the students and getting to know the culture and rhythms of the three classes. We participated in class on Mondays as students examined quiz and discussed the instructional "map" for the week. After becoming integrated into regular classroom activity, we began collecting written student artifacts and video records of classroom conversations about assessment scores on each Monday. We recorded conversations with one stationary camera at the back of the room. We qualitatively analyzed classroom videos of conversations with an eye toward students using data representations to make inferences about their learning, or about the mechanisms that created the assessment data. We also looked for ways students coordinated different representations of data aggregations with social formations of collective responsibility.

Results

This work is ongoing design research. As such, some of our most valuable research products are the evolving *conjectures* we are iteratively testing and refining (c.f. Sandoval, 2014) and the *tools and routines* that we are developing, implementing, and refining as we build a theory of the activity we are working to support. Here we describe some of these conjectures and tools.
Our early work in this classroom highlighted that most students were unfamiliar with the mathematics underlying their grades (e.g. averaging), and in the face of an inscrutable process of converting quiz and other grades to a report-card grade, many substituted morally-charged explanations for these grades. These explanations often implied self-critiques, such as not having studying hard enough or not doing their homework well. However, these critiques did not appear to be concretely actionable, and learners were unable to take small steps to improve.

Conjectures: Challenges in Reasoning about Aggregate Data and Collective Activity

Our aim in supporting reasoning about classroom assessment data has been to foster concrete actions that build (and build *on*) connections between individuals and aggregates in both the mathematical and social spheres. Below is a list of current conjectures guiding our design: (1) Connecting individual and aggregate levels, and related changes in those levels, would be challenging in both mathematical and social dimensions, and creating representations that support students to *link* these domains would support fruitful analogous reasoning across the mathematical and social. (2) Exhortations to make visible changes to aggregate quiz data would spur reasoning about concrete social actions that could be taken at the whole-class level. (3) Seeing changes in aggregate data representations could support a social interpretation as feedback about success in collective action, and data representations would increasingly become tools to motivate, guide, and refine social action over time. (4) Shared experiences of success would promote a sense of individual and collective agency and responsibility, extending beyond the narrow bounds of quizzes to the broad enterprise of classroom learning.

Tools: Supporting Varieties of Reflection and Analysis

In supporting students reasoning about actions to change performance on quizzes we have developed two broad forms of data representation. The first is closely related to a standard "dot" plot: it built upon the students' early efforts to order and structure data captured on square post-it notes and arranged on the class whiteboard during interpretive discussion. This tool has been useful for promoting students' ability to read data displays, reason about distributions and clumping, and argue for "summative" measures to answer the question "Did we improve?" For instance, proposals for evidence of improvement included: Fewer 0s; More 100s; More people above the pass/fail cut score of 70; More people going up than down, and so forth. In addition, the use of *Tinkerplots* provided opportunities to trace changes in data across linked representations. For example, students traced those that scored "0" in the quiz to observe their score on the retake as potential site for evidence about collective improvement. On the other hand, large numbers of absences complicated not only claims about individual improvement but also inferences and claims at the class level, a subtle and group-worthy data modeling topic.

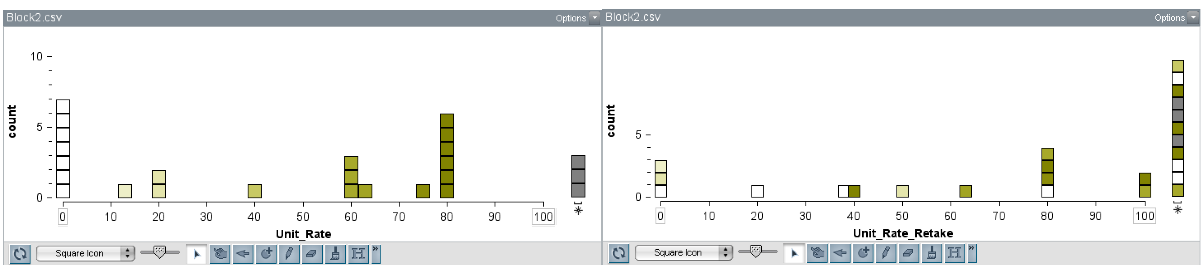

Figure 1. Post-It Inspired Dot Plot displays for a quiz (left) and a retake (right).

However, there have also been limitations to the discussions supported by the dot plot representations. Although we wanted to foster discussions about concrete actions that the group could take to improve, students often left these conversation with morally charged interpretations that were similar to our initial observations. Thus, we developed a second tool, supporting students in disaggregating quiz scores into item level data, and then aggregating that item level data to the class level in a non-standard representation that we have named DIGI/WIGI ("**D**id **I** **G**et **I**t/**W**hy **I** **G**ot (or didn't get) **I**t"). Students record their score on each (dichotomous) item on the quiz, and then describe the mathematical knowledge they used (for correct answers) or would need to have (for incorrect ones). Students have used DIGI aggregations (see Fig 2) to explore counts (which detected data-entry errors), assess relative item difficulty, and identify mathematical gaps for the class to work on together. Our use of this form suggests it can help to shift the focus of conversations from only *student quiz scores* to include comparative group-level performance on *items*. We have seen preliminary evidence that this shift may support more meaningful and concrete interpretations of assessment data.

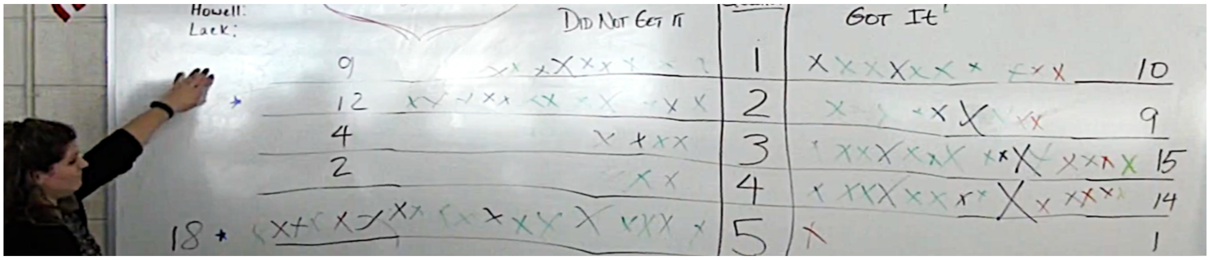

Figure 2. Aggregation of DIGI data for a 5-question quiz.

Discussion

Data science education can help us understand how to apprentice learners in creatively making sense of themselves and phenomena in the wide, information-saturated world (e.g. Lehrer & Schauble, 2002; Taylor & Hall, 2013). Nonetheless, it is important for this emerging field *also* to attend to quotidian activities and data systems that significantly impact students' identities, learning opportunities, and lived experiences. In this paper, we illustrate the rich learning opportunities afforded by mundane but periodic, small-scale classroom assessment data. The meanings students generate from data are constructed in relation to local goals, routines, and conceptual systems. We are exploring how learners' individual and collective relations to classroom assessment data can support them in flexibly constructing meaning with representations. Reciprocally, we are exploring how building interpretations about aggregate data representations can drive individual and collective action to effect improvements detectable by those representations. Although weekly quizzes may seem prosaic, we are finding evidence that students can become empowered to operate more critically, intentionally, and effectively as individuals and groups in this familiar but consequential context.

CONSTRUCTING INFORMAL VOCABULARY: A MIDDLE-SCHOOLER'S PATH TO PROBABILISTIC REASONING

Kelly Findley
Florida State University
kfindley@fsu.edu

Sebnem Atabas
Florida State University
sa16n@my.fsu.edu

Our research investigates the probabilistic reasoning of middle-school students making sense of sample space, distribution, and long-run likelihood. Eight students participating in a 3-week summer class on probability participated in games and activities that focused on concepts from the Common Core State Standards for grades 6-8. These activities utilized both concrete and simulated environments. Through engagement with the games and activities, we captured seeds of probabilistic reasoning that emerged with one student in particular, Evan, and took note of the vocabulary he and the class created to make sense of seemingly paradoxical situations. Implications for instruction on probability are briefly discussed.

Keywords: Probability, Interactive Simulations, Distribution, Sample Space

The Common Core State Standards have called for instructional emphases in probability and statistics in the wake of a data-driven society (National Governors Association Center for Best Practices, Council of Chief State School Officers [NGA & CCSSO], 2010). However, probability has proved notoriously difficult to teach, due in part to its varying colloquial uses as both something subjectively felt and something objectively calculated (Batanero, Chernoff, Engle, Lee, & Sánchez, 2016). Conflation is furthered through the term "randomness" due to nuanced distinctions in its use in statistics, mathematics, and everyday life (e.g., random sampling, random variable, randomly occurring) (Jones, 2006). The integration of probability in the middle-grades standards puts a considerable burden on teachers who report low self-efficacy for teaching probability and statistics (Chernoff & Zazkis, 2011; Lovett & Lee, 2017).

This report examines middle-school students' experiences grappling with probabilistic concepts, highlighting how one student's reasoning emerged. We discuss the role of interactive simulations in his development of probabilistic reasoning and the class' use of vocabulary to name these nuanced distinctions of probability and randomness. Our results also offer insight for instruction and the importance of student construction of vocabulary.

Conceptual Framework

This report investigates what role students' informal vocabulary played in developing greater understanding of probabilistic concepts. We use probabilistic reasoning as a lens for recognizing how these spaces connect. Savard (2014) states that probabilistic reasoning involves considering both variability and randomness. Variability is a consideration of what is possible by considering an outcome in terms of a distribution and a sense of how those results should manifest over the long-run. Randomness involves conceiving probability as non-deterministic, meaning we cannot ascribe certainty to outcomes. We view students' grappling with variability and randomness as the basis for probabilistic reasoning and an avenue for making sense of unfamiliar situations.

We emphasize a constructivist perspective on students' development of probabilistic reasoning that seeks to identify the ways students orient themselves to probabilistic situations and draw on their own experiences to make sense of these phenomena. The literature notes the seemingly paradoxical nature of many probabilistic situations (e.g., Batanero et al., 2016). For that reason, we are wary to assess students' progression of learning on this topic in terms of adopting and articulating rule-based responses. Rather, we keep in mind considerations offered by Chernoff and Zazkis (2011), who define a desirable pedagogical approach as "one that uses the learner's ideas as a starting point" (p. 19). Our methodology and analysis kept this point central as we sought to identify what students were bringing to this topic rather than their take-up of certain instructional ideas. We ask: How do middle-school students' use of vocabulary help them reason probabilistically about sample space, distribution, and long-run likelihood?

Methodology

Setting

This work stems from a research project studying students and teachers' use of PhET interactive simulations (sims) in middle-school mathematics (https://phet.colorado.edu/). The original intent of this summer class was to test drive elements from a two-week probability sequence that the research team had created for 7th grade involving the PhET sim "Plinko Probability." An instructional sequence was created prior to the summer class, with revisions being made after each lesson to adjust for students' progress and pressing questions. Eight students who were rising 6-8th graders participated for at least half of the classes. The students were gender and ethnically diverse. Each class was co-taught by us (the authors), with each class taking place at a local library branch and lasting 90 minutes.

Our findings focus on Evan, a rising 8th grader who reported "disliking" mathematics on an entrance questionnaire. We highlight Evan because he was present for more classes than any other student (11 out of 12) and elicited noteworthy probabilistic reasoning that did not often lead to correct conclusions. However, these episodes of reasoning were conceptually complex and led to important discussions that led to the creation of more refined vocabulary.

Data Collection and Analysis

Data sources include video recordings from each of the 12 classes, student work, including activity sheets and posters, student journals, and pre- and post-assessments. This preliminary report identifies examples of Evan's probabilistic reasoning embedded in brief narratives that help explain activity elements that facilitated his reasoning. Because of the instructional setting, we were able to implement activities and learning opportunities that responded to students' reasoning from day to day, allowing us to test explanations we were developing. Across the instructional sequence, students' vocabulary emerged as central to facilitating opportunities for probabilistic reasoning. We report two sequences from the class, highlighting how Evan's reasoning developed and made sense of class vocabulary when encountering new ideas.

Findings

Sloppy and Unsloppy Sample Spaces

After two introductory days of ice-breakers, administrative details, and a fraction review, students spent the rest of the first week immersed in the probability of spinners. When reasoning about the probability of landing on a certain space with an equally spaced spinner, students were all comfortable using a *how-many-out-of-how-many* approach (e.g., there is a 3/8 probability of landing on a space with a star since 3 spaces out of 8 have stars). When the size of the spaces on the spinner were no longer equal, students initially tried to adapt the how-many-out-of-how-many approach before recognizing that it was different. Students decided to describe this as a "sloppy" sample space, which they defined as a sample space with unequally likely outcomes. Figure 1 presents the poster that Evan's group made to describe this situation. This designation of sample spaces was an important step in distinguishing how variability can be apportioned differently across sample spaces—a stepping stone into thinking about distributions.

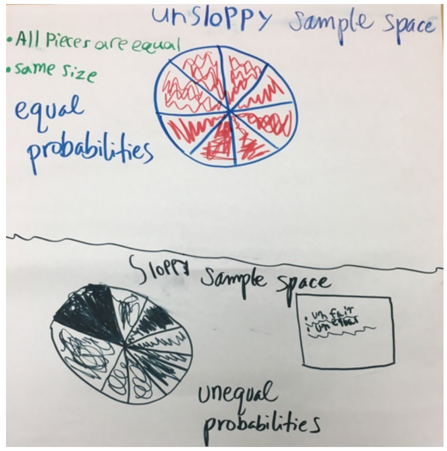

Figure 1. Student Poster for "Sloppy" Sample Space

Bountiful and Scarce Data

When reasoning about the sample space of rolling one die, Evan and others quickly described this sample space as unsloppy, with each of the options 1-6 being equally likely. However, when we discussed the probabilities associated with the sum of rolling two dice, students were initially divided. Jada felt it would be unsloppy: "I think they'd still be equal, even if you have two of them, because the possible numbers would still be the same." Evan claimed that the sum of two dice was a sloppy sample space: "To get a 5, you can get there a few different ways, but there's only one way to get a 2." Next, each group rolled a pair of dice 75 times, agreeing as a group that the sum of two dice appeared sloppy. Evan responded, "we didn't even get a two…in order to be unsloppy, you need to get an even amount of each number." The teacher then probed this idea: "If it wasn't exactly even, what if I got like six 2's, five 3's, five 4's, eight 5's, four 6's, like if it was just a little bit bumpy, would that be okay?" Evan said no, adding that "Unsloppy's perfect."

We followed up on this question of perfectly even by asking the class what they thought would happen if we threw just one die 75 times and recorded results. Evan changed his mind, now believing this might also be sloppy. After recording our results, the distribution was quite bumpy, with considerably more 5's than any other value. Students posed several ideas, claiming that the dice were either rigged, unreliable, or actually more likely to land on certain sides due to the distribution of dots. Evan viewed this as evidence for a sloppy sample space. We gathered 75 more rolls and continued to find bumpy results, further reinforcing students' notions that the sample space was quite sloppy. When the teacher reminded students that they had all agreed the theoretical probability was 1/6, Evan posed the idea that we could think of there being a theoretical sample space and an experimental sample space that could be considered together.

We want to highlight Evan's reasoning here because at one level, it could be easily dismissed as incorrect, but at another, it is quite complex and resonant with Bayesian approaches (Chib, Clyde, Woodworth, & Zaslavsky, 2003). Evan was cognizant of a theoretical (prior) distribution, while also being responsive to experimental results. The next day, we wrestled with how to balance these two notions. We began with a presentation about sloppy and unsloppy, but we introduced a new idea that emerged: having few results and tons of results (i.e., an experimental and theoretical distribution). Using online dice simulations, we revealed a more complete picture of rolling one and two dice many times. Evan used "bountiful" to describe when lots of data was collected, with "scarce" describing when only a few results were collected. This vocabulary helped Evan and others consider underlying variability in tandem with randomness as a factor.

Discussion

Our findings highlight two layers of vocabulary that, together, helped students make sense of rather complex notions involved in reasoning about probability. These vocabulary layers assisted students as we ventured into the last segment of the course, long-run likelihoods. Using both a coin-flipping game (involving making left and right turns based on the flip) and Plinko Probability, students were able to connect their vocabulary from the dice activities with new situations to conceive of both an underlying theoretical distribution and the randomness of experimental outcomes. Figure 2 displays how students were able to make sense of balls bouncing down the plinko peg-board based on theoretical probabilities, but could also explain why only running a handful of balls down the board resulted in clumpy results using the bountiful/scarce language. This combination of vocabulary layers led to productive probabilistic reasoning by attending to both distribution and randomness in the data. There are instructional implications from these findings, including the importance of leaving room for student ideas and names, even when these names are not officially in the curriculum. We hope to explore these ideas further by implementing an updated instructional sequence in a 7th grade classroom.

altabad@live.com.mx

We hereby present an exploration about graphs interpretation by students who are becoming kindergarten teachers. We also pretend to identify the notions which have about representative value from a data set. In this study there were 91 future kindergarten teachers participating to whom some information represented through a frequency graph was presented for them in order to answer a set of questions. The analysis shows the levels of interpretation of the participants, it is perceived that most of the teachers gather explicit information from the graph. However, they present some difficulties to integrate and combine data in order to make appropriate interpretations. The results are a reference in order to design intervention proposals which can help in the future teachers in training and the ones in current service as well as to reduce the breaches in the statistics learning in kindergarten.

Keywords: Data Analysis and Statistics, Teacher Knowledge.

Introduction

The interpretation of statistic graphs is an everyday activity which people do. Nowadays, most of the information is represented through graphs or tables so that when interpreting them, people can make decisions or just satisfy their curiosity about any topic of their interest. This has led into the necessity to train the future teachers so that they have the abilities and knowledge necessary about statistics and so, in that way they train the future citizens. In Mexico, the study of representation and interpretation of graphs is seen from the kindergarten level (see SEP, 2011, p. 57). This objective is part of the knowledge that a kindergarten teacher in training must acquire during his/her initial training (see SEP, 2012, pp. 20 and 22). Due to this, in this current research, we have the objective to identify the interpretation level of the future kindergarten teachers about frequency graphs as well as to explore their notions in relation with the representative value from a set of data.

There are several studies which give relevant information about graphs interpretation by the basic education teacher. González, Espinel and Ailey (2011), Jacobbe and Horton (2010), Alacaci, Lewis, Brien and Jiang (2011) and Sanoja and Ortíz (2013) report that the difficulties which the teacher face when interpreting the graphs, sometimes, are the result of the lack of understanding of basic concepts in statistics (e.g. scale, origin, axis, variable, dependency, independency, scattering, among others). From this, the interest of some researchers has focused on the mathematical knowledge for interpreting graphs (e.g. Alacaci et al., 2011). For Ball, Lubienski and Mewborn (2001) the teacher must build a solid knowledge during his/her initial training so that he/she has the basis to teach mathematics, thus statistics. On the other side, Llinares (2013) considers that the future teacher has to re-learn the mathematics he/she already knows in order to build a specialized knowledge which lets him/her state and give meaning to the mathematics to be taught in the classroom.

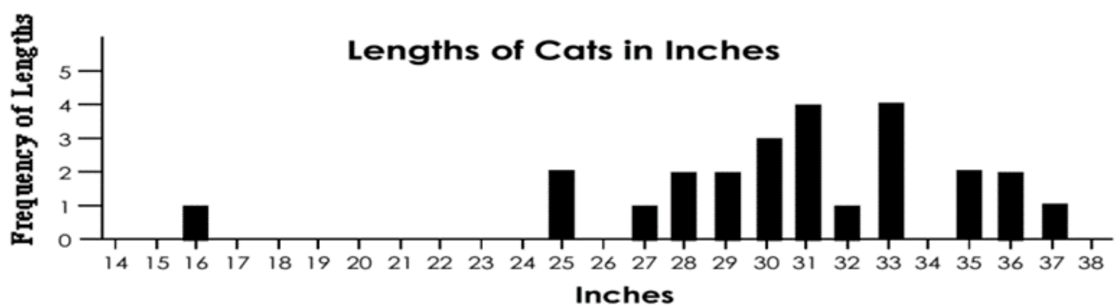
Conceptual Framework

For the interpretation of statistical graphs, Curcio (1989) defines three levels: 1) *Reading the data*, copy or reproduce the information or the facts which are explicitly expressed in the graph without going any further; 2) *Reading between the data*, combine and integrate data from the graph in order to obtain information, for example, by making comparisons or basic algorithms; 3) *Reading beyond the data*, predict or infer non-directly expressed information in the graph. In terms of Ball, Thames and Phelps (2008), the first two levels make reference to *basic knowledge (Common Content knowledge)* to extract information or data from statistic graphs, and the last level is related to the *specialized knowledge* which involves statistic reasoning.

Method

In this study, 91 future kindergarten teachers in training from a Mexican public school participated. Their ages were from 18 to 21 years old. A questionnaire about four problems, which included frequency graphs and a set of questions related with these graphs, was implemented for each participant. It is important to mention that the problems were taken from scientific literature. In the current document, only the results of one of the problems are reported (see Figure 1). The analysis of the gathered information is of the descriptive type and it was made through coding (Birks & Mills 2011). For this, firstly, words or groups of words or phrases were identified which derived from the answers of the participants and then, they were categorized based on the levels of Curcio (1989).

A group of students has been investigating information about their pets Several students have cats. They decided to collect some information about each of the cats. One set of data they collected was the length of the cats measuring from the tips of the cats' noses to the tips of their tails. Here is a bar graph showing the information they found:



1. How many cats are 30 inches long from nose to tail? How can you tell?
2. How many cats are there in all? How can you tell?
3. If you added up the lengths of the three shortest cats, what would the total of those lengths be? How can you tell?
4. What is the typical length of a cat from nose to tail? Explain your answer.

Figure 1. Problem of *lengths of cats*, taken from Bright and Friel (1998).

Results

The levels of interpretation on which the participants, taking the answers to the problems as a reference, are exposed as follows.

1. How many cats are 30 inches long from nose to tail? How can you tell? The answer to this question is the lowest level, *Reading the data*, and it was expected that the participants located the value of the variable corresponding to 30 inches and its frequency. This level was achieved by 90% of the participants. One example of the answers given was the following: "There are three cats with a length of 30 inches. Because in the bars graph it is shown that in the frequency of the inch number 30 is 3." The rest of the participants made at least one mistake when reading the frequency in the Y axis of the graph. They based their answer on the idea that each bar represented a cat so they gave confusing answers or did not answer the question.

2. How many cats are there in all? How can tell? In order to answer this question, the level *Reading between the data* was expected because it only required basic knowledge such as identifying the frequency in each bar and add them up. Only 67% of the participants achieved to give a correct answer and get into this level of interpretation. This is reflected on the answer which one of the participants gave: “There are 25 cats, because it is the total sum of the frequencies.” The answer to this question showed the difficulty for some of the teachers in training to read among the data. Such difficulty is related to making mistakes when counting or adding up the frequencies of the cats, interpreting each bar as a cat, not knowing how to determine that total as well as to give confusing answers or not answering at all.
3. If you added up the lengths of the three shortest cats, what would the total of those lengths be? How can you tell? The answer involves the level *Reading between the data*, due to locating the minor values of the variables is enough. These were 16 and 25 inches, and their frequencies 1 and 2 respectively. Besides, they had to add those values up ($16 + 25 + 25 = 66$). The future teachers associated the idea of small cat with the bars with the lowest frequency. 54% of them added up three bars of the lowest frequency. In some cases, they were three consecutive bars and in others, three bars chosen by any other criteria which is not clear. An example of this is the following: “$16 + 27 + 32 = 75$. Because the smallest cats have a measure of 16, 27 and 32 inches. Then 16 + 27 are 43 + 32 are 75.” 25% answered correctly (66 inches). Other participants made mistakes adding up, gave confusing answers or stated not being able to determine the required value. In some cases, they just added up the values of the variable which corresponded to the cats with the smallest length without considering the frequency of the variable.
4. What is the typical length of a cat from nose to tail? Explain your answer. The answer makes reference to *Reading beyond the data*. The notion which the future teachers handle of typical value matches with the one of average as mode (61.5%), as they took the mode to interpret a distribution and this is reflected when considering just as “the most” and not as a representative value (Mokros & Russell, 1995). An example of those answers is: “31 – 33 inches because it is the number which is repeated most of the times.” Other teachers did not answer. They considered that the typical value matched with the frequency which was repeated the most (2), they mentioned the average, considered the median or did not show a clear answer.

Conclusions

The teachers in training are able to reading the data without difficulty but when requiring them to reading between the data, they show difficulty to infer or interpret the graph. In relation with the answers of the second and third questions, the participants backed up on their basic knowledge such as the algorithm of adding up or multiplying (this was a mistake), they made it evident in a lower number of answers corresponding to combine and integrate the data because it was difficult for them. As in the study of Bright and Friel (1998), where the participants were children from 11 to 14 years old, the difficulties from the teachers in training are recurrent such as interpreting each bar of the graph as the representation of a cat, or that the small cats were represented by the bars with lower frequency. As it was mentioned in the introduction, some authors consider that this type of difficulties appear because teachers do not have clear some of the basic concepts in statistics. The future teachers show confusion when determining the frequencies in the bar graphs and operating with them. Besides this, the interpretation of the variable together with its frequency can be a non-achieved task by any of them. Concerning the approximations of the representative value, from a set of data, the average as mode is the one used the most, maybe 8% of the participants is close to the notion of average as a media point, as they consider the median to justify their answers. The results also show that a great percentage of teachers in training for kindergarten level have basic and specialized knowledge that allows them to literally read the graph or infer information from it. However, the need to reinforce this knowledge during their training is evident. Due to the exigency of the society and educational reforms which we live nowadays in Mexico, it is expected that the future teacher has wide knowledge (Jaworski, 2008), These results show that research focused on how the kindergarten teacher presents in the classroom the use and integration of the graphs is required and so to study the idea of arithmetic media as a representative value from a set of data.

Stephanie M Gardner
Purdue University
sgardne@purdue.edu

Historically, mathematics, statistics, and biology are courses taught in isolation. Yet, there are some tasks that invite students to combine these different types of knowledge. In this study, 10 undergraduate biology students were asked to make a graph from a given set of data embedded in a biology context. Graphs were analyzed to identify features such as variables plotted, number of graphs created, and type of graph used to represent the information (e.g., scatter plot, line graph, or bar graph), and whether the graph showed an understanding of the purpose and features of the scenario. Participants made a variety of graphs. Graphing data was a task that invited them to combine knowledge from different disciplines. Looking forward to the field of mathematics education, graphing could be one activity that invites our community to interact with other disciplines, embrace our common practices and diverse ways of knowing.

Keywords: Graphing, Biology, Statistics, Undergraduate, Interdisciplinary

In mathematics classrooms, we usually ask students to make a graph to represent linear, quadratic, or exponential patterns. In these tasks, students usually identify the role of two given variables (i.e., independent and dependent variable), determine a couple of coordinates to then construct a graph. Meanwhile in statistics classrooms, students use graphs such as a line graph, bar graph, or scatterplot as a way to analyze patterns in the data. If students are given a set of data, it usually contains more than one variable and students have to explore and determine what relationship could be represented from the given set of data (Wild & Pfannkuch, 1999). While it is known that mathematics and statistics tasks have real-world contexts in common, in mathematics this could be optional, while in statistics, the context is an essential element of the situation (Scheaffer, 2006). In other science fields, such as biology, one skill that students are expected to develop is the construction of graphs as part of the scientific process where they can use them to summarize data, which comprises evidence to support the validity of a hypothesis. One practice that is common across mathematics, statistics, and biology is understanding information that graphs convey in order to create an effective representation of data with which the graph creator and others can interpret and draw conclusions. For example, in biology, students might be asked to design experiments to evaluate the effectiveness of a treatment. In this context, students need to integrate different types of knowledge to create an appropriate graph of their data to discern patterns. Knowledge about the biological system under study, so that they understand the context, limitations of measurement and study design, and properties of the measured variables. Knowledge about mathematics, to operate symbols and use a mathematical language to communicate with others. Knowledge about statistics, to explore data, acknowledge variation, and select an appropriate graph that allows them to communicate patterns in the data.

In the construction and reading of graphs, adults and K-12 learners struggle at the time of conveying information and making interpretations from them. For example, Chick (2004) found that secondary school students' graph choices were not always suitable and they did not used strategies that could have made their graphs clear. Working with a similar population, D'Ambrosio, Kastberg, McDermott, and Saada (2004) found that students had difficulties interpreting graphs. Specifically, students wrestled integrating the context and the mathematics involved in graphs. Studying graphs created by adults, Tufte (1983) identified graphs published in magazines or periodicals that promoted misleading information for readers. In science fields such as biology, Angra and Gardner (2017) explored graph constructions of professors, undergraduate and graduate biology students. The authors found that in comparison to professors and graduate students, undergraduate biology students struggled deciding which data to select and represent, what type of graph to use, and aligning their graph construction decisions with the question and/or hypothesis under consideration.

The difficulties learners face making and reading graphs could be seen as a lack of mathematics or statistics content preparation. However, we contend that it is not competence with the knowledge and skill in any one of the relevant disciplines, but that in order to successfully analyze, represent data, and communicate its patterns in biology contexts; students need a combination of all of these types of knowledge. We acknowledge that this task is challenging given that students are seldom given explicit instruction preparing them to combine knowledge from different disciplines. Therefore, in this study the authors built from Williams' et al. (2016) concept of interdisciplinarity to explore graph construction as a task that involves working on the edge of three different disciplines: statistics, mathematics, and biology. Particularly, the authors explored the types of graphs biology undergraduate students constructed from a given set of data and discuss the mathematics, statistics, and biology knowledge used in their graphs' construction.

Methods and Analysis

These data were collected as part of another study (Angra & Gardner, 2016, 2017) in which biology undergraduates, graduate students, and biology professors were engaged in a pen-and-paper think-aloud graphing task. The data presented here are from a subset of the full data corpus and are comprised of data from 10 undergraduate biology students' first graphs construction and their descriptions. There were two isomorphic biology scenarios assigned to the participants: two treatments, five time points, and three replicates within the context of plant growth and cell culture experiments. Participants were asked to graph any aspect of a given set of data. Figure 1 shows data from the plant growth context.

Plant leaves scenario
Imagine you are a botanist. You are particularly intrigued by how the amount of water influences plant growth. In order to answer your question, you set up an experiment that measures the growth of a particular type of plant at two different water amounts. You collect your data and display it in a chart shown below.

	Number of Leaves					
Time (Hours)	15ml of water/day			5ml of water/day		
	Plant 1	Plant 2	Plant 3	Plant 1	Plant 2	Plant 3
0	0	1	0	0	0	0
30	2	1	3	0	1	1
60	3	3	5	2	1	2
90	4	3	5	2	1	3
120	6	5	7	3	1	4

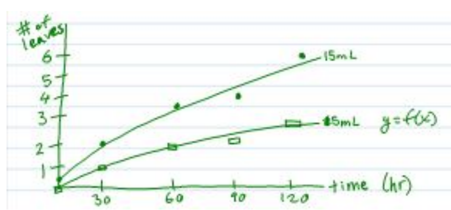
Figure 1. Scenario and data given to the participants.

In a first level of analysis, participants' graphs were examined independently of their think-aloud. The graphs were coded according to different characteristics. Variables plotted, number of graphs created, type of graph used to represent the information (e.g., scatter plot, line graph, or bar graph), and whether the graph is *aligned* with the purpose and features of the study in the scenario (i.e. comparing growth over time in two treatment groups and the use of replicates within each treatment). In a second level of analysis, commonalities and differences among participants' graphs were identified and organized along with participants' verbal descriptions of their graphs during the think-aloud. The authors used Konold, Higgins, Russell, and Khalil's (2015) framework as a way to describe their interpretations of participants' views of data: aggregate, classifiers, case values, and pointers.

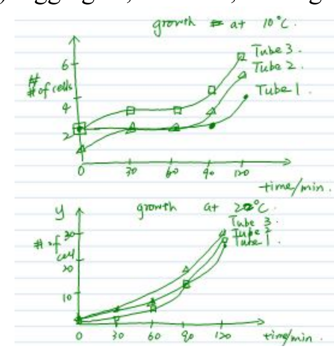
Results and Discussion

Four out of 10 participants drew a graph that showed a comparison of the two treatments (see Figure 2a)). In these cases, time was considered the independent variable, and the average of the results per plant, as the dependent variable. Three out of 10 participants graphed the results of each plant, or tube, per treatment using two separated graphs (see Figure 2b) and c)). In Figure 2b) the participant was assigned a context related to cells culture and she drew two graphs. One graph representing the number of cells in the tubes exposed to the 10 degrees Celsius treatment, and the other graph for the 22 degrees Celsius treatment. Finally, three out of 10 participants represented the results of each plant under the two treatments. This approach generated three different graphs, one per plant (see Figure 2d)).

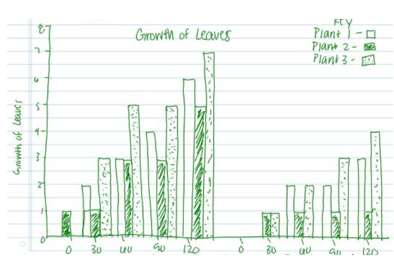
a) Aggregate (reduced) no variation, aligned



b) Aggregate, raw data, misaligned



c) Aggregate, raw data, aligned



d) Case values, misunderstanding replicates, aligned

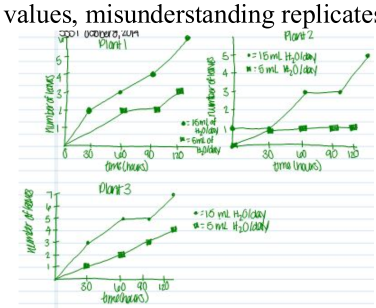


Figure 2. Examples of participants' graphs using Konold's et al. (2015) language.

When researchers looked at the participants' background information, they learned that those with research experience created one graph that communicated a comparison of the two treatments. However, none of them explicitly acknowledged variability in their graph construction (e.g., using error bars). In relation to the type of graphs, six out of 10 participants used line graphs, 2 out of ten scatter graphs, and the rest bar graphs. The majority of the participants used time as the independent variable in the x-axis, and number of leaves, or cell, as the dependent variable. Participants' reasoning for using time as the independent variable was based on understanding time as a continuous variable, which for them it meant to be placed in the x-axis.

Students created a variety of graphs to represent the same set of data. However, the majority of them considered time as the independent variable. As shown in other studies (e.g., Chick, 2004; D'Ambrosio et al., 2004) representing a given set of data in a graph was not a simple task for participants. Creating a clear graph that conveyed information about the results of the experiment was something that four out of ten participants successfully did (see Figure 2a)). Yet, statisticians would argue that those participants' graphs with their descriptions lacked of explicitly acknowledging variability.

The authors consider that those participants who created one graph that showed a comparison of the two treatments are examples of students combining biology, statistics, and mathematics knowledge. The need for a graph originated from the context of the task: exploring the results of an experiment where plants or cells where exposed to two different treatments. To compare both treatments, students needed to see data as aggregate (Konold et al., 2015), which four students interpreted as plotting time versus the average (reduced data) of the results of each plant or cell. This procedure, or way of thinking, could be associated to mathematics or statistics depending on the student's academic background. Finally, the type of task used in this study seems to encourage students to combine different types of knowledge learned in college coursework. However, authors cannot claim with certainty what prompted participants to use a combination of mathematics, statistics, and biology knowledge. It seems that having research experience could be an antecedent to be considered for future studies. The authors also consider that teaching graphing to undergraduate students using interdisciplinary lenses is another way to advance their graphing skills further.

UNDERSTANDING PROBABILITY LITERACY OF HIGH SCHOOL STUDENTS

Fred A. Coon, IV
University of North Carolina at Charlotte
fcoon@uncc.edu

Anthony Fernandes
University of North Carolina at Charlotte
Anthony.Fernandes@uncc.edu

Keywords: Probability, High School Education

Probability and statistics have taken prominence in the era of big data. Thus, there is a need to ensure that high-school students have a thorough grounding in probability concepts or probability literacy. Probability literacy is a collection of knowledge, skills, attitudes, and habits of the mind about probability. Gal (2005) placed all aspects of this into two categories with subtopics under each. Those two categories are knowledge elements and dispositional element. The underlying concerns of this study are the big ideas and figuring probabilities under the knowledge element. Multiple reliable tasks will be used to centered around randomness, chance, independence, and sample space. The result of understanding probability literacy of high school students will help understand the teaching needs of students in schools. Currently, there is little research that examines the conceptions that high school students have about randomness, chance, independence, and sample space (Jones, Langrall, & Mooney, 2007).

The purpose of the study is to understand the probability literacy of high-school students as stated by Gal's (2005) framework. Namely: what is the probability literacy of high-school students? In particular, what do high school students understand about the following probability concepts of chance, randomness, independence and sample space?

Fischbein, Nello, and Marion (1991) reported students' responses from a study of probability where students correctly answered probability questions with incorrect reasoning. One such response was, "the probability is the same because the result cannot be predicted" (Fischbein, Nello, & Marion, 1991, p. 538). The student's response was to a task involving the flipping of two coins. The student correctly answered the question, but the reasoning points to the fact the student has little understanding of probability. Hence the need for more thorough understanding of students' misconceptions or probability is needed to better inform the instruction to prevent such misconceptions from propagating. The information that this study hopes to uncover will provide researchers and practitioners with insight about probability literacy among high school students.

The research will be conducted using taped semi-structured oral interviews and parallel student written interviews as adapted from Rubel (2007) where she was seeking to uncover students' justifications in addition to correctness. She found inconsistencies in student responses between the two forms that might lead to insight to students' probability literacy. A pilot study will be conducted during the summer of 2018 to inform the main study that will take place during the spring of 2019.

MIDDLE AND SECONDARY TEACHERS' PCK WITHIN IIR CONTEXTS

Christopher Engledowl
New Mexico State University
chriseng@nmsu.edu

James E. Tarr
University of Missouri
TarrJ@missouri.edu

Keywords: Mathematical Knowledge for Teaching, Data Analysis & Statistics

Over the past decade, research on pedagogical content knowledge (PCK) for statistics has been identified as a critical area of need, particularly the need to study teachers' PCK in the context of informal inferential reasoning (IIR) (Langrall et al., 2017). A majority of the work in statistics education, for both PCK and IIR, has focused on *students* across PK-16. Within the narrow body of literature on middle level and secondary mathematics teachers' PCK, although some teachers have been found to develop strong PCK (Peters, 2013), many struggle to develop it, despite strong content backgrounds (Callingham et al., 2011). This study utilized Groth's (2013) statistical knowledge for teaching framework—focusing on the PCK components of teachers' knowledge of content and students, and knowledge of content and teaching—and operationalized it through the descriptions of four hierarchical PCK levels expressed by Callingham and Watson (2011), set within the context of responding to tasks designed to illicit IIR. Due to space, this study focuses only on teachers' PCK and does not attempt to analyze their IIR engagement.

Data come from a stratified purposeful sample of 9 middle and secondary mathematics teachers as they responded to a set of 4 LOCUS (Jacobbe, 2016) tasks during two 60-90 minute task-based interviews. After completing the tasks on their own, the following two questions were asked, as in Watson et al (2008), to aid in identifying teachers' statistics PCK: 1) What are some appropriate and inappropriate student responses? 2) How might you respond to a student who offers an inappropriate response? The interview protocol included follow-up questions based on predicted teacher responses, as well as example student responses to offer, when necessary. Results indicate that when teachers were responding to explicit IIR items, as opposed to those not requiring reasoning about inferences (e.g., reasoning only about center, spread, and shape), they tended to fall within the lowest level of PCK. However, when responding to items not requiring IIR, their PCK could be characterized at higher levels of PCK and there was less consistency with content background knowledge. Additional findings will be shared and implications for future research and teacher education will be offered on the poster.

HIGH SCHOOL STATISTICS TEACHERS' DEVELOPMENT OF KEY UNDERSTANDINGS OF HYPOTHESIS TESTING THROUGH SIMULATION

Amber L. Matuszewski
Middle Tennessee State University
Alm6p@mtmail.mtsu.edu

Keywords: Data Analysis and Statistics, Mathematical Knowledge for Teaching, Technology

In general, students and teachers can often learn the associated computations and procedures of a hypothesis test but struggle with the reasoning and basic concepts of this procedure (Harradine et al., 2011). Even with intense remediation efforts, it is often difficult to convey an understanding of these abstract ideas (Thompson et al., 2007). Using simulations for hypothesis testing is a growing trend in statistics education due to the belief that simulations help make the abstract ideas behind hypothesis testing become more concrete and understandable (Erickson, 2006). Cobb (2007) described the simulation process as "The three R's: randomize, repeat, reject. Randomize data production; repeat by simulation to see what's typical; reject any model that puts your data in its tail" (Cobb, 2007, p. 12). In other words, using simulated sampling distributions to reject or fail to reject the null hypothesis.

With this trend in statistics education in mind, I conducted an explanatory case study to answer the following question, "How does engaging in the process of using simulations to conduct a hypothesis test influence a high school statistics teacher's understanding of this topic?" Before engaging in the simulation tasks, the participant could correctly define terms and explain some of the steps that should occur for hypothesis testing. However, when attempting to answer questions or provide explanations that required a more in-depth understanding, she was unable to do so. For example, when she did not have the steps in front of her, she stated the you should reject the null hypothesis when the *p*-value is large. She believed a large *p*-value meant that your data would likely be replicated again, so your null hypothesis is probably true.

My poster will describe the lesson plan design used for the simulation tasks and describe how the participant interacted with the tasks. Additionally, the results of how the tasks influenced the teacher's content knowledge for hypothesis testing will be shared.
The tasks allowed the teacher to visualize the sampling distribution and correct many of her misconceptions. After the tasks, she correctly described when to reject the null hypothesis and was able to articulate how the alpha-level was related to a Type I error. Additionally, the lesson plan design helped her to understand the logic of hypothesis testing. The poster will highlight important elements to incorporate into professional development to help teachers foster a deeper understanding of hypothesis testing using technology to conduct simulations for inference.

A FRAMEWORK FOR ANALYSIS OF AP STATISTICS TEXTBOOKS FOR INFERENTIAL REASONING

Asli Mutlu
North Carolina State University
mamutlu@ncsu.edu

Hollylynne S. Lee
North Carolina State University
hollylynne@ncsu.edu

Keywords: Data Analysis and Statistics, Curriculum

The textbook has served as the centerpiece of learning for almost every academic discipline, although the relationship between the course and its textbook is complex. As a fundamental resource, Advanced Placement (AP) Statistics' textbooks have the potential to shape the way the instructors teach and the students learn (Zieffler, Isaak, & Garfield, 2013). While a growing body of research has sought better ways to improve the teaching of inferential reasoning in AP Statistics course, there is a lack of research on particularly focusing on the textbooks' analysis for inferential reasoning (Zieffler et al., 2013). Inferential reasoning is not only an ultimate learning goal of the AP Statistics course, both its early introduction and implicit instruction is also recommended by the Guidelines for Assessment and Instruction in Statistics Education (GAISE) report (Franklin et al., 2007). Recent research efforts have focused on its implicit learning goal as "informal" inferential reasoning where students drawing conclusions about populations based on data before the procedures of formal inference are introduced (Zieffler et al., 2013).

In this poster, we will describe a framework that we have developed to answer the following: What is the nature and extent of inferential statistics concepts contained in AP Statistics textbooks?

We have developed a two-dimensional, four by five matrix structured framework. One dimension is the four phases of the statistical investigative cycle, which is defined by GAISE as *posing a question, collecting data, analyzing data* and *interpreting results*. The other dimension is comprised of the five key aspects of inferential reasoning proposed by Lee (2017). They are the five columns of this framework as *Context, computations and graphs, variability, uncertainty* and *beyond data at hand*. Each cell of this matrix will have evaluation criteria. For instance, in the cell of the intersection of the row of *posing a question* and the column of *context*, students' interest will be the evaluation criteria. The two dimensions of our framework embody the key recommendations for developing informal inferential reasoning and capture the common attributes, which pave the way to inferential reasoning. This framework acknowledges a continuum within each dimension that reveals implicit and explicit pedagogical choices made by textbook authors and publishers that directly influence students' opportunities to learn.

Our framework analyzes the expositions and tasks in AP Statistics textbooks, which are recommended by College Board. Under the lenses of our framework, we will present, the preliminary findings of the analysis of two AP Statistics' textbooks,

Palabras clave: Actividades y Prácticas de Enseñanza, Discurso del Aula, Educación Post-Secundaria, Análisis de Datos y Estadística

Con el objetivo de estudiar la evolución de los procesos de enseñanza de la estadística cuando se integran recursos tecnológicos digitales, analizamos los esquemas de acción y utilización (Gueudet & Trouche, 2012) de una profesora de estadística universitaria, quien integra en sus clases el lenguaje de programación R. Más específicamente, esta profesora diseñó su curso a través de una serie de actividades basadas en R, con el objetivo de promover el entendimiento de conceptos de estadística, por parte de sus alumnos. Se observó la práctica de esta profesora en dos cursos avanzados de nivel universitario, durante un periodo de tres semanas; dichas observaciones fueron complementadas con datos de una entrevista semi-estructurada, recursos materiales (las hojas de trabajo de las actividades en R, evaluaciones, etc.) y otros recursos relacionados con su práctica docente. Los resultados fueron analizados cualitativamente usando el Enfoque Documental (Gueudet & Trouche, 2012) para inferir la génesis documental de esta profesora relativa al uso que hace de los recursos. La génesis documental se refiere al proceso mediante el cual, a través de la selección, modificación y recombinación de recursos, el profesor desarrolla un sistema de recursos junto con un esquema de utilización y/o acción que guía la actividad de enseñanza situada.

Para este póster, nos centramos en los esquemas de utilización y acción de los recursos del lenguaje que surgieron al analizar las relaciones e interacciones entre los recursos digitales y no digitales. Se identificó cómo esta profesora usaba diferentes tipos de lenguajes –oral, corporal, estadístico y de programación en R— como esquemas de acción. En el discurso de la profesora, hay una continua traducción entre el lenguaje estadístico, el lenguaje de programación y los lenguajes oral y corporal, por medio del cual se expresan las hipótesis, las relaciones observadas y las interpretaciones que se hacen a partir de la exploración de los datos contenidos en los problemas planteados en las actividades. De esta manera, los lenguajes oral, corporal y estadístico se combinan y articulan con el lenguaje de programación R, constituyéndose así en 'recursos de lenguaje', y sus usos son esquemas de acción de la profesora que promueven la comprensión de conceptos y de relaciones entre éstos, a la vez que ayudan a desarrollar la capacidad de los alumnos para conducir análisis estadísticos.

Agradecimiento

Financiamiento parcial para nuestro estudio provino de los proyectos PAPIME PE204614 y PE207416 de DGAPA-UNAM.

A STATISTICS TEACHING CASE STUDY BASED ON THE R LANGUAGE: SCHEMES OF ACTION AND DISCOURSE

Perla M. Ruiz-Arias
CINVESTAV, México
pmruiz@cinvestav.mx

Ana Isabel Sacristán
CINVESTAV, México
asacrist@cinvestav.mx

Keywords: Instructional Activities and Practices, Classroom Discourse, Post-Secondary Education, Data Analysis and Statistics

In order to study the evolution of teaching processes for statistics when integrating digital technological resources, we have analyzed the schemes of action and utilization (Gueudet & Trouche, 2012) of a university statistics teacher, who conducts her lessons using the R programming language. More specifically, this teacher designed her course through a series of R-based tasks, with the aim of promoting a more conceptual understanding in her students. We observed this teacher in two advanced university courses over the course of three weeks; those observations were complemented with data from semi-structured interview, material resources (the R tasks worksheets, assessments, etc.) and other documents related to her teaching practice. The results were analyzed qualitatively using the Documentational Approach (Gueudet & Trouche, 2012) in order to infer this teacher's documentational geneses related to the use of resources, The documentational genesis refers to the process by which, through selection, modification and recombination of resources, a teacher develops a system of resources together with schemes of utilization and/or action that guide the situated teaching activity.

For this poster, we focus on the schemes of utilization and action of language resources that emerged when analyzing the relationships and interactions between digital and non-digital resources. We identified that the teacher used different types of language –verbal, body, statistical and R programming ones— as schemes of action. In the teacher's discourse, there was a continuous back-and-forth and translation between the statistical language, the programming language, and the oral and body languages, through which she described and expressed the hypothesis, observed relationships and interpretations derived from the explorations of the data contained in the problems presented in the R-based tasks. In this way, the verbal, body and statistical languages are combined and articulated with the R programming language to shape the 'language resource', and its use constitutes schemes of action that help students understand and identify relationships between concepts, as well as develop abilities to carry out a statistical analyses.

SUPPORTING SECONDARY STUDENTS' PERSEVERANCE FOR SOLVING CHALLENGING MATHEMATICS TASKS

Joseph DiNapoli
Montclair State University
dinapolij@montclair.edu

Perseverance, or initiating and sustaining productive struggle in the face of obstacles, promotes making sense of mathematics. Yet, engaging in struggle can be grueling and is avoided for some students. I investigate the effect of scaffolding mathematics tasks on student perseverance. The results show how prompting secondary students to conceptualize a mathematical situation prior to problem-solving can encourage re-initiating and re-sustaining mathematically productive effort upon reaching an impasse. For learning mathematics with understanding, these findings suggest specific methods by which student perseverance in problem-solving can be supported.

Keywords: Instructional Activities and Practices, Problem-Solving, High School Education

Perseverance, or initiating and sustaining in-the-moment productive struggle in the face of one or more mathematical obstacles, setbacks, or discouragements, is a productive process by which understandings are developed. The idea of withstanding uncertainty and persevering past obstacles has long been recognized as a key process by which meanings can be formed (Dewey, 1910; Polya, 1971). These ideas have been echoed for learning mathematics because students develop their understandings through productive struggle, or as they grapple with mathematical ideas that are within reach, but not yet well formed (Hiebert & Grouws, 2007). Additionally, reconciling moments of impasse, or times of significant uncertainty or discouragement, is critical for mathematics learning; the processes of struggle to approach, reach, and make continued progress despite a perceived impasse puts forth cognitive demands upon the learner that are conducive for development of conceptual ideas (VenLehn et al., 2003). As such, encouraging student perseverance has been made explicit as a mathematical and pedagogical demand for reform to help improve teaching and learning in mathematics education (NCTM, 2014).

Supporting Student Perseverance with Mathematics Tasks

Despite widespread educational support around the notion of struggling with challenging mathematics, both students and teachers can be reluctant to engage in and offer opportunities for perseverance (DiNapoli & Marzocchi, 2017). Consequently, several recent research efforts have sought to make explicit classroom practices that support or constrain student perseverance with challenging mathematics. Kapur (2009) found that providing consistent opportunities for students to persevere with unfamiliar mathematical tasks encouraged more variability in problem-solving strategies and greater learning gains, compared to providing consistent opportunities to engage with more procedural mathematics. All students, however, were unlikely to make additional attempts at solving a problem after reaching an impasse – an area of concern. Bass and Ball (2015) explored the nature of perseverance by implementing classroom tasks with familiar entry points yet a complex structure (i.e., low-floor/high-ceiling tasks). The researchers observed children leveraging these opportunities to persevere in their efforts despite challenge and seemingly make mathematical progress. The authors urge for future research to document the student perspective around such perseverance and if it was indeed productive. Warshauer's (2014) exploration of productive struggle found that teachers used probing questions and encouragement as effective methods to nurture perseverance at times of immense student struggle, but had great difficultly providing consistent support for all classroom students for logistical reasons. Noteworthy outcomes of these studies are ideas for how perseverance can be operationalized, and suggestions for future research to carefully study perseverance from the student point of view to better understand how it can be supported.

Additionally, in a recent journal series on nurturing perseverant problem solvers, several teaching practices were identified and described as advantageous. These included encouraging independent student thinking by restricting teacher reassurance feedback during problem-solving (Bieda & Huhn, 2017), scaffolding students' experiences with tasks through assessing questions, advancing questions, and judicious telling (Freeburn & Arbaugh, 2017), and scaffolding student engagement with mathematics through establishing a culture of guiding, exploratory self-questioning (Kress, 2017). These studies offer insight into effective teacher moves for supporting student perseverance with mathematical tasks, but also call attention to logistical concerns about teachers providing targeted support for each and every student (Warshauer, 2014).

One method to bypass these logistical concerns is to embed similar scaffold supports into the mathematical tasks themselves to better insure each student has an opportunity to engage with them. Anghileri (2006) explains different levels of scaffolds that can be applied to tasks to help students problem-solve. Most relevant to supporting student perseverance are embedded conceptual thinking scaffolds, which provide opportunities for students to conceptualize the situation by making connections from their prior mathematical knowledge to the task at hand and mapping out their own strategies for problem-solving. Such conceptualization scaffolds provide a structure for thinking and acting that can organize a problem-solving plan coming entirely from a student's own ideas. Moreover, these scaffolds align with Polya's (1971) stages of problem-solving through which learners approach a task. While stages 3 and 4 help describe the actions of perseverance, it is stages 1 and 2 that can theoretically support those actions by encouraging students to conceptualize the mathematical situation at hand (see Figure 1).

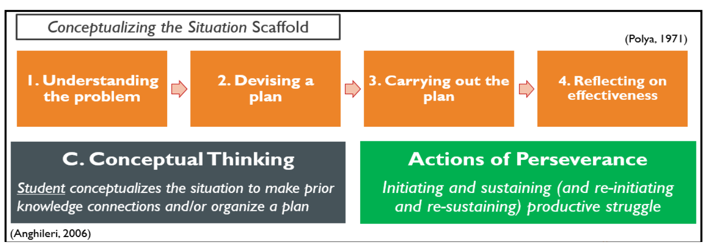

Figure 1. Scaffolding Perseverance in Problem-Solving

There is ample work that shows how conceptualization scaffolds encourage initial engagement with challenging mathematical tasks: when students have opportunities to make connections to what they already know and record all of their ideas and plans prior to the actual execution of problem-solving strategies, they are better suited to initiate and sustain their engagement with the task (e.g., Hmelo-Silver & Barrows, 2006). However, it is less clear how conceptualization scaffolds affect student perseverance upon reaching a perceived impasse – a moment that could be leveraged for key conceptual learning gains (VenLehn et al., 2003). If scaffolds are to support student perseverance during problem-solving, they must not only support initiating and sustaining productive struggle at the outset, but also support re-initiating and re-sustaining productive struggle after a student encounters a significant setback and is uncertain about how to continue. Therefore, via the student point of view, this study addressed how initially engaging with conceptualization scaffolds embedded at the start of low-floor/high-ceiling mathematics tasks supported perseverance, especially after a perceived impasse.

Methods

The participants for this study were 10 ninth-grade students from one suburban-area high school algebra class in a Mid-Atlantic state. These participants were purposely chosen to have demonstrated, via pretest, the prerequisite knowledge necessary to initially engage with each mathematical task included in the study.

To collect data, each participant was observed engaging with five mathematical tasks, one per week. These tasks were rated as analogous, expert-level tasks by the Mathematics Assessment Project (MAP) because of their low-floor/high-ceiling structure, two objectives, and required generalization a mathematical situation. I also solicited independent mathematics education experts to rate the difficulty of these tasks; no differences were reported. Additionally, each participant was given an opportunity to reflect on task difficulty after their participation and reported no differences. Three tasks were randomly chosen to be scaffolded, and two tasks were randomly chosen to be non-scaffolded. The conceptualization scaffold embedded into the scaffolded tasks was "*Before you start, what mathematical ideas or steps do you think might be important for solving this problem? Write down your ideas in detail*." Each participant worked on these set of five tasks in a random order. For context and to help follow the results in this paper, Cross Totals (a scaffolded task) asked students to generalize rules about how to arrange the integers 1-9 in a symmetric cross such that equal horizontal and vertical sums would be possible or not possible. Triangular Frameworks (a non-scaffolded task) asked students to generalize rules about how to build different triangles using the triangle inequality theorem if the longest side was even or odd in length.

This study prioritized the student point of view of their perseverance, so I incorporated many opportunities for participants to make explicit their in-the-moment perspectives during problem-solving. For each task and participant, I conducted think-aloud interviews while they worked on a task and video-reflection interviews immediately after they finished working. Additionally, once a participant had engaged with all five tasks (and thus all five think-aloud interviews and video-reflection interviews), I conducted an exit interview to give each participant an opportunity to comment on their overall experience working on the five tasks. In all, I conducted 11 interviews with each participant, or 110 interviews in total for this study.

To analyze the data, I developed the Three-Phase Perseverance Framework (3PP) (see Table 1) that I used to operationalize the construct in this context. It was designed to reflect perspectives of concept, problem-solving actions, self-regulation, and making and recognizing mathematical progress. The 3PP considered first if the task at hand warranted perseverance for a participant (the Entrance Phase), considered next the ways in which a participant initiated and sustained productive struggle (the Initial Attempt Phase), and considered last the ways in which a participants re-initiated and re-sustained productive struggle, if they reached an impasse as a result of their initial attempt (the Additional Attempt Phase). A participant was determined to have reached a perceived impasse if they affirmed they were substantially stuck and unsure how to continue (VenLehn et al., 2003). Mathematical productivity was determined based on the extent to which the participant perceived themselves as better understanding the mathematical situation as a result of their efforts. To substantially capture the student point of view during engagement with tasks, coding decisions – or whether or not certain engagement constituted evidence of perseverance – depended on student cues from all interviews.

Table 1: Three-Phase Perseverance Framework (3PP)

Entrance Phase	
Clarity	Objectives were understood

Initial Obstacle	Solution pathway not immediately apparent
Initial Attempt Phase	
Initial Effort	Engaged with task
Sustained Effort	Used problem-solving heuristics to explore task
Outcome of Effort	Made mathematical progress
Additional Attempt Phase (after perceived impasse)	
Initial Effort	Engaged with task
Sustained Effort	Used problem-solving heuristics to explore task
Outcome of Effort	Made mathematical progress

I used a point-based analysis with the 3PP to help inform deeper investigation of the ways in which participants persevered on scaffolded and non-scaffolded tasks. Each participants' experiences with each task were analyzed using the framework, and each component in the Initial Attempt and Additional Attempt Phases were coded as 1 or 0, as affirming evidence or otherwise, respectively. Coding decisions were based off of interview quotes. For instance, participants earned a 1 for an Outcome of Effort component only if they affirmed perceiving mathematical progress; such decisions were not based on my own perceptions. Since each task had two objectives and six components per objective, there were 12 framework components to consider, per participant, per task. Thus, 3PP scores ranged from 12 to 0, depicting optimal to minimal demonstrated perseverance in this context, respectively. Participants did not need to completely solve the task to earn a 12, they just had to exhibit perseverance in all 3PP components. Once 3PP scores were determined for all participants' experiences with all tasks, I conducted matched-paired *t*-tests to compare means of 3PP scores between work on scaffolded and non-scaffolded tasks. I also inductively coded interviews to uncover from the participant perspective why they persevered differently on scaffolded tasks compared to on non-scaffolded tasks. For trustworthiness, I enlisted help from two independent coders to analyze participant perseverance and their reasons for doing so. Our inter-rater reliability was 93%.

Results

Participants demonstrated higher quality perseverance when working on scaffolded tasks compared to on non-scaffolded tasks, in general, as evidenced by significantly greater mean total perseverance scores ($M_S = 8.73$, $SD_S = 2.07$, $M_{NS} = 6.00$, $SD_{NS} = 2.60$; $t(9) = 6.816$, $p < .001$) (see Table 2), as well as by participant reports. Differences in participants' perseverance in the Additional Attempt Phase of the 3PP drove this general finding. Participants demonstrated higher quality perseverance after encountering a perceived impasse while working on scaffolded tasks compared to on non-scaffolded tasks. This was evident by significantly greater mean Additional Attempt Phase perseverance scores ($M_S = 3.67$, $SD_S = 2.50$, $M_{NS} = 1.60$, $SD_{NS} = 2.58$; $t(9) = 4.083$, $p = .003$) (see Table 2), as well as by participant reports. All participants affirmed in the Entrance Phase that they understood the objectives, but did not know how to solve each task. Also, all participants reported a perceived impasse as a result of their engagement with each task.

Table 2: Three-Phase Perseverance Scores

Total Perseverance Scores (Maximum of 12 Points)		
Task Type	**Mean**	***n***
Scaffold	8.73	30 (3 tasks per 10 participants)
Non-Scaffold	6.00	20 (2 tasks per 10 participants)
Difference	2.73*** (*p* < 0.001)	

Additional Attempt Perseverance Scores (Maximum of 6 Points)		
Task Type	**Mean**	***n***
Scaffold	3.67	30 (3 tasks per 10 participants)
Non-Scaffold	1.60	20 (2 tasks per 10 participants)
Difference	2.07** ($p < 0.01$)	

The most prevalent difference between participants' perseverance on scaffolded and non-scaffolded tasks was whether and how they re-initiated and re-sustained a productive additional attempt at solving the problem. This means that while working on scaffolded tasks, participants often continued to productively struggle toward a solution after reaching a perceived impasse. This was not often the case after reaching an impasse while working on non-scaffolded tasks. When considering the specific Additional Attempt Phase components of re-initiating, re-sustaining, and outcome of effort, participants working on scaffolded tasks demonstrated more aspects of perseverance compared to their work on non-scaffolded tasks (see Table 3).

Table 3: Perseverance Frequencies in Additional Attempt Phase

Component	On Scaffolded Tasks	On Non-Scaffolded Tasks
Re-Initiated Effort	80% (24 out of 30)	35% (7 out of 20)
Re-Sustained Effort	70% (21 out of 30)	35% (7 out of 20)
Productive Outcome of Effort	57% (17 out of 30)	20% (4 out of 20)

While talking about their engagement with the five problem-solving tasks in the study, all participants reported a general positive effect of their preliminary conceptualizing work prompted by the scaffolds on their mathematical engagement. Related, none of the participants engaged in any noticeable preliminary conceptualizing work on tasks that did not prompt it (i.e., the non-scaffolded tasks). Most of the participants explicitly mentioned in their interviews that the reason they did not engage in such preliminary work on non-scaffolded tasks was because the task did not specifically ask them to do so, even though they recognized such work was helpful to them. Several more specific themes emerged from the analysis of all interviews that helped explain why participants found it easier to persevere on scaffolded tasks compared to on non-scaffolded tasks, especially after reaching an impasse (e.g., the scaffolds helped participants re-visit a different idea, re-conceptualize the situation after a mistake, stay organized, and establish momentum to stay interested and engaged).

Illustrative Case: James's Experiences with a Scaffolded and Non-Scaffolded Task

To illustrate how perseverance was better supported in scaffolded tasks compared to non-scaffolded tasks, especially by helping participants make a quality additional attempt, consider participant James's experiences with the Cross Totals task and Triangular Frameworks task. For James, Cross Totals was his fourth overall task and his third and final scaffolded task. Triangular Frameworks was his fifth and final task, the second of two non-scaffolded tasks. James passed through the 3PP Entrance Phase on both tasks by affirming he understood the objectives, but that had "no idea what to do." James earned 3PP scores of 6 in his Initial and Additional Attempt Phases, resulting in a maximum overall score of 12 for his work on Cross Totals. On Triangular Frameworks, James earned 3PP scores of 6 and 0 in his Initial and Additional Attempt Phases, respectively, resulting in an overall score of 6, with the most notable difference being no additional attempt at solving after reaching an impasse on Triangular Frameworks.

On Cross Totals, James began his work with the scaffold prompt, brainstorming about the mathematics present, including ideas about the parameters of possible and impossible cross totals and that the middle number would be included in both horizontal and vertical sums. After recording his conceptualization ideas, James started his initial attempt at solving the problem stating he would try to "find some possible ones first, and those might connect to impossible ones." He initiated and sustained his effort by guessing and checking different arrangements of integers along two lines representative of the lines of the cross, with one integer in the middle of both lines, and finding their sums. James noticed he was not having success with his plan, and affirmed he was at an impasse when he said "I'm stuck. This is harder than I thought." During his video-reflection, James revealed "I felt stressful here because I never learned this and there was not any way I would know how to do it. I definitely panicked." He did, however, believe he made some mathematical progress toward both objectives by figuring out "that you couldn't just throw numbers in [the cross], you had to think about big numbers and small numbers."

After James revealed he was at an impasse during his think-aloud, he paused and admitted "I don't know what to do now." Frustrated, he started looking around at his papers in front of him and eventually pointed to his list of mathematical ideas under the scaffold prompt and said, "Well I haven't used [the middle number] yet really. Something might be special about the middle number." During his video-reflection, he explained his point of view during these moments, "I had kind of forgotten that I wrote all this stuff down. So I saw again that middle number idea. It was kind of like my life-preserver…it kept me from giving up."

When James revisited his original conceptualization of this problem, prompted by the embedded scaffold, he was propelled forward into making an additional attempt at solving. He thought-aloud about his plan to re-initiate his effort by studying the middle number in possible and impossible cross totals. He began re-sustaining his effort by changing his point of view, a different problem-solving heuristic, and examined the given example. He noticed that "this one has 9 in the middle to get a 27, they are balancing the big and small numbers... something about the evens and odds." James wrote down his observations around the provided example and went on to explore his own examples (see Figure 2) and solve the problem by concluding and defending that "all solutions are odd, like the middle can't be even to do a cross total."

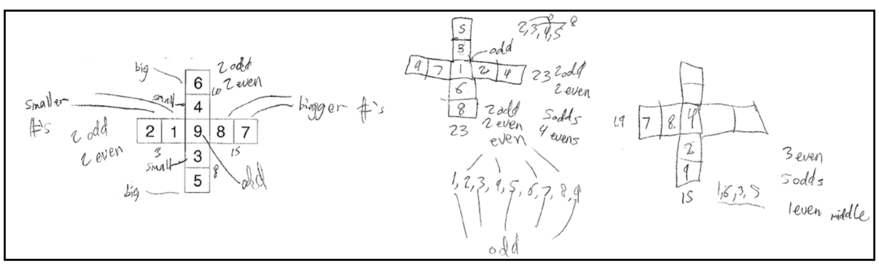

Figure 2. James's Work in Additional Attempt Phase on Cross Totals

On Triangular Frameworks, a non-scaffolded task, James did not record his initial conceptualization of the mathematics in the task. He started his initial attempt toward both objectives by saying "I'll try to find some other evens and odds that work out." He initiated and sustained his effort by guessing and checking different triangles, the same initial heuristic he used in Cross Totals the week before. James examined the given example of six frameworks made with a longest side of 7m, and made mathematical progress when he built four frameworks with a longest side of 6m, writing "6-5-4, 6-5-3, 6-5-2, 6-4-3" on his paper. James concluded, "It looks like it's one less for odd or two less for even, so the rules might be that." Before James wrote his rules, he said, "Wait, let me look at something." Clearly troubled, James went on to write "5-4-3" and "5-4-2" on his paper. Then, seemingly ignoring what he had just done, he wrote his rules about the situation (rules that were incorrect), that if the longest side, *c*, is odd he can make *c*-1 frameworks, and if *c* is even he can make *c*-2 frameworks. Finally, he said "I'm done" and stopped working without making an additional attempt.

While reviewing the video of the aforementioned moments during his first attempt at solving Triangular Frameworks, James admitted that he was, in fact, at an impasse during the latter stages of his first attempt. He said, "I was looking at if 5 was the longest side and my rule didn't work! There should have been four of them but there were only two, 5-4-3 and 5-4-2…so I panicked and pretended like it worked." When asked why he pretended, he said, "I panicked when it didn't work. I didn't even know where to start to fix it. So I really wanted to stop." James' experiences with Cross Totals and Triangular Frameworks are illustrative of the ways in which participants persevered while working on scaffolded tasks compared to on non-scaffolded tasks. Similarly to his engagement on Cross Totals, James leveraged his initial conceptualization work while working on the two other scaffolded tasks to help make a quality additional attempt at solving despite encountering frustrating impasses. On the other hand, similar to his work on Triangular Frameworks, James did not make an additional attempt at solving the other non-scaffolded task; he cited overwhelming stress and feeling disorganized after encountering a setback as the primary reason he did not persevere. During his exit interview, James shared his perspective on how initially attending to conceptualizing the mathematical situation had a positive effect on his engagement for all scaffolded tasks:

> You have to have a plan of what you can try to do…Like the ones that made me write down what I thought first. That was really good. I used that a lot because sometimes you forget where you're going in a problem, it's like chaos – like on [Triangular Frameworks]. But on other ones, like [Cross Totals] I got stuck but had a way out of it. It seems easier with that because you don't have to think of a way out when you're mad or stuck or something.

For James, and for almost all participants in this study, responding first to the conceptualization scaffold served as a "life-preserver" of sorts later, when participants were "panicked" and most tempted to give up. In these moments, the conceptual thinking recorded after engaging with the scaffold prompt acted as an organizational toolbox from which to draw a fresh mathematical idea, or a new connection between ideas, to use to help re-engage with the task upon impasse and to continue to productively struggle to make sense of the mathematical situation. Participants were persevering in problem-solving cyclically, with each additional attempt as a new opportunity to productively struggle supported by their own conceptual ideas (see Figure 3). Without recording their conceptual thinking on non-scaffolded tasks, participants felt lost and frustrated after a setback and often gave up without making an additional attempt at solving.

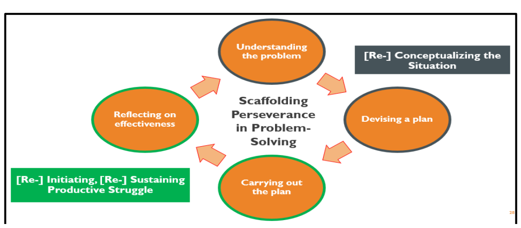

Figure 3. Rethinking Scaffolding Perseverance in Problem-Solving

Discussion and Conclusion

Prior research on supporting student perseverance with mathematical tasks was limited to a focus on the low-floor/high-ceiling structure of the task itself (e.g., Bass & Ball, 2015), teacher moves that nurtured independent student thinking (e.g., Freeburn & Arbaugh, 2017), and using conceptualization scaffolds to encourage initial engagement (e.g., Hmelo-Silver & Barrows, 2006), but did not examine in detail the student perspective around moments when perseverance is necessary, especially upon perceived moments of impasse. Addressing classroom logistical concerns by embedding scaffolds directly into low-floor/high-ceiling tasks (Anghileri, 2006), this study extends past research by investigating from the student point of view how conceptualization scaffolds help students persevere re-initiate and re-sustain productive struggle after reaching an impasse. In sum, the results showed positive effects of prompting students to record their initial conceptualization of a mathematical situation prior to problem-solving, as evidenced by more and higher-quality perseverance on scaffolded tasks compared to on non-scaffolded tasks. Arguably the most notable effect occurred when students reached an impasse while problem-solving, because often they were able to leverage their initial conceptualization to overcome that obstacle and continue to make progress. This implies such scaffolding can help students persevere past impasses and continue to make progress, if provided the opportunity to explore mathematics as a discipline of activity (Schoenfeld & Sloane, 2016). Further, greater efforts are needed to establish attending to conceptual thinking as a normative and welcomed school practice during all problem-solving, not just when prompted (Warshauer, 2014).

Future work should seek to further validate the impact of conceptualization scaffolds on student perseverance after impasse. Especially important is collecting evidence to refute the alternative explanation that differences in task difficultly could explain these data reported here. Although I made several efforts to ensure each task was similarly difficult (vetted by MAP, analyzed by experts, rated by participants), a follow-up study could randomize the assignment of scaffolds to tasks for each participant to better control for this potential bias.

ACHIEVING, LABORING, AND SURVIVING: POSITIONING THROUGH MATERIAL AND IDEATIONAL IDENTITY RESOURCES IN STUDENT AUTOBIOGRAPHY

Emma Carene Gargroetzi
Stanford University
egroetzi@stanford.edu

This study examined the identity resources used and the subject positions taken by secondary students in autobiographical narratives of their experiences with mathematics (mathographies). Data consisted of mathographies from 54 students in two differently tracked math courses at a large, diverse public high school in Brooklyn, NY. The study asked 1) What material resources do students use to position themselves as different kinds of mathematics students? What typology of mathematics identities is revealed? And, 2) What ideational resources do students use to position themselves as different kinds of mathematics students? Findings revealed three predominant mathematics subject positions: celebrated high achiever, earnest laborer, and trauma survivor. Ideational identity resources included discourses of mathematics, of America and American schooling, and of race, language, and immigration.

Keywords: Equity and Diversity, Identity, High School Education

Mathematics is a high status, high power discipline–one that confers special status on those with recognized facility in the content and practice (Apple, 1993). The notion that there exists such a thing as a 'math person,' and assumptions about who gets to be one, are connected to issues of power. Who is seen as smart, who has a pathway to college, and who has access to an upwardly mobile career are all connected through the status of mathematics as a gatekeeper in American society (Martin, Gholson & Leonard, 2010). Even with increasingly abundant research that conceptualizes learning as a process of inclusion, participation and belonging (e.g. Wenger, 1998), questions that examine the conditions of possibility for belonging are still left largely unattended in mathematics education research.

Students, teachers and schools are faced daily with the high-stakes negotiation of who is recognized as a 'math person,' and students from historically marginalized groups in particular have especially complicated access to this high-status marker of success. Studies of the educational landscape of the United States often use demographic data to document stratification at the levels of both access and achievement for young people in mathematics. These studies repeatedly demonstrate inequitable outcomes (National Center for Education Statistics, 2013), as well as inequitable opportunities, (Storage, Horn, Cimpian & Leslie, 2016) along the lines of race, ethnicity, language, gender, (dis)ability and socio-economic status. Even as some research has shifted from a focus on an outcome-oriented "achievement gap," to an input-oriented "opportunity gap," these studies still tell an incomplete story. Adding an otherwise absent dimension to this work, recent scholarship demonstrates ways in which schooling, and even mathematics learning itself, can include "*racialized forms of experience* [emphasis original]—that is, … experiences where race and the meanings constructed around race become highly salient" (Martin, 2006, p. 198). Beyond its well-understood status as gatekeeper, mathematics education has the potential to reproduce racialized experiences present in other aspects of social, political and economic life.

In one example of racializing experiences found in mathematics learning spaces, Shah & Leonardo (2016) share the story of a South Asian American student, Akshay, who performs at a high level in his AP Calculus course only to find his effort dismissed by a classmate who comments that he simply does well because he is Indian. In the same school, a Black student, James, is treated with surprise and even disbelief when his classmates see that he is enrolled in an advanced math course. As these examples suggest, mathematics education may actually contribute in complex ways to *minoritization* – the formation of a marked minority status due to racial, ethnic, linguistic, immigration or another social status that diverges from an historical or ideological norm (Omi & Winant, 2002).

Contrary to the popular belief that mathematics is culture-neutral or culture-free, research in the last decade has begun to illuminate how mathematics teaching and learning may play a role in the process of minoritization (e.g. Shah & Leonardo, 2016). Minoritizing experiences of mathematics are particularly problematic because they function to "other" certain students in both their successes and their failures, reproducing exclusive notions of who gets to participate or belong within the discipline of mathematics. Throughout this paper, the word "minoritized" references a broad group of young people for whom their status as a minority is often constructed in direct contradiction to their numerical presence in their school, neighborhood, or even city. This contradiction makes clear the need to understand how this status is produced and reproduced, and in particular what role mathematics education plays in this process.

With these concerns in mind, mathematics education research has begun to attend to the identities of minoritized youth in mathematics, both by asking about the math learning experiences of specific social groups, and by asking about how mathematics identities are shaped by being part of a social identity group (Berry, Thunder & McClain, 2011). Studies of identity, often understood as including both the ways a student defines themself as well as how they are perceived by others, have the ability to bring together questions about learning, participation and inclusion. However, even as identity has become widely accepted as a crucial analytic lens for understanding learning (Gee, 200; Wenger, 1998), the ways that people understand and analyze identity in mathematics education vary significantly (Darragh, 2016; Langer-Osuna & Esmonde, 2016) and we still know little about the interaction between, and co-construction of, social and academic identities in mathematics. Furthermore, we know almost nothing about the *identity resources*–ideas, materials and relationships (Nasir & Cooks, 2009)–that students draw upon or how they use them in order to make sense of themselves in the world of mathematics. In order to explore this gap, the research questions guiding the study were:

1. What material resources do students use to position themselves as different kinds of mathematics students? What typology of mathematics identities is revealed?
2. What ideational resources do students use to position themselves as different kinds of mathematics students?

Methodology

This study took a new approach to understanding the identity work of young people. By looking at the discourses that students draw upon, and analyzing how students use these discourses as identity resources, this work provides insight into the conditions of possibility that shape and constrain student identities in mathematics. By examining *mathographies*–narrative autobiographies of student experiences with mathematics–written by Brooklyn high school students in response to a prompt from their math teacher, this work centers student voices as they describe and comment on their own experiences. Discourse analysis was used to illuminate the sets of language and ideas that students drew upon as identity resources and to identify common subject positions that students took as they positioned themselves as different types of math students.

Context and Data

The 54 mathographies examined in this study were written by students enrolled in a Regents Algebra 2 and Trigonometry course (n=29) and students enrolled in a non-Regents Geometry course (n=25) at a large, racially and linguistically diverse public high school in Brooklyn, NY. In their mathographies, students mentioned over 20 language varieties and 15 different ethnic, racial, or national origin groups. Students in both courses were in the 10th or 11th grades. The mathographies ranged from one to six paragraphs and 200-1043 words. By examining the writing of students at the same school, and in the same grade band, but in two differently tracked courses, the sample attempted to account for a broad representation of experiences of success and perceived ability with regards to mathematics while holding other factors such as age, school site and teacher constant.

Mathography writing was an instructional activity assigned at the beginning of a new semester by one mathematics teacher to two classes of students. The activity was framed as both a “getting to know you” task and an opportunity for student reflection on previous learning experiences. Students had one week to complete and submit their written work to their teacher. The same writing prompt was used in both classes.

The questions in the writing prompt included inquiry into personal details about family and language, as well as questions about experiences with mathematics such as what does math at home look like, when have you learned the most math, and have you ever had a ‘math moment’? Students were also invited to share hopes and dreams for the future and something a math teacher might not know about them if they only knew them in math class. Students were prompted to respond in narrative form to any subset of the questions, provided it told a story of them and mathematics. They did not have to respond to all questions in the prompt.

Coding and Analysis

This study made use of discourse analysis (Wortham & Reyes, 2015), examining student language in their mathographies in order to map the ways in which their language use both served to situate themselves within existing discourses and also at times worked to challenge those discourses. Discourse analysis allowed the researcher to track the linkages between micro-interactional moments and social structures at the institutional and societal levels. Insight into how the micro and macro work together is essential in the treatment of identity and mathematics education. As students negotiate identity they do so drawing not only on classroom-based interaction but also on their full repertoire of experiences as members of the social, cultural, and political world.

Discourse analysis entails identification of patterns both within and across “speech events” (Wortham & Reyes, 2016). In this study, the speech event unit was one mathography (n=54) and the speech act unit was a paragraph (as demarcated by students using conventional line breaks or indentation) (n=233). Coding schema were developed through open coding, and then focused coding was used to further nuance the coding schema (Emerson, Fretz & Shah, 2011). Analysis was conducted through the use of analytic memos. Strategic searches for code co-occurrence and patterns across the memos were conducted using both Excel and Dedoose, a qualitative coding software.

Coding was conducted in three phases. The first phase of coding and analysis focused on research question 1, *What material resources do students use to position themselves as different kinds of mathematics students*? *What typology of mathematics identities is revealed?* First, I identified speech acts (paragraphs) in which students made claims about themselves as mathematics learners or recounted others making claims about them as particular types of mathematics students (n=148) and wrote an analytic memo for each. Patterns were noted in the identity claims being made by students. The memos were compared and cross referenced such that it was possible to propose a typology of mathematics student identity positions that accounted for all of the instances. These speech acts were then also coded for material evidence and analysis identified the material evidence most commonly associated with each identity position from the typology.

The second phase of coding and analysis focused on research question 2, *What ideational resources do students use to position themselves as different kinds of mathematics students?* This phase started by re-examining the speech acts that included student positioning and the material resources that students used to position themselves in order to identify the discourses of mathematics that students were drawing on in these moments. Another round of analytic memos were written for each positioning act. These memos asked for each positioning act, how does the student frame mathematics in the world. Specifically, memos addressed "what is math?", "mathematics for what?" and "mathematics for whom?" for each positioning act.

In order to expand from discourses of mathematics to other potential discourses at play, a third phase of coding identified speech acts in which students positioned their families, languages, culture or nation of origin in relation to their own experiences of mathematics (n=85). A final round of analytic memos were written examining each of these speech acts. Two additional discourse categories were identified: discourses of America and American schooling, and discourses of race and immigration, along with core sub-components of each discourse.

Findings

Three Math Student Subject Positions and the Material Evidence for Each

In response to research question 1, I identified three mathematics subject positions: *celebrated high-achiever*, *earnest laborer*, and *trauma survivor*, explained below. These subject positions can also be thought of as available identities that a mathematics student might assume, achieve, or have ascribed to them. In their mathographies, as students positioned themselves as particular types of math students, or recounted having been positioned by someone else, each student also provided evidence to substantiate the position. The evidence they provided reveals the *material identity resources* that students found available to them for making sense of themselves as different kinds mathematics learners. In the 54 mathographies, 24 students positioned themselves at one point as celebrated high achievers – those with status based on the visibility of their successes in math. Twenty-seven (27) students positioned themselves at one point as earnest laborers – those whose status relies on effort, and 21 students positioned themselves at one point as trauma survivors – those with a significant negative experience that has shaped their current orientation toward math. Note that the sum is greater than 54 (the number of individual mathographies) because many students made use of more than one position over the course of their mathography. A summary of the typology with the related material evidence and one example from each position is provided in Table 1.

Table 1: Typology of positional mathematics identities with material identity resources

Position	Material Resources	Example
Celebrated High Achiever (n=24)	Course grades Test scores Regents Exams Course enrollment Class rank Awards Competition Visibility (positive) Being first, being fast	In school I was doing math like it was nothing. I was top in my class. But every year I'll have a competition with someone to get top place. Always someone that smarter than me. So I'll go home and try to be ahead, going to tutoring and asking my dad, freshman year I was a 95% average student in math had the best teacher, Ms. Alexander. That year math was my focus, I past every test with 95-100. That made the teacher and my parent proud. (MS23G)
Earnest Laborer (n=27)	Course grades Test scores Regents Exams Too much content, too fast Attending tutoring Homework completion Learning steps and procedures Practice and repetition	I'm really not that great in math but I somewhat like mathematics because every time I solve a math problem it makes me feel like I'm intelligent, I'm like everybody else, it's a challenge sometimes that comes with my best effort. Every time I use math in my daily life it greatly benefits me, that being said it is something I use every day and almost at any time especially when it's dealt with money. It's always been difficult for me to learn math, I sometimes feel as if math is like my kryptonite. I know I can't get every question right but at least I know I tried my best even if I don't know what I'm doing. (MS09T)
Trauma Survivor (n=21)	Course grades Test scores Regents Exams Course enrollment Competition Public humiliation Being last, being slow Visibility (negative)	My most negative math moment would be long dividing in the fourth grade. I absolutely hated it, and most of my peers already knew how to do it. Which made me more embarrassed to know that I was the only one in the class that didn't know how to do it. Another negative would be in the 6th grade where I basically got 60s on all my math tests because I didn't get what he was teaching as well as how I even got a 65. I was at the lowest level of dumb in math. (MS26T)

Three Discourses as Ideational Resources

Findings showed that students used cultural and institutional discourses as ideational resources as they positioned themselves, their families, languages and cultures or nations in relation to mathematics. The discourses they used throughout were *discourses of mathematics*, *discourses of American schooling and meritocracy*, and *discourses of race, language, and immigration* in the United States. An overview of the three discourses that students drew upon as identity resources, and the core components of each, as used by students is found in Table 2.

Dominant Discourses of Mathematics. Findings show that even as students relied on varied material resources to position themselves as different kinds of mathematics students, the material resources they used point to a set of widely shared dominant discourses of mathematics itself. Those discourses were that 1) mathematics ability is innate and fixed, and 2) mathematical competence is comparative, exclusive, and measurable through time constrained performances, usually of procedures. These discourses are visible throughout the examples shared in Table 1.

For example, one Algebra 2/Trig student wrote, "I'm really not that great in math" (MS09T), reflecting the perceived fixed-ness of her mathematics ability status. A Geometry student marks her competence through indicators of ease and comparison to her classmates, followed by a description of a competition to prove her status: "In school I was doing math like it was nothing. I was top in my class" (MS23G).

Discourses of American Schooling and Meritocracy. In their mathographies, students also drew on discourses of schooling and the American social context more broadly, layering these with the dominant discourses of mathematics. The two core components of discourses of America and American schooling that students drew upon were 1) Innate ability in tension with development psychology and lived experience and 2) American meritocracy as advancement through legitimate systems that reward both innate talent and work ethic. Whereas discourses of mathematics elevate ideas about innate talent, which are corroborated in discourses of American meritocracy, discourses of American schooling and meritocracy offer an alternative but well-established narrative that elevates the importance of lived experience as well as the merits of hard work. Students who positioned themselves as earnest laborers or trauma survivors wrote about challenges faced and overcome through personal effort and perseverance that shaped the student's relationship with mathematics.

Discourses of Race, Language and Immigration. American liberal ideals that value both individual ambition and competition as well as egalitarianism are complicated by the pressures of assimilation for minoritized racial and ethnic groups and immigrants in the United States. Both standing out and fitting in are complicated for minoritized students. Furthermore, discourses of racial inferiority, both genetically and in terms of educational attitudes, sit as a backdrop, in particular for minoritized students, as they attempt to position themselves with worth and dignity in front of their current math teacher. Throughout their mathographies minoritized students consistently explained experiences of visibility – both positive and negative – as attributable to some form of racial, ethnic, linguistic or cultural experience of difference. They describe experiences of confronting ideologies of racial and linguistic inferiority and they draw on discourses of cultural deficiency themselves. One student wrote,

> The most negative experience happened in second grade. My teacher at that time didn't try to teach me but also made fun of me. I didn't know that much English at time and some of the math problems were in words. It was really difficult to me. My teacher gave up on me but she didn't try at all. She insisted that I should go get my ears checked. She also asked if I'm a mute (MS16T).

At the same time, many more students position themselves and their families as model minorities, citing appropriate attitudes toward education and orientations of aspiration and investment that make them stand out in their success, or, if not in their success, at least in their work ethic. One student attributes her own success to her immigrant parents, positioning their attitude toward mathematics as the appropriate one:

> Having parents that find math one of the most important subjects in school shaped me to be how I am in math class today. I've always found math to be an easy subject to wrap my head around; getting 4's on my state tests. … Whenever my parents talk about currency I love to convert the dollars to taka (Bangladesh currency) with a pen a paper instead of just searching it up on google. It's nice when I get the calculations correct (MS03T).

Table 2: Discourses used as ideational identity resources in student narratives

Dominant Discourses of Mathematics	Discourses of American Schooling and Meritocracy	Discourses of Race, Language, and Immigration
Mathematics ability as innate and fixed	Innate ability in tension with psychology, development, and lived experience	Ideologies of racial and linguistic intellectual inferiority
Mathematics competence as comparative, exclusive, procedural, and time-bound	American meritocracy, work ethic, and advancement through investment in legitimate systems	Discourses of deprivation and deficit alongside discourses of investment and models of success

Discussion

This study contributes to existing theory on the development of mathematical identities for young people by proposing new ways of understanding the identity work in which young people engage. The voices of students as heard through their mathographies reveal the resonance of discourses of mathematics, of schooling and American society, and of race and immigration in the United States. These discourses both shape and constrain the possibilities for how young people understand themselves and present themselves to the world. At the same time, these discourses act as available tools that students necessarily use when shaping ideas about themselves, and bidding for particular representations of themselves in the world.

Ideas about what math is significantly shape and constrain how students see themselves as different types of mathematics students and learners. The material evidence that students used to instantiate their various mathematics student positions demonstrates the limited nature of the notion of mathematics most readily available to students. Discussion of grades, tests, speed, awards, homework, attendance records, and comparisons to other students abound as students position themselves as mathematics students of a certain type. This reveals the extent to which student notions of mathematics are constrained by the dominant discourse of mathematics as a set of skills and procedures, measured comparatively and through time-bound mechanisms. Students position themselves with self-worth and merit in front of their math teacher within the constraints of this dominant discourse of mathematics. Their reliance on the positions of celebrated high-achiever, earnest laborer and trauma survivor likely reveals more about the ways that dominant discourses in mathematics shape the identities available to students than it does about the students themselves as participants in or learners of mathematics.

Discourses of American ambition and American meritocracy complicate and constrain how minoritized students see themselves and present themselves because the meanings behind visibility and achievement have different stakes when they are racialized. Discourses of American society both resonate with and diverge from the dominant discourses in mathematics. As is true in mathematics, American ideals celebrate ambition, standing out and high achievement, especially as compared to others. At the same time, American ideals of hard work, labor and perseverance act as an alternative axis of merit available to students for whom traditional high achiever positions are inaccessible. In their mathographies, students drew widely on the American ideals of hard work and perseverance, presenting their own efforts as valuable and as deserving of recognition, both when they told stories of high achievement, and when their efforts were called upon to stand in the place of high performance.

That said, standing out and fitting in are inscribed with different meanings when the students doing so are racialized or minoritized as existing outside of the dominant norm. Fitting in, when it means assimilation, can be high stakes. Where students associated family or language with negative visibility they often employed deficit discourses to themselves or their home lives. At the same time, where minoritized students experienced positive visibility it was often framed as standing out as compared to other minoritized students. Rather than being celebrated as an exceptional student (full stop), the celebration was of being a model *minority* student. As seen in their mathographies, young people work consonantly to find ways to understand and position themselves as worthy mathematics students, often contesting the centrality of innate ability. However, if the other most readily available discursive tools are the also-racialized American myths of hard work and meritocracy, student options remain severely constrained.

SOCIAL JUSTICE DRIVEN STEM: ACHIEVING EQUITY GOALS THROUGH INTEGRATED MATHEMATICS EDUCATION

Frances K. Harper
University of Tennessee – Knoxville
francesharper@utk.edu

Deepa Deshpande
University of Tennessee – Knoxville
ddeshpan@vols.utk.edu

This study investigated how integrating social justice issues, STEM practices, and mathematics may support equity in mathematics education. We analyzed video of four lessons focused on inverse trigonometry and disability rights from a STEM project-based geometry class. Using an established observation protocol, we identified themes related to access and participation in coherent and cognitively demanding mathematics, student voice, and opportunities to develop positive mathematics identity. Findings provide insights into project and lesson structures that support balancing mathematics and social justice goals across STEM projects and point to additional considerations of equity not fully captured by the existing observation protocol.

Keywords: Equity and Diversity; Geometry; High School Education

Calls for integrated STEM education in K-12 schools have increased in recent years, and strategic STEM education plans often identify project-based learning (PBL) as one approach to integrated STEM education (e.g., Chief Education Office, 2016; STEM Leadership Council, 2018). These STEM education plans argue that full integration of STEM education in K-12 learning is necessary to ensure all students, particularly those from economically disadvantaged in STEM fields. Simultaneously, efforts to use mathematics to critically investigate social justice issues increasingly offers another approach to integrating mathematics and other learning goals (e.g., Esmonde, 2014; Keith McNeil & Fairley, 2016). Some mathematics education scholars argue that teachers face a moral and ethical imperative to transform mathematics classrooms into spaces for the development of critical social awareness and social transformation (Stinson, 2014). Both of these approaches to integrating mathematics with other content areas and topics overlap in their goals to make mathematics learning more accessible and equitable for those students who have been systematically and historically marginalized in mathematics.

Envisioning integrated models for mathematics education may hold promise for addressing longstanding inequities in mathematics. This study investigates the intersection of STEM PBL and social justice in mathematics classrooms with students from economically disadvantaged backgrounds and minoritized racial/ethnic groups. In integrated mathematics lessons, however, balancing mathematics learning goals with other goals (e.g., social justice, STEM) presents significant challenges for teachers (Bartell, 2013), and little is known about whether or not students actually experience these integrated lessons as more equitable (Harper, in press). Thus, the possibility exists that attempts to integrate social justice goals and STEM might further exacerbate equity issues. We aim to investigate the potential for integrating social justice and STEM goals into mathematics education by asking: does (and if so, how does) the integration of social justice mathematics with STEM PBL support goals for equity in mathematics education?

Theoretical Framework

Historically, research towards equity in mathematics education has prioritized achievement and access. *Achievement* relates to tangible outcomes on measures such as standardized tests or course-taking patterns, and *access* relates to tangible resources such as high-quality mathematics teaching and rigorous, coherent mathematics curricula (Gutiérrez, 2012). Achievement and access reflect dominant dimensions of equity in mathematics education because of the widespread, historical attention these aspects have received and because of the acceptance of their importance in mainstream mathematics education research. In addition to these dominant dimensions of equity, we include a focus on under-recognized and under-explored dimensions of equity, identity and power, in this study (Gutiérrez, 2012). Students develop their mathematics *identities* based on dispositions and beliefs about their ability to learn, do, and use mathematics (Martin, 2006). Because school mathematics traditionally marginalizes certain ways of knowing, students must negotiate their personal (racial, ethnic, gender, etc.) identities as they develop their mathematics identities, but students of Color and students who are economically disadvantaged rarely have opportunities to see themselves as competent mathematics learners, doers, and users (Gutiérrez, 2012; Martin, 2006). Alternative ways of knowing in mathematics challenge traditional *power* structures in mathematics classrooms, and a more complex conception of equity attends to issues of social transformation such as whose voice is heard and what mathematics reveals about social justice issues (Gutiérrez, 2012). Identity and power represent critical dimensions of equity in mathematics education because attention to identity and power reflects a more recent sociopolitical turn in mathematics education (Gutiérrez, 2013). We adopt this framework for equity, which attends to both dominant and critical dimensions, and aim to describe what these dimensions look like in classroom interactions among teachers and students. Namely, we sought to answer the following questions: (1) How does access to mathematics content and the emphasis on student identity and power vary across a social justice-oriented, STEM project in a mathematics classroom?; and (2) What dimensions of equity within a social justice-oriented, STEM project-based classroom are not captured by current frameworks for observing mathematics classrooms?

Research Design and Methods

This study drew on a subset of data from a larger study that examined how students took up, negotiated, shifted, or resisted an innovative approach to coupling equity-minded mathematics instruction with STEM PBL across an academic year. The study took place at a STEM-themed magnet school, in a low-income area of a small Midwestern city, whose mission emphasizes technology-driven (1:1 student-to-computer ratio) PBL. The study occurred in one ninth grade geometry classroom in which the teacher integrated various equity-oriented instructional approaches, including integrating social justice and mathematics topics, into STEM PBL in mathematics. Of the 16 consented research participants, six are young men (4 white, 1 Black, 1 Latino), and ten are young women (9 Black; 1 Asian American). The teacher participant is a White woman who was in her fourth year of teaching. She and the first author collaborated on social justice mathematics for three years, and the teacher sought various other professional development opportunities (e.g., technology, equitable collaboration).

The research design was rooted in ethnographic and critical traditions of educational research (Anderson-Levitt, 2006; Skovsmose & Borba, 2004). The first author observed 93 total class sessions as a participant-observer. Data included video and audio recordings, field notes, and photographs from seven major projects and two mini-projects (all teacher-designed), as well as interviews assessments with students This study examined only video data from a mini-project in late April focused on inverse trigonometry and disability rights (hereafter, the mini-project).

Mini-Project Overview

Across four days, students worked in pairs to determine whether or not ramps at the school were compliant with regulations set by the *Americans with Disabilities Act* (1990). The primary mathematics goal focused on learning to use inverse trigonometric functions to find an unknown angle when two or more side lengths of a triangle are known. The primary social justice goals focused on understanding the meaning and need for the *Americans with Disabilities Act* (ADA) and reflecting on whether persons with disabilities had fair access to and within the school. Students utilized technology and engaged with some aspects of design work, but the integration of STEM practices was more limited in the mini-project than in the major projects. The design aspects of the project involved collecting measurement data from physical ramps at the school and creating scaled drawings of ramps. Although students had an option to use dynamic mathematics software to model ramps, all students elected to draw by hand. Technology use mostly involved word processing, calculators, and researching ADA history and regulations. As the final mini-project artifact, students wrote letters to the principal about their investigation, making recommendations for school improvements using recently acquired funding. Although there were distinct goals for mathematics learning, social justice learning, and STEM practices, various activities throughout the mini-project and the final letter required integration across these goals and practices.

Data Analysis

Because achieving equity goals in mathematics education depends upon particular relationships between teacher and student behaviors, we sought to operationalize access, identity, and power based on observations of the entire class – teacher and students – throughout the mini-project. We did not consider achievement because pre- and post-assessment data reflected progress over the entire year, not over individual projects. We used the Teaching for Robust Understanding of Mathematics (TRU Math) Rubric (The Algebra Teaching Study and Mathematics Assessment Project, 2014) to describe how access to mathematics content and the emphasis on student identity and power varied across the mini-project. We chose this rubric because it was designed to capture overall activities and interactions (i.e., not distinguishing between teacher and student behaviors) along five dimensions, which the rubric developers claim comprehensively describe powerful mathematics classrooms (Schoenfeld, 2014). The identification of these five dimensions as key aspects of mathematically powerful classrooms (i.e., "classrooms that produce students who do well on tests of mathematical content and problem solving" (Schoenfeld, 2014, p. 406)) was based on cumulative research in mathematics education suggesting that access to coherent and cognitively challenging mathematics, an emphasis on mathematical sense making, and equal participation are necessary aspects for students' mathematics success. These dimensions of powerful mathematics classrooms, and thus the TRU Math Rubric, map onto ways equity in mathematics education has historically been theorized (Gutiérrez, 2012), making this rubric a particularly good starting point for considering whether social justice, STEM, and mathematics integration achieved equity goals. More specifically, we used the TRU Math Rubric to operationalize *access* as the extent to which participation in coherent and cognitively demanding mathematics was available to students and *identity* and *power* as the extent to which student voice, thinking, or contributions drove the mathematics and gave students an opportunity to develop a positive mathematics identity. Table 1 gives an overview of the five dimensions included in the TRU Math Rubric and shows how we mapped each dimension to the theoretical constructs of access, identity and power.

Table 1: A Map of Dimensions of Equity to the Dimensions of the TRU Math Rubric

Access	**Mathematics**	*The extent to which the mathematics discussed in the observed lesson is focused and coherent, and to which connections between procedures, concepts and context are addressed*

(dominant dimensions)	**Cognitive Demand**	*The extent to which classroom interactions create and maintain an environment of productive intellectual challenge that is conducive to students' mathematical development*
	Access to Mathematical Content	*The extent to which classroom activity structures invite and support the active engagement of all of the students in the classroom with the core mathematics being addressed*
Identity & Power (critical dimensions)	**Agency, Authority, & Mathematical Identity**	*The extent to which students have opportunities to conjecture, explain, make arguments, and build on one another's ideas in ways that contribute to students' development of agency, authority, and identities as doers of mathematics*
	Uses of Assessment	*The extent to which the teacher solicits student thinking and instruction responds to those ideas, by building on productive beginnings or addressing emerging misunderstandings*

Each author independently analyzed video recordings using the TRU Math rubric to: (1) identify segments by participation structure (whole class, group work, or individual work); (2) divide segments by participation structure into five minute or less segments; and (3) rate (1 – low level, 2 – mid level, 3 – high level, 8 – not enough information, and 9 – not applicable) the activities of each segment along the five dimensions described in Table 1 by using unique rubrics corresponding to each participation structure (for full rubrics see Schoenfeld, A. H., Floden, R. E., & the Algebra Teaching Study and Mathematics Assessment Project, 2014). Each recording was approximately one hour in length and was split into fourteen segments on average. We used spreadsheets to record the participation structure, duration, TRU Math rating for each dimension, and brief memos about observations on each segment. We ensured reliability by meeting and comparing our ratings and memos for each segment and resolving differences through discussion and rewatching that segment together until we reached consensus.

Findings

Across the mini-project, we observed three classroom participation structures: whole class activities (36.49% of total time across four days), group work (28.3%), and individual work (31.37%). Note that 3.85% of total class time was identified as not applicable and is shown in gray in Figures 1 and 2. Whole class activities included launch of activities (18.62% of total time across four days), teacher exposition (6.94%), and whole class discussion (23.15%). Table 2 summarizes mini-project activities and their durations.

Table 2: Summary of Mini-Project Activities and Their Duration

	Activity Summary / Participation Structures	Time (min)	% of Lesson
Day 1	Warm-up by solving equations using inverse operations Launch, Individual work, Discussion	11.75	23.8%
	Introduction to using inverse trigonometric functions to solve for unknown angles in right triangles Launch, Exposition	5	10.2%
	Inverse trigonometry task, adapted from the CPM (2013) *Core Connections: Geometry*, Lesson 5.1.3, involving hypothetical wheelchair ramps Launch, Group work	32.5	66.0%

Day 2	Connecting math practices necessary for project to evaluation rubric	32.95	58.9%
	Launch, Individual work, Discussion		
	Measuring base, height, and/or hypotenuse of selected ramp in school	22.95	41.1%
	Launch, Group work, Exposition, (N/A)		
Day 3	Revising measurements, producing scaled drawings, calculating angles of measured ramps	46.4	83.0%
	Launch, Group work, (N/A), Exposition		
	Writing letters to summarize findings and make recommendations	9.5	17.0%
	Individual work, Exposition		
Day 4	Reflection on evaluation from previous project	5.9	11.6%
	Launch, Individual work, Exposition		
	Writing letters to summarize findings and make recommendations	33.2	65.4%
	Launch, Individual work, Exposition		
	Discussion of meaning/importance of ADA law and equity concerns raised through this investigation	11.7	23.0%
	Launch, Discussion		

Access to coherent and cognitively demanding mathematics content

Figure 1 shows the average TRU Math Rubric scores for three dimensions for each participation structure across the four days of the mini-project. Duration of participation structures are drawn to scale, with whole class activities in blue (light blue for launch, dark blue for exposition, and blue for discussion); group work in green; and individual work in orange.

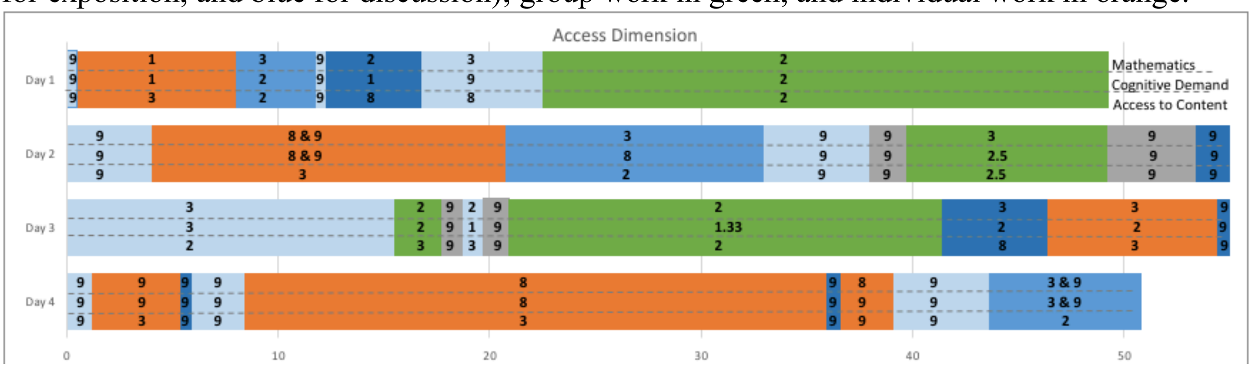

Figure 1. Access Dimension. Average TRU Math Rubric Scores for Mathematics, Cognitive Demand, and Access to Mathematics Content by Participation Structure

Taken together, the three dimensions shown in Figure 1 provide insights into how participation in coherent and cognitively demanding mathematics (i.e., access), as well as STEM practices and social justice content, varied by participation structure and day. Average scores (calculated by averaging scores across segments for the duration of each participation structure) for the "access to content" dimension suggest that, overall, broad (i.e., equitable) participation was achieved (score of 3). In some cases, uneven participation was observed, but the teacher made efforts to achieve equitable participation (score of 2). The average scores for the "mathematics" and "cognitive demand" dimensions provide information about the nature of that participation, respectively, the coherence/meaningfulness of mathematics and the level of cognitive challenge involved in participation. Although overall average scores of 2-3 were common for these dimensions, we noticed some variation by participation structure and day.

During group work on Day 1 and 3, the mathematical content students engaged with was largely skills-oriented (solving for an unknown angle using inverse trigonometry) with some connections to the meaning of inverse (in Day 1) and to the context of the ramps (Day 1 & 3) ("mathematics" score of 2), but the teacher largely drove these connections ("cognitive demand" score of 2). On Day 2, however, students had an opportunity to engage with explanation of mathematics practices/content as they collaborated to measure a ramp within the school ("mathematics" score of 3). The ramp students selected could not be measured in a straightforward way because it was two combined ramps (i.e., involved a switchback) and was adjacent to stairs. As students worked to decide how to define and measure the height and base of each ramp, they (rather than the teacher) took on the cognitive challenge involved with explaining and justifying their mathematical thinking ("cognitive demand" score of 2.5).

Unlike in group work, whole class and individual activities often focused on coherence and connections in mathematics ("mathematics" score of 3), but the teacher was the primary driver making these connections ("cognitive demand" score of 2). Exceptions included the launch on Day 3 in which students' were challenged to make sense of their ramps measurements by connecting to mathematical ideas and the context and the final whole class discussion (Day 4) in which students undertook the cognitive work of making connections between the mathematics and the social justice issue ("cognitive demand" scores of 3). Further, scoring the "mathematics" and "cognitive demand" for whole class and individual activities presented challenges (indicated by scores of 9: not applicable and 8: not enough information). In some cases, these dimensions were not applicable because the activities did not involve mathematics content. For example, launches and teacher exposition commonly scored 9 because these activities focused on logistics (e.g., how to complete an activity) without any attention to mathematics content. In other cases, however, the challenge of using the rubric to rate segments arose because of the interdisciplinary and integrated nature of activities. For example, rating these dimensions during individual letter writing was challenging because it was impossible to discern students' mathematical thinking from their thinking about writing and the social justice issue. Further, topics of discussion were not always explicitly connected to mathematics (e.g., whole class discussion on Day 4).

Emphasis on student identity and power

Figure 2 shows the average TRU Math Rubric scores for two dimensions for each participation structure across the four days of the mini-project. Duration of participation structures are drawn to scale, with whole class activities in blue (light blue for launch, dark blue for exposition, and blue for discussion); group work in green; and individual work in orange.

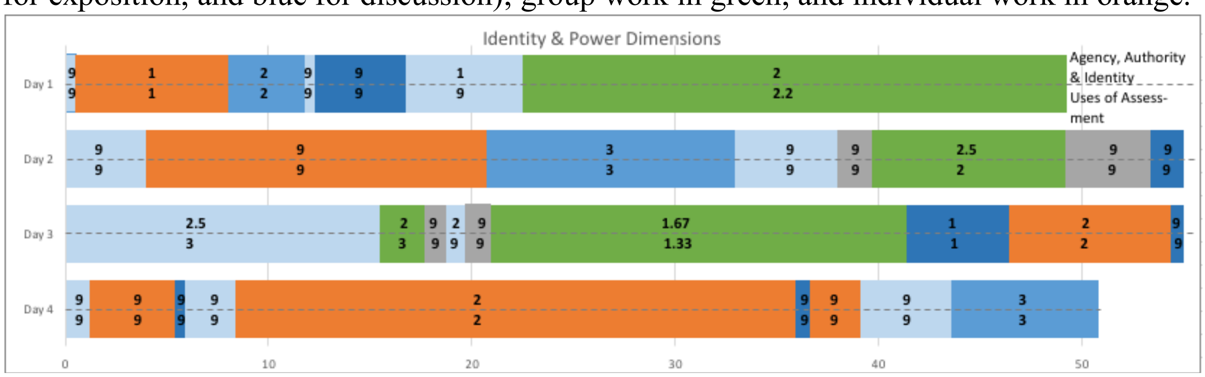

Figure 2. Identity and Power Dimensions. Average TRU Math Rubric Scores for Agency, Authority, and Identity and Uses of Assessment by Participation Structure

Taken together, the dimensions in Figure 2 provide insight into the extent to which student voice, thinking, or contributions drove the mathematics (i.e., power) and gave students an opportunity to develop a positive mathematics identity. Overall, during group and individual work, at least one student had an opportunity to talk about mathematical content, but the teacher drove conversations and determined mathematical correctness. Students were not supported to build on each other's thinking ("agency, etc." score of 2), and the teacher did not necessarily build on student ideas (e.g., lead students in the "right" direction) ("assessment" score of 2). In whole class activities on Day 2, 3, and 4, however, students had an opportunity to explain their thinking, with other students building on those ideas, the teacher ascribing ownership to those ideas ("agency, etc." score of 3) and instruction building on those ideas ("assessment" score of 3). These instances corresponded to high levels of mathematical coherence/connections and cognitive demand (scores of 3) but uneven participation ("access" score of 2; Figure 1).

Discussion and Conclusion

With increasing recognition of mathematics' important relationships to other disciplines, attempts to integrate other topics (e.g., social justice, STEM) into mathematics education will necessarily require that teachers spend instructional time focused on topics that are not explicitly mathematical. In efforts to integrate social justice goals and mathematics goals, concerns about balancing the focus on mathematics and other goals are not new (Bartell, 2013). A major concern is that time taken away from a direct focus on mathematics may exacerbate inequities in mathematics (Harper, in press). This study provides insights into how particular project structures might support balancing mathematics goals with social justice and STEM goals.

Although aspects of the mini-project focused on skill-oriented mathematics, non-mathematical topics, or project logistics, the activities that scored poorly on measures of coherent and cognitively demanding mathematics seemed to have served an important purpose in the overall scope of the mini-project. The work that students did on Day 1 and the first half of Day 2, combined with the integration of STEM practices in the second half of Day 2, likely prepared students to engage in coherent, cognitively demanding mathematics as they measured ramps and made sense of those measurements by connecting to mathematical ideas (from Day 1) and the context at the beginning of Day 3. Although subsequent mathematical work was largely procedural and letter writing was not always focused explicitly on mathematics, scores of participation were highest when students worked in pairs or individually on their letters to integrate mathematics, social justice, and STEM learning from across the mini-project. In other words, *all* students engaged with the intended mathematics, social justice, and STEM ideas, at least to some degree. Further, the final whole class discussion provided some insight into the integrated and equitable learning that occurred through this letter writing process. Although participation was somewhat uneven in this final discussion, the project culminated with high levels of coherent, cognitively demanding mathematics and student voice and authority with meaningful connections to the social justice issue.

Finally, this study provides insights into additional considerations that are likely important for achieving equity goals through integrated mathematics education. Namely, models for powerful mathematics classrooms, and the observation protocols designed to capture dimensions of those classrooms, do not account for the ways that non-mathematical aspects of social justice-oriented STEM PBL support access to coherent and cognitively demanding mathematics (as discussed previously) and how those non-mathematical aspects may foster additional aspects of power and identity. The framework used in the current study only captured power as student voice and authority and focused only on mathematics identity. In this study, the level of engagement with and passion for discussing the social justice issues during the whole class discussion on Day 4 are not reflected in the current analysis. Because students negotiate their personal (racial, ethnic, gender, etc.) identities as they develop their mathematics identities (Martin, 2006), attempts to frame equity in observations of mathematics teaching and learning must also incorporate a way to identify opportunities for students to bring other salient identities into the mathematics space through integrated mathematics education. For social-justice, STEM PBL specifically, this might involve adding an additional dimension that identifies the extent to which students use mathematics and/or STEM practices as analytical tools to understand and transform social justice issues (i.e., power) and how students see those issues as important and relevant to them (i.e., personal identity). Considering the level of engagement with disability rights that students came to recognize as relevant and important through this mini-project, non-mathematical discussions present an important opportunity to understand how students see their other identities as salient in mathematics when that mathematics is integrated with social justice and STEM. Looking ahead towards integrated mathematics education demands that we re-imagine what dimensions are necessary for powerful mathematics classrooms so that those classrooms support broader equity goals.

We present study findings that depict the natural and fractional number knowledge of one third grade student with learning disabilities (LDs) in seven experimental sessions. We utilize qualitative analysis methods to illustrate how this student evidenced her knowledge of natural number and fractions through her interactions with varied learning situations. We argue the child reverted to pseudo-empirical abstractions and tricks to make sense of the situations as opposed her own reasoning. Providing children interventions that promote procedures and actions may be preventing children from adapting their thinking structures.

Natural and rational number understandings are among the most relentless areas of difficulty in school mathematics, especially for children who have varying exceptionalities, such as learning disabilities (LDs) (Mazzocco & Devlin, 2008). Difficulties in understanding natural numbers and fractions impact these students from the early elementary years through their adult life (e.g., Lewis, 2014; Mazzocco, Myers, Lewis, Hanich, & Murphy, 2013) and effect problem solving, computational procedures, and development of reasoning and sense making.

In this paper, we present findings from a design experiment that depicts the natural and fractional number knowledge of one third grade student with learning disabilities (LDs) in seven experimental sessions. We utilize qualitative analysis methods to illustrate how this student evidenced her knowledge of natural number and fractions through her interactions with varied learning situations. Through presenting this data, we raise questions about the child's reality and what the child's apparent knowing and learning was relying upon. The research questions are (1) What is one child identified with a LD's mathematical reality specific to her number and fractional knowledge as modeled across varying task types and (2) What persistent difficulties did the child experience? What seemed to be the function of these difficulties?

Theoretical Framework: The Mathematical Reality of Children with LDs

Historical perspectives regarding the mathematical realities of children with LDs arose from a medical depiction of LD as either innate, neurological impairment (Lewandowsky & Steelman, 1908) or an acquired 'disabling' of calculation centers in the brain despite normal language and speaking skills (Henshan, 1928). Over time, children not affected by injury and thought to have otherwise average or above average intelligence showed similar 'impairments' in mathematics performance (U.S. Office of Education, 1968). Researchers began to define ways to address the perceived impairments in mathematical knowledge (e.g., Hudson & Miller, 2006). In recent years, specific factors (e.g., working memory, processing, spatial reasoning, retrieve basic facts, identifying and/or compare number magnitudes and symbols) were tested alongside instruction (or before and after instruction) in a predictive manner to both explain and remediate the child's mathematical reality (e.g., Compton, Fuchs, Fuchs, Lambert, & Hamlett, 2012; Jordan, 2007; Mazzocco & Devlin, 2008; Murphy, Mazzocco, Hanich, & Early, 2007; Vukovic, 2012). By and large, the field continues to define LDs in children's mathematical realities as innate, neurological differences even today.

Yet, this definition of LD is incomplete and at times misleading for those who do not equate *biological difference* as a *disabler* or a *remediation* with *learning*. We argue that biological variations in the brain are far more dissimilar than they are similar (Compton et al., 2012) and that regardless of variations from a norm, these children still hold knowledge (DiSessa, 1988). If this is true, then we also have to accept that even if children labeled LD may evidence knowing or engage with situations in unexpected ways that their reasoning cannot be conceptualized as “impaired” or even “different”. It must be conceptualized as *their knowing*: a complex, unique organism truly known only to the child. In this way, we draw from Piaget (1972/1980), who viewed *learning as adaptation*, one that any child makes to her internal cognitive schemes, as she navigates her environment. In this way, Piaget (1972) links adaptation with instruction.

Adaptations children make in their reasoning, or not, become negotiated by *the environment and the larger system*. These negotiations *do* begin in the child’s mind, yet the child’s mind and the goal-driven activity that produces learning is variant and system dependent. Depending on the system, a child with “LDs” might very well be considered disabled in one classroom or learning environment and not another (McDermott, 1993). In a similar way, this child could be disabled in one kind of mathematical instruction (Lambert, 2014) but not in another. These factors can work to enable or disable aspects of the child’s unique knowing and learning.

Number Sequences and Composite Units

Within the child’s mind lies the potential construction of a meaningful mathematical reality. Steffe and Cobb (1988) describe four distinct types of number sequences children may evidence and adapt to understand other mathematics: (1) Initial Number Sequence, (2) Tacitly-Nested Number Sequence, (3) Explicitly-Nested Number Sequence, and (4) Generalized Number Sequence. Each number sequence can be related to children’s composite unit coordination.

Initial Number Sequence. Steffe (1992) posits that children who “count on” think with an *Initial Number Sequence (INS).* A child who uses an INS is characterized by her counting of single units and then segmenting of a numerical sequence. Through this segmenting, the child unitizes numerical sequences and interiorizes the rules of patterns (e.g., develop one composite unit and count on from this composite unit to a second composite unit, 4…5-6-7-8).

Tacitly-Nested Number Sequence. Once a child has developed and coordinated composite units through an INS, she can use composite units both as a unit in which to count on from and one to keep track of when counting. This is a *Tacitly-Nested Number Sequence (TNS).* The activity, while similar to an INS, supports the child to hold a start and stop value AND count on additional items from the stop value (e.g., three more items were added to the total of 8…9-10-11). Essentially, a child who thinks with a TNS take the result of her counting as a composite unit in which to use for a new problem. Ulrich (2015) explains this child is aware of her counting acts as both (a) a segment of a numerical sequence (i.e., the difference between 4 and 11 is 5, 6, 7, 8, 9, 10, 11) and (b) the numerical sequence created through this segmenting (i.e., 5 is 1, 6 is 2, 7 is 3, 8 is 4, 9, is 5, 10 is 6, 11 is 7). The awareness of one number sequence contained inside another, or *double-counting,* is an indication of TNS, as is a skip count to solve early multiplicative kinds of problems, such as how many 3’s are contained in 39.

Ulrich and Wilkins (2017) further distinguish between two types of TNS, early TNS (eTNS) and advanced TNS (aTNS). The two main distinctions between these subsets of TNS are described as the degree of abstraction a child relies on when understanding one composite unit while developing a second composite unit. For instance, when asked to find the parts of a whole in a fraction task (with a continuous model), a child who thinks with an eTNS will engage in *equi-segmenting* where she develops a composite unit that she needs to adjust in relation to the whole (Steffe, 2002; Ulrich & Wilkins, 2017). A child who thinks with an aTNS anticipates using a composite unit prior to the activity in a task. The common aspect of each way of reasoning is the propensity to be aware of one number sequence in relation to another number sequence.

Explicitly-Nested Number Sequence. Children who use composite units and the whole simultaneously disembed parts from wholes and develop iterable units of one. These children are thinking with an *Explicitly-Nested Number Sequence* (ENS) (Olive, 1999; Ulrich & Wilkins, 2017). An ENS supports children to multiplicatively understand a single unit and a composite unit without disrupting the whole because they see the summation of the parts and the whole as interchangeable (2017). Olive explains that each nested unit needs to be understood abstractly, allowing two levels of units as a singular abstract composite unit. This nesting of abstract units provides children number structures that are necessary for multiplicative reasoning. For example, a child at an aTNS stage versus an ENS stage would solve the following task in very different ways: 1 + 1 + 1 + 1 + 1. A child at an aTNS stage would need to consider each 1 as its own unit in which to understand the whole (e.g., 1+1=2, 1+2=3, 1+3=4; 1+4=5). A child at an ENS stage would be able to consider the five 1s and the whole 5 simultaneously.

Other sequences: Doubles and halves. Doubling and halving are described as representing initial forms of partitioning and iterating development that children use when transitioning from additive structures towards multiplicative structures. Research studies focused on doubling and halving are minimal in mathematics education (i.e., Confrey, 1994; Kieran, 1994; Empson & Turner, 2006; Steffe, 2002). Findings from these studies suggest that children do not need multiplicative structures to initialize engagement with halving because they can develop doubling operations through symmetry and halving operations through activity such as considering parts of parts (Author, Confrey, 1994).

Kieran (1994) first noted that young children were aware of multiplicative patterns through paper folding; Empson and Turner (2006) further explored this development with elementary school age students. Empson and Turner found that engagement with empirical material resulted in four types of development (non-recursive activity, emergent recursive activity, recursive activity, and functional multiplication). Through this development, Empson and Turner noted that young children began by not being able to relate their folds to the number of parts and to use this solution to solve problems (non-recursive activity) and that first-grade students did not transition beyond this activity. After transitioning from non-recursive activity, students could build towards early recursive activity (emergent recursive) and develop recursive activity (recursive activity) and multiplicative structures where solutions were anticipated (2006). These stages in students' development suggest another means in which to make sense of how students transition from additive, natural number structure structures, towards other mathematics, such as multiplicative or fractional knowledge.

Methods

"Gina"

"Gina" (age = 10 years) attended elementary school in the Northwestern United States. She was identified by her school system as having a learning disability that affected her mathematics performance. Gina's performance on the mandated standardized state measure of math performance was at a low level. Her reading scores were at average levels. Gina received additional support in mathematics concepts and operations that included explicitly modeled strategies and procedures for operations. Gina's individual learning differences included significant difficulties with working memory.

Initial Interview and Design Experiment

Data collection was collected in two semi-structured clinical interviews (Ginsburg, 1997) and seven sessions of a design experiment (Cobb, Confrey, DiSessa, Lehrer, & Schauble, 2003). All sessions were used in data analysis. Sessions took place during school hours and were in addition to the child's regular math class time. The first author was the interviewer and the researcher-teacher and attended all sessions. The second author collaborated throughout the retrospective analysis of sessions. The first author utilized explanations and indicators of Gina's possible number (Olive, 2001), multiplicative (Hackenberg, 2013; Tzur et al., 2013), and fraction (Olive, 2001; Steffe & Olive, 2010; Tzur, 1999, 2000, 2007) conceptions to build a theoretical model of Gina's initial ways of operating. Then, we worked with Gina individually in sessions that lasted about 40 minutes. Although sessions were planned for 40-min time increments, not all sessions lasted 40 min (range of time = 30 to 50 min; average time per session ≈ 40 min). Researchers collected three sources of data: video recordings, written work, and field notes.

Tasks to promote Gina's number knowledge. Consulting the available research and resources (e.g., Tzur & Lambert, 2011), we designed several learning situations to support Gina to adapt her schemes for number toward abstract composite units. Our goal was to promote Gina to "know" that fluent addition strategies use number relationships and the structure of the number system- that numbers can be decomposed and added on in parts, not just by ones. One platform task involved rolling a dice and moving a marker across a linear number game board (Tzur & Lambert, 2011). The object of the game was for the child to tell "How Far from the Start" she was after combining two addends. Another platform task involved counters and covers. In some cases, counters were quantified by the child; the researcher then added to or subtracted from the total and asked about the new total. Constraints on the platform tasks (i.e., covering of an addend or both addends, larger numbers, moving the location of the unknown questions to promote anticipation) were planned such that Gina would hold a start value in her head, count on using the structure of numbers through ten as parts and wholes mentally to add two numbers- an early ENS with small composites. A third task involved small and large units presented as bakery pans. Gina was asked to convert back and forth between the larger (e.g., 3) and the smaller (i.e., 1) to "fill orders".

Fraction knowledge. We also included a second set of learning situations to assess and support Gina's unit fraction concept (Tzur, 2007). Unit fraction concepts can be initially accessed with a tacit number sequence. One platform task was to equally share one item among two people and then share among three and four people. Constraints (no folding for 3 sharers; make the size in fewest number of attempts for 4+ sharers) were designed such that Gina would use iteration, or repeating, of a unit she estimated to be the correct length across the whole and make adjustments opposite the number of pieces.

Data Analysis

Ongoing analysis of critical events (Powell, Francisco, & Maher, 2003) in the child's thinking and learning were noted and discussed before and after each session. The focus was on generating (and documenting) initial hypotheses as to what conceptions could underlie the child's apparent problem-solving strategies during these critical events. These hypotheses led to planning the following teaching episode.

Next, the researchers engaged in a blend of retrospective analyses (Cobb et al., 2003) and fine-grained analysis (Siegler, 2007) to consider Gina's adaptations and interactions with the learning situations. To begin, we gathered the video data for all sessions and transcribed these sessions verbatim. We also examined corresponding written student work and anecdotal notes taken during these sessions. Then, we closely inspected the data for evidence of Gina's understandings and/or shifts in understandings. That is, we conducted a line by line examination of the transcribed data with a side by side of video data to consider how Gina's thinking progressed, or not, across the sessions. We then chunked the data into smaller, more meaningful parts. For each identified segment, we examined very closely each child's spoken and gestured actions along with her utterances and representations, consistently and systematically searching for confirming or disconfirming evidence (Strauss & Corbin, 1994) to ensure credibility. This process allowed us to elaborate on the model of Gina's mathematics as she interacted with the learning environment over time (Steffe, 1995) to gain a clearer picture of adaptations made to her thinking.

Tacit, Trick, OR "Teach": What is Gina's Mathematical Reality?

Gina's Initial Mathematics: Clinical Interview and Session One

In the clinical interview, Gina solved several tasks involving whole number operations the revealed a seemingly tacit nature of her thinking. For instance, she skip-counted by threes to 18 yet had to resort to the use of ones after 15 (e.g., "3, 6, 9, 12, 15…16-17-**18**; 19-20-**21**…."). When asked to solve 8 + __ = 14 in a contextualized story problem, Gina stated, "bottom number bigger, break apart a ten", first counting back with her fingers from 14, keeping a double count, and wrote a number sentence (algorithm). Interestingly, she writes "108" as the answer. When asked if that matched what she did with her fingers, Gina stated that "you have to put a ten there". When asked different ways to make 17, Gina stated there were not many. When given a start number of six, Gina counted up from five to 11 with her fingers, then counted up another six verbally to 17. She did not put the five and six together as a solution. We were unsure of Gina's number sequence.

We also asked questions around Gina' fraction knowledge. When asked to say for which of two cookies she would get a bigger share (one is cut into two parts vertically; the other diagonally), Gina stated that they were the same because "they each are a split of one cookie". In another problem, Gina worked to share a thin rectangular paper called a French fry (Tzur & Hunt, 2014) between two friends. Gina suggested partitioning the bar "into halves", partitioning the bar in the center. When asked if there was a way to know the parts are equal, the child made three parts on each side of the partition line and seemed to explain "equal" as the same number on each side. When asked to share the fry among three people and constrained not to use cubes or fold, the child drew three relatively equal parts that did not take up the entire rectangle. To address the space not used by her three parts, Gina suggested we cut off the rest of the rectangle.

To confirm the participatory nature of Gina's tacit number knowledge, we began Session 1 with the "How Far from the Start Are You?" game. *Excerpt a* begins with Gina's response to "How Far from the Start" she was after rolling 9 then 11 (the first nine spaces were covered with a paper and a "9" was written on the cover):

Excerpt a: Move nine spaces, then move 11 spaces. How far from start are you?

R: Are you thinking about how to make nine?
G: Yeah let me show you [counts up five, places a finger, then counts another four and places a finger, then counts up one and places a finger].
R: Hmm. So, you did five- 1-2-3-4-5 – and then you figured out that the other part of nine was four [child nods]. Did you figure that out in your head before you did anything?
G: Yeah, I was about to do three plus one is four [rolls dice again and gets 11]. I'm trying to figure out how to get to the 11; I haven't done that one before [child uses game board to count ten more by ones, then another for 11 spaces].

R: So, we went nine [grabs cover and writes “9”; covers first nine spaces] and then we went 11. How far from the start are we?
G: [*pauses for 6 seconds; the grabs pencil and begins to write algorithm*]. R: Can you figure it out without writing it down?
G: [*pauses for 9 seconds*] 20. R: How’d you know it was 20?
G: Whenever I do math problems, it’s like a paper and pen to the wall showing the math problem and the numbers magically appear. It’s just my brain.
R: Tell me what you were thinking in your brain. G: [writes down 9 + 11 = 20 vertically]
R: Tell me what that means.
G: This [points to 9 + 11 that she wrote, write 9 + 1 = 10] is how much this adds up. It’s sort of like we’re grouping.
R: So, you took the nine and the one from the 11 and you did ten?
G: [Smiles] Or - you could do 9 [lifts fingers one at a time]…10-11-12-13-14-15-16-17-18-19-20.

In the first session, Gina evidences what could be viewed as tacit knowledge of number through a count on. That is, she seems to start from the nine and count up 11 to stop at 20. Yet, because she already solved the problem visually by “showing the math problem on the wall”, we asked her another problem involving 2 + __ = 8. Gina’s thinking in this problem told a different story.

Namely, Gina began to count up from five and stopped. She then stated that four and four is eight, raised two fingers, began to count up and stopped at seven. The child then began to verbally recite number facts and, after several attempts, eventually stated that two and six would make eight. We also used the fraction tasks from the first session, yet this time we asked Gina to test a share size to see if it was the correct size for one of three equal shares. To do so, Gina repeated the share three times to show a length, yet called the part “one-half”. She then described her activity as “two times”, further explaining the activity as 2 + 1. Looking across the tasks, Gina’s activity suggested that she was operating with a participatory tacit number sequence. Yet, procedural residue made it difficult to say this with certainty.

Sessions Two and Six

In session two, Gina continues to display what we called tacit knowledge in both number and in fractional knowledge. Excerpt b begins with Gina’s response to a missing addends task where she was shown six counters, then the counters were covered. The researcher then said, “I placed more counters under the cover; altogether there are 13. How many counters in my hand?”:

Excerpt b: 6 counters covered, 7 in the researcher’s hand
G: [mumbling]. Six… [pauses 12 seconds] Trick question. R: How so?
G: Well, I already know that six plus four is ten. The trick I was taught was to add another three [shows three fingers to R]. So, it would have been six plus…like…13 [shugs]. Because there’s possibly no way to get to 13 because we’ve already got six [shows six fingers, stares at her fingers. Then begins to raise two more fingers]. Eight…. [pauses 7 seconds] it’s 12. I have to get to….
R: Well I had six and I added some more and now I have 13. You were trying to think about… G: Is this some sort of trick question or what [smiles]?
R: [smiles at child] Let’s back up to something you were saying. Did you say that you had six, and then you put four more onto that and got to ten?
G: [nods]
R: Then how many more did you say to 13? G: Three more.
R: So [shows three on one hand and hour on the other]?
G: 30…34. No, seven. Seven?
R: Do you think I put seven under there?
G: Yes [lifts covers and counts to check, smiles].

In the second session, Gina continues to show a kind of tacit knowledge of number through a count on. That is, she seems to start from the six and counts up to 10. Interestingly, she then seems to no longer rely on her own knowledge. Instead, she reverts to a “trick” to get from 10 to 13. Good evidence for this claims rests in the notion that Gina could not put the four [6… 7-8-9- 10] with the 3 to arrive at a missing addend of seven. Instead, Gina sees a “trick question”.

Similar activity seemed to continually show and then fade in Gina’s reasoning throughout the remainder of the sessions, and became exacerbated when the location of the session was changed from the small environment used in the first four sessions to the room where Gina was used to coming for small group math intervention time during the school day. In the seventh session where Gina’s response to task where she was shown 4 red units (each red unit measured 2 white units). The researcher asked Gina to think about how many white units would be needed to equal the same length. Gina aligned the white units long ways, reasoning that three white units aligned with the red unit as opposed to two and muttered, “3, 6, 9, 12, 15, 18” and smiled. Excerpt c begins with a request from the teacher to consider the total amount of white units if two more red units were added. Gina answered incorrectly and was asked to explain:

Excerpt c: Add two more red units (3s)- how many total white units (1s)?

G: Because this and that [taps table]...it’s like a multistep...so...what we do in my classroom. It’s like, um, it’s supposed to be hard. It used to be hard for me but...it’s easy [writes down the word multistep on the paper]. So that would be considered multistep. Six red and you need two more red. And you already have this over here down [references red units she modeled earlier]. And so, six plus two equals eight [points to where she wrote "multistep"]. It’s a multistep. Then 18 [writes 18] plus two, I mean eight.
R: Why eight?
G: [looks over at other teacher in room] Because six plus two equals eight.
R: That is true. How many white units equal one red unit? G: Three.
R: How many reds are you adding? G: Ah ha! 11! This all equals 11! R: Tell me how.
G: Because this right here... [draws a circle in the air over her earlier representation of the red and white units]. Because this [swipes where she wrote "multistep"] and three equals ... 11.

This excerpt provides clear evidence that what may have disabled Gina was not her innate, cognitive differences but instead prior “tricks” and teaching “strategies” that prohibited her from negotiating her own reasoning in the learning situation. Moreover, the mere presence of the teacher in the room seemed to change Gina’s goals away from reasoning and sense making and toward displaying learning “strategies”. While these strategies were arguable now part of her reality, we question whether this thinking was really “hers” in that she could not call upon it to explain and justify her words. We will expound upon further examples to illustrate this point further in session.

Discussion

We investigated how one student, Gina, evidenced her tacit use of composite units and early fractional reasoning. We begin to describe the difficulties this child experienced - namely, the use of tricks and previously taught strategies to engage with the mathematics as opposed her own reasoning. Toward this end, we add a unique contribution to the literature. Namely, we found that when Gina engaged in natural number tasks, she did appear to be relying on tacit knowledge, at least in part. However, when engaging with other tasks, she reverted to pseudo-empirical abstractions and tricks to make sense of the situations. Gina seemed to take up procedures that prevented her from reflecting on her actions upon units such that she might adapt her thinking structures. For instance, in session 2, Gina segmented the number sequence between six and 13 into four and three. However, we posit that these actions were not organized in such a way that Gina could make sense of the potentially powerful way of operations (i.e., a through ten thinking, or a breaking of seven into four and three). Instead, strategies and tricks seemed to be taught arbitrarily to Gina to afford her success in counting and performance in adding and subtracting.

In other sessions, Gina seemed to have a goal of mimicking her intervention teacher. This is evidence that learning is contributed to by both children and teachers and are negotiated by factors such as interactions, school curriculum, classroom culture, and so forth. For example, a teacher's reaction to a child with an exceptionality who has supplied a solution that they did not expect or time taken to answer may be, "That's not right" followed by explicitly taught teacher thinking. These responses likely reinforce the child as possessing the "problem." Yet, another response (e.g., "Say more") might change the context, opening up space for the child to access the mathematics from his or her own conceptions and develop practices that align with academic success. The interactional context of, "Did they say what I was expecting?", becomes replaced by, "How are they thinking about it?". The problem, removed from the child, becomes explorable as the narrative of the child as disabled begins to unravel.

We argue that instruction for Gina would have better served her mathematical needs if she had been given more opportunities for adapting *her own thinking* constructed within her own mathematical reality. When well-intentioned educators provide children interventions that promote procedures and actions, not only are they not serving their children's mathematics learning needs, they may be preventing them from engaging in learning situations that support the children to adapt their thinking structures and advance their learning. In this sense, from working with Gina, we have lingering questions regarding her development. For instance, over the course of the sessions, Gina evidence an affinity towards doubles and symmetry both within natural number development and early fractional reasoning. Other studies (e.g., Empson & Turner, 2006) have found students rely on doubles and halves in varying tasks. Although not fully reported here, Gina seems to rely heavily on these units across learning situations and across natural and fractional number reasoning. Could this have been a pathway forward which Gina could utilize to overcome her reliance on tricks and make sense her own thinking? More research is necessary to determine real causes of students' difficulties with number alongside research that conforms models of teaching that facilitate these children's understanding, reasoning, and sense-making.

OBSERVING CHANGE IN STUDENTS' ATTITUDES TOWARDS MATHEMATICS: CONTRASTING QUANTITATIVE AND QUALITATIVE APPROACHES

Wes Maciejewski
San José State University
wesley.maciejewski@sjsu.edu

A student's attitude towards mathematics affects how they learn and perform in mathematics. What exactly is meant by attitude and how this interacts with mathematics education is a current debate in the mathematics education research community. Regardless, practitioners often acknowledge a consideration of improving students' attitudes towards mathematics in their course design. This creates an impetus to study attitudes towards mathematics in a way that lends itself to observing changes over a course in mathematics. The current study draws on two approaches to observing and measuring attitudes towards mathematics in an effort to contrast disparate approaches and deepen an investigation of students' changes in attitudes. Results indicate there is no superior approach; that the multi-dimensional nature of attitude defies a succinct description, but methods exist to allow us to get a handle on this construct, nonetheless.

Keywords: Attitudes towards mathematics, undergraduate mathematics education

Introduction and Literature Review

Education practitioners often lament their students' attitudes towards mathematics, and this is employed as an explanation of their poor performance (Di Martino and Zan, 2010). But what is meant by attitude? How might this construct be operationalized, and with a clear articulation of "attitude" in hand, how might students' attitudes be transformed through education and these transformations be observed? Despite decades of research on affect in mathematics education, these questions are only now being addressed in any substantial way (Pepin and Roesken-Winter, 2015; Goldin, et al., 2016).

The most current perspective on attitude is that it is a multi-dimensional construct, with affective, social, emotional, temporal, and other components (Hannula, 2012). Attitude can co-emerge with the setting, and depends on social and individual aspects. In brief – attitude's messy.

Three-dimensional Model for Attitudes (TMA)

In an effort to improve parsimony of the attitude construct, Di Martino and Zan (2010) introduce the Three-dimensional Model of Attitudes (TMA) framework, which conceives of attitudes towards mathematics having i) Emotional, ii) Vision of Mathematics, and iii) Perceived Competence components. These three form stable dimensions of the attitude construct, being based on ~1,600 student essays describing their relationships with mathematics, but each dimension could be further refined in a multitude of ways. Vision of Mathematics could be split into instrumental and relational views following Skemp (1976), for example, or it could be understood in terms of Sfard's structural/relational model (1991). Di Martino and Zan (2010) provide a way to parse the otherwise difficult to grasp attitude construct.

However, theirs is only one such way; indeed, the origins of attitudinal work in mathematics education are in the creation and validation of Likert-type scales; see, for example, (Fenema and Sherman, 1976). Di Martino and Zan (2010) level a valid criticism against much of these origins, in particular against the "measurement era" of creating Likert-type instruments. In particular, Di Martino and Zan (2010) characterize much of the literature as defining "attitude" a posteriori through the instruments used to measure it, creating a researcher's tautology: we chose our research foci because the outcomes of our research indicate they are important and problematic.

It is necessary, then, to have a relatively clear articulation of “attitude” before rigorous research on it can proceed.

Other criticisms towards instruments intended to measure attitudes are presented in Di Martino and Zan (2010). Among these are, i) items run the risk of being chosen in a way that may not be relevant to the survey/instrument responders – responders may be tasked only to give opinions on the items and their underlying structures that are of value to the researchers; ii) how are the scores for grading the items determined? This question is especially relevant to Likert-type instruments, where researchers sometimes take the, totally erroneous, approach of assigning numbers to the Likert responses, calculate subsequent means, for example, and use these for comparison; iii) the act of measuring with a pre-defined scale necessarily compresses or projects the multi-dimensionality of attitude onto smaller dimensions, and thereby loses nuance. They mention further that the enterprise of measuring attitude assumes it can be measured (read: quantified) and can therefore be related to other quantifiable variables present in education. These are valid and powerful criticisms and highlight to this author a need to investigate further the interactions between various measurement approaches present in the literature and, for example, the TMA framework proposed by Di Martino and Zan (2010) to further explicate the attitude construct.

Mathematics Attitudes and Perceptions Survey

Not all attitudinal survey instruments have been created in the same way: at least one, the Mathematics Attitudes and Perceptions Survey (MAPS; Code, et al., 2016) is grounded in empirical data, with the items and scales originating from students' comments about learning in STEM fields, and used not as an objective measure of students' attitudes, but rather as a measure of students' attitudes relative to mathematicians'.

The MAPS items were initially adapted from the Colorado Learning Attitudes About Science Survey (CLASS; Adams, et al., 2006), which were in turn emergent from student interviews. Items were subsequently refined, added or dropped based on student and faculty interviews. The survey then was completed by 3,411 students in differential, integral, and multi-variable calculus, and introduction to proof. An exploratory factor analysis was performed on a subset of this data, with a subsequent confirmatory factor analysis on another. From this cyclical development process, seven categories emerged: growth mindset, a view of the relevance of mathematics to the real world (shortened: real world), confidence, interest, persistence, a drive to make sense of mathematical answers (shortened: sense making), and a view on the nature of mathematical answers (shortened: answers). Though these descriptors are largely self-explanatory, the reader is referred to (Code, et al., 2016) for further elaboration of the categories.

Importantly, data was also gathered from mathematicians, giving the final MAPS items an expert consensus rating. A student's response to each item is scored relative to the corresponding expert consensus: +1 if in the same “direction” as the mathematician – that is, agree or disagree – and -1 if in the opposite direction. A score of 0 is given for neutral responses.

The intention with this approach was to construct an instrument that could observe movement of students' expert-like views of mathematics. This approach avoids the arbitrariness of other instruments (Fennema and Sherman, 1976) and assesses the students' attitudes, or aspects thereof, relative to the mathematics community's prevailing attitudes. This facilitates a way of understanding how an education in mathematics might bring students into the culture of mathematics, or push them away.

Previous implementations of the MAPS survey have revealed interesting results that corroborate results in the wider STEM literature (Code, et al., 2016): aspects of attitude do correlate with academic achievement, though the directionality of this relationship is unclear; the higher the course in the mathematics sequence, the more expert-like dispositions of the students, though this may be a self-selection effect; and the typical mathematics course experience tends to push students away from more expert-like attitudes towards the field. Disheartening as this, this appears to be the norm; post-secondary education selects those most oriented towards the field, and seldom develops such orientation.

Coordinating approaches to observing attitudes

Given the proliferation of methods and ways of observing, measuring, and understanding attitudes towards mathematics, it seems a worthwhile endeavour to employ multiple methods on a particular group of students in a particular context to explore how each measure might contribute to an overall picture of the students' attitudes towards mathematics. Both the TMA and MAPS have strengths – the TMA provides a way for the students' voices to be heard, and the MAPS lends itself to large-scale educational institutions – and weaknesses – the TMA is applied only to what the student articulates, and the quantitative aspect of MAPS can be construed as feigning "rigor", with educators desiring metrics. It seems that both ought to lead to a more complete picture of students' attitudes towards mathematics.

This study takes this approach with two such methods: the MAPS instrument and a TMA analysis of students' writing about experiences with mathematics. In particular, we attend to the questions: i) is the same attitudinal construct identified by students' free-form writing about their experiences with mathematics identified with a TMA analysis of their writing as that that is identified by their responses to the MAPS instrument? ii) Are the two approaches complementary or supplementary? iii) how might both be used to asses *changes* in attitudes exhibited by students over a mathematics course?

Methods

The data for this study comes from students enrolled in a 5-week Summer pre-university preparation program at San José State University (SJSU). Students in this program were admitted to SJSU, but did not pass an entry-level mathematics test. As a consequence, they were required to enroll in developmental courses during their first year of university. In an effort to get a lead on these courses before the start of the semesters, those students of greatest financial and academic need were invited to attend the Summer program, which is intended to smooth the students' transitions to university and improve their overall chances of success.

The Summer program consisted primarily of courses in elementary mathematics and English, but also included a series of sessions conducted by the university's counseling services that targeted students' attitudes towards mathematics. Specifically, the sessions focused on mindfulness, fostering a positive attitude, self-esteem and confidence in relation to performance, academic skills, stereotype threat, and relaxation. The inclusion of these counseling sessions was intended to target and improve the developmental students' attitudes towards mathematics, as developmental students are known, in general, to have less favourable attitudes towards mathematics than their non-developmental counterparts and that this significantly hinders their progression through university (Maciejewski and Tortora, *under review*). The content of the Summer program is not the focus of the current paper. Rather, I seek to observe changes in students' attitudes towards mathematics as revealed in their writing about mathematics and their responses to a survey instrument on attitudes and dispositions towards mathematics.

Specifically, students in the Summer program were invited at the start and end of the program to write a short response to the prompt:

Tell us about a personal experience you've had with math. Try to write at least 200 words.

This prompt was chosen to be as open as possible and to not narrow responses to be specifically about attitude or approaches to mathematics, etc. The intention here is for the student to recall a memory of their own interactions with mathematics; such memories are known to have associated emotional content, which is often articulated (Maciejewski, 2017).

Prior to writing their response to the above prompt, the students responded to the MAPS instrument. Both the MAPS and the essay responses were completed online, during a class time.

Start-of-program essays ($N = 134$) were matched with end-of-program essays ($N = 134$) and complete MAPS responses (start: $N = 123$; end: $N = 123$) to form the dataset ($N = 116$ start/end matched essay pairs and MAPS responses) for this study. Each essay was scored by the author according to the TMA framework of Di Martino and Zan (2010) following the descriptors in Table 1. As an example of this scoring, consider the following essay.

> I usually prepare for a test by doing a practice test with sample questions. However, I could never get a good grade one a test because when the test comes, my mind freezes. The problem feels completely different and more difficult. Even though sometimes the difference in the problem was just a few numbers. I try to get through the problem by thinking hard about the practice test and writing all the formulas down.

This essay was assigned a "-" in the Emotional category for the language around the problem feeling "different and more difficult"; an "i" in the Vision category for the view of mathematics as formulas, and a "l" in Competence, because of their admission of not being able to attain a good grade.

Table 1: TMA dimensions and accompanying scores, in parentheses.

TMA Dimension	Possible Score		
Emotional Disposition	N/A	Positive (+)	Negative (-)
Vision of Mathematics	N/A	Relational (r)	Instrumental (i)
Perceived Competence	N/A	High (h)	Low (l)

After each essay was scored, the aggregate scores were assessed using χ^2 and z tests to test for statistically-significant differences between start- and end-of-term essay response categorizations. As will be discussed, there is not a singular best way to analyse the aggregate score data. However, the dichotomous parsing of the TMA categories employed here is sufficient to observe appreciable differences in start and end of term essay responses.

The MAPS responses were scored by the author according to the instructions in the MAPS literature (Code, et al., 2016). The start and end of term MAPS results were compared on each category using Kruskal-Wallace tests.

Both TMA and MAPS data were then compared with standard logistic regression methods. This was intended to articulate the relationships between the MAPS and TMA categories .

Results

The results presented below reveal some aspects of the participating students' attitudes towards mathematics changing over the course of the Summer program. However, that is not the focus of the results; the reader is encouraged to attend to i) how the start and end of term TMA data are compared – the TMA framework has not been used to assess changes in students' attitudes over the duration of a course or program, as far as this author is aware; ii) the contrasting MAPS results; iii) relationships between MAPS and TMA categories present in the data.

In all, the underlying theme of the results takes the form of a question, that deserves being presented as a result in and of itself:

How best to determine if a change of attitudes occurred?

TMA

As reported elsewhere (Maciejewski, *under review*), there was a statistically-significant change in the TMA scores, taken as a proportion of positive/relational/high to total number of non-N/A scores ($p < 0.01$). A summary of the raw counts for each TMA category is in Table 2. The main observation here is that a TMA analysis of the student essays reveals a change in their attitudes towards mathematics.

Table 2: Results of a TMA analysis of the student essays.

	Pos./rel./high		Neg./ins./low		N/A	
	Start	End	Start	End	Start	End
Emotional	30	44	49	41	37	31
Vision	10	12	63	53	43	51
Competence	32	53	76	56	8	7

Changes in individual students' attitudes towards mathematics were observed by comparing their start and end of term essays. However, as is presented in (Maciejewski, *under review*), these are not necessarily *improvements*, which would be a normative assessment of the student writing. Indeed, the writing was often sufficiently rich to defy such a normative assessment.

MAPS

A comparison of the start and end-of-program MAPS scores indicate only one category with a statistically-significant change: Interest decreased ($p = 0.03$). On the surface, this seems to be a null, or negative, result. However, results from previous studies conducted with the MAPS instrument typically indicate a decrease in *all* MAPS categories over the duration of a program or course (Code, et al., 2016). The maxim, *if you can do no good, at least do no harm*, seems apropos.

Interactions Between MAPS and TMA scales

In an effort to understand better the seemingly disparate results from the TMA essay analysis and the MAPS results, I seek statistical relationships between the two. That is, this subsection of the results answers the question, do high or low MAPS category scores correspond to either of the values of the TMA category variables?

To this end, a logistic regression analysis is performed between each of the, non-zero, TMA variables and the MAPS variables; the N/A values in the TMA categories are not included in this analysis, to reflect the practice of excluding neutral responses in the MAPS analysis.

The results of the logistic regression analysis are summarized in Table 3. This analysis reveals that there are significant interactions between each TMA variable and multiple MAPS categories.

Table 3: Logistic regression model results for MAPS and TMA data. Only significant ($p < 0.05$) results are reported. Odds ratios are reported with χ^2 and p-values in parentheses.

	TMA Dimension		
MAPS Category	Emotion	Vision	Competence
Growth Mindset			
Real World	10.45 ($\chi^2(1) = 12.48$, $p < 0.01$)		
Confidence	10.81 ($\chi^2(1) = 7.46$, $p < 0.01$)	14.61 ($\chi^2(1) = 11.11$, $p < 0.01$)	15.76 ($\chi^2(1) = 19.76$, $p < 0.01$)
Interest	10.04 ($\chi^2(1) = 12.5$, $p < 0.01$)	4.88 ($\chi^2(1) = 4.93$, $p = 0.03$)	3.28 ($\chi^2(1) = 4.77$, $p = 0.03$)
Persistence			
Sense Making			
Answers			5.66 ($\chi^2(1) = 6.35$, $p = 0.01$)

Many of these relationships ought to be expected – confidence and interest cut across all TMA categories, for example. It is a reasonable expectation that these two do lead to more positive emotions towards mathematics and are related in some way to competence, though the analysis here cannot discern the direction of the relationship; perhaps improved competence leads to both greater confidence and interest. Persistence not being related to any of the TMA categories is also a plausible result – people persist for any number of reasons, whether they are competent or like it or not.

Some of the relationships are not expected, both in terms of relationships present and missing. For example, it is not clear why the Real World category ought to be related to emotions in mathematics – perhaps an appreciation of the pervasiveness of mathematics in one's life results in greater comfort or otherwise positive emotions. The lack of a statistically-significant relationship between the MAPS Answers and the TMA Vision of Mathematics categories is also unexpected, as these ought to be two different perspectives on the same underlying phenomena. However, the p-value ($p = 0.08$) in the logistic regression analysis between these variables was not far from the arbitrary significance cut-off of 0.05. The students in this study had a fairly uniform instrumental vision of mathematics, and the dichotomous parsing of the Vision category may have overlooked some of the nuance present in their true views of the nature of mathematics.

Discussion

This work concerned observing change in students' attitudes towards mathematics through two different methods and analyses. The first, an application of the TMA framework (Di Martino and Zan, 2010) to student essay responses, revealed significant positive changes in student attitudes towards mathematics over the duration of the program. The second, a start and end-of-program administration of the MAPS instrument (Code, et al., 2016), revealed only one significant change: student interest decreased. How might we understand these seemingly disparate results?

Returning to the research questions posed near the start of this paper, I address (iii) first. Changes in students' attitudes towards mathematics are difficult to identify and describe. The MAPS categories, by their quantitative nature, give the illusion of readily being able to describe change. However, changes do not always occur in terms of moving towards or away to experts. It is possible for a student to have a "horizontal" shift in their attitudes – they may develop a love for solving rich modeling problems and increasingly despise computation, the net effect of which is that the student is no closer to the experts in that aspect of attitude towards mathematics. The MAPS is also restricted to revealing those aspects of the students' attitudes that are asked about by the MAPS items. Though the MAPS categories tend to be identified in the research

As revealed through logistic regression analyses, there are significant interactions between the TMA essay analyses and MAPS results. This lends support to the following hypothesis, phrased in terms of a mathematical analogy.

A student's attitude towards mathematics is a multi/high-dimensional object. As articulated in the literature (Goldin, et al., 2016; Pepin and Roesken-Winter, 2015; Hannula, 2012), *attitude* consists of psychological, social, emotional, and temporal states. Any attempt to observe, describe, and otherwise measure the attitude object necessarily results in a reduction of dimension. A student writing about their relationship with mathematics reveals only some features of attitude, and a subsequent TMA analysis slices through those features. A MAPS instrument implementation reveals sections of a students' attitude object, that they may or may not have written about, and attempts to quantify these, metrizing the sections along the MAPS categories/dimensions. The MAPS sections may, as in the data reported here and revealed through the predictive variables in the logistic regression, intersect with the TMA slices, or be parallel.

The key with this mathematical analogy is that a high-dimensional object is difficult to comprehend by humans embedded in a spatially three-dimensional world. This difficulty is not an impossibility, since we have ways of bringing high-dimensional objects into three-dimensions, but this dimensional reduction necessarily results in a loss of information. In our efforts to understand that which is not readily graspable, we lose features of the object. Bringing the object into our world in one way may reveal the smooth curves of one side, and leave the sharp corners and divots of another hidden.

Taking this view of attitude towards mathematics as a high dimensional object avoids privileging of one method to understand that attitude over another. That is, a qualitative analysis of a student's writing about their relationship with mathematics is neither better nor worse than the student's responses to a Likert-based questionnaire on attitudes towards mathematics, or vice-versa. Both approaches reveal only restricted features of attitudes, and subsequent analyses further reduce those features. Both taken together can reveal more features of overall attitude than either one alone.

Acknowledgments

MATHEMATICS AND LANGUAGE INTEGRATION IN A CLIL CLASSROOM: AN ANALYSIS OF GENRE

José Manuel Martínez
Michigan State University
mart1580@msu.edu

Teachers in mathematics classrooms where the language of instruction differs from students' first language face competing demands regarding mathematics and language teaching. In this study, I conducted an analysis of genre of teaching episodes to examine how a teacher in a Spanish immersion third-grade classroom in the US responded to those demands. Findings indicate that the genres on which the teacher drew are associated with mathematics and with language classrooms, in addition to general genres that can be found in either classroom. I argue that the teacher's awareness of school demands and of students' needs influenced how genre-switching unfolded. I discuss how genre analysis adds to conceptualisations of mathematics and language as integrated in CLIL classrooms.

Keywords: Equity and Diversity, Instructional activities and practices

Mathematics teachers face competing demands in classrooms where the language of instruction differs from students' first language.[1] Teachers have the double responsibility of supporting students' development of mathematics and the additional language (Nikula, Dalton-Puffer, Llinares, & Lorenzo, 2016). These teachers confront the decision of how to split class time between these two competing demands. An alternative is to approach mathematics and the additional language as integrated. Integration is the premise of Content and Language Integrated Learning, CLIL, frameworks (Nikula et al., 2016). In CLIL classrooms, the language of instruction differs from students' first language[1]. Rather than regarding the role of the teacher as complying with competing content and language demands, CLIL teachers integrate the two.

In this study, I draw on the concept of genre to consider the role that societal forces play in mathematics CLIL classroom interactions. I follow Bakhtin's (1986) notion of genre that considers both linguistic and social influences on interactions. I propose a view of classroom episodes as representing teaching genres that are particular to mathematics or to language classrooms. I ask the following research question: How does a teacher in a CLIL classroom integrate mathematics and foreign language to respond to competing demands? I argue that a dialogic dynamic among language, content, students' needs and school demands drove the teacher's efforts toward integration. Both individual and school orientations toward mathematics and the foreign language influenced how integration unfolded.

This paper relates to the theme of the conference of celebrating 40 years of PME-NA. The paper focuses on one of the enduring challenges in mathematics education research that the conference addresses: supporting *all* students through equitable teaching informed by bodies of knowledge that the conference has supported. Specifically, the paper sheds light on the role

[1] Following Johnson & Johnson's (1999) definitions, I refer to **first language** as the language to which a person is exposed from birth and in which the person is raised. A **second language** refers to a language other than the first language that is widely used in the person's community (for example, English is a second language for Spanish speakers living in the US). A **foreign language** is a language other than the first language and that is not widely used in a person's community. An **additional language** encompasses all languages other than a person's first language.

teachers play in mediating competing demands in mathematics classrooms where the language of instruction is different from students' native language.

Theoretical Framework

Mathematics and Language

I draw on a perspective that regards mathematics and language as integrated and inseparable. Instead of delimiting where mathematics ends and where language begins, this perspective defines the two as an entanglement. Rather than a final representation of an already existing idea, language is part of developing, communicating and refining mathematical ideas (Barwell & Pimm, 2016). Accordingly, mathematics and the additional language develop in tandem. Mathematical activity involves continuous learning and relearning the additional language as it emerges in interaction (Brown, 2002). Additionally, using particular languages influences mathematical activity. For example, certain languages express particular mathematical concepts in a more transparent way than other languages (Martínez, 2018). Teachers may draw on the language that more transparently represents a mathematical idea if such language is valued at school. The intersection between a language and mathematical activity presents particular complexities, including the social orientations about what languages to use in academic settings.

CLIL in Mathematics

I draw on definitions of CLIL as an umbrella term that refers to classrooms where students learn both content and an additional language (Nikula et al., 2016). CLIL classrooms have both content and language goals and expectations. The focus of CLIL, however, is on integration: "[CLIL's] distinctiveness lies in an integrated approach, where both language and content are conceptualised on a continuum without an implied preference for either" (Coyle, 2007, p. 545). Because of this attention to integration, CLIL is consistent with this study's purpose of exploring how a teacher integrates language and content to respond to competing demands.

In addition to the focus on integration, CLIL highlights that contextual forces influence classroom interactions. The purpose of CLIL pedagogies is not exclusively to bring a set of pre-existing grammar structures to the mathematics classroom. Instead, CLIL draws attention to how expectations about language, mathematics and schooling affect pedagogical decisions: "CLIL teaching [is] a site where diverse institutional, educational, personal and pedagogical scripts and purposes intersect" (Nikula et al., 2016, p. 27).

Genre Analysis

I follow a Bakhtinian definition of genre as a socially discernible type of language use (Bakhtin, 1986). Rather than being classifications that specialist linguists propose, genres are sets of cultural conventions (Gerofsky, 1999). That is, genres are what a collective believes them to be and they are influenced by the ideologies, expectations and histories of a specific culture (Gerofsky, 1999). This simultaneous attention to language use and social influences is consistent with this study's purpose of exploring a mathematics CLIL classroom in light of institutional and societal expectations and demands. I build on research on genre that is consistent with a perspective of mathematics and language as integrated. These studies attend to both linguistic features and social orientations and demands that influence language use. For example, when studying lectures as a genre in mathematics education, Gerofsky (1999) drew attention to linguistic features such as the non-inclusive we/us, ambiguous use of nouns, and saturation of imperative forms. Simultaneously, he regarded social expectations for the interaction as constitutive of the genre, including who is supposed to be silent and who is expected to speak.

For the purpose of this study of exploring how a CLIL teacher integrated mathematics and language to respond to competing demands, I focus on genres as teaching episodes associated with language or mathematics classrooms, as well as general genres associated with multiple classrooms. Particular types of language use, and teachers' and students' actions can be thought of as typical of language teaching or mathematics teaching. Different genres respond to specific institutional and social demands, with some genres motivated by demands about language acquisition and others motivated by demands about mathematics learning. Drawing on different genres throughout a lesson and a unit, teachers respond to competing demands: "The focus would be on the different intended and perceived purposes embedded in different genres, and on a mastery and enjoyment of genre-switching" (Gerofsky, 1999). This approach acknowledges social influences in recognising and using language at the level of classroom interactions.

Methodology

Sites and Participants

This elementary school was located in the Midwest region of the United States in a mostly White, middle class, English monolingual community. The school offered a Spanish language immersion program. Following a language enrichment full immersion model, all instruction was in Spanish, except for one hour taught in English per day. Mathematics was taught in Spanish. The classroom was a third grade with nine female students (one Latina, one African American, seven White) and 14 male students (two African American, 12 White). All students spoke English at home. All 23 students were able to comfortably initiate and sustain a conversation in Spanish. The teacher, señora Abad (all names are pseudonyms) was a US-born Latina who considered both English and Spanish her native languages. Her educational background was in Spanish bilingual education. She had been a teacher for three years.

Data Generation

I used ethnographic methods (participant observation, interviews and field notes) to generate data on how the teacher integrated language and mathematics and how such integration related to competing demands external to the classroom. Consistent with this study's purpose of illustrating how the teacher drew on different genres rather than claiming this is an exhaustive list, I focus on one geometry unit. I chose this unit because it took place toward the end of the academic year when patterns of interaction were stable. I video recorded three lessons per week which resulted in nearly 11 hours of video for 12 lessons. I transcribed all video recorded lessons. Throughout the unit, I conducted unstructured interviews where the teacher and I discussed preliminary findings, confirming or redirecting my analyses. I documented references to forces external to the classroom that influenced the lesson, including the teacher's references to the pacing guidelines, communications with parents, the textbook, and assessment. I transcribed interviews.

Data Analysis

Analysis focused on video data and interview data supported interpretations. The unit of analysis were teaching episodes which I defined as class moments beginning with a change in topic, task or teaching method. The 12 lessons in this unit resulted in 85 teaching episodes. Consistent with the discussion of genre above, during a first stage of analysis I examined both linguistic features and social conventions in each episode. Drawing on Gerofsky's (1999) tools to analyse genre, I annotated the following dimensions in each teaching episode: who influenced the direction of the conversation, modes of communication (written, spoken, gestures), types of questions asked and who asked them, resources being used (for example, textbooks and manipulatives), who addressed who (teacher-student, teacher-whole class, student-student), mathematical content, mathematical practices (for example, giving an answer and describing a problem solving strategy), languages being used, and the level of attention to language accuracy.

During a second stage of analysis, I looked for patterns across transcript annotations. I grouped similar episodes and characterised each group. I conducted this process three times, refining classifications and interpretations, resulting in 11 teaching genres. During the third stage of analysis, I classified each genre as associated with language or with mathematics teaching, or as general. This classification corresponds to the focus of the episode, the teacher intentions as expressed in interviews, and my interpretation of whether the observed episode was recognizable as typical of mathematics or language classrooms or both.

Findings

Analysis revealed that the teacher drew intermittently on clearly discernible mathematics and language teaching genres to respond to demands on each of the two areas. Moreover, some of the genres seem to be associated with both mathematics and language classrooms. Table 1 synthesises the distribution of teaching episodes in each genre and genre category.

Table 1. Number of teaching episodes by genre.

Genre Category	Genre	Number of episodes
General	Whole class discussion	21
	Small group task	18
	Task launching	11
	Teacher explanation	8
	Student presentation	4
Language teaching	Info gaps	6
	Artifact description	4
	Role playing	2
Mathematics teaching	Textbook work	6
	Number talk	3
	Test	2
Total number of episodes		85

Due to space restrictions, I focus on the most frequent genre in the language and the mathematics categories. In the transcripts below, text in brackets describes actions.

Mathematics Episodes: Textbook Work

In the textbook work genre, students worked individually or in pairs solving problems from the textbook. One example of this genre took place during the seventh lesson of the unit. Students were working in pair on a page that asked them to find three rectangles with a perimeter of 12 centimetres. Afterwards, students needed to fill out a table with the lengths of the adjacent sides and the area of each rectangle. The teacher told students they could get geoboard dot paper if they wanted to draw their rectangles. A few minutes into the task, Señora Abad approached two students, Lisa and John. They were working in silence and looking at each other's textbook. John had drawn a 2x2 square and Lisa had written 2 and 2 in the first row of the chart and 2 and 4 in the second row. Señora Abad asked the students what the perimeter of their square was. Putting her finger in the middle of the square, Lisa answered that the perimeter was four.

Table 2. Example of the textbook work genre.

Speaker	Original Utterance	Transcribed Utterance

Señora Abad	El perímetro es afuera.	Perimeter is outside.
Lisa	[Mira el dibujo en silencio.]	[Looks at the drawing quietly.]
John	[Mira a la señora Abad] ¿Estamos sumando o multiplicando?	[Looking at señora Abad] Are we adding or multiplying?
Señora Abad	¿Qué es perímetro? [Mira a Lisa y a John.]	What is perimeter? [Looks at Lisa and John].
Lisa	Afuera.	Outside.
Señora Abad	Afuera. Entonces, ¿qué hago para buscar el perímetro de esta figura?	Outside. So, what do I do to look for this shape's perimeter?
Lisa	Sumar.	Add.
Señora Abad	Mmhm. ¿Qué sumo? [Mira a los dos.]	Mmhm. What do I add? [Looks at both.]
Lisa	Dos mas dos mas dos mas dos.	Two plus two plus two plus two.
Señora Abad	Y eso es…	And that is…
Lisa	¿Ocho?	Eight?
John	[Borra los números 2 y 2 que había escrito en su cuadro.]	[Deletes numbers 2 and 2 that he had written in his table.]
Señora Abad	Ocho. Pero yo necesito rectángulos con un perímetro de doce. Tú me dices que dos y dos te da un perímetro de doce.	Eight. But I need rectangles with a perimeter of twelve. You say from two and two you get a perimeter of twelve.
Lisa	No.	No.
Señora Abad	OK. Puedes usar tu cuadrícula de puntos [señala al papel de John.] Aquí en esta [señalando a la segunda fila del cuadro en el libro] tú me estás diciendo que un lado tiene 2 y otro 4 en un rectángulo, ¿si? Si esto es 4, esto también va a ser 4 [Dibuja un rectángulo y señala dos lados opuestos]. Si esto es 2, esto también va a ser dos [señala los otros dos lados opuestos]. ¿Cuál es el perímetro de esto?	OK. You can use your dot grid [points at John's dot paper.] Here in this one [pointing at the second row in the table in the textbook] you are telling me that a side is 2 and another one is 4, right? If this is four, this has to be 4 too [Draws a rectangle and points at opposite sides]. If this is 2, this is going to be 2 too [points at the other opposite sides]. What is the perimeter?
Lisa	Doce.	Twelve.
Señora Abad	¡Ajá! Entonces ese, está bien ese. Ahora tienes que buscar dos rectángulos mas que tengan un perímetro de doce.	Aha! So, this one, this one is correct. Now you have to look for two more rectangles that have a perimeter of twelve.

Several characteristics of the textbook work genre are present in this excerpt. Both teacher and students influenced the direction in which the conversation went. The teacher elicited students' thinking and definitions of concepts (i.e "¿Qué es perímetro?"—*what is perimeter?*). Students' questions had to do with the correctness of their answers, what they had to do, or specific definitions or procedures (i.e "¿Estamos sumando o multiplicando?"—*Are we adding or multiplying?*). Lisa presented her answers as questions, indicating the exploratory nature of her work and acknowledging that there was one correct answer that señora Abad could confirm. Modes of communication included spoken language, mathematical symbols and drawings.

Despite the interactive nature of the excerpt above, episodes in the textbook work genre did not necessarily involve student talk. Students could decide to work silently, as was the case at the beginning of the episode described here. Conversation frequently started when the teacher approached each pair. Although both the teacher and the students contributed to this conversation, students had the option of remaining silent or limiting their spoken utterances. For example, John only spoke once in the excerpt above and most of Lisa's turns consisted of one word. On the contrary, señora Abad's turns are longer and consist of full sentences. The focus of episodes in the textbook work genre was on mathematical ideas. These explorations, however, did not revolve around the generation of ideas but rather on recollection of definitions and strategies previously discussed. In the example above, the teacher did not elicit explanations or justifications. Instead, she gave definitions (i.e. "perímetro es afuera"—*perimeter is outside*) or reminders and students used phrases or isolated words to give answers.

In an interview, the teacher mentioned she used the textbook genre to review mathematical ideas, focusing on accurate application of procedures to get correct answers. The teacher used this genre after students had generated ideas and made sense of specific concepts. According to the teacher, she frequently drew on this genre as formative assessment that informed subsequent lessons, as well as a review before tests. In this example, the class had already discussed perimeter and area, and strategies to calculate each. The teacher mentioned that from previous lessons she had concluded the class needed to work on differentiating area and perimeter, which was one of her goals in this episode.

Language Episodes: Info Gap

In the info gap genre, students worked in pairs. Each student had some of the information necessary to solve a problem. The teacher gave a slip of paper to each student in a pair and students could not see each other's slip. One slip was designated "Student A" and the other one "Student B." First, each student needed to figure out what the information in the slip was by completing a language driven task. Then, students requested the missing information from each other. Although the information discussed was mathematical, the focus was on accurate production of the Spanish language.

One example of the info gap genre took place during the eighth lesson of the unit. In pairs, one student got a slip labelled Student A with information about a shape. This student needed to unscramble the words in each sentence. Student B had incomplete sentences about the same shape. This student needed to formulate questions to request the missing information. Señora Abad approached two students, Malik and Daniel.

Table 4. Example of the info gap genre.

Speaker	Original Utterance	Original Utterance
Señora Abad	¿Qué te hace falta aquí? [señalando la palabra "cuadrilatero."]	What's missing here? [pointing at the word "cuadrilatero."]
Malik	Oh! [Agrega tilde en "cuadrilátero."]	Oh! [Adds accent mark in "cuadrilátero."]
Señora Abad	Muy bien. [Murmura mientras señala cada frase.] Los lados cortos suman… La figura tiene… Hmm… ¿Cómo se dice esto?	Very good. [Whispering as she points at each sentence.] Both sides add up… The shape has… Hmm… How do you say this?
Malik	Oh! La figura tienes 4 ángulos rectos. Wait, no! Es correcto.	Oh! The shape have four right angles. Wait, no! It's correct.
Señora Abad	Hmm… ¿Recuerdas la historia de los caminos? Los caminos eran…	Hmm… Do you remember the story about the roads? The roads were…
Malik	Um largos y… Oh! [Borra "rectos ángulos" y escribe "ángulos rectos."]	Um long and … Oh! [Erases "rectos ángulos" and writes "ángulos rectos."]
Señora Abad	¡Muy bien! ¡Ángulos rectos! Ahora trabaja con Daniel que ya terminó.	Very good! Right angles! Now, work with Daniel; he is done.
Daniel	Ahora yo te pregunto.	I ask you now.
Malik	Mmhm.	Mmhm.
Daniel	¿Qué figura es?	What is the shape?
Malik	La figura es un cuadrilátero.	The shape is a quadrilateral.
Daniel	[Escribe en su papel] ¿Cuánto suman los lados adyacentes?	[Writes on his paper] What is the sum of the adjacent sides?
Malik	Los adyacentes lados suman nueve centímetros [Sonríe.]	The sum of the sides adjacent is nine centimetres[Smiles.]
		[Starts to write] What?! No!

Daniel	[Comienza a escribir] ¿Qué?! ¡No!	[Laughs.]
	[Risas.]	
Daniel	Malik, ¿no sabes decir eso?	Malik, don't you know how to say this?
Malik	[Sonríe] Es los lados adyacentes suman nueve centímetros.	[Smiles] It's the sum of the adjacent sides is nine centimetres.
Daniel	[Escribe.]	[Writes down.]

This example illustrates characteristics of the info gap genre. For example, students worked independently some of the time, with the teacher intervening only when she saw inaccuracies in language use. When the teacher intervened, she explicitly pointed at errors and asked the student to correct. That was the case when señora Abad asked Malik what was missing in the word he had spelled as "cuadrilatero" and when she asked him how to write a specific sentence ("ángulos rectos"). The questions señora Abad asked were not related to the mathematical meaning of the ideas in the slips. The teacher asked questions that drew Malik's attention to language inaccuracies ("¿qué te hace falta aquí?" and "cómo se dice esto"). Specifically, señora Abad asked "¿recuerdas la historia de los caminos?" referring to a short story the class had read about long roads and straight roads (caminos largos y caminos rectos) to focus on the noun-adjective word order in Spanish. Instead of inquiring about students' mathematical sense making of the ideas, the teacher focused on accurate spoken and written language production. That was the case when Malik playfully changed the standard "lados adyacentes" for "adyacentes lados" and how Daniel realised there was an error. Additionally, interactions in this genre were guided. Students engaged in the task writing or taking turns to ask and answer questions. Both students in the pair needed to communicate actively in order to complete the task.

In an interview, the teacher mentioned she used the info gap genre to focus students' production of mathematics discourse. Moreover, the class used the product of tasks in this genre as input for problem-solving tasks focused on mathematical ideas. Señora Abad commented that she drew on this genre when she thought it was necessary for the class to review the mathematical meaning and accurate use of specific terminology and phrases. The teacher mentioned that parents were frequently familiar with these tasks as associated with language learning and that they appreciated this focus on language. Therefore, she sometimes sent the individual part of these tasks as homework.

Discussion

This study suggests that the teacher navigated the competing demands by flexibly drawing on mathematics and language specific genres. The tasks, types of interactions, linguistic features, resources used, and purposes of episodes were similar within a genre and were typical to either mathematics or language teaching. This dynamic genre-switching resonates with Gerofsky's (1999) conceptualisation of genre-switching as a pedagogical tool to reach and support diverse students. Through genre-switching, the teacher foregrounded one of the two areas at different moments of the unit. In doing so, the teacher responded to mathematics and language related demands. This finding sheds light on how the teacher used genre-switching as a mechanism to respond to competing demands in a CLIL classroom specifically.

This study illustrates an analytical framework that does not disrupt the mathematics and language integration. By drawing on genre analysis of teaching episodes as associated with mathematics or language teaching, this study adds to previous research on CLIL mathematics classrooms that has mainly focused on students' language acquisition (Nikula et al., 2016). Rather than differentiating whether each teaching episode dealt with language or with mathematics, this genre analysis maintained the assumption that the two are inseparable. It was the types of tasks, interactions and teacher moves that were susceptible of being characterised as typical of a mathematics classroom or a language classroom. Analysis of teaching episodes focused on the interplay between mathematics and language during mathematical activity. During episodes in all genre categories the teacher provided opportunities to use and develop the language while simultaneously developing mathematical ideas.

This study attended to school influences on classroom interactions that the teacher perceived. Summative assessment, school pacing guidelines and parents' perceptions of language tasks informed how the teacher selected and sequenced specific genres. Characteristics of the school also informed the interplay between mathematics and language in this classroom. The teacher was a Latina, Spanish native speaker with formation in bilingual education. Moreover, she was aware of parents' interest in their children language proficiency. The school guidelines required the teacher to use Spanish at all times, resorting to English only to clarify specific words. Students had been in this language immersion classroom for nearly three years and were able to understand and maintain conversations in Spanish. Accordingly, in this classroom, Spanish was valued and positioned as useful at all times. In other contexts where language minority students learn mathematics in the community's dominant language, teachers frequently lower expectations, water down the mathematical curriculum or pull students out of mathematics classes until they develop what the school considers sufficient language proficiency (Setati & Moschkovich, 2013). In this classroom, rather than seeing students' language acquisition as a barrier, school, teacher and student characteristics supported the teacher's pursuit of mathematically challenging tasks in Spanish.

THE INTERPLAY OF FRUSTRATION AND JOY: ELEMENTARY STUDENTS' PRODUCTIVE STRUGGLE WHEN ENGAGED IN UNSOLVED PROBLEMS

Jenna R. O'Dell
Bemidji State University
jodell@bemidjistate.edu

In this study, I investigated Grade 4 and 5 students' emotions while they engaged in the exploration of unsolved mathematics problems, including parts of the Graceful Tree Conjecture. Ten students from an after-school program in the Midwest participated in seven task-based interviews. The students exhibited a variety of emotions throughout the study, with frustration and joy displayed most frequently. I found the interplay of these emotions, joy and frustration, to describe the productive struggle that the students experienced while working on parts of the unsolved problems. A descriptive case of two students, Bernice and Alia, are included to describe how the interplay of frustration and joy characterize productive struggle.

Keywords: Affect, Emotion, Beliefs, and Attitudes; Elementary School Education; Problem Solving

The purpose of this paper is to document what productive struggle look like. To do this, I examined the emotions ten students displayed while they were engaged in problem-solving with unsolved mathematics problems. The use of the unsolved problems permitted the students the opportunity to display multiple emotions and engage in struggle. Hiebert and Grouws (2007) defined *struggle* as when "students expend effort to make sense of mathematics, to figure something out that is not immediately apparent" (p. 387). Allowing students, the opportunity to struggle is beneficial (e.g., Hiebert & Grouws, 2007; Kapur, 2010; Reinhart, 2000). When students have spent time learning mathematics while engaged in productive struggle, they significantly outperform similar ability students who were not given the opportunity to struggle on a task (Kapur, 2010). According to Kapur (2010), these same students who have engaged in productive struggle are also able to engaged and transfer their knowledge to work on challenging mathematics concepts they have yet to explore. While past research has documented that productive struggle is beneficial, there is no research that described what productive struggle actually looks like as children are engaged in mathematical problem solving (Warshauer, 2015; Zeybek, 2016).

When students are engaged in problem solving, they experience both positive and negative emotions (Goldin, 2000a; Hannula, 2015). However, the bulk of the previous research on emotions is limited to surveys and does not document students' emotions while they are engaged in problem solving (Hannula, 2015). In order to look forward in mathematics education, it is critical to document the different emotions students experience while engaged in problem solving and to describe what it looks like when students are experiencing productive struggle.

Research Questions

The following questions guided my research study:

1. What are the emotions students displayed when they were engaged in the exploration of unsolved problems?
2. How are the emotions of frustration and joy related to the struggle students experience while they are engaged in the exploration of unsolved mathematics problems?

Theoretical Framework

Positioning theory has been used in mathematics education as a way to analyze social interactions (e.g., Turner, Dominquez, Maldonado, & Empson, 2013; Wood, 2013; Yamakawa, Forman, & Ansell, 2009). Daher (2015) and Evans, Morgan, and Tsataroni (2006) have identified that students' emotions are linked to their positioning. In this study, positioning theory (van Langenhove & Harré, 1999) was employed as an overarching theoretical framework for how students positioned themselves through their interactions with other students and the mathematics. Their positions were displayed through their dispositions or more specifically, their emotions.

Positioning theory is "the study of local moral orders as ever-shifting patterns of mutual and contestable rights and obligations of speaking and acting" (van Langenhove & Harré, 1999, p. 1). It is "the discursive construction of personal stories that make a person's actions intelligible and relatively determinate as social acts and within which the members of the conversation have specific locations" (van Langenhove & Harré, 1999, p. 16). People can position themselves or be positioned by others in many different ways, such as being good at mathematics or bad at mathematics. A person is positioned based on actions and conversations. The conversations create storylines. The storylines can document students emotions at the moment they are displayed through their dispositions.

Methods

In this qualitative study, I investigated ten Grade 4 and 5 students (Alia, Amanda, Becca, Bernice, Edward, Hector, Iris, Joella, Karly, and Trevor; all of the names have been changed) while they engaged in the exploration of unsolved problems. The study took place at an after-school program at a community center in the Midwestern United States. Students participated in seven semi-structured, task-based interviews (Goldin, 2000b), which I will refer to as problem-solving sessions. These seven problem-solving sessions took place over three weeks and each lasted between 35 and 45 minutes. For the first six Problem-Solving Sessions, students worked on the Graceful Tree Conjecture. During Session 7, students were introduced to Collatz Conjecture.

Graceful Tree Conjecture

During the first six problem-solving session students worked on the Graceful Tree Conjecture. The Graceful Tree Conjecture is an unsolved conjecture from graph theory that is accessible to young children. The problem has students exploring different types of tree graphs, graphs that are connected (one piece) with no cycles (see Figure 1). This means a tree graph is acyclic, which means if you follow a path from node to node along the edges, you will never cycle back to the same node without repeating an edge. This means that tree graphs always have one more edge than node.

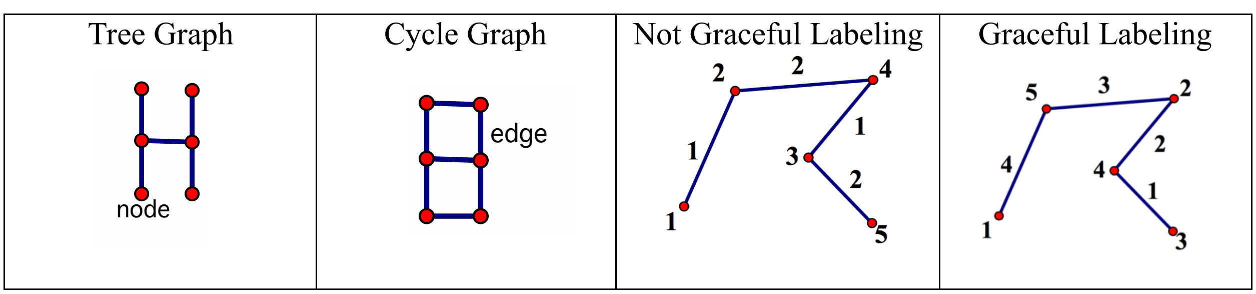

Figure 1. Concepts of the Graceful Tree Conjecture.

Tree graphs are assigned numbers to the nodes that induce labeling of the edges. For a tree graph of order n, every node is labeled distinctly from 1 through n and the edges are labeled with the absolute value of the difference of the labels on their endpoints. For a tree graph to be labeled gracefully, the edges need to be labeled distinctly 1 through n-1 (see Figure 1).

Overview of Problem-Solving Sessions

During the first six sessions, students explore different categories of tree graphs in increasing sophistication (see Figure 2). I challenged the students to not only create a graceful labeling for each graph but to find a pattern or justification to show that any tree graph in the category could be labeled gracefully. While exploring the different tree graphs, students were given a page that contained four distinct tree graphs in a given category, enlarged copies of each of the graphs, and numbered circle and square chips (see Figure 3). This allowed students to try multiple solutions without having to erase.

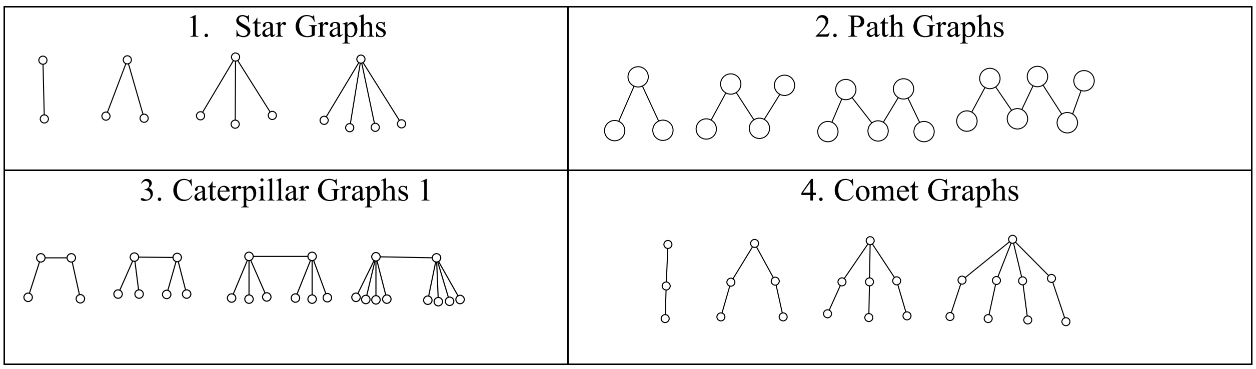

Figure 2. Tree Graphs in increasing sophistication.

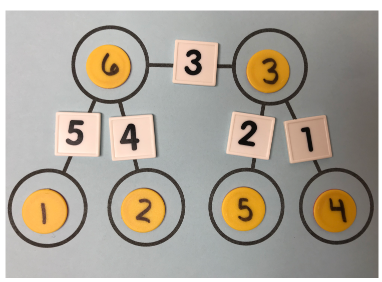

Figure 3. Enlarged Caterpillar Graph and circle and square numbered chips.

During Session 1, students were introduced to tree graphs, learned what a graceful labeling was, and explore a five node tree graph. Throughout Session 2, students worked to find a graceful labeling for Star Graphs. In Session 3, students finished Star Graphs and began to work on labeling Path Graphs. During Session 4, students continued to work on labeling Path Graphs. In Session 5, students finished labeling Path Graphs and began to work on Caterpillar Graphs. In Session 6, students worked on labeling Caterpillar Graphs. In Session 7, Collatz Conjecture was introduced but after twenty minutes of work the participants requested to continue working on the Graceful Tree Conjecture. The students then began to work on gracefully labeling Comet Graphs.

Analysis

All seven problem-solving session were video recorded and student work was collected. All video was transcribed including non-verbal actions, such as facial expressions or arms raised in the air. Next, I constructed an analytic framework based on the ideas from Else-Quest, Hyde, and Hejmadi (2008) to characterize the emotions students displayed while they were engaged with the mathematics. During my first round of analysis, I modified Else-Quest et al.'s framework by combining emotions such as joy, pleasure, and pride because I was not able to distinguish a difference between these emotions without interviewing students to know how they were specifically feeling (see Table 1 for the emotion framework).

Table 1: Emotion Analytic Framework

Emotion/Code	Definition	Example
Anger/Disgust	Irritability, temper, rage	I hate you.
Tension	Worry, Tautness, rigidity	I don't want to work with my sister.
Sadness	Anguish, grief, misery	I am really sad.
Boredom/Apathy	Fatigue, lack of interest, indifference	I don't want to work on this today. I am tired.
Affection/Caring	Friendliness, warmth, encouragement	I can help you with this one.
Humor	Banter, joking, comedy	That looks like a tree.
Contempt	Snobbery, ridicule, mimicking	Bad job for you. Stop being scary.
Joy/Pleasure	Delight, excitement, happiness	I got it! Graceful!
Distress/Frustration	Complaining, impatience, upset, disappointment	I don't get it. I can't do it.

After creating my analytic framework, I examined all of transcripts from the problem-solving sessions and used the framework to document anytime an emotion was displayed by a student. If the student displayed several statements of frustration in a row, each individual statement was documented as its own sign of frustration. I did this process twice to check for consistency, similar interpretation, and to make sure nothing was missed. This process was completed using the qualitative software, Transana (Woods & Fassnacht, 2016). Next, I created reports through the use of Transana to account for each emotion that was displayed by a student.

Results

During analysis, I explored the emotions students displayed when they were engaged with the exploration of unsolved problems (see Table 2). Through my Transana reports, I found that the two most common emotions students displayed were joy and frustration.

Table 2: Emotions Displayed by Session

Emotions	1	2	3	4	5	6	7	Total
Anger/Disgust	0	0	0	0	0	0	0	0
Tension	0	0	0	0	0	0	0	0
Sadness	0	0	0	0	0	0	0	0
Boredom/Apathy	1	0	1	2	0	0	0	4
Affection/Caring	2	5	1	0	3	7	0	18

Humor	3	9	0	3	1	2	3	21
Contempt	4	13	6	3	3	15	5	49
Joy/Pleasure	23	32	21	14	25	44	18	177
Distress/Frustration	22	26	56	21	23	38	37	223

Frustration

Documented a total of 223 times, frustration was displayed the most throughout the seven problem-solving sessions. Bernice, Trevor, and Joella displayed the emotion of frustration most commonly during the sessions (see Table 3). These emotions were most typically displayed while the students were working on finding a graceful labeling of a graph. Comments such as, "I don't get this," "Oh my gosh," "This is hard," and "It won't work" were common statements students made that indicated the emotion of frustration. They also had actions like slamming their hand on the table or making moaning sounds.

Joy

Joy was the second most common emotion displayed. It was documented 177 times. Becca, Alia, and Bernice displayed the emotion of joy most frequently throughout the seven sessions (see Table 3). Joy was displayed most frequently when students found a graceful labeling for a graph. Comments marked as joy included statements such as, "Got it!" "I am done," "I did it, I finished it!" "Finished," and Graceful!" Many times these comments were also made with students throwing their arms in the air in celebration or with clapping.

Productive Struggle

Because of the large number of times students displayed joy and frustration, I wanted to examine frustration and joy in more detail. I broke down frustration and joy by student and session (see Table 3). When I did this, I found that every student displayed both frustration and joy multiple times throughout the problem-solving sessions. Upon a closer look at when the students were displaying the frustration and joy, I found that students would display multiple signs of frustration followed by a moment of joy. Most of the time the joy was displayed when a student found a graceful labeling of a graph. I will share two students' stories throughout a session to document the interplay of frustration and joy.

Table 3: Frustration and Joy By Student and Session

	Alia		Amanda		Becca		Bernice		Edward		Hector		Iris		Joella		Karly		Trevor	
Session #	F	J	F	J	F	J	F	J	F	J	F	J	F	J	F	J	F	J	F	J
1	2	4	3	1	-	-	6	6	2	5	0	1	0	0	3	3	1	0	5	3
2	0	12	1	2	3	3	8	0	2	2	-	-	0	3	3	2	-	-	9	8

Total	19	41	9	14	26	24	58	28	9	17	13	5	5	13	35	13	7	5	42	17

Note. – means a student was absent for the problem-solving session. F stands for frustration and J stands for joy.

Bernice. Bernice was a Grade 4 student. Her story was chosen to be documented because she was vocal in her feelings and displayed the most frustration and the second most amount of joy.

During the Session 6, Bernice began with attempting to gracefully label the fourth graph in the Caterpillar class. This graph contained 10 nodes (previously she had only done graphs that contained eight nodes). Bernice began her attempts at labeling the graph. Several minutes into working she said, "Oh, dang it. I need a nine," showing frustration. She continued to work and changed her frustration into excitement with the statement, "I am doing it, I am doing it." Only two minutes later, while she was still trying to label the graph gracefully she said, "One, two. What happened? Oh no, I missed one." (A labeling of a node.) Again shifting from joy back to frustration. This frustration continued as she worked and the following conversation took place with myself, the teacher.

Bernice: Seven minus three equals four (has her yellow page almost filled). Oh my god, Ms. Teacher, look how close I was. But this last one doesn't make sense.

Teacher: Well are you looking at your sheet for a pattern?

Bernice: No.

Then Bernice continued to struggle while displaying signs of frustration with the following statements: "This makes, oh my god this doesn't make sense" and "It does not make sense."

Several minutes later, Bernice completed a graceful label and shouted with her arms in the air, "I did it. I am done. I need a pen. Ms. Teacher, I did it." At this time her frustration oscillated to joy (see Figure 4 of her work on the first set of Caterpillar graphs).

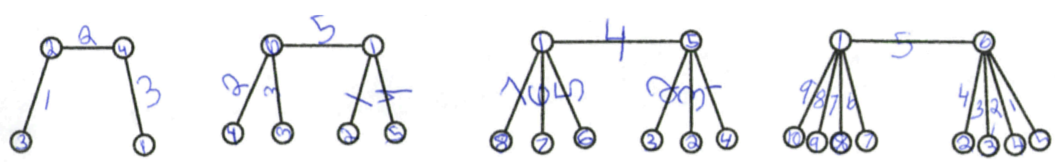

Figure 4. Bernice's work on Caterpillar Graphs.

Alia. Alia was a Grade 4 student. She had a very positive and cheery demeanor. She also displayed her productive struggle through an oscillation of frustration and joy. Her story was chosen be documented because she displayed the most total accounts of joy throughout the sessions.

During Session 6, Alia was working on gracefully labeling Caterpillar graphs. After a few minutes of working, Alia said, "I am lost" and erased her page, displaying frustration. After another thirty seconds, Alia stated aloud, "Okay, I got it" and continued to work for several more minutes. Alia then noticed that she was missing an eight on one of her nodes and shouted, "No! I need an eight." This showed her frustration. Alia continued to work on finding a graceful labeling and just twenty-seven seconds following her last shout of frustration, she clapped her hands and then threw her arms in the air and shouted, "I did it! Woo!" changing her frustration to joy.

Alia began to work on labeling her next caterpillar graph gracefully. Two minutes into working, Alia took her hand and slammed it on the table and stated, "Oh, I messed up." Only twenty-four seconds later, Alia clapped her hands together and said, "I was right. I was right." This again showed her oscillation from frustration to joy. Alia continued to work. After six more minutes of work, Alia shouted with her arms in the air, "Oh, I am good at this" and continued to work. Several seconds later, Alia said, "No" displaying frustration and a solution that was not a graceful label. After six more minutes of working, Alia shouted, "Yes" with her arms in the air. After recording her solution, Alia turned to the instructor and said, "Okay, I am ready for the next one." Alia continued working throughout the rest of the time with the similar pattern of joy and frustration. She displayed frustration when she was struggling to find a solution followed by joy and excitement when she made progress on her work.

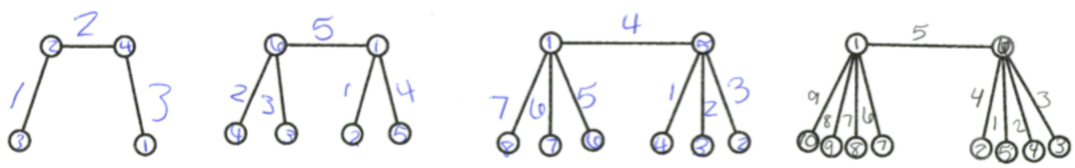

Figure 5. Alia's work on Caterpillar Graphs

Similar to Bernice, Alia also displayed a range of emotions and oscillated between being frustrated and then displaying signs of joy or pride when she produced a graceful labeling. I found this oscillation between joy and frustration a sign of productive struggle. This struggle was similar to the productive struggle Alia, Bernice, and the other students demonstrated during all the problem-solving sessions.

Discussion and Conclusions

The most common emotions that students displayed were frustration and joy. These results are similar to Else-Quest et al. (2008) who found the most common negative emotion students displayed were frustration and distress and the most common positive emotions students displayed were joy and pride. Students in this study also showed emotions of contempt, sadness, boredom, humor, and acts of caring.

Past research has documented different ways to help students during productive struggle (Warshauer, 2015; Zeybek, 2016), and that productive struggle is beneficial (Kapur, 2010). But, there is limited research in what productive struggle actually looks like as children are problem solving (Warshauer, 2015; Zeybek, 2016). Through this research study, I have documented that while students are engaged in productive struggle, they display the emotions of frustration and joy. Students display frustration while struggling through a portion of a problem. Frustration was displayed multiple times throughout their work. Once a student found some success or made progress towards the solution, they enacted joy. This process was repeated throughout the mathematical problem solving.

Overall, I believe a significant finding of this study pertains to the oscillation of joy and frustration which I have interpreted as the construct of productive struggle. All of the students in this study were able to persist through the struggle and were able to find joy and pride in their work. Unsolved mathematics problems are not typically part of elementary school education but I found that these types of problems allowed students the opportunity to engaged in productive struggle and experience mathematics more similar to how a mathematician might experience mathematics.

MATHEMATICS ANXIETY AND MEDITATION

Geillan Aly
Hillyer College, University of Hartford
aly@hartford.edu

Mathematics anxiety debilitates many students, reducing academic success and quantitative literacy. Although various treatments have been researched, there has been no successful intervention for this phenomenon. Meditation has been recognized as helping individuals reduce other forms of anxiety. Research in this field is limited due to the internal nature of meditation. In this study, a device called a Muse Headband addressed some of these limitations. Results showed that meditation can potentially help students reduce their mathematics anxiety.

Keywords: Affect, Emotion, Beliefs, and Attitudes; Technology

Mathematics anxiety, "a feeling of tension and anxiety that interferes with the manipulation of numbers and the solving of mathematical problems in … ordinary life or academic situations" (Richardson & Suinn, 1972), challenges many students. This phenomenon, although related, is distinct from general or test anxiety because of the association with mathematics. Researchers disagree on the prevalence of mathematics anxiety. However, conservative estimates indicate that this problem disproportionately affects females (Dowker, Sarkar, & Looi, 2016).

The consequences for students who suffer from mathematics anxiety can be significant. These students can have lower grades (Richardson & Suinn, 1972), be less fluent in mathematics (Ashcraft & Faust, 1994), avoid enrolling in mathematics courses (Stubblefield, 2006), and prefer procedural mathematics courses that are not conceptually driven (Norwood, 1994). These factors lead to students being less quantitatively literate, affecting prospects for employment.

Interventions to help alleviate or prevent mathematics anxiety vary, although there is no comprehensive cure (Dowker et al., 2016). Such interventions include having a student reappraise the student's belief in the negative consequences of their mathematics anxiety. Another intervention has the student write out their worries and fears. Focused breathing exercises have also been shown to help math-anxious students better perform on a series of arithmetic tasks (Brunyé et al., 2013). Overall, interventions to alleviate mathematics anxiety focus on calming the mind, directing it away from worrisome thoughts.

Considering mathematics anxiety as a specific type of general anxiety, successful interventions for general anxiety may inspire ways to help students with mathematics anxiety. Meditation is one particular intervention. Mindful meditative practices, where an individual directs attention to their breathing or focuses on their body while in a relaxed state has shown to potentially help an individual's cognition (Zeidan, Johnson, Diamond, David, & Goolkasian, 2010) and mitigate their anxiety (Khusid & Vythilingam, 2016). Mindfulness and the associated calmness, clarity, and stability in the mind can allow an individual to "respond" rather than "react" to potentially anxiety-producing situations more effectively (Miller et al., 1995, p. 197).

Meditation and related activities have been used in mathematics classrooms to support student learning. Students have demonstrated increased speed and accuracy in computations after practicing tai chi and yoga (Field, Diego, & Hernandez-Reif, 2010). Furthermore, mindfulness impacted general anxiety, but did not impact performance on lower-stakes mathematics homework assignments (Bellinger, DeCaro, & Ralston, 2015). By helping students explore meditative states and mindfulness, can we positively impact students' mathematics anxiety?

Researching mindfulness and meditation is difficult due to the internal nature of focused meditation (Davidson & Kaszniak, 2015). There is no way to measure to what extent a participant is mentally focused or actively meditating. Furthermore, due to the internal and personal nature of meditation, it is difficult for a novice to know when they are in a meditative state and how they affect their meditative experience. How can a person know whether they are truly meditating? These challenges can be overcome with an electroencephalogram (EEG) to provide data and feedback. An EEG measures an individual's brainwaves and determines the degree to which an individual is in a meditative state. EEGs are cumbersome and expensive. Researchers need a portable, affordable way to measure students' mental state; students need a way to receive feedback to understand and control their state of mind.

The Muse Headband: Measuring States of Mind

A Muse Headband is a portable EEG, a lightweight headband that measures brainwaves, and interprets and records the extent to which a user is in a meditative state. Users wear the headband which is paired with a mobile application (app) while listening to audio prompts during the session. A Muse session occurs in two phases, a calibration phase and a meditation phase.

In the calibration phase, the user is prompted to close their eyes and let their mind flow naturally, allowing wandering or distraction. A baseline wherein the individual's general state of mind is then recorded. Since an individual's mental state varies, calibration must occur at the start of each session. After calibration, the meditation phase of the Muse session begins. The user sets the length of the session and is prompted to focus on their breathing, while trying to calm and focus the mind. Background sounds, such as water lapping or ambient music, are played. The data collected in this phase are compared with data collected during calibration to determine the extent to which the user's mental activity differs from the calibration, measuring the extent to which the user can focus his or her mind. Depending on how the mental activity during the meditative session differs from the calibration session each moment is labeled as active, neutral, or calm. The user's goal is to maximize how long they were calm or were able to maintain a difference in brain activity between the calibration and meditation phases of the Muse session.

Using a Muse Headband, students can learn how to focus their mind and maintain a meditative state. Consequently, many challenges posed by researching meditation can be eliminated since actual brain activity is recorded and both users and researchers can know whether they are in a calm focused state. As a result, it is possible to determine the extent to which meditation can help students alleviate their mathematics anxiety.

Methods

In this study, students at a small university in the northeastern United States participated in meditation sessions using a Muse Headband to reduce their mathematics anxiety. This project sought to answer the question: *Does using a Muse Meditation Headband significantly reduce students' mathematics anxiety?* This study was conducted during the Fall 2017 semester.

Two algebra classes, an experimental and control group, participated in the study. The course covered factoring polynomials, graphing and solving quadratics, and manipulating rational expressions. Both classes were taught by the same instructor and had identical assignments, assessments, and lessons. Nine students in the control class and 13 students in the experimental class consented to participate. At the beginning and end of the semester, all students were given the Mathematics Anxiety Rating Scale – Short Version (MARS-S) (Suinn & Winston, 2003), a scale which measures mathematical test anxiety and numerical (calculating) anxiety. The experimental class meditated with the Muse Headband for 3-5 minutes at the beginning of each class, including exam days. Lessons were modified to account for this time. On the last day of data collection, students meditated for 10 minutes prior to taking the MARS-S post-test.

Results

Complete data from seven students in the experimental group and nine students in the control were collected and analyzed. These data included pre- and post-test MARS scores in both classes and data from at least 10 meditation sessions in the experimental class. A total of 10 males and 6 females participated. A repeated measures ANOVA was conducted to address the research question. This analysis was conducted twice; the first analysis included a student in the control group, the second did not. This student experienced a death in his immediate family early in the semester. At the end of the semester, prior to completing the MARS-S posttest, he was again absent due to related family obligations. This student's MARS-S score decreased by 16 points, a decreased unmatched by any participant in either class. It is possible that this decrease in the MARS-S score was related to this personal trauma. The student may have been more focused on their personal loss than on academic success. This student's unfortunate experience requires that we consider these scores an outlier and analyze the data with and without these data.

Results of these repeated measures ANOVA are mixed. If the outlier is not included in the analysis, results indicated a significant decrease in students' anxiety scores from the pre-test to the post-test for students in the experimental class, $F(1, 13) = 6.712$, $p = 0.022$. If the outlying student in the control group is included in the analysis, then results did not indicate a significant decrease in students' anxiety, $F(1, 12) = 3.342$, $p = 0.089$. The source of the interaction effect was the difference between the experimental and control groups at post-test. A pairwise comparison of post-test scores is not statistically significant, $p = 0.094$. Overall there is a plausible decrease in anxiety scores that warrants further investigation. See Tables 1 and 2.

Table 1: MARS-S Scores, Excluding Outlier

	Pre-Test (M ± SD)	Post-Test (M ± SD)
Control Group (n=8)	71.75 ± 16.49	78.75 ± 12.36
Experimental Group (n=7)	69.57 ± 22.28	64.29 ± 18.4

Table 2: MARS-S Scores, Including Outlier

	Pre-Test (M ± SD)	Post-Test (M ± SD)
Control Group (n=9)	73.44 ± 16.24	77.89 ± 11.85
Experimental Group (n=7)	69.57 ± 22.28	64.29 ± 18.4

Limitations

The small sample size in this study cannot be overlooked. It would be premature to draw conclusions stating that meditation contributes to differences in students' mathematics anxiety. The sample size also makes it difficult to discern whether a students' anxiety level decreased due to having the opportunity to meditate or just from having a moment to mentally pause and quietly reflect at the start of class. Finally, the sample size makes it difficult to determine what aspects of this experience contributed to potential changes in students' mathematics anxiety.

Although the researcher sought out identical classes, the two classes did not have identical student bodies. The control class consisted mostly of first-year students who placed directly into the class. Students in the experimental class were mostly second-year college students and were retaking this course or had taken and failed the prerequisite developmental course.

Discussion

This study demonstrates a potential for meditative practices to reduce mathematics anxiety. Future research studies with a more robust sample size could allow for a more thoughtful investigation into the connections between meditation and alleviating mathematics anxiety, including whether changes in MARS-S scores could be attributed to long-term effects that resulted from meditating over the course of the semester, or from the meditation session which occurred immediately preceding the student completing the MARS-S.

Finally, as mathematics educators and teachers, we should recognize how mathematics anxiety affects students' experiences and progress in our classrooms. This project has once again demonstrated that mathematics anxiety is a common phenomenon and needs to be addressed. By focusing on affective factors such as mathematics anxiety, a phenomena that has continuously challenged mathematics education researchers, we would be taking another step towards re-humanizing mathematics and mathematics education (Gutierrez, 2018). Reducing mathematics anxiety has the potential to address the needs of all students.

Acknowledgments

The author gratefully acknowledges the support provided by Hillyer College at the University of Hartford through the J. Holden Camp Faculty Fellowship and the John Roderick Grants for Pedagogical Innovation. The author would also like to thank Jessica Summers at the University of Arizona for her guidance and help with the quantitative analysis.

THE UNDERGRADUATE MATHEMATICS LEARNING CENTER: PERSPECTIVES OF PEER TUTORS

Katie Bjorkman
San Diego State University; University of California, San Diego
kbjorkman2@gmail.com

Virtually all calculus-offering post-secondary institutions in the United States provide mathematics tutoring for undergraduates, but these tutoring interactions are not well studied. This study observed tutoring in a mathematics learning center (MLC) and interviewed four tutors about their role within the MLC and the role of the MLC in mathematics learning at the institution. The tutors all felt that the MLC was a unique space both socially and academically that provided a qualitatively different learning opportunity for students. Formal observations of interactions within the MLC support this view. Suggestions are made for increased research of MLCs and tutors providing distinct mathematics learning opportunities, with the intention of improving student outcomes through extending research-based instructional practices to the learning space provided by an MLC.

Keywords: Affect, emotions, beliefs, and attitudes; Informal education; Post-secondary education; Instructional activities and practices

According to the recent MAA National Study of College Calculus (Bressoud, Mesa, & Rasmussen, 2015), a study that collected data from departments and individuals in a stratified random sample of over 200 non-profit colleges and universities across the United States, almost all calculus-offering institutions in the United States offer mathematics tutoring on campus. Furthermore, 40% of Calculus I students surveyed reported that they had utilized the campus-provided tutoring center for mathematics at some point and the study showed that merely the existence of a tutoring center improved student attitudes toward mathematics (Bressoud et al., 2015). Clearly, mathematics tutors and tutoring centers impact or have the potential to impact post-secondary mathematics students in positive ways. Yet at the same time, there is very little extant research into undergraduate mathematics tutoring and mathematics learning centers (MLCs) (Mills, Tallman, & Rickard, 2017).

One study by Solomon, Croft, and Lawson (2010) considered MLCs at two UK universities through the theoretical lens of figured worlds (Holland, Lachicotte, Skinner, & Cain, 1998). Figured worlds provides a socio-cultural perspective of identity formation through ongoing authoring and positioning work in social interactions. Their primary finding was that the MLC was viewed as a distinct academic and social space by mathematics students, and that these distinctions allowed for different types of mathematical identity work versus the interactions that took place in a classroom or within the offices of their professors or teaching assistants. The present study sought to extend our understanding of the MLC and undergraduate peer tutors by considering an MLC as a similarly potentially unique social space where mathematics learning and teaching takes place in ways outside of traditional, classroom-based paradigms. In contrast to Solomon, et al (2010), this study had a focus on the perspective of tutors rather than students, and took place in the US where tutors and tutoring centers may have different, though equally distinct and perhaps even more ill-defined, academic and social connotations. The study sought to address the research question: how do undergraduate mathematics peer tutors describe the figured world of a mathematics learning center and their role within it? The figured world framework allows for a description of the social space that accounts for broader culture, specific interactions, and the beliefs and attitudes of individuals. There is currently a lack of research around undergraduate mathematics peer tutoring in the US (Mills, Tallman, & Rickard, 2017) so rather than an empirical study this work was exploratory to describe an MLC and thus give context to inform continuing and future research.

Setting

The study took place in the MLC of a large, public university in the Southwestern United States, which offers drop-in tutoring for all mathematics courses, emphasizing the Precalculus through Calculus II sequence. The university also has an appointment-based writing center and various on-campus organizations offer supplemental instruction sections and other venues for tutoring, including mathematics tutoring. The MLC is located in the campus library and employs 20-30 undergraduates for drop-in tutoring over 46 hours during the week. Between two and five tutors may be working at a time, depending on the time of day and other factors like upcoming exams. Observed tutoring interactions lasted an average of 10-20 minutes with an individual student, although depending on tutoring demand, tutors sometimes remained longer or returned again to the same student for another interaction.

Methods & Analysis

Four undergraduate peer tutors were recorded going about their normal tutoring duties once a week over several weeks. Following each recorded observation the tutors joined the researcher in watching the footage of their tutoring interactions and explaining their decision-making and thought process to the researcher in the form of a stimulated recall interview (Dempsey, 2010). During the stimulated recall interview the participant was asked to "think aloud" about their tutoring actions and explain to the researcher their decision-making processes. The research also asked clarifying questions about specific enactments. A total of 15 tutoring shifts were video recorded and 71 distinct tutoring interactions were discussed in stimulated recall interviews. Each participant also participated in a in a final semi-structured interview with the researcher where they were asked to more globally describe their perspective on the MLC and their role(s) within it. The table below summarizes key characteristics of the participating tutors.

Table 1. Case study participants' demographic information.

Case Study Participants*	Year	Major	Ethnicity	Time Tutoring in the MLC
Danielle	Junior	Mathematics	White/Caucasian	1-2 years
Eric	Senior	Mathematics	Chinese-Filipino	1-2 years
Jake	Sophomore	Engineering	White/Caucasian	<1 year
Lily	Junior	Mathematics & Physics	Cambodian	1-2 years

**Gender-preserving pseudonyms chosen by the participants*

Stimulated recall interviews and final interviews were transcribed. Episodes and potentially relevant actions or utterances were logged for observed tutoring shifts which allowed for easy reference when analyzing stimulated recall interviews, but observations were not completely transcribed. Grounded theory was used to develop a coding scheme (Corbin & Strauss, 1990). Interactions were coded as a unit with field notes, log notes from the researcher watching the recording of the interaction, and stimulated recall transcripts were considered together.

Results

Aligning with the work of Solomon, et al (2010) tutors reported that the MLC provided something more than a central location or extended hours – that the space and the help provided there were different than that provided by professors and TAs. From the perspective of figured worlds, these tutors explained the MLC as a figured world where mathematical struggle is valued, and where the role of a tutor within the MLC to be that of a more advanced peer. Their role included normalizing student struggles, creating a non-judgmental environment, and explaining things in ways that were accessible to students. As one tutor put it:

> "The intimacy level and the time provides a different environment if that makes sense. Not only do [professors], sometimes, not only would they know what's going on better but they might try to reach it faster and not be as elaborate in their explanations. And again because the tutor might not be on the same page as the lecture it might take some more bungling and some more muddling and some more sharing of experiences and tools." – Eric

Eric saw this muddling as a good thing, validating student struggles and reinforcing that the material isn't meant to always be easy. He saw himself in the position of a near-peer offering help to a fellow student. Lily shared a similar view, seeing in fact her lack of extensive expertise in more advanced mathematics and her having recently taken the courses herself as potentially beneficial in providing clear explanations and making students feel welcome:

> "[W]e have this math learning center here so that students can come ask for help with people who are around their age, also going through the same ideas, the same process of going to school, trying to learn, they're struggling also, in a way. But that they've gone through these classes and they know what it's like. Because, I mean, professors if they're not the newest professors it's been quite a while since they've taken a class on Calc II… Meanwhile we're students and we're like 'oh, we just took this two years ago' or maybe even a year ago," – Lily

Jake and Danielle echoed that it was important for there to be a nonjudgmental space, a space were students would feel comfortable asking questions. The existence of such a place, Jake believed, allowed students to persist rather than giving up:

> "They can ask a question about their class and not worry about their professor being like 'Did you read the syllabus?' And so I think it makes it more comfortable for them and yet it helps them learn. I think that obviously more people would be failing if we didn't have a place like this because we have a place to come ask questions rather than just giving up on it." – Jake

> "Well I'm not going to judge them… I think that by coming to the MLC talking to someone who doesn't know you at all and who isn't grading your stuff, there's not a lot of judgement that is there." – Danielle

The tutors studied here see their work as being distinct from that of a professor or TA, and the MLC as providing a nonjudgmental space that encourages a certain form of help-seeking and provides a valuable and unique service for mathematics students.

Observations of participant's tutoring and their explanations in stimulated recall interviews suggest that these beliefs about their roles and the figured world of the MLC influence tutoring interactions. For example, participants were observed to sit whenever possible while tutoring, and when a chair was not available to bend or kneel rather than remaining upright. When asked about this behavior, multiple participants expressed that being eye-level was important so that the student never felt that they were being talked down to.

Conclusion

The perspectives of the tutors in this study highlight the ways in which a peer tutor and a MLC are likely to be distinct in their social and academic environments from classrooms and classroom-based instructors. In particular, the tutors interviewed described themselves as being less intimidating and perhaps more helpful to students as near-peers than the more intimidating, non-peer role of a professor or TA. This informed their role as tutors to include behaviors like intentional affirmation of the realities of struggling as a mathematics student, and positioning themselves in non-authoritative ways. While the current study is considering a single mathematics learning center and a subset of tutors, it is my hope that further studies into MLCs and the tutors who work in them will continue to be conducted as we learn more about the role that these individuals and spaces play in improving student outcomes in mathematics.

MATHEMATICAL IDENTITIES: NARRATIVES AND DISCOURSES OF FEMALE STUDENTS IN AN 8TH GRADE CLASSROOM

Bailey Braaten
The Ohio State University
braaten.7@osu.edu

This research in progress examines two 8th grade female students' socially constructed mathematical identities. Using ethnographic and discourse analytic methods, the study examined how these evolving mathematical identities intersect with gender identities. Preliminary results indicate female students in this study actively disrupt stereotypes of femininity and of women in mathematics. This study offers a fine-grain analysis of how female students identify with mathematics at a social and cultural level, and it provides insight on how these mathematical identities can develop and change over time.

Keywords: Classroom Discourse, Gender, Diversity and Equity, Middle School Education

Introduction

Between May of 2009 and May of 2015 employment in science, technology, engineering and mathematics (STEM) occupations grew by 10.5% in the United States (Fayer, Lacey & Watson, 2017). The STEM job market is the fastest growing job sector in the United States, and mathematics and computer occupations are predicted to have the most growth in the coming years, over 25% between 2014 and 2024 (Fayer, Lacey & Watson, 2017). Yet, women are still vastly underrepresented within STEM occupations, particularly mathematics and computer science, with women occupying only 25.5% of these occupations in 2016 (U.S. Department of Labor, Bureau of Labor Statistics, 2017). There are many questions that arise as to why this under-representation of women in the STEM labor force persists, and what factors may be contributing to this under-representation. An area of literature that has yet to be explored in detail is the social and cultural construction of mathematical identities in the classroom (Bishop, 2012), in particular female students, and how they identify themselves in relation to mathematics while also navigating the complexities of social life in schools. Mathematics coursework is a foundation for STEM majors and careers, and this academic area is part of students' educational trajectories from their first days in school (Shapiro & Sax, 2011). Middle and high school mathematics experiences are particularly foundational for students interested in pursuing STEM careers (Shapiro & Sax, 2011). How students identify with mathematics is an essential component of students' mathematics experiences (Bishop, 2012). Thus, this study in progress proposes to examine students' socially constructed mathematical identity and how this intersects with gender over the course of 8th grade.

Background

A prominent way of defining identity for educational research purposes, is that identity is constructed at a social and cultural level and realized through social interactions (Anderson, 2007; Boaler, 2002; Bucholtz & Hall, 2005; Davies & Harre, 1990; Duff, 2002; Mendick, 2005; Nasir & de Royston, 2013; Solomon, Lawson & Croft, 2011). Since this study takes a social and cultural lens of classroom and student interactions, *identity* is defined as socially constructed and negotiated in specific contexts and informed by personal history and narratives (Anderson, 2007; Boaler, 2002; Bucholtz & Hall, 2005; Davies & Harre, 1990; Duff, 2002; Mendick, 2005; Nasir & de Royston, 2013; Solomon, Lawson & Croft, 2011). For the purposes of this research, the socially constructed conception of identity is a persuasive definition based on theoretical grounding of social constructivism, in which meanings that we take from the world are inherently dependent upon social relationships which we are a part of, and our sense of self must be generated through social processes (Gergen, 2009). Now following in the broader definition of *identity*, *mathematical identity* is located, which for this study is defined as a person's socially constructed and negotiated identity in the mathematics context, which is also informed by a personal narrative of one's mathematical self both inside and outside of the classroom (Anderson, 2007; Bishop, 2012; Boaler, 2002; Cobb, Gresalfi, & Hodge, 2009).

For the purposes of this study, gender is conceptualized as a broader category than merely sex, male vs. female, and instead as a socially constructed phenomenon of interest that is consequential in mathematical identity formation (Damarin & Erchick, 2010). When a student is identified by others in a social context as female, and/or if the student self-identifies as female, this holds social consequence, especially in mathematics where mathematical ability is often gendered as a male characteristic (Mendick, 2005). This study holds significance in understanding how gender plays a role in students' construction and performance of their mathematical identities in classroom spaces during a formative time in their schooling, which is their 8th grade year of mathematics, one year prior to the transition to high school.

Research Design and Methods

This study provides results from the first year of a two-year ethnographic and discourse analytic study of students' mathematical identities over the course of 8th grade and 9th grade, as students have to navigate a major transition in their academic life. This study highlights the importance of two female students' construction of their mathematical identities and narratives through two interviews, and performance of their mathematical identities in day to day classroom interactions during their 8th grade year. This study also examines how these two female students' mathematical identities intersect with social constructions of gender. In conducting the research for this project, both an ethnographic and discourse analytic perspective were taken (Blommaert & Jie, 2010; Bloome, et. al, 2005; Green & Bloome, 2004; Heath & Street; 2008).

The site for this research project collection is an 8th grade mathematics classroom at a middle school in a large suburban district in the Mid-Western United States. The two female focal students, Cayla and Paris, were selected based on their well-articulated personal narratives that they gave in their first interviews, and their self-awareness of how mathematics relates to their lives. To protect the participants within the study, all names are pseudonyms.

The data collected for this study were two interviews with each student, one conducted in the fall and the other conducted in the spring, of their 8th grade year of school. The interviews were conducted as semi-structured interviews, and each interview was audio recorded and later transcribed. The other source of data for this study were 50 classroom observations throughout the school year, field notes and video recordings of each classroom observation. Selections from the classroom observations were transcribed, which illustrate the mathematical identities of the two students and also instances where gender becomes salient within the two students' classroom discourse were transcribed and analyzed. The transcripts of the interviews were analyzed from an ethnographic perspective using discourse analytic techniques (Bloome, et. al., 2005).

Findings

The in the interviews, first focal student, Cayla, expressed a dislike of mathematics prior to her 8th grade year, but now enjoys the algebra concepts that they are learning. She is positioned by the teacher and other students as being one of the top performers in the class. She positions herself as a hard-worker who now enjoys mathematics, but does not label herself as smart. Through classroom observations, there has been a shift in her social engagement over the course of the year from being excessively social with classmates, to the point of distraction, to being more focused and often times choosing to separate herself from other students who may be potential distractions.

In the interviews, the second focal student, Paris, expresses her relationship with mathematics as closely tied to her struggle managing Attention Deficit Hyperactive Disorder (ADHD) symptoms and school. She says that her mathematics experience is very dependent on how responsive the teacher is to her needs as a student with ADHD. Paris is positioned by her teacher and peers as a middle performer within the class. Paris positions herself as a meticulous worker, who mainly associates with a single friend in the class. In class she has proclaimed that she has a love-hate relationship with mathematics, and sees herself as being stuck with mathematics through school, but enjoys mathematics applied in other contexts like science.

Data show Cayla and Paris display mathematical identities that have shifted over time. They are also actively engaged in producing identities that disrupt traditional notions of femininity, and make conversational moves to assert that even though they are young women, this does not mean they have to be constrained to feminine constructs. To illustrate this type of move, the following is an excerpt from class where Cayla disrupts traditional feminine notions of a classmate as they work on a project creating a poster that illustrates an example of a linear equation, with an emphasis showing slope and y-intercept:

Richie: This is easy. (Pointing to the assignment instructions.)
Cayla: I can't draw.
Richie: You literally just have to do that (points at instructions for the assignment.) Just write little flowers and show growth.
Cayla: Just because I'm a girl doesn't mean I'm feminine and have to draw flowers on my paper.
Richie: Yeah, it does.
Kyle: No, it doesn't.
Cayla: No, I don't even like flowers.
Richie: Then draw a bicycle.
Cayla: What do bicycles have to do with slope and y-intercept?

Cayla is asserting that her conception of what it means to be female does not have to align with traditional conceptions of femininity, as well as at the end of the conversation shifting the focus of the conversation back to the mathematics assignment, indicating focus as a mathematics student. Another illustration of this type of move occurred when

Conclusion

The implications of this study are important for better understanding the female experience in male-dominated areas of STEM, and why there is a persistent underrepresentation of women in STEM majors and careers (U.S. Department of Labor, Bureau of Labor Statistics, 2017). If the experiences of Cayla and Paris are indicative of the broader experience of young women, then it can be seen how much work is required in navigating mathematics as a young woman. Paris views mathematics as a necessary step towards her personal goals, but nothing that she wishes to pursue further. Cayla's narrative is similar, despite feeling an affinity towards the mathematics content that she has learned in 8th grade, she does not proclaim excitement or a strong desire to continue mathematics coursework beyond what is required of her. It is important to continue to explore young women's experiences in mathematics in middle and high school related to their identity development, to better understand how these experiences influence choices to pursue STEM majors and careers which require advanced coursework in mathematics.

PROVIDING STUDENTS CORRECT VS. INCORRECT CALCULUS EXAMPLES

Jeneva Clark
University of Tennessee
dr.jenevaclark@utk.edu

JoAnn Cady
University of Tennessee
jcady@utk.edu

Ji-Won Son
SUNY Buffalo
jiwonson@buffalo.edu

This study seeks to determine differences in learning when calculus learners analyze correct or incorrect work samples and to investigate students' perceptions of the effect of analyzing work samples on their learning of mathematics. Results suggest that when students analyze incorrect work samples, they are less likely to repeat the errors they have seen. Results also suggest that students perceive correct work samples as more beneficial to learning than incorrect work samples. However, both correct and incorrect work samples were found to challenge students' thinking and promote student independence. These findings have implications for teacher practice and curriculum development.

Keywords: Metacognition, Instructional Activities and Practices, Advanced Mathematical Thinking

Although experienced teachers may predict common student misconceptions, this knowledge is fruitless unless it can inform instruction. While many believe that any exposure to errors will overwhelm or confuse students and thus avoid addressing common errors altogether, others recommend having students analyze others' work, including incorrect work, in hopes of challenging student thinking and revealing common misconceptions (Kramarski & Zoldan, 2008). Borasi (1994) suggests using errors as springboards for inquiry and found examination of errors to improve learning and attitudes about math. This article tackles this instructional dilemma by investigating learning associated with analyzing correct and incorrect student work samples and by investigating students' perceptions of how this analysis impacted their learning: (1) Are there differences in learning outcomes (exam scores, problem-solving, avoiding errors) associated with students' analysis of correct or incorrect examples? (2) Are there differences in how students perceive the benefits or hinderances of analyzing correct and incorrect examples? (3) How do students describe analyzing work samples and its influence on learning?

Literature Review

Errors can encourage communication of ideas, justification of solutions, questioning, reflection, critical thinking, inquiry, and flexibility in reasoning (Kramarski, 2004). However, it is unclear what the role of students' errors and misconceptions should be within ambitious teaching practices. Participants' experiences were viewed as intertwinings of thoughts, observations, and understandings, consistent with Marton's (1995) phenomenographic approach. This study uses the framework of IMPROVE (Mevarech & Kramarski, 1997), a metacognitive approach which encourages students to ask themselves questions and includes four factors: (a) comprehension, (b) connections, (c) strategies, and (d) reflection. We assumed that using this framework to analyze others' work would also encourage students to ask questions when they are solving problems themselves. This study was influenced by Knowles' (2011) self-directed learning, allowing learners to take initiative in learning, assuming learners' experiences and reflections are valid learning resources, and assuming learners are somewhat intrinsically motivated to learn due to curiosity and perceptions of relevance.

Materials and Methodology

Learning modules (LMs), asked students to analyze work samples by presenting them online. Students saw the same math problem, but some students saw a correct solution, and others saw an incorrect solution. Completion was compulsory and conducted outside of class meetings.

Participants. Our data was collected from 181 enrollees in 10 sections of Basic Calculus at a large university in the United States, and nine of those were interviewed the following semester. The sections met together for 50-minute lectures twice per week and separately for 75-minute recitations (led by graduate students) once per week. The gender distribution of participants was 68.51% female and 31.49% male. Each recitation section had two approximately equal-sized randomly assigned groups within it, one analyzing correct and one analyzing incorrect work samples. Interviewees were selected by their positive response to an electronic invitation.

Data Collection. From relevant problems on exams, scores and error rates were collected. Also, students' perceptions were measured by survey; each LM ended with a survey asking students to rate the LMs' helpfulness on a five-point scale. The survey's alpha coefficient was .96, suggesting high internal consistency. Semi-structured 30-minute interviews (n=9) were conducted. After a pilot study, the pre-test, the sampling techniques, the exams, the interventions, and the interview protocol were improved based on expert validator critique.

Data Analysis. (1) The pre-test and final exam scores were analyzed, using ANCOVA, to reveal if work-sample correctness was associated with students' overall achievement. (2) Responses to certain pre-test and exam questions, similar to those in the LMs, were scored by rubrics. Prior knowledge was accounted for by pre-test questions, and ANCOVA was conducted to analyze possible association with ability to solve similar problems. (3) To reveal differences in error rates, all pre-test and exam problems which provided opportunities to make those errors were analyzed through ANCOVA. (4) Each LM ended with a survey asking students to rate the LMs' helpfulness in learning. Independent samples *t*-test tests were conducted to compare students' ratings of correct work samples to incorrect work samples. (5) Semi-structured interviews (n=9) were transcribed and analyzed using inductive analysis. Domains emerged by finding semantic relationships in the data. Then, weak domains were abandoned, some were combined, and some emerged as salient. Further analysis was conducted within and between them to identify themes.

Interventions. The incorrect-work LMs featured common errors. Questions were formed that would elicit students' reflection, metacognition, and advanced mathematical thinking and in a manner that would offer approximately the same level of challenge to students in both groups.

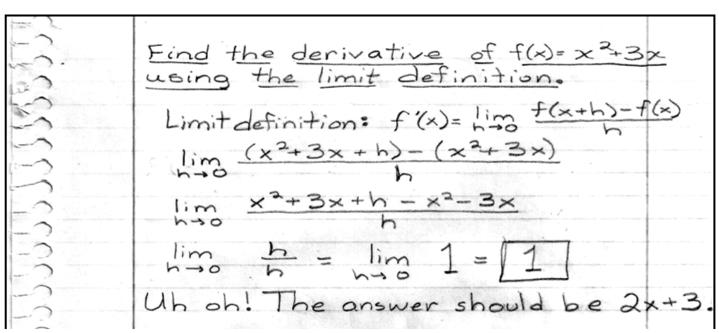

Figure 1. An example of an incorrect example showing a common error

Results

Final Exam Scores and Problem Solving

After controlling for pre-test scores, the ANCOVA revealed no significant difference in the two groups' final exam scores; $F(1, 169) = 1.24$, $p = .267$. When adjusted for pre-test scores, the mean final exam score for analyzers of incorrect work was 82.79, while the mean for correct work was 80.78. When analyzing only problems similar to those in the LMs, the difference between exam-question scores for analysts of correct and incorrect work was not statistically significant after controlling for pre-test scores; $F(1, 169) = 0.82$, $p = .367$. Exam-problem scores for analysts of incorrect work had an adjusted mean of 79.92, while the scores for analysts of correct work had an adjusted mean of 78.35.

Making Errors

Error rates differed significantly, after controlling for pre-test error rates; $F(1, 1048) = 4.80$, $p = .029$. Participants who analyzed incorrect work made these errors 3.7% of the time, while the participants who analyzed correct work made them 5.5% of the time. Table 1 shows ANCOVA results and adjusted error rates (e(c)= error rate for students who analyzed correct work, e(i) = error rate for students who analyzed incorrect work) for the two groups.

Table 1: Making Errors, Results of ANCOVAs

Incorrect Cancellation	$F(1, 159) = 1.13$, $p = .289$	e(c)=2.5% e(i)=3.3%
f(x)+h instead of f(x+h)	$F(1, 150) = 1.98$, $p = .162$	e(c)=5.3% e(i)=1.8%
Omission of negative solution	$F(1, 163) = 1.17$, $p = .280$	e(c)=8.2% e(i)=6.2%
Confusion of exponent rules	$F(1, 126) = 0.14$, $p = .705$	e(c)=8.5% e(i)=7.0%
Not using quotient rule	$F(1, 154) = 2.12$, $p = .147$	e(c)=5.0% e(i)=2.2%
Confusion of f(x) & derivatives	$F(1, 143) = 2.58$, $p = .110$	e(c)=7.9% e(i)=4.3%

Students' Perceptions about Effectiveness of Interventions

Those who examined correct work consistently rated the LMs as having greater association than those who examined incorrect work. Independent samples *t*-test indicated that overall, ratings by those who examined correct work were significantly higher than those who examined incorrect work. Also, tests were conducted to compare the perceptions of helpfulness to each aspect of learning, and significant differences were discovered within all aspects except for attitudes.

Interview Analysis Results

After reading the transcripts and considering that the overarching goal of this study, the frames of analysis were selected to be (a) understanding underlying concepts, (b) using rules and procedures, (c) using strategies, (d) communicating about math, and (e) attitudes. Domains were identified using semantic relationships. To conduct an analysis within these domains, Marton's perspective of *capability* and *constraint* (1995, p. 171) was considered, and domains were viewed as either depictions of capability, which positively associate with learning, or depictions of constraints, which inhibit learning. The major findings from this study are delineated below and mirror the 5 strands of mathematical proficiency (NRC, 2001):

- Both correct and incorrect LMs made students think about concepts underlying procedures (**Conceptual understanding**).
- Explaining math was also a task that promoted use of procedures (**Procedural Fluency)**.
- The correct LMs helped students form strategies to begin problems. Explaining connections between steps emerged as an aid to the use of specific strategies (**Strategic Competency)**.

- When asked how the LMs influenced the students' abilities to talk about math to others, several mentioned the LMs "made them think" about the mathematics. (**Adaptive Reasoning).**
- Related to confidence, incorrect work samples seemed to ease anxiety by illustrating others make mistakes and mistakes are fixable (**Productive Disposition)**.

In addition, we observed two overarching themes from analyses of semantic relationships between domains—independent learning and student engagement. Students felt as if they had interacted (or were more engaged), as opposed to hearing a lecture, which led to more independent learning as students were not just "fed" the material. The open-ended nature of the analyses, both of correct and incorrect work, influenced some aspects of learning, such as improving attitudes and flexible use of strategies.

Discussion

This study reveals that if students analyze incorrect work, they may be less likely to make the errors. However, ironically, students perceive correct work samples as more helpful to learning. With these juxtaposed findings, we see that students are not always aware of what is most effective in their own learning. They may experience challenge and interpret it as less helpful than a low-risk lecture. Teachers should not avoid using both correct and incorrect work samples when teaching and developing tasks because, as evidenced in this study, (a) both are effective in promoting problem-solving skills and achievement, (b) seeing common errors in work samples of moderate difficulty-level discourages students from making those errors, and (c) using both may prevent predictability that can constrain attitudes and student thinking. Teacher educators should make preservice and in-service teachers aware of these results in order to counter the fears that students will replicate errors. Future research could investigate whether results will differ with error type, or could include a group analyzing both correct and incorrect work.

In this paper, we consider the ways in which out-of-school educational programs extend support to young high-achieving African-American students with an interest in STEM. We present a qualitative case study of three female African-American students enrolled in a mathematics summer camp intended for high school students interested in higher-level mathematics. We report on how these students found the program impacted their own growth and development in several specific domains.

Keywords: Equity and Diversity, Gender, High School Education, Informal Education

There is growing evidence that out-of-school educational programs contribute to young people's interest, understanding, and participation in STEM (National Research Council, 2015). In this paper we consider the ways in which out-of-school educational programs extend support to young high-achieving African-American high school students with an interest in STEM. In particular, we focus on how these students describe the support provided to them from their own perspective. The research questions guiding this study are: How do young African-Americans attending an out-of-school mathematics program describe the support provided to them with respect to the development of their (a) mathematical competence, (b) mathematical identity, and (c) sense of belonging to a community of mathematics learners?

Literature Review

Gasman and colleagues (2009) present a comprehensive review of the literature on students of color in STEM. They note that STEM education has traditionally been characterized by a survival-of-the-fittest approach in which "lack of attainment in STEM fields for underrepresented minorities is attributable to students' background characteristics, including socioeconomic status, parental education, family support, preparation in high school, and even genetics." (p. 66) Strayhorn (2011) measured the effect of summer bridge programs (SBP) on preparation for college in four areas: academic self-efficacy, sense of belonging, and academic and social skills. He found that students participating in SBP with high self-efficacy earned greater first semester GPA's than those with low self-efficacy, and that academic achievement prior to college was the most powerful predictor of success in the first semester of college.

Namakshi (2016) conducted a qualitative case study in which the impacts of an informal mathematics program on four former female students were examined. Namakshi found that the math camp had a crucial impact on the participants' future higher-education/career trajectory by increasing their social capital and positively influencing their mathematical identity.

Methods

Seven African-American students were enrolled in the math camp in this study. Each of the seven students had been provided a scholarship to enroll in the program through a private foundation that provides assistance to young African-Americans. Three of the seven students were chosen for this study based on their transcripts, letters of recommendation, and application essays submitted during the application process to the math camp. The students selected were chosen to represent a wide range of previous academic achievement.

Context of the study

The math camp in this study is a 6-week multi-level residential program for 60-68 talented high school students located in the southwest part of the United States. The participants were from 18 different states. The first-year participant class was 25% African-American. Students are immersed in studying mathematics at a high level while learning the process of doing research. Students learn to explore problems deeply, compute examples, make conjectures and give careful, rigorous mathematical proofs. In their first year, students study number theory with an associated Mathematica programming lab. In subsequent summers, the students take more advanced courses including Abstract Algebra, Combinatorics and Analysis, and work in groups on a research project guided by a faculty mentor.

All of the students work in nightly study groups of 4 students, with each study group having a camp counselor. The counselors are former campers who oversee daily problem sessions and provide feedback on the problem sets for student work. They are role models who give the campers help and guidance throughout the summer.

Participants

The first participant, Abigail, was a rising sophomore in high school and exhibited a strong love for mathematics in her application essay. She had been attending math enrichment programs since the 3rd grade and enrolled in a college-level calculus course in the 7th grade. Abigail had independently studied subjects such as linear algebra. Abigail's primary interests in coming to the math camp were to develop her knowledge of mathematics so that she could better understand how to apply mathematics to her interests in physics and computer science.

Brianna was a rising junior in high school. In her application essay, she stated that she wanted to "be the best that I can be in all things math and science." At her school, Brianna won a competition in which she successfully remembered the most digits of the number Pi. Brianna has an interest in going to medical school to study oncology or genetic exploration. To accomplish this goal, Brianna intends to apply to several elite universities.

Candice was a rising junior in high school. As a child, Candice was strongly encouraged to join STEM focused clubs in her elementary school. She had received a perfect score on the math portion of the PSAT in her sophomore year of high school. Candice was described by her teacher as a critical thinker and problem solver with a willingness to help others. Candice's interests in coming to the camp came from her desire to conduct meaningful research in a STEM field that could make a significant impact in the lives of others.

Data Collection

In addition to the transcripts, letters of recommendation, and application essays, this study also drew upon several other sources of data. While at the math camp, the students completed weekly electronic journals that served as reflections of their experiences from that week. Observations of the nightly study groups were conducted, and field notes were taken. After each observation, a one-page reflection report was written that focused on the interactions and general flow of events that occurred. During the fifth week, semi-structured interviews were conducted with the three participants and their counselors. Electronic post evaluations were collected from the students. These reflections provided the students a chance to critically reflect on their overall experience in the camp and opened a door to discuss any problems or concerns directly with the Director.

Data Analysis

We defined mathematical competence following Boaler and Greeno (2000), who defined knowing and understanding as "… [the ability to] engage in sense-making and problem-solving using and developing mathematical representations, concepts, and methods as resources… [through participation] in the practices of mathematical discourse and thinking" (p. 172). To conceptualize mathematical identity, we defined identity as a set of stories about a person (Sfard & Prusak, 2005). In this way, the mathematical identity of the participants could be revealed through the stories they told about themselves within their application essays, journals, and interviews.

The application essays, journal entries, and interviews were read over to gain familiarity with the data. The codes were then compared to ensure reliability. The coding consisted of identifying evidence of change in mathematical competence, identity, and sense of belonging as a result of attending the camp. This analysis was followed by a cross-case synthesis (Yin, 2017). In the following section, we present a synthesis of the results

Preliminary Findings and Results

Mathematical Competence

Each of the three students entered math camp with a strong record of achievement in mathematics as attested by their transcripts, applications, and teacher recommendations. They all reported improvement in problem solving techniques and proof writing skills. Abigail, in addition, felt that during camp she improved in her ability to attack problems and explain the solution to others once they were solved. Candice also found how, "effective communication in mathematics was an important skill to have and led to a better understanding of math." Brianna referred to changes in her views of learning, and how "true understanding stems from being able to take apart these core concepts …. learning is about always asking why, questioning everything …asking questions is never a sign of weakness or ignorance." Candice attributes camp to her change in attitude towards math. Rather than take formulas as true statements, she now wants to understand why the formula works. She also felt that she was overcoming her fear or failure because she had learned how important failure is in learning to write proofs. While Brianna and Candice developed a sense of confidence and comfort through challenges, they acknowledged there are "still some topics that are confusing for me." By the end of camp, Abigail reported how she would like to test her mathematical competence by entering math competitions and, "hopefully qualify for math prizes." The students remain focused on the goals that they had set prior to attending camp. They reported that they felt an increase in their mathematical ability and competence in Number Theory, writing proofs, and in doing mathematics in general.

Mathematical Identity

The mathematical identity of the participants could be seen to evolve through their perceptions of what mathematics means to them. When prompted to describe her views and her personal growth and development over the summer, Brianna responded that "Being here at [the camp] has given me an all new meaning to math. It has taught me that math doesn't have to be a part of just another agonizing cyclic process in school that has been defined as 'learning.'" In addition, she explains that she felt no limitations when it comes to learning. Brianna and Abigail talk about their persistence despite struggles, stating that "my optimism keeps me going along with me keeping my eye on the prize and knowing that the struggle won't last very long and the destination is in sight." Both of Abigail and Candice also provided commentary on how they had developed a greater appreciation for the utility of mathematics. Abigail stated in one journal that "[the camp] has shown me that math can be important all across the STEM field." Candice wrote about her fear of failure and how she learned to "embrace failure and learn from my mistakes." Thus, the mathematical identity of the participants can be seen to have been changed by positively impacting their feelings, attitudes, and beliefs.

Sense of Belonging

The participants described their sense of belonging to a community of mathematics learners through their interactions with other students. Each of the participants placed value on the opportunity to work on challenging mathematics together with likeminded individuals. Both of Abigail and Brianna described themselves as being motivators for the study groups to interact with each other. Abigail explicitly identified herself as the leader of her study group during her interview. At times, the participants expressed doubt about their ability to keep up with other students. Candice mentioned in her final evaluation that, "After talking with the other students at [the camp] on the first day, I felt underprepared when I entered the first Number Theory class…" However, Candice explained in the same entry that she felt she was at the same level as her peers in the beginning because the number theory class started from the basics.

Conclusion

In this paper, we have reported on several ways in which the participants of this study described the support provided to them during their time at a summer math camp. The participants recounted their experiences in the camp as it related to the positive development of their mathematical competence, mathematical identity, and sense of belonging to a community of mathematics learners. The impact of these out-of-school experiences can be critical to reaching out to and preparing African-American students (and all students) for careers in STEM. Further work is needed to better understand the supports provided, and how these supports each played a role in supporting the participants growth and development.

To investigate performance differences between undergraduate mathematics students whose instructors implemented an inquiry-oriented curriculum and those whose instructors did not, we analyzed 513 content assessments. The data was disaggregated by gender to examine how inquiry-oriented instruction relates to the pattern of underrepresentation of women in mathematics. While we detected no gender performance-gap in a national comparison sample, we did find one in the inquiry-oriented group. Notably, this gap came from male inquiry-oriented students outperforming male students from the comparison group, while female inquiry-oriented students performed the same as female students from the comparison group.

Keywords: Post-Secondary Education, Gender, Equity and Diversity, Assessment and Evaluation

Active learning in undergraduate STEM classes has been linked to improved student success and learning (see Freeman et al.'s (2014) meta-analysis of 225 studies). Additionally, in undergraduate mathematics specifically, Laursen, Hassi, Kogan, and Weston's (2014) work suggests that Inquiry-Based Learning (IBL) courses – which promote collaborative learning environments – 'level the playing field' for male and female students. While these findings are powerful, the mechanisms connecting active learning approaches to more equitable student outcomes are not well understood. As Singer and colleagues argued in the National Research Council's (2012) report, the identification of critical features of instructional approaches is crucial for exploring the ways those approaches may impact particular groups of students. Thus, in this study we present a narrow investigation into the relationships between one carefully defined instructional approach, namely inquiry-oriented instruction (IOI) (Kuster, Johnson, Keene, & Andrews-Larson, 2018), and student performance on a content assessment.

Our work draws on data collected in an NSF-funded project, Teaching Inquiry-oriented Mathematics: Establishing Supports (TIMES), that aims to explore what is needed to support instructors learning to teach in inquiry-oriented ways. Of specific interest here is one of three sets of materials utilized in this project, namely the Inquiry-Oriented Abstract Algebra (IOAA) curriculum (Larsen, Johnson, & Weber, 2013). We analyzed 513 completed content assessments to investigate performance differences between students whose instructors implemented the IOAA curriculum (with professional development support from the TIMES project), and those whose instructors did not. Specifically we address the following two research questions: 1) What is the relationship between inquiry-oriented instruction, as manifested by the TIMES program, and student performance on a content assessment?, 2) Is the pattern consistent across genders? Given Freeman et. al's (2014) findings, we expect to see the TIMES students outperforming Non-TIMES students. Additionally, given the similarities between inquiry-oriented instruction and IBL, we expect to see Laursen et al.'s (2014) findings replicated, with men and women performing more similarly in the IOI setting than in non-IOI settings.

Literature Review and Theoretical Perspective

In IOI, the intent is for the students "to regard the knowledge they acquire as their own private knowledge, knowledge for which they themselves are responsible" (Gravemeijer, 1999, p. 158). Thus, through inquiry and collaborative group work, the objective is to reposition students as central to the process of constructing and reinventing important mathematical ideas. Some literature suggests that classrooms emphasizing collaborative work, problem solving, and communication may be supportive for women (Du & Kolmos, 2009; Springer, Stanne, & Donovan, 1999). However, research on the nature of social interactions in collaborative decision-making and facilitated discussions offers additional insights into the negative ways in which students may experience the mathematics classroom as a gendered and racialized space. For example, when groups are tasked with arriving at a decision, women in predominantly male groups speak less and are interrupted more than men (Karpowitz, Mendelberg, and Shaker, 2012). Further, within the same classroom, students often receive different opportunities to participate in whole-class math discussions in ways that follow patterns of gender, race, and class (Black, 2004; Walshaw & Anthony, 2008).

Most closely related to our research context, i.e., mathematics education at the undergraduate level, Laursen et al. (2014) found that "in non-IBL [inquiry-based learning] courses, women reported gaining less mastery than did men, but these differences vanished in IBL courses" (p. 415), suggesting that instructional approaches involving collaborative problem solving may 'level the playing field' for male and female students. Their IBL context is commensurate with, but distinct from, our inquiry-oriented context. Both IOI and IBL promote collaborative group work, prioritize student engagement with authentic mathematical activity, and decentralize classroom authority. However, IOI places special emphasis on reinvention and inquiry – by both the students and the teacher (see Kuster et al. (2017) for a description of IOI).

Thus, due to the undergraduate mathematics setting and similarities between IBL and IOI, we had reason to believe that we would see Laursen et al.'s (2014) findings replicated in our study. However, our study had some key differences. Specifically, our analysis examines student content assessments (not affective reports of learning gains) and takes place within the context of a long-term, multi-faceted professional development model that emphasized a narrowly defined instructional approach.

Methods

There were 12 IOAA TIMES Fellows. These fellows received three forms of professional development support: curricular support materials, summer workshops, and online working groups that met every week as the Fellows were implementing the IOAA curricular materials.

The TIMES Fellows asked their students to complete the Group Theory Content Assessment (GTCA) (Melhuish, 2015). This assessment, developed to measure conceptual understanding of key concepts in group theory, included: binary operations and their properties, group structures, element properties, and functions. In order to produce a robust validity argument, the GTCA began with open-ended tasks, which were converted to a multiple-choice format based on student responses. As a result of the development process, we have a large, nationally representative 'control' group from which we can draw comparisons with our IOI students.

From the 12 TIMES Fellows, there were a total of 174 students, 80% of whom completed the GTCA. For our "Not-TIMES" group, we analyzed data from 374 students from 33 institutions. For these students, we make no claim about the form of their instructional experiences. Thus, they are a control for the TIMES project, but not necessarily for IOI. However, nationally the proportion of teachers using "non-lecture" instructional approaches in abstract algebra is less than 10% (Fukawa-Connelly, Johnson, & Keller, 2016). Between the treatment (TIMES, *n* = 139) and control (Not-TIMES, *n* = 374) groups, we have a total of 513 student content assessments. In total there were 269 males, 237 females, and 9 who otherwise identify or declined to identify their gender. The percentage that identified as female was not significantly different ($p = .413$) between Not-TIMES and TIMES (47.59% and 42.45%, respectively).

The primary analysis in this research was an investigation of performance on the GTCA and group comparisons therein. Summary statistics were computed for the overall sum score based on the 15-item subset that was consistent across data collection iterations. Independent sample *t*-tests were used to compare mean performance by gender within instructional treatments and overall; effect sizes were computed where indicated.

Results and Discussion

When tabulating the collective assessment results of all students on the GTCA, we report the average performance to be a score of 6.33 items correct out of 15, with a standard deviation of 2.95. We found that the TIMES students slightly outperform the Not-TIMES students by about half a unit (6.65 vs. 6.21), but this difference is not statistically significant ($t = -1.516$, df = 511, $p = .130$). When considering performance differences by gender, we see that males generally outperform females (when aggregating TIMES and Not-TIMES students) by about one correct answer (6.75 vs. 5.79). This difference, while statistically significant ($t = 3.703$, $p < .001$), is of little practical importance as judging by the small effect size ($d = .33$). Thus, we view this as a fairly minimal performance gap. However, when disaggregating the data by instructor classification, this trend is inconsistent.

Gender comparisons within each group revealed no significant difference in the Not-TIMES group (males outperform females by about half-point on average, $p = .095$). In the TIMES group however, males outperformed females by over 2 points on average. This difference was appreciable both in terms of statistical significance ($p < .001$) and in practical importance as judging by the large effect size ($d = .7257$).

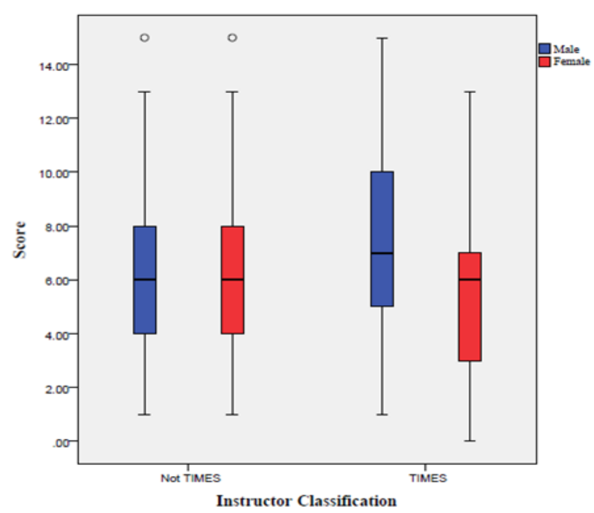

Figure 1. Gender Comparisons of Students on GTCA

In summary, males outperform females in both groups (though not significantly in the Not-TIMES group), but when considering the differences within gender across categories of instruction, we see that the performance gap widens in the TIMES group because the average male score registers a statistically significant improvement of 1.1 units (t = 2.69, p = 0.008) while the average female score declines (albeit insignificantly) by .58 units (t = -1.37, p = .174).

We see the detection of a gender performance-gap within the IOI setting as an unfortunate finding. We are not insinuating that the TIMES project, or the implementation of IOI in general, is detrimental to female student achievement; in fact, both male and female TIMES students performed as well or better than the national comparison sample. We take the improved scores for male students as evidence that IOI has the potential to improve student learning. However, the question remains as to why female students did not share the same degree of improvement. It is our intention to use our findings to inform a critical examination of the effect of our interventions on the gendered experiences of our students and call on others to do the same.

LATINX BILINGUALS' PERSEVERANCE ON A MATHEMATICAL TASK

Hector Morales, Jr.
Northeastern Illinois University
h-morales3@neiu.edu

Joseph DiNapoli
Montclair State University
dinapolij@montclair.edu

This paper examines the problem-solving practices of Latinx bilingual students with a challenging mathematics task. Studying the collaborative efforts of two groups of Latinx bilinguals, our findings suggest these students can spontaneously and dialogically leverage communicative resources to help persevere with in-the-moment obstacles, but only when provided freedom to explore mathematics via their dynamic bilingualism.

Latinx students are one of the fastest growing populations in the U.S. (NCES, 2016), yet dehumanizing school practices continue to marginalize this group's linguistic, social, and cultural capital (Langer-Osuna et al., 2016). All students must have access to study rigorous mathematics, and thus be supported in their perseverance with such challenges (NCTM, 2014). This notion of perseverance exists at specific times during problem-solving when productive struggle, or grappling with mathematical ideas not yet well formed, is necessary to develop conceptual knowledge (Hiebert & Grouws, 2007). Despite efforts to support perseverance by emphasizing collaborative communication, Latinx bilinguals' mathematical engagement is often viewed from deficit perspective by ignoring their linguistic and cultural repertoire and instead privileging the dominant school language (Garcia, 2017; Morales Jr., 2004). This naturalistic study aims to describe the translanguaging and perseverance practices of Latinx bilingual students during problem-solving with challenging mathematics.

Translanguaging and Persevering to Learn Mathematics

We draw on translanguaging to reconceptualize bilingualism as a liberating and empowering communicative practice, and a resource capable of transforming learning that goes beyond the transition to a dominant school language. Translanguaging is an interrelated communicative practice that make up bilinguals' linguistic repertoire. Garcia (2017) posits, "…speakers use their languaging, bodies, multimodal resources, tools and artifacts in dynamically entangled, interconnected and coordinated ways to make meaning" (p. 258). A translanguaging lens allows us to better understand holistically how bilingual students use their linguistic, multimodal, and mathematical repertoire to make meaning as they persevere with challenging ideas. Perseverance is a cycle of initiating and sustaining in-the-moment productive struggle in the face of one or more obstacles, setbacks, or discouragements (DiNapoli, 2018). Because productive struggle is helpful in developing mathematical meaning, analysis of perseverance should consider the ways in which students first wrestle with an uncertain mathematical situation, and, if necessary, how they amend their first effort to continue to make mathematical progress. Yet, for Latinx bilingual students, questions remain about how perseverance might manifest working across two languages and how teachers might take a translanguaging stance (see Garcia, 2017) to provide opportunities to leverage communicative and linguistic repertoires to build understandings.

Methods

We observed two groups of 12th-grade Latinx bilingual students from different classes with the same monolingual, English-speaking teacher (Ms. Patrick) working on a multi-day task necessitating perseverance. The task referenced *Alice in Wonderland,* in which Alice's height is doubled or halved by consuming certain potions. All but one student (Ines, see below) were born

in the U.S., yet all students still use home language (Spanish) as part of their linguistic repertoire. We employed a perseverance analytical framework (see DiNapoli, 2018) that identified how productive struggle was initiated and sustained from the outset with a challenging task (Initial Attempt) and how it was re-initiated and re-sustained in a new way (Additional Attempt(s)) if a first effort did not lead to a solution. We consider how students engaged in translanguaging practice and persevered at specific moments during their problem-solving.

Findings

Here we share detailed findings from Group A, who exemplified translanguaging and perseverance practices while conceptually exploring exponential growth. We then briefly share, due to space limitations, apparent themes from Group B, who demonstrated little to no evidence of such practices. Our observations show how student spontaneous translanguaging can help support perseverance with challenging mathematics, but only when students had an opportunity to productively struggle without teacher intervention. Consider the following vignettes from Group A's three-day collaboration around the task. Group A had demonstrated evidence of understanding the goal of the problem on Day 1, but did not know how to solve it. We share findings from Day 2, as Group A makes their Initial Attempt at solving.

JESSICA: ¿Qué era la primera, se hace así? Okay, dice: Alice changes when she eats the cake, assume that her height doubles for each ounce she eats, so that means if she eats one ounce, that means that she grows twice, dos ¿qué? Double, no double, two. (*What was the first one, do you do it like this? Okay, it says: Alice changes when she eats the cake, assume that her height doubles for each ounce she eats, so that means if she eats one ounce, that means that she grows twice, two what? Double, no double two*.)
JESSICA: See, so when two is four, and then three is six, and four is eight, y así, y así vamos hacer la graph. Going like that para arriba. (Gesturing) You get it? (*See, so when two is four, and then three is six, and four is eight, like this, and this is how we are going to make the graph. Going like that, up.* (Gesturing) *You get it?*)
ELENA: Um hmm. Pero, how do we times it? (*But how do we times it?*)
JESSICA: Porque mira, two, times two. Well no. (*Because look, two, times two. Well no*.)
ELENA: But that's what you were telling me yesterday y yo pensé que no. Okay so we. (*But that's what you were telling me yesterday and I didn't think so. Okay so we*.)
JESSICA: Double it by, nomás double the number of ounces…[Elena interrupts] (*Double it by, just double the number of ounces…*)
ELENA: Two times two, y luego four times two, y luego six times two, is that your idea? (*Two times two, and then four times two, and then six times two, is that your idea?*)
JESSICA: Más o menos como sumando el mismo número. (*Like adding the same number*.)
CARINA: Pero es lo mismo de sumando si lo multiplicas por dos. (*But it is the same as adding if you multiply by two.*)
INES: [Referencing table from year one] Lo que parece es como hicimos un in/out table y ya lo sacamos. (*It looks like we just did an in/out table and that's it*.)
CARINA: Yeah. In times two equal out.

The students made their Initial Attempt at solving by coordinating their meaning making actions and deploying their linguistic repertoires. After reading, the students began to interpret the task and the nature of doubling. In dialogically entangled ways, they expressed linguistically across Spanish and English what doubling meant to them (e.g. double, two, dos, grows twice, sumando el mismo numero, multiplicas por dos, times it). They also explored and questioned how to represent their ideas symbolically, which demonstrates their productive struggle regarding understanding the nature of doubling. Drawing on such linguistic and mathematical resources is further evidence of spending diligent effort during their Initial Attempt to make sense of the function. They did not, however, realize immediately that they were multiplying the number of ounces of cake by two, instead of *Alice's* height. Their equation correctly spanned the table of values, yet these representations did not model an exponential function.

Not completely agreeing with the other students' mathematical representation, Ines' own metacognitive awareness of the mistake during their Initial Attempt helped collectively move the discussion in a direction that considered *Alice's* initial height. The entire group collaborated around this new idea and persevered together as a learning community. At the end of Day 2, Ines recalled her prior experience with the *Alice* problem from her sophomore year and raised the issue of starting with an initial height. This helped the others rethink about the mathematics, cross out their table (Figure 1, left), and begin on Day 3 to think about starting a new one.

> *INES*: …empezamos de cuatro pies. Si toma si come un pedacito son ocho, si come un pedacito son dieciseis, el tercer pedazo dieciseis y dieciseis. Treinta y dos ¿no? (*…we start at four feet. If she drinks, if she eats one piece it becomes eight, if she eats one piece it becomes sixteen, the third piece, sixteen and sixteen, thirty two, no?*)
> *JESSICA*: Pero, ¿cómo sacastes eso? (*But how did you get that?*)
> *INES*: Porque si empezamos con cuatro pies, como yo les digo, si come un pedacito y sale, aumenta de altura de doble. (*Because, if we start at four feet, like I'm telling you, if she eats one piece and it comes out to, her height grows double*.)
> *JESSICA*: Ohh, her height doubles.
> *ELENA*: You know it's the same thing mira. Dos, you multiply one times two is two, two times four is eight, y si pones two times two is four, four times four is sixteen. (*You know it's the same thing look. Two, you multiply one times two is two, two times four is eight, and if you put two times two is four, four times four is sixteen*.)
> *CARINA*: In squared times 2 is equal to your out.

At the start of Day 3, Ines tried to help the group understand that *Alice's* initial height is necessary to compute subsequent heights. The task was written in English, yet Ines leveraged her home language to re-voice the problem. She modeled mathematically the concept of doubling for her group members in Spanish and also gestured to demonstrate how *Alice's* height doubles for each ounce of cake she eats. This helped Jessica have her "a-ha" moment realizing that she needed to double *Alice's* height not the number of ounces of cake.

This translanguaging exchange exemplified further perseverance by exploring what it means to double and illustrated how Group A became aware about the flaws in their first attempt to make sense of the function. What makes this so significant is the students' commitment to collaboratively draw on linguistic (including their home language) and mathematical resources fluidly as they continue to try to overcome the conceptual obstacle of doubling. The combination of these interactions affords Jessica her liberating moment of understanding, which leads these students to amend their plan and adapt their thinking to continue to persevere.

Following this discussion, the students created a new table of values (Figure 1, center) that correctly modeled *Alice's* exponential growth. This new approach demonstrated the end of their Initial Attempt and the start of their Additional Attempt by the group amending their plan and making a second attempt to make sense of the *Alice* function. Unfortunately, the equation was not correct and did not span all of their entries. Again, this is an important opportunity for the group to recognize more mistakes and continue to persevere. Near the end of Day 3, the students used a graphing calculator to make a table of values for $y = 2x^2$ (Figure 1, right) and discovered that it did not match their current table. Consequently, they were ready to continue to explore ways to change their equation and make another Additional Attempt, but Ms. Patrick interjected to go over the answers. Although Group A did not yet find the proper equation to span their IN/OUT table in this episode, they were agents of their own translanguaging repertoire and leveraged this practice to help persevere and think more deeply about exponential functions.

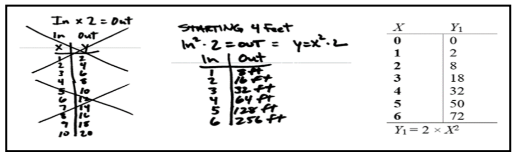

Figure 1. Progression of Student Tables (recreated by authors)

Group B did not have similar learning experiences as Group A, likely because Group B was not given the chance to persevere with the *Alice* task themselves. Instead, Ms. Patrick directed students to a correct procedure from the outset and students rehearsed these routines. As such, these students had no opportunity to use translanguaging practice to help overcome conceptual obstacles, and instead simply waited for Ms. Patrick to instruct them about what to do next.

Discussion and Conclusion

What emerges from the data are different trajectories of mathematics teaching and learning, revealing how the unintended consequences of instructional choices can detrimentally affect Latinx students' perseverance. Our observations show how the level of involvement and proceduralized guidance by the teacher can impact opportunities for student perseverance and conceptual development. When students had freedom to struggle, this facilitated an evolving mathematical understanding of exponential functions. Students leveraged their translanguaging repertoire to help persevere past mathematical obstacles and make progress toward a solution. Without freedom to struggle, other students only used their bilingualism to monitor routine steps, not navigate meaning. This suggests Latinx bilinguals can use bilingualism to their advantage when engaging with challenging mathematics, but only when given the opportunity to grapple with uncertain mathematical relationships. However, we cannot expect students to always spontaneously engage in translanguaging practice. Latinx bilinguals need explicit classroom support systems to encourage such engagement. Future research must clarify how teachers can create space to leverage their students' bilingualism for forming mathematical meanings.

EFFECTS OF AN INTENSIVE REMEDIAL MATH COURSE ON ENGINEERING STUDENTS' MATH ANXIETY AND MATH SELF-EFFICACY

Gustavo Moran-Soto
Instituto Tecnológico de Durango
gmorans@clemson.edu

Paran R. Norton
Clemson University
pfisch@clemson.edu

This article explores the relationship between an intensive remedial math course for freshmen engineering majors and students' math anxiety (MA) and math self-efficacy (MSE) levels. MA and MSE have been shown to influence students' pursuit and completion of a math-related major, making these important factors to consider for these students in their first semester. Data were collected from 565 students using items from the existing Mathematics Anxiety Rating Scale and the Mathematics Self-Efficacy Survey. This study uses Analysis of Covariance (ANCOVA) to determine the effects of the remedial course on students' MA and MSE while controlling for confounding variables such as student's gender and type of high school. Results showed there was a significant increase in students' MA and MSE levels after the intensive course. Implications for math instructors designing this type of remedial course are discussed.

Keywords: Affect, Emotion, Beliefs, and Attitudes, Post-Secondary Education, Measurement

Introduction

There is a current need to match the projected demands for new engineering professionals in some countries like the U.S., and one way to reach this goal is keeping more engineering students in their undergraduate programs. Engineering majors currently have high attrition rates (Geisinger & Raman, 2013), and students' math preparation and attitudes toward math-related activities have been shown to be significant factors in students' decision to pursue and complete an engineering major (Hackett, 1985). This research focuses on two important factors influencing students' perceptions about math-related activities: math anxiety (MA) and math self-efficacy (MSE). Once enrolled, engineering students may perceive math courses as barriers, and struggling to complete these courses could make them more likely to quit or change majors (Suresh, 2006).

Richardson & Suinn (1972) defined **math anxiety** as "feelings of tension and anxiety that interfere with the manipulation of numbers and the solving of mathematical problems in a wide variety of ordinary life and academic settings" (p. 551). Math anxiety is not just a dislike of mathematics, but a set of feelings that affect performance in math-related activities that may lead to avoidance of math courses. Math anxiety is typically linked to perceptions of low math ability, prior unsuccessful experiences, and lack of studying and poor test preparation skills. High MA levels has shown to be a significant predictor of poor math performance and is also negatively correlated with the decision of pursuing a math-related major (Suinn & Winston, 2003). Women have shown to be more likely to report MA feelings when they perform math activities, and these negative feelings normally affect them in their decision to continue taking math courses (Sherman & Fennema, 1977).

According to Bandura (1986), **self-efficacy** refers to "people's judgments of their capabilities to organize and execute courses of action required to attain designated types of performances" (p. 391). Self-efficacy beliefs are task-specific, and one's skills in a particular task may influence only the individual performance on that task. Students with a high MSE have shown to be more interested in pursuing a math-related major like engineering (Hackett, 1985; Lent et al, 1991). On the other hand, low MSE levels have been shown to have an influence on students' decisions to avoid math-related activities that may lead them to have feelings of stress and anxiety. Math self-efficacy has been shown to be lower for students leaving STEM majors, and this factor was more significant for students leaving college during their first semesters (Eris et al., 2010).

If MA and MSE are not established and measured as independent factors, developing a conclusion about their effects on students' behaviors becomes a challenging task. However, it is important to recognize that MSE is related to MA, and that these two factors are normally influenced by similar past experiences (Hackett & Betz, 1989). Although students' intentions to engage in math-related activities are related to their MA levels, this effect has shown to lose significance when MSE is also examined (Meece et al., 1990). If engineering educators could develop interventions focused on improving students' MSE and ameliorate students' MA, then students may be better prepared to complete the math courses required by their engineering major. This led to the following research question: What is the effect of an intensive math intervention on the MA and MSE of first-year engineering students?

Methods

Participants were selected from a Mexican university that were engineering majors. To be accepted in this university, students must complete a four-week summer math course designed to standardize their math knowledge with a grade of 70% or better. Students meet 5 times a week to have a fast pace review of basic pre-college math, and they are evaluated once a week.

All freshmen students taking the math course for the Fall 2016 semester ($N=565$) completed a survey on the first and last days of the course before an exam (diagnostic and final). The survey presented 20 MA Likert-type items with scores from 1 "not anxious at all" to 5 "very anxious", and 36 MSE items where students rated their level of confidence performing math-related activities on a scale ranging from "no confidence at all" (0) to "complete confidence" (10). The MA items were selected from the 30-item Mathematics Anxiety Rating Scale (MARS 30-item) (Suinn & Winston, 2003), based on relevance to the context in the Mexican university. For the MSE items, this research used 36 of the 52 Mathematics Self-Efficacy Survey (MSES) items (Betz & Hackett, 1983). Only the math problem-solving (18) and the everyday math tasks (18) MSES items were considered relevant for this population. All survey items were translated from English to Spanish. Both the MARS 30-item and the MSES were selected for this study due to its high reliability shown in prior studies, with coefficient alpha values ranging from 0.84 to 0.96 (Brown & Burnham, 2012).

An average of the items was calculated as a total MA score (between 1 and 5) and a total MSE score (between 1 and 10), and independent scores for each of the constructs were also calculated. In order to determine if the math intervention had an effect on students' MA and MSE, a repeated measures Analysis of Covariance (ANCOVA) was conducted. This statistical model tests for a significant treatment effect among repeated observations while controlling for confounding variables. A mixed model was developed for each construct (total math anxiety, math tests anxiety, math activities anxiety, total math SE, math activities SE, and math problems SE). Fixed terms were included for treatment (pre/post), covariates (gender, type of high school, origin) and the interaction effects. A within-subjects random factor was also added to account for the repeated measures of the students. Finally, a correlation analysis was conducted to determine the relationship between MA and MSE before and after the math intervention.

Results

The results for the fixed effect F-tests of the treatment terms for MA and MSE are given in Tables 1 and 2 below. Covariate adjusted means for each construct for before and after the intervention are also given.

Table 1: Treatment Effect and Adjusted Means for Math Anxiety

Construct	F- Ratio	p- value	Pre- Mean	Post- Mean
Total Math Anxiety	14.2030	0.0002*	2.4153	2.7463
Math Test Anxiety	12.8993	0.0005*	2.8717	3.2434
Math Activities Anxiety	7.2271	0.0081*	1.9579	2.2493

Table 2: Treatment Effect and Adjusted Means for Math Self-Efficacy

Construct	F- Ratio	p- value	Pre- Mean	Post- Mean
Total Math Self-Efficacy	31.0563	<.0001*	7.1439	8.0029
Math Activities Self-Efficacy	1.2462	0.2663	8.4603	8.2966
Math Problems Self-Efficacy	65.7355	<.0001*	5.8262	7.7051

The ANCOVA results revealed a significant difference between pre and post mean scores for total MA and total MSE (see Tables 1 & 2). Each of the different constructs, math tests anxiety, math activities anxiety, and math problems self-efficacy, showed a significant difference with higher adjusted mean post scores. The only construct with no significant difference in the mean scores was the math activities self-efficacy. Also, there was a significant difference in math test anxiety scores between male ($M=2.87$) and female students ($M=3.25$) ($p=0.0052$). For all constructs, no interaction terms were significant, meaning that the treatment effect was consistent regardless of students' gender, type of high school, and origin. Next, the correlation analysis revealed a significant negative correlation between total MA ($M=2.416$, $SD=0.658$) and total MSE ($M=7.33$, $SD=1.24$) before the intervention ($r = -0.47$, $p < 0.0001$). There is also a significant negative correlation between total MA ($M=2.63$, $SD=0.74$) and total MSE ($M=8.16$, $SD=1.08$) after the intervention ($r =-0.54$, $p < 0.0001$). Even though this correlation is stronger for the post scores, it is not significantly different than the pre scores ($p= 0.1008$).

Discussion and Conclusion

The increase of students' MA and MSE after the course suggests that intensive remedial courses could help students improve their math knowledge, but there may be secondary effects on students' feelings about their math abilities. The increase of MA levels is a clear disadvantage for this type of course, making students more likely to decide to avoid math-related activities, thinking that they will feel stressed and perform poorly (Betz & Hackett, 1983). On the other hand, the MSE increment may have a positive impact. Higher MSE feelings could help to keep students' interest in developing their math abilities and desire to complete their engineering major despite facing some struggles during their first college math courses (Eris et al., 2010).

Developing a deeper understanding about the possible effects of this type of remedial math course could help math educators to better design these courses. The focus of these courses should be on enhancing students' math knowledge and building better MSE, but there must be an emphasis on creating an environment that could help students to develop their math abilities without generating anxiety feelings during the process. For this specific course, the stress generated by the need of obtaining a passing grade in the weekly tests may have contributed to creating a stressful environment for the students. Math and engineering educators should consider the stress and anxiety generated by frequent assessments, especially for students who may need more time to practice enough to feel confident to be evaluated. Female engineering students showed to be more affected by the math test anxiety than their male peers, but these MA levels were not higher in the total MA assessments. Despite literature suggesting that females are more likely to experience feelings of anxiety while performing math-related activities (Hackett & Betz, 1989), the research findings from this study that focuses on engineering students show no significant difference between males and females for total MA. These results suggest that this could be because female engineering students might be better prepared to deal with math courses in college than other female students in different majors.

This research found that MA and MSE have a negative correlation, suggesting that MSE beliefs are normally higher when MA levels are low. Despite finding a negative correlation, both factors showed a significant increment in the post course measurements. The MA increment stresses the importance of considering strategies that are directly focused to ameliorate negative feelings when students are learning math. Even when students start improving their math knowledge and self-efficacy by engaging with math-related activities, if the learning environment makes them feel stressed and anxious, then these students may be less likely to get interested in seeking more math activities aiming to further develop their math knowledge.

Math courses should keep the goal of improving students' math abilities, but there must be a greater awareness about the negative repercussions that students may have if they learn math in stressful environments. Groups like females have shown to be more likely to feel stressed during math tests, and this perception could result in higher MA feelings that may push students away from math courses and activities. If math courses increase students' feelings of anxiety, then these students could start doubting their abilities to finish their engineering major due to the challenges that completing all the required math courses could present. Math instructors should be prepared to support students and create a class environment that promotes their learning and MSE while developing the necessary tools to manage their anxiety while performing math.

LATENT CLASSES OF MIDDLE GRADES STUDENTS ON MATH ANXIETY

İbrahim Burak Ölmez
University of Georgia
i.burakolmez@hotmail.com

The purpose of this study was to identify differences in middle grades students' math anxiety levels based on 952 Turkish 8th grade students' responses to the Math Anxiety Scale (Erol, 1989) from nine schools located in different regions of Turkey. A mixture partial credit model analysis revealed three distinct latent classes based on homogeneities in response patterns. Latent class membership indicated that students in Class 1 had the lowest anxiety towards mathematics lessons, mathematics in daily life, and test and evaluation, and highest self-confidence about mathematics as opposed to students in Class 3 with the highest anxiety in these characteristics and with the lowest self-confidence about mathematics. Characterizing differences between members of each latent class extends recent advances in measuring math anxiety.

Keywords: Affect, Emotion, Beliefs, and Attitudes, Middle School Education, Research Methods

One main challenge in current educational settings is to identify affective constructs, such as anger, anxiety, and depression, and to provide intervention as early as possible for improving students' learning. Math anxiety is one of these constructs that lead to confusion about manipulation of numbers and solving problems related to mathematics. (Richardson & Suinn, 1972). In addition to physiological reactions such as sweaty palms and being sick, a student with high math anxiety level tend to have less self-confidence about mathematics (Luo, Wang, & Luo, 2009), and select career paths that to do not involve mathematics (Ashcraft & Moore, 2009).

To identify math anxiety levels of students, past research has used exploratory and confirmatory factor analysis for measuring the dimensions of math anxiety (e.g., Baloğlu & Zelhart, 2007) and structural equation modeling of the relationship between math anxiety and variables such as mathematics achievement (e.g., Harari, Vukovic, & Bailey, 2013). However, these studies were based on total scores obtained from summing all ratings from each student to items of a math anxiety scale, and using total scores has the potential of missing fine-grained information on characteristics of each student for math anxiety levels. Given the importance of math anxiety on learning and career choice, there is an urgent need for using methods that rely on individual item scores instead of total scores to detect students with different math anxiety levels and to identify those differences on math anxiety. One such method is the use of mixture item response theory (IRT) models. Based on past research (e.g., Rost, 1990), mixture IRT models can be useful in identifying latent classes of individuals on affective constructs such as differences in personality traits including depression (Hong & Min, 2007). The only study, to my knowledge, that has examined the utility of using mixture IRT models in detecting latent classes of 6th and 7th grade students on math anxiety is Ölmez & Cohen's (2017) study and they found two latent classes with students in Class 1's being less anxious than those in Class 2 towards mathematics lessons, mathematics in daily life, and test and evaluation, students in Class 2's having less self-confidence about mathematics. Hence, the purpose of this study was to identify differences in 8th grade students' math anxiety levels based on their responses to the Math Anxiety Scale (MANX; Erol, 1989). 8th grade is a critical grade level for dealing with math anxiety as early as possible because math anxiety has been known to peak during the secondary grades (Hembree, 1990). The following research questions were addressed in this study:

1. How many distinct latent classes of 8th grade students do exist in the population?
2. What does the existence of these latent classes (if any) imply about the different response patterns of math anxiety that exist in this population?

Theoretical Framework

The theoretical framework for this study follows the mixture Rasch model (MRM; Rost, 1990) that assumes the existence of distinct latent classes in the population. While the MRM specifies a separate item difficulty for each latent class, it determines a probability of being a member of a particular latent class for each individual. The polytomous form of the MRM based on scoring items with more than two categories such as never, sometimes, usually, and always, is called a partial credit model (PCM; Masters, 1982). In the mixture form of this model, the mixture partial credit model (MixPCM), the relationship between the probability of selecting a particular response category and the latent trait (i.e., math anxiety) changes across latent classes. The differences in response patterns to each item of a scale indicate homogeneities in characteristics of members of each latent class. Based on the differences in response patterns, the MixPCM could assign two individuals with same total scores to different latent classes.

Methods

The sample consisted of 952 Turkish 8th grade students from nine schools located in different regions of Turkey. Students' age range was between 14 and 16 years (female=478, male=474). A written consent form was obtained from one of the parents of each student before the study. The *Math Anxiety Scale*, developed by Erol (1989), is a four-point Likert type scale written in Turkish with options for each item ranging from "never" to "always." Higher scores demonstrate a higher math anxiety level. An internal consistency reliability estimate of .95 was obtained in this study. In a sample of 754 middle school and high school students, Erktin, Dönmez, and Özel (2006) identified four factors, which were test and evaluation anxiety, apprehension of math lessons, use of mathematics in daily life, and self-confidence for mathematics.

To analyze the data with the MixPCM, WINMIRA (von Davier, 2001) program was used. First, different numbers of latent classes were estimated in separate models to determine the relative fit of each model. Second, three indices for each model were compared to select the best fitting model: the Akaike information criterion (AIC), the Bayesian information criterion (BIC), and consistent AIC (CAIC). The model with the smallest BIC value was selected as the best fitting model (Li, Cohen, Kim, & Cho, 2009). Next, the characteristics of each latent class were analyzed by focusing on places where members of one latent class considered items to be easier or harder to endorse than other latent classes.

Results

Unidimensionality of the Scale

An exploratory factor analysis using maximum likelihood estimation indicated eigenvalues of the first three factors as 14.3, 2.6, and 1.9, with the total variance explained by the first factor as 31.7%. This indicated an evidence for essential unidimensionality of the Math Anxiety Scale based on Reckase's (1979) criterion.

Number of Latent Classes

Table 1 presents the indices for model selection. Minimum values for BIC as 66738.28, and CAIC as 67148.28 suggested a three-class solution in the data with 383 students (40.2%) in Class 1, 354 students (37.2%) in Class 2, and 215 students (22.6%) in Class 3.

Table 1. Model fit indices of the mixture Rasch model

Model	AIC	BIC	CAIC
One class	67128.86	67748.38	67884.38
Two classes	65687.50	66931.12	67204.12
Three classes	64870.58	**66738.28**	**67148.28**
Four classes	64500.46	66992.25	67539.25
Five classes	**64180.87**	67296.73	67980.73

Note. AIC = Akaike information criterion; BIC = Bayesian information criterion; CAIC = Consistent Akaike information criterion; the smallest information criterion index is bold.

Item thresholds indicate the extent of propensity when members of each latent class endorse each item. While thresholds lower on the scale such as -3 or -2 indicate a greater propensity of examinees to endorse that response category, thresholds higher on the scale such as 2 or 3 show that examinees have a greater propensity to endorse a higher response category.

Analysis of Item Location Parameters and Raw Responses

Item location parameter is the mean of all item threshold parameters for the particular item. While higher numbers on the logit scale demonstrate lower propensities of endorsement, lower numbers refer to higher propensities of endorsement. Thus, item location parameters are helpful for identifying differences in response patterns across latent classes. Moreover, I also compared item response distributions between the three latent classes by examining the percentages of raw responses in each latent class. This analysis led to three main results: (1) Students in Class 1 had the lowest anxiety towards mathematics lessons, mathematics in daily life, and test and evaluation, and highest self-confidence about mathematics than students in Class 2 and in Class 3; (2) students in Class 3 had the highest anxiety in terms of these characteristics, and lowest self-confidence about mathematics; and (3) students in Class 2 had medium anxiety and self-confidence regarding all these characteristics.

Items reflecting anxiety related to mathematics lessons (i.e., Items 7, 16, 36) were most difficult to endorse for Class 1 and easiest to endorse for Class 3. For example, for Item 36, "I struggle with listening to the teacher in the math class" the proportions selecting the options of "never" and "always" were 83% and 1%, respectively, in Class 1; 39% and 6%, respectively, in Class 2; and 29% and 35%, respectively, in Class 3. Furthermore, items that asked students to rate their ideas about mathematics exams and evaluation anxiety (i.e., Items 2, 3, 14, 25, 30, 41) were hardest to endorse for students in Class 1 and easiest to endorse for students in Class 3. For Item 25, "I feel uneasy a week before the math exam" (Class 1, Class 2, and Class 3 item locations were 0.75, 0.21, and 0.18), the proportions selecting the option "never" were 86%, 33%, and 44% for students in Class 1, Class 2, and Class 3, respectively. And, the proportions selecting the option "always" were 0% for Class 1, 8% for Class 2, and 31% for Class 3.

Items focusing on anxiety about the use of mathematics in daily life (i.e., Items 9, 29, 38) were hardest to endorse for students in Class 1 and easiest to endorse for students in Class 3. For Item 38, "I feel bothered by the necessity of making calculations by solving mathematical problems in my daily life even if they are simple", 80% of the students in Class 1, 38% of the students in Class 2, and 30% of the students in Class 3 selected the option "never."

Finally, items involving self-confidence for mathematics (i.e., Items 23, 27, 43) were hardest to endorse for students in Class 1 and easiest to endorse for students in Class 3. For Item 23, "I cannot dare to ask the points I do not get in the math class", the proportion selecting "always" was 1% in Class 1, 13% in Class 2, and 37% in Class 3.

Discussion

In this study, I examined the differences in middle grades students' math anxiety levels by identifying their latent classes using the MixPCM on a math anxiety scale. The first research question indicated three distinct latent classes with different patterns of math anxiety. The second research question showed that Class 1 consisted of students who were less anxious towards their mathematics lessons, mathematics in daily life, and test and evaluation, and who were more self-confident about mathematics than students in Class 2 and Class 3. On the other hand, Class 3 consisted of students who were more anxious regarding these characteristics, and who were less self-confident about mathematics than those in Class 1 and Class 2. The results of this study confirm the findings reported by Ölmez & Cohen (2017) based on 244 Turkish 6th and 7th grade students' responses to the same math anxiety scale. The only difference between the two studies appears to be the number of latent classes in each study (2 latent classes versus 3 latent classes). This might either stem from the fact that the sample sizes are different in both studies (N = 244 versus N = 952) or due to the focuses on different grade levels (6th and 7th grades versus 8th grade). The present study revealed that relying on individual item scores instead of total scores can provide fine-grained information about the differences in students' math anxiety levels. By using the MixPCM analysis, teachers can identify students in their classrooms with different patterns of math anxiety and make interventions accordingly based on the needs of each student. Future research should focus on conducting similar studies with other popular math anxiety scales to demonstrate a more complete understanding of math anxiety in middle grades.

LATINA/O STEM MAJORS' PERSPECTIVES OF EXPERIENCES SUPPORTING THEIR MATHEMATICAL SUCCESS

Sarah Oppland-Cordell
Northeastern Illinois University
s-cordell@neiu.edu

Katherine Bird
Northeastern Illinois University
k-bird@neiu.edu

This study uses an identity lens and qualitative methods to examine eight Latina/o STEM majors' perceptions of experiences that supported their mathematical success throughout their lives. Using NVivo software, an iterative coding scheme is applied to analyze interview data. Drawing on Leyva's (2016a) three-tiered analytical framework, critical race theory, and Latina/o critical theory, preliminary cross-case analysis reveals that participants' mathematical success is related to complex experiences negotiated within institutional, interpersonal, and ideological dimensions. Such experiences are related to their racial identity constructions, gender identity constructions, the co-construction of their mathematical identities with other salient identities, and experiences negotiated in multiple sociopolitical contextual layers.

Keywords: Equity and Diversity, Post Secondary-Education, Gender

Purpose and Background

This research project is a response to Leyva's (2016a) call "for more nuanced conceptualizations of gender in future mathematics education research that examine its social construction at different intersections of identity (e.g., gender/race) as well as at different levels of influence (e.g., institutional, interpersonal, ideological)" (p. 190). Drawing on Leyva's (2016a) three-tiered analytical framework, this research uses an identity lens and qualitative methods to examine eight Latina/o STEM majors' perceptions of experiences that supported their math success at the institutional, interpersonal, and ideological levels. The research questions are: (1) How do participants define experiences that support their math success at the institutional, interpersonal, and ideological levels? and (2) How do participants negotiate *what it means to be an underrepresented student* in relation to experiences that support their math success at these three levels? Understanding the complexities, avenues, and transformations that support Latina/o students' math success will further expand knowledge about how to provide students with math supports that are identity-affirming and equitable.

Literature Review

Emerging math education research has advocated for conducting more holistic explorations of underrepresented students' participation, learning, and experiences in mathematics, including the roles of sociopolitical, sociocultural, and psychological mechanisms (e.g., Gutiérrez, 2010). Of the small number of math education studies that have conducted in-depth explorations of underrepresented students' perspectives of their math experiences, few have investigated the lives of *mathematically successful* underrepresented students to understand their perceptions of experiences that have supported this success (exceptions include Leyva, 2016a, 2016b). Further, much of this work has been conducted on African American students and not Latina/o students (exceptions include Leyva, 2016a, 2016b). We argue that capturing aspects of Latina/o students' experiential knowledge they perceive as linked to their math success can assist the math education community in better supporting both underrepresented and represented students in attaining math success. Such information will shed light on how to create equitable math learning environments, how to empower students as math learners, and how to provide opportunities that support students' math success throughout the educational pipeline.

Mathematics education equity scholarship situated within broader sociopolitical perspectives (e.g., Gutiérrez, 2010; Martin, 2009) offers theoretical approaches for uncovering the mechanisms underlying underrepresented students' math participation, learning, and experiences that contribute to their success. Sociopolitical scholarship supports using critical race theory (CRT) and Latina/o critical theory (LatCrit) to examine marginalized students' math experiences (Gutiérrez, 2010; Martin, 2009). CRT and LatCrit frameworks encourage examining marginalized students' experiences through counter-storytelling methods while emphasizing the significance of race and racism and how they intersect with other forms of oppression (Solórzano & Yosso, 2002). Leyva (2016a) drew on both CRT and LatCrit to apply his analytic framework, which consisted of institutional, interpersonal, and ideological dimensions, to explore Latina/o students' math success. Such work expands knowledge about how Latina/os construct positive mathematical identities while taking into consideration the intersectional nature of race and gender.

This study addresses a gap in the math education literature by employing CRT and LatCrit and applying Leyva's framework (2016a) to examine how Latina/o STEM majors succeed in mathematics. Understanding the math experiences of this particular student population is critical because they can reflect on their elementary through undergraduate math experiences and reveal the roles of, for instance, sociohistorical forces and constructs, contextual influences, agency, and resilience. Understanding their experiences will broaden the math education community's understanding of how to devise math supports drawn from the experiences of underrepresented students who have succeeded in mathematics. We will be able to understand critical factors that supported them in persisting and succeeding in math throughout their lives, obstacles they had to overcome in their math trajectories to succeed, the various sociopolitical contexts in which they managed factors that supported their success in math, and how their identity constructions (e.g., math, racial, gender, class) contributed to their mathematical success.

Methods

This project uses qualitative methods (Yin, 2009) to explore participants' experiences related to their mathematical success and how such experiences are related to their lives as underrepresented STEM students. The data analyzed for this study is part of a larger study on underrepresented STEM students conducted at a diverse, Hispanic-serving urban university located in Chicago, Illinois during 2013-2015. This larger study involved recruiting African American, Latina/o, Native American, low-income, and/or first generation college students. Recruitment tactics involved sending emails to students in 200 and 300 level undergraduate STEM courses and posting flyers near classrooms where STEM classes were held. All Latina/o STEM majors that responded to our recruitment tactics and completed the entire data collection process were selected for this particular study. STEM majors included students that were actively pursuing a STEM major or had recently graduated with a STEM major at the time of the study. Table 1 describes participant demographic information for the eight Latina/o participants.

Table 1: Participant Demographic Information

Students	Racial/Ethnic Background	Gender	Birth Country	University Classification
Amelia	Latina/o	Male	Mexico	Junior
Antonio	Latina/o; Honduran	Male	Honduras	Graduate student
Elias	Latina/o; Columbian-American	Male	US	Junior

Caleb	Latina/o; Mexican	Male	US	Senior
Diego	Latina/o; Columbian	Male	Columbia	Senior
Juan	Latina/o; Mexican-American	Female	US	Senior
Maria	Latina/o; Mexican	Female	US	Junior
Ricardo	Latina/o; Mexican; Puerto Rican	Male	US	Senior

In-depth interviews were the primary data source; questionnaires were secondary data sources. The in-depth interview consisted of open-ended questions that aimed to capture a holistic understanding of participants' perspectives of their life-long math experiences. As categories were identified, additional interviews were used to investigate the emergent categories. Data collection continued until saturation of main categories was reached. All interviews were audiotaped, a subset of interviews were videotaped, and all interviews were transcribed. Using NVivo software, an iterative coding scheme will continue to be applied to analyze interview data. Interview codes will continue to be developed and compared until theoretical saturation is reached (until no new codes or categories emerge). Finally, a theoretical model that explains the experiences participants described as supporting their mathematical success will be developed.

Preliminary Results

Table 2 displays preliminary findings for this study. Preliminary cross-case analysis resulted in the following main themes regarding experiences that supported the participants' math success: (a) access to advanced math, math curriculum and pedagogy, and STEM support resources in the institutional dimension; (b) experiences involving teacher, family, and peer interactions and relationships in the interpersonal dimension, and (c) powerful experiences related to self-histories, critical roles of math transitions, complex aspects of math identities, and the intersectional nature of math identities and other complex identities in the ideological dimension. Such experiences that supported participants' math success were complexly related to racial identity constructions, gender identity constructions, the co-construction of their math identities with other salient identities, and experiences negotiated in multiple sociopolitical contextual layers. For example, emergent connections between experiences that supported their math success and their racial identity constructions included: resisting racialized experiences, functioning as cultural math role models, and engaging with cultural academic role models. Participants' counter-stories reveal how inequities, sociohistorical forces, sociopolitical constructs, contextual influences, agency, and resilience are intimately related to their math success.

Table 2: Preliminary Themes and Subthemes

INSTITUTIONAL DIMENSION	INTERPERSONAL DIMENSION	IDEOLOGICAL DIMENSION
Access to Advanced Math • Advanced math course tracking • Math classes with older students • Summer math classes **Math Curriculum & Pedagogy** • Non-traditional aspects of the math curriculum	**Teacher-Participant Interactions & Relationships** • Math classroom management approaches • Nurturing personalities • Passionate personalities	**Powerful Experiences Related to Self-Histories** • Experiences that motivated them to pursue their major • Overcoming life challenges **Critical Roles of Mathematical Transitions** • Elementary to high-school shifts in perspective • High-school to college shifts in perspective

• Effective math pedagogical approaches • Connections between math curriculum and broader academic/ professional/ personal goals **STEM Support Resources** • Math tutoring • STEM-related professional development programs/activities • STEM-related mentorship/ advisement	**Family-Participant Interactions & Relationships** • Family valuing/ supporting educational pursuits • Comparisons to family members **Peer-Participant Interactions & Relationships** • Cooperative learning inside & outside of classroom spaces • Comparisons to peers	• Community college to four year college shifts in perspective **Complex Aspects of Mathematical Identities** • Awareness of mathematical strengths • High mathematical expectations • Recognition of the importance of mathematics in their lives • Recognition of the important role of work ethic/curiosity/creativity in learning mathematics • Agency/resilience as math learners **Intersectional Nature of Mathematical Identities and Other Complex Identities** • Role of racial identities • Role of gender identities • Role of socioeconomic statuses • Role of the intersectional nature of complex identities

Conclusion

Emerging math education equity research indicates that we cannot fully understand students' math achievement, participation, and learning without taking into account their identity development as math learners. Such research also supports that the math education community must embrace the sociopolitical nature of underrepresented students' math participation, learning, and experiences because this more expansive theoretical lens can provide additional knowledge regarding *how* and *why* they attain mathematical success. This research project addresses a gap in existing math education research by raising important considerations regarding the significance of understanding what it means to be Latina/o with respect to math participation, learning, and success.

STUDENTS' EXPERIENCES IN AN UNDERGRADUATE MATHEMATICS CLASS: CASE STUDIES FROM A LEARNER-CENTERED PRECALCULUS CLASS

Brooke A. Outlaw	Karen Allen Keene	Gregory A. Downing
NC State University	NC State University	NC State University
baoutlaw@ncsu.edu	kakeene@ncsu.edu	gadownin@ncsu.edu

In this case study, we report the results from qualitative research set in a large-size undergraduate mathematics classroom. We provide evidence that students perceived that their participation in tasks where students work together to solve real life math problems involving precalculus concepts was helpful to their learning. Students expressed positive attitudes with regards to the collaborative efforts in this math classroom, often different from a traditional math course. Additionally, they expressed gratitude towards learning math in a way that was different than traditional mathematics courses, which we interpret to mean a more conceptual versus procedural-type of a mathematical learning.

Keywords: Post-Secondary Mathematics; Affect, Emotions, Beliefs, and Attitudes; Instructional Activities and Practices

There is great interest in improving undergraduate STEM courses across the country (P-CAST, 2012). More specifically, there is significant ongoing work on how to improve undergraduate mathematics courses by introducing the use of learner-centered teaching strategies, particularly what is often called active learning. This educational research is important for mathematics educators and policy makers in order to learn whether new instructional approaches support positive student affect and learning in STEM fields. Freeman and colleagues (2014) published significant results of a meta-analysis that addressed articles about using active learning in STEM and student outcomes. Performance outcomes, attitudes, persistence, and confidence in doing math has been shown to be higher when incorporating these strategies into the classroom (e.g. Freeman et al, 2014; Laursen, Hassi, Kogan, & Weston 2014).

There has not been significant work done to study the results of introducing new practices into service-level mathematics courses, such as Precalculus, that have been taught traditionally with procedural content or significant work done in large lecture classes. Being able to show how these strategies can be introduced and the results of using them in these large classes is an important contribution to mathematics (and more generally STEM) education.

In this case study, we interviewed several students from a large-scale Precalculus course where learner-centered strategies were used. These students expressed their attitudes and beliefs about different aspects of the course. We specifically chose to listen to students' experiences from their own perspective because too often, their perspectives are not acknowledged. This research is important because it sheds light on how new strategies that are implemented in these large-scale mathematics course affect students' overall experiences. The research question addressed in this paper is: What are students' perceptions of their experience in a large-scale Precalculus course where learner-centered strategies are employed?

Literature Review

With the existence of a great variety of learner-centered instructional strategies, we propose that there are many ways to vary methods of teaching in a large lecture classroom beyond direct instruction (Kennedy, 1998). Personal response systems, also knowns as Clickers, is one tool that can enhance students' learning when done properly (e.g., Boyle & Nicol, 2003; Vajravelu &

Muhs, 2016). Vajravelu and Muhs (2016) found that when courses are intentionally designed with the structure and opportunity for students to become active learners in conjunction with their classmates through clickers and team-based activities, students will work together to solve mathematical problems and engage in discussion in large lecture classrooms.

In addition to using learner-centered strategies, student attitudes and self-efficacy are important areas for further study. Núñez-Peña and colleagues (2013) found that poor success rates in math courses are related to negative attitudes towards math. Additionally, both student attitudes and self-efficacy play an integral part in perceived usefulness of math, in choosing careers involving math, and in opting to take more math courses beyond those required for their degree (e.g., Núñez-Peña, Suárez-Pellicioni, & Bono, 2013; Wilkins & Ma, 2003). Wilkins and Ma (2003) report on the importance of social influence, challenging curricula, and engaging activities as ways to help students see the importance of math in their own lives. The choices instructors make on the activities presented in class can make a difference in how students view math in general (Wilkins & Ma, 2003). These activities should be both engaging and include problem-solving. Yusof and Tall (1999) found that "when students are doing problem-solving, their attitudes change in the direction desired by the mathematics lecturers" (p. 77).

Methods

This case study was designed to study the introduction of evidenced-based instruction to explore students' experiences as they relate to various instructional components. For this study, outcomes are defined to mean achievement, attitudes, persistence, interest, and self-efficacy. This was part of a larger study, in which student-centered strategies were analyzed holistically.

This research was carried out at a large (~50,000 students), public university located in southern United States. There were 94 students enrolled in a 4-credit hour Precalculus course that met for 1.5 hours, 4 days a week during the summer of 2016. The students sat inside of an auditorium-style lecture hall, large enough to seat 300 students. Most class meetings consisted of traditional lecture delivered by the instructor with daily Clicker questions. The clicker questions were given to students frequently throughout the daily lecture and were based on the material being taught that day. These included a mixture between procedural and conceptual questions.

Along with normal classroom hours, students were required to participate in a computerized portion of the course called Smart Lab for 2 hours per week, which was facilitated by the course's 5 graduate teaching assistants (TAs). During these hours, students received extra help, were encouraged to complete math assignments, and completed examinations for the course.

Several times throughout the course, students also participated in Team Activities that lasted an entire class. Students worked in teams of 3-4 to solve application problems. An example of a team activity is when students used trigonometry and a sextant to estimate the height of a building. The five TAs were available during the days in which Team Activities were completed.

In the first week of class, students were asked to complete an online survey. This 43-item pre-survey addressed attitudes, perceived self-efficacy, and interest in math. Towards the end of the course, the students were given a post-survey which consisted of the same items. Finally, during the last week of the course, students were also asked to participate in a semi-structured interview where they answered questions about their attitudes and experiences towards different parts of the course, i.e., Team Activities, Clickers, and Smart Lab. Although many students were included in data collection, only the 5 students who completed the pre-survey, post-survey, and interview were included in this study. The participants included: Magdelina, Kadeem, Nancy, Teo, and Rajiv (pseudonyms). Their experiences are reported next.

Results

Overall, the participants had relatively positive experiences in the course where evidence-based strategies were introduced. In this section, we report on these experiences.

Team Activities

With regards to Team Activities, participants' experiences appeared fairly mixed. One of the main positive comments made by the participants pertained to the social aspect of the Team Activities. In particular, students enjoyed and felt like they benefitted from working with others. For example, Nancy commented, "It's nice working with other people because sometimes you don't get it and they get it." Another participant, Kadeem, also stated, "I think they contributed to your learning because if you, if you're trying to solve a problem, umm, and you don't really know what to do or there's a problem, you have teammates there that probably know something you don't know. Or something you forgot."

Although the participants had mixed feelings about the Team Activities, their negative feelings consisted of comments such as: they are conceptual, they don't correlate to the tests, they are difficult, they are too long, etc. For example, Magdelina commented "we didn't have enough time to finish most of them", while another participant, Nancy, stated "I just feel like team activities are really hard or really long and it takes too long to finish". These concerns, although conveyed as negative from the students, could be interpreted as positive from a researcher standpoint. Thus, these mixed feelings may not tell the whole story.

Clicker Questions

With regards to the Clicker questions, in general, the participants found them to be helpful for learning, they allowed productive collaboration among their peers, and they were presented in a more conceptual way that tied into their learning. For example, Kadeem stated "I, umm, I liked those because it's like, it's more interactive. And usually the problems he would put up there were not the typical homework problems." Another participant, Teo, also stated,"It kind of umm, helped the progression, because as he was going through the class, it kind of helped you okay, at like different points you could say 'Yeah, okay. I understand it up to here. Or I understand this concept up until right here'." Of the students interviewed, only one student stated that Clicker questions were not helpful to his learning.

Smart Lab

Similar to the Clicker questions, Smart Lab was also perceived as mostly positive. The main comments addressed by the participants with regard to the Smart Lab were that it provided a space to specifically focus on math homework and that the presence of the TAs was helpful. For example, Kadeem, mentioned:

> Whenever you have an issue with a certain problem, [the TAs] are right there to help you. And say if you went to the lecture and didn't understand anything, and that happened once or twice. Umm, the tutors are right there, and they can explain it for you.

Similarly, Magdelina expressed, "That's just very helpful if you don't understand something, you have, umm… either a tutor or then you can click on like an option that guided you step by step on how to do a problem." With regards to providing a space to work on assignments, Teo stated, "it gives you a time, umm… a set time where you can just focus on your math stuff and that if you need some help, you can, you know […] there's someone there to help you."

Surveys

Overall, the results from the surveys of these 5 participants were positive. We saw an increase in average score across all items from the pre-survey to the post-survey. Among our participants, the largest increases from pre- to post-survey occurred on the following items:

"Knowing math will help me in my life", "Mathematics is important for a good career", "I am not nervous when I am in math class", and "Mathematics is easy for me to understand". This leads us to believe that including learner-centered instructional strategies can have an effect on students' perceived experiences in a large-scale pre-calculus course, with those focused more on mathematics in the real-world showing the largest gains.

Conclusion

In this paper, we chose to discuss one portion of our research. Currently, most research focuses on either student outcomes or teachers' moves, and gives little-to-no voice to the students themselves. Therefore, we found it important to give those students a voice in this study and listen to their perspective to help inform our analysis.

We found that it is possible to bring learner-centered instructional strategies to a large-sized mathematics undergraduate class. The students in this study expressed mostly positive attitudes towards these student-centered learning strategies, in addition to demonstrating a similar change in attitude from a pre- to post-survey. To implement these strategies successfully, we suggest starting with a few activities and then slowly adding more activities to the course. We also found the TAs to be an important addition to the course. With a large class size of about 100 students, five TAs were utilized to help the Team Activities run more smoothly. We suggest including several TAs for these student-centered learning strategies to be more of a success.

In conclusion, we propose trying to incorporate the types of student-centered learning strategies as described in this paper into undergraduate mathematics courses. Educators need to be mindful of the pace at which these strategies be introduced in these courses and the number of TAs needed to make the course as successful as possible. With thoughtfulness and more research, these student-centered learning strategies could be the next step towards improving student attitudes and self-efficacy in large-scale, undergraduate mathematics courses.

DOES TEACHER FEEDBACK ON HOMEWORK IMPROVE STUDENT MATHEMATICS ACHIEVEMENT BETTER THAN ONLINE COMPUTER FEEDBACK?

Ji-Won Son
University at Buffalo
jiwonson@buffalo.edu

Amir Mahmood
University at Buffalo
am232@buffalo.edu

Despite the benefits of homework and teacher feedback on students' mathematics achievement, relatively limited work has been done on analyzing the effect of feedback on homework. This study examined the effects of four types of feedback on eighth grade students' achievement in mathematics: no feedback, effort-based teacher feedback on paper-and-pencil-based homework, ability-based teacher feedback on paper-and-pencil-based homework, and online programmed feedback on computer-based homework. A total of 59 students from an inner-city school district in New York participated in the study. A repeated measures experimental design was employed to isolate/minimize the between group variability. Analysis of results revealed that although effort-based feedback appeared to be a variable of interest, there was statistically insignificant relationship between the effect of different type of feedback and academic achievement.

Keywords: Teacher feedback, Effort feedback, Online feedback, Student achievement

Introduction

Homework and feedback have been identified as significantly related to academic achievement. The fundamental reason for assigning homework is meant to extend and supplement in-class activities (Cooper, Robinson & Patall, 2006). Most studies examining the relationship between academic achievement and homework found a positive and statistically significant correlation between the two variables (Cooper & Valentine, 2001; Cooper et al., 2006; Doorn, Janseen, & O'Brien, 2010). Although feedback can lead to large positive gains on student performance, relatively limited work has been done on analyzing the effect of feedback type on homework and its relationship with mathematics achievement.

The purpose of this study is to investigate the effect of teacher feedback on paper-and-pencil-based homework compared to computer feedback on online homework. Although an extensive amount of research has been conducted on teacher feedback on student homework, relatively limited work has been done in analyzing the effect of feedback type on homework and its relationship with academic achievement. In particular, despite the availability and popularity of online homework, the research on the impact of online assignments is limited in the current literature. Dweck (2006) highlights the importance of a growth mindset over a fixed mindset and the need for effort-based feedback/praise over ability-based feedback in motivating students to accept more challenging tasks. However, little is known about the effects of teachers' different feedback types (e.g., ability versus effort feedback) on students' homework behaviors and motivation in the paper-and-pencil-based homework setting compared to computer-based homework setting. This study hypothesizes that not all feedback types have a positive relationship to achievement. This study focuses on two distinct areas – 1) homework and teacher feedback and 2) the intersection of homework type (i.e., paper-and-pencil versus online) and feedback type (i.e., effort-based feedback, ability-based feedback and computer-generated feedback). The study analyzes the effect of no feedback, effort-based feedback, ability-based feedback on paper-and-pencil based homework, and computer-programmed immediate feedback on online homework and their relationship with the improvement of middle school students' achievement in mathematics. This study also explores differences in students' attitudes towards mathematics depending on feedback type. The research questions that guide this study include: (1) Is there any difference in students' mathematics achievement depending on feedback type (i.e., no feedback, effort-based feedback, ability-based feedback using paper-and-pencil based homework)? and (2) Is there any difference in students' mathematics achievement depending upon homework type (i.e., paper-and-pencil versus computer based)?

Theoretical Framework

This study was guided by expectancy-value theory (Eccles 1994; Wigfield, Tonks & Eccles, 2004) to explain and understand the cognitive and behavioral aspects of students' reasoning regarding homework. In addition, this study builds on mindset theory as proposed by Dweck (2006) for feedback type. First, according to the expectancy-value theory, student achievement and choices related to achievement are determined by two factors: expectancy for success, or how confident the students are in their ability to complete the task on hand, and subjective task values, which is the perceived value of the task for the student. Expectancy-value theory is used in this study to understand and evaluate the factors that motivate a student to choose a particular behavior while completing homework assignments. In addition, this study builds on Dweck's (2006) mindset theory to guide the feedback aspect. Mindset theory offers a correlation between a person's self-belief or mindset and their motivations and achievements. If students believe that they are capable of improving their knowledge or intelligence, they have adopted a growth mindset, whereas if they are under the assumption that intelligence is a precise and pre-established concept then they are following a fixed mindset. Two main types of feedback or praise have been reported in the literature: effort-based praise ("Good try"; "You've been working hard"), where teachers provide feedback focusing on the process of students' work and task performance and highlight the possibilities for learning to motivate students, and ability-based praise ("Well done; you are really smart"; "Gee, you are a good student"), where teachers provide feedback focusing on students' innate attributes or ability rather than the quality of their work (Son, 2016). The study compared the effects of four methods of feedback on student achievement: no feedback on paper-and-pencil based homework, effort-based teacher feedback on paper-and-pencil-based homework, ability-based teacher feedback on paper-and-pencil-based homework, and online programmed answer based feedback on computer-based homework.

Methods

Repeated measures experimental design, a powerful tool to control for existing subject differences between groups (Howitt & Cramer, 2011), was employed to explore the correlation between homework, feedback, and academic achievement, in which each student is part of each treatment condition. The participants for this study was comprised of two 8th grade classes from an inner-city junior high school located in New York State; 59 students in total with ages ranging from 13 to 14 years. 53% participants were female and 47% were males. In the repeated measures design, all participants took part in all possible treatment conditions, and they were assigned to each treatment condition randomly.

All participants took a pre-test and filled out a Homework Feedback Survey to collect information on students' reported practices and perceptions regarding homework, feedback from teachers, quality of homework, value of homework, and expectancy beliefs. Participants were then randomly divided into four groups A, B, C, and D comprised of about 15 students each coming from two different classes. The four treatments were: assigned homework returned with no feedback, assigned homework returned with teacher effort-based feedback, assigned homework returned with teacher ability- based feedback, and online-based homework with IXL-generated immediate feedback.

To answer the first research question that explored whether different types of homework feedback improved students' mathematical achievement, one-way repeated measures ANOVA was used to test that the difference between means were statistically significantly for feedback type. To answer the second research that investigated the effect of teacher provided feedback on students' attitudes towards mathematics in the light of different type of feedback, a two factor repeated measures ANOVA was conducted. Feedback type was treated as factor one with three levels (no feedback, effort-based feedback and ability-based feedback), and attitude was factor two with three levels (homework effort, expectancy, and value) as well.

Summary of the Findings

Effect of Feedback Type on Achievement

The first research question asks whether different types of homework feedback improve students' mathematical achievement. In order to answer the first research question, the effect of four different types of feedback, provided on students' mathematics homework and its relationship with mathematics achievement as measured by gain scores (difference between post-test and the pre-test scores) were explored. Table 1 shows the mean and standard deviations of pre-test scores and post-test scores, along with gain scores by each feedback type provided on students' homework.

Table 1: Descriptive Statistics by Feedback Groups

Feedback Type	Pre-Test		Post-Test		Gain Scores	N
	Mean	SD	Mean	SD		
No Feedback	49.82	20.16	53.38	18.16	3.47	59
Effort-based Feedback	48.05	19.25	54.58	21.02	6.53	59
Ability-based Feedback	48.14	16.40	52.37	18.92	4.24	59
IXL-based Feedback	48.98	18.80	52.29	20.26	3.31	59

Regardless of the feedback type, students showed improved scores in the post-test. In addition, the gain scores show the difference between mean pre-test scores and the mean post-test scores were the highest for participants provided with effort-based feedback; they showed an increase of little more than 6.5 percent points. The gain in post-test scores shown by ability-based feedback was next at little more than 4 points, whereas the gain made by IXL based immediate feedback and no feedback were comparable at about 3.5 points. We found that the difference between gain scores among the four feedback conditions were not statistically significant, $F(2.71, 157.15) = .38, p = .75 > .05$. Although, observed pairwise comparisons from Table 2 show positive differences in favor of effort-based feedback, post-hoc test using Bonferroni correction revealed that none of these differences were statistically significant. Although there are differences in gain scores among the four feedback types, this study was not able to find a statistically significant relationship between teacher feedback and students' mathematics achievement.

Students Attitudes and Feedback

The second research question asked whether there was any difference in student's attitudes towards mathematics depending on feedback type. To answer this research question, Homework Feedback Survey, which consisted of six constructs comprising of 26 items, administered to 236 participants was used. To analyze the relationship between feedback and attitude, a two-way repeated measures ANOVA was employed, the two within-group factors were attitude with three levels (i.e., expectancy belief, homework effort, and value belief) and feedback also with three levels (i.e., no feedback, effort-based feedback, and ability-based feedback) and gain scores by feedback type as the dependent variable. We found that the main effect of attitude is statistically significant $F(1.63,96.64) = 30.47$, $p = .001 < .05$. This finding indicates that students' attitudes are positively associated with their performance in mathematics. However, the interaction effect of feedback type and attitude is not statistically significant, $F(3.39,196.70) = 1.57$, $p = .19 > .05$. Thus, although students' attitudes are positively related to mathematics achievement, this relationship is not moderated by different type of feedback employed in this study.

Discussion and Implications

The findings of this study suggest that the effect of feedback type on mathematics homework did not have a positive relation to academic achievement. The study could not find statistically significant difference between the gains made by students who were provided different types of feedback on mathematics homework, though nominal difference in favor of effort-based feedback were higher, especially for females. The study also did not find a statistically significant interaction between feedback and gender, suggesting the above findings are equally applicable to both male and female students. In addition, although attitude was strongly related to mathematics achievement, this relationship was not moderated by the three feedback types employed in this study. However, our study showed that students who were provided effort-based feedback perceived teachers' feedback to be more useful as compared to ability-based feedback and no-feedback groups, and they attached a higher value to it. Nevertheless, this usefulness did not translate into statistically significant higher achievement levels. This study provides implications for future researchers and educators to gain an inside access to a low performing classroom and observe how feedback and homework are related to the academic performance of students in mathematics.

EXPLORING THE PHENOMENON OF PEDAGOGICAL EMPATHY

Karina Uhing
University of Nebraska - Lincoln
karina.uhing@huskers.unl.edu

Interactions between teachers and students are an essential part of learning in educational settings. In this study, I explore the phenomenon of pedagogical empathy, which is conceptualized as empathy that influences teaching practices. Specifically, I examine how mathematics graduate teaching assistants (GTAs) might express pedagogical empathy when providing feedback to student questions. Data was collected through interviews of current pre-calculus instructors in which participants were shown samples of student work and asked to respond to questions about that work. Preliminary analysis has revealed varying abilities of GTAs to express and attend to student emotion.

Keywords: Affect, Emotions, Post-Secondary Education

Learning mathematics is an emotional experience for students (Hannula, 2002). Mathematics education researchers have studied student affect and teacher affect independently within the context of learning and teaching mathematics. However, little attention has been given to the relationship between teachers and student affect (Philipp, 2007). At the post-secondary level, both emotional reactions and interpersonal relationships have been shown to influence what is learned in the classroom (Lowman, 1994).

Graduate teaching assistants (GTAs) play a large role in the instruction of lower level undergraduate mathematics courses (Speer, Gutmann, & Murphy, 2005). As a result, GTAs have opportunities to interact with a variety of students on a day-to-day basis and develop interpersonal relationships with them. These interactions likely influence GTAs' identities as teachers and shape their teaching philosophies (Kung, 2010). However, little is known about GTAs' teaching experiences and only recently has the mathematics education community begun to study their development as teachers and potential future faculty members (Kung, 2010; Speer et al., 2005).

This study seeks to add to the growing body of information about mathematics GTAs' pedagogical beliefs and teaching practices by investigating the awareness of GTAs to student feelings using a qualitative research design. In doing this, I aim to develop a better understanding of a new theoretical construct, *pedagogical empathy*. Building upon a definition used by Tettegah and Anderson (2007) in their study of empathic dispositions of pre-service teachers, I define pedagogical empathy as "the ability to express concern and to take the perspective of a student" (p. 50) and *the influence that this ability has on teaching decisions*. With this in mind, the purpose of this study is to explore how GTAs might express pedagogical empathy when providing feedback to students. To examine this phenomenon, I pose the following three research questions:

1. Can the feedback that GTAs provide to student questions be characterized as attending to possible student emotions?
2. Given sample written work on a typical pre-calculus problem, what feelings might GTAs attribute to students?
3. How might GTAs take student feelings or emotions into account when answering student questions?

Theoretical Framing

The process of learning is complex and involves both cognitive and affective factors. In particular, emotions have an effect on student learning and teachers play a significant role in influencing those emotions (Mortiboys, 2012). To better understand the relationship between emotions and learning, Hannula (2002) developed a framework to analyze a student's attitude towards mathematics using the psychology of emotions as a foundation. This framework separates attitudes into four evaluative processes: 1) The emotions the student experiences during mathematics related activities; 2) the emotions that the student automatically associates with the concept 'mathematics'; 3) evaluations of situations that the student expects to follow as a consequence of doing mathematics; and 4) the value of mathematics-related goals in the student's global goal structure (Hannula, 2002, p. 26).

With respect to this study, I focus on the first part of this framework, which attends to the emotions that students experience while working on math problems. Whereas the framework was analyzed from the perspective of a student, I aim to explore how the framework might be viewed from a teacher's perspective and how the responses of a teacher might take into account the initial process of the framework when interacting with students. For this study, it is also important to distinguish between feelings and emotions. Hansen (2005) defines feelings as conscious perceptions used to describe emotions. Because feelings are perceivable and can be articulated by the individuals who experience them, I use this term for discussing student displays of emotion.

Methods

The participants in this study were 14 mathematics GTAs at a large Midwestern university. Each GTA had at least one semester of experience as the instructor of record for a pre-calculus class, and none were international GTAs. Data was collected during the 2016-2017 school year through structured interviews with the GTAs. Participants selected their own pseudonyms, which are used below. During the interview, participants were asked to solve a typical pre-calculus problem in order to familiarize them with the problem. After working through the problem, the participants were then shown five different samples of student work for the problem and asked to respond to questions about the work. The samples of student work were fictitious examples of actual student work based on the author's experiences as a pre-calculus instructor. Student questions about the work were presented through audio recordings intended to simulate an actual student asking the question. Examples of questions asked in the audio recordings include, "Am I doing this right?" and "How do you know what is x and what is y?" Finally, at the end of the interview the participants were asked to reflect on how they thought each student might have felt when working on the problem and if they would respond differently to any of the students after thinking about what they might be feeling. Participants were provided with a list of feeling words to use a reference during this part of the interview. After data was collected, select interviews were transcribed and analyzed using open coding.

Preliminary Findings

By conducting this study, I aimed to determine whether feedback to student questions could be characterized as attending to emotion. Through open coding, I found that many of the responses to interview questions focused on helping students develop either procedural or conceptual mathematical knowledge and did not attend to student emotion. However, several participants mentioned potential student feelings during the interviews, even before being prompted by the interviewer to describe how each student might have felt after viewing their work. In a few notable cases, GTAs were unable to articulate possible student feelings using descriptive feeling words. These responses were categorized under the code “non-feeling” and were common among only a few participants. In addition to the mathematical responses and emotional responses, GTAs also gave reflective responses during the interview. These reflective responses often involved taking the perspective of a student or drawing upon prior personal experiences, which may be an indicator of expressing pedagogical empathy. Table 1 shows the primary codes that emerged from the interviews along with representative excerpts from 4 different participants. These codes help to categorize GTA responses to student questions.

Table 1: Characteristics of GTA Responses

Code	Description	Interview Excerpt
Procedural Mathematical Knowledge	Responses involving procedures, algorithms, rules, or formulas that do not directly attend to conceptual mathematical ideas	*Nicole:* If I plug in 25,000 students, do I get out the 13,000?
Conceptual Mathematical Knowledge	Responses connected to underlying mathematical concepts or content including discussion of abstract ideas or relationships	*Floyd:* What sort of function are we trying to come up with here?...Think of the function as a machine.
Student Feelings or Emotions	Anything about what a student might be feeling or anything related to underlying emotions that students might be experiencing	*Paul:* It’s less that they don’t know the math and more sort of fear or being uncomfortable with story problems.
Non-feelings	Use of words that are unrelated to emotions to describe what a student might be feeling when specifically prompted	*Phillip:* They probably feel medium.
Student-centered Reflection	Evidence of reflection centered on student thinking or past experiences with students	*Paul:* Even though my students see me make mistakes, they still want my pat on the back.
Instructor-centered Reflection	Evidence of self-reflection that is centered on the participant rather than the students, including personal beliefs	*Phillip:* I feel like in that situation, I would feel stupid.

Further analysis is ongoing to identify common feelings that GTAs might attribute to particular students and whether some feelings were more prevalent than others. Several feelings were mentioned in the interviews including fear, nervousness, confusion, anger, annoyance, uncertainty, insecurity, frustration, anxiety, vulnerability and confidence. Some participants also made an effort to distinguish between different levels of student emotion. For example, Floyd tried to distinguish between vulnerability and insecurity when discussing how one student might have felt while working on the problem:

> Floyd: Maybe vulnerable is a good way to describe that. It’s not so much insecure as much as they’re afraid to make a mistake I think – like a different level of insecurity than just not being sure of what they’ve done.

From the preliminary analysis, it is evident that the GTAs who participated in this study were aware of the potential for student feelings to arise when working on a math problem, but varied in their abilities to express those feelings. For example, James found it difficult to attribute emotions to students:

James: I guess I have a hard time ascribing emotion to people as they're working on math problems. That's not something I really consider too much.

Other GTAs, however, were able to articulate student feelings and discussed how taking student feelings into account was something that they would usually do when responding to student questions. In response to the question, "Would you respond differently to any of the students after thinking about what they might be feeling?" both Nicole and Aubrey replied similarly:

Nicole: I don't think so. I mean I think that's something that I do think about when a student asks me a question, like where they are in terms of not only like mathematically, but also like emotionally.

Aubrey: Probably not. I try to think on the spot about how they're feeling and look at people's faces...You get to know your students, and I try to pay attention to how they're feeling.

Discussion

The feedback that GTAs provided in response to student questions not only addressed the mathematical content required to solve the problem, but also attended to potential student feelings. In addition, a variety of possible feelings were brought up organically by several GTAs throughout the interviews. This observation draws attention to the fact that GTAs are trying to account for student emotion when helping students work through problems. However, further analysis is still needed to explore how pedagogical empathy might be manifested in teaching practices like providing feedback to students and how different experiences might help the development of pedagogical empathy in mathematics teachers.

SELF-EFFICACY BELIEFS OF ADULTS WHO DISLIKE MATH: CHALLENGING HOW WE MEASURE THE SOURCES

Kevin J. Voogt
Michigan State University
voogtkev@msu.edu

According to Bandura (1977, 1997), four sources of information inform people's self-efficacy beliefs: mastery experiences, vicarious experiences, verbal persuasion, and physiological and emotional states. To date, most research on the sources of mathematics self-efficacy has been quantitative in nature. The purpose of this study was to qualitatively examine the sources of self-efficacy for a small group of young adults who dislike mathematics to uncover the more covert aspects of the sources of their mathematics self-efficacy. In this paper, I share evidence from this study that reveal flaws in the methodology used in prominent quantitative studies examining the sources of mathematics self-efficacy.

Keywords: Affect, Emotion, Beliefs, and Attitudes; Mathematics Education; Self-efficacy

In the late 1970s, Bandura (1977) introduced a framework for understanding how people's self-beliefs affect how they act in given situations, especially when the circumstances are challenging. Bandura (1977, 1997) defined one such self-belief, *self-efficacy*, as the belief one has about his or her own capabilities to organize and execute the courses of action needed to attain certain goals. Since the 1970s, self-efficacy has received considerable attention in educational research and has been shown to affect students' level of achievement, academic motivation, persistence, competence, and feelings in various domains (e.g., Hackett & Betz, 1989; Pajares & Valiante, 1997).

With such striking correlations, it would be important to better understand the sources, or the factors that influence self-efficacy beliefs. Bandura (1977, 1997) hypothesized people form self-efficacy beliefs based on four sources of information, the most influential of which is one's interpretations of their performance outcomes, or *mastery experiences*. Also influential are *vicarious experiences,* where one relies on social comparison with and outcomes achieved by a model as a source of information about his or her capabilities (Bandura, 1997). *Verbal persuasion* can also influence self-efficacy beliefs, and is hypothesized to have a more limited effect on self-efficacy than the previous two, as outcomes are only described, not directly encountered (Bandura, 1997). Lastly, fatigue, anxiety, and other *physiological and emotional states* are often interpreted as indicators of capability (Bandura, 1997).

Much of the research on the sources of mathematics self-efficacy has been quantitative and has focused on secondary and college students. Here I attend to some inherent problems in measurements used by three particular oft-cited quantitative studies (Klassen, 2004; Lent, Lopez, & Bieschke, 1991; Matsui, Matsui, & Ohnishi, 1990). To measure mastery experiences, Klassen (2004) and Matsui and colleagues (1990) used only students' self-reports of their mathematics course grades from the previous year. Bandura (1997) postulated that it is not one's objective outcomes that count as mastery experiences, but his or her *interpretation* of those experiences that matter. For instance, a grade of a B may encourage some, leave some unaffected, or devastate others (Usher & Pajares, 2008). For vicarious experiences, Klassen's (2004) survey items in this category focused only on how the seventh-grade students compared themselves to their peers while others (Lent et al., 1991; Matsui et al., 1990) had their questions include teachers and parents along with peers. All three studies failed to explore whether other models such as non-immediate family members, experts in the field, or others had any impact on the participants, or which experiences were most meaningful to the students.

Verbal persuasion had greater correlation with students' mathematics self-efficacy levels in the three mentioned studies, but all three seemed to simplify encouragement or discouragement as positive and negative persuasion. This simplification eliminated the meaning (or consequences) those statements may have had for the recipients of them. For the last source, emotional states, Matsui and colleagues (1990) had students mark a level of agreement with the phrase "I really hated math." What is not clear, however, is whether this feeling about mathematics was an *effect* of the students' self-efficacy or a cause.

The quantitative instruments outlined above failed to investigate the experiences that *develop* an individual's self-efficacy beliefs. Qualitative instruments, however, such as a semi-structured interview, could allow participants to provide details about those experiences that they feel have been most influential on their beliefs over time (Usher & Pajares, 2008). Hence, in this paper, I report the results of a study where I explored the experiences of young adults who reported disliking mathematics to uncover the more covert aspects of the sources of their mathematics self-efficacy. For the purposes of this report, I analyzed data from semi-structured interviews intended to address the following research question: *How is the genesis of the young adults' dislike for mathematics explained by the four sources of self-efficacy proposed by Bandura?*

Methods

Participants (Elissa, Julia, Kayla, and Kyle – pseudonyms) were four young adults (ages 22-33), all of whom had attended public schools, completed at least three years of post-secondary education, and reported disliking mathematics. Three participants were female and in their post-college careers whereas the male was in his fourth year at a large Midwestern University.

Semi-structured interviews were conducted in Spring 2017 to explore the reasons people give for disliking mathematics and how they might or might not fit within Bandura's (1997) sources. Questions about the sources of self-efficacy were modified from those used by Zeldin and colleagues (2008) in their study of the self-efficacy beliefs of men and women who were successful in STEM fields. Each participant was also asked to self-report their level of self-efficacy with the following question: *On a scale of 1-10, how would you rate your confidence in doing mathematical tasks?* Interviews were audiorecorded and then transcribed. I began with open coding to look for factors mentioned as affecting their feelings of capability or confidence in doing mathematics. Surprisingly, all factors fit well within Bandura's four sources, which I had used as my initial categories (*Mastery Experiences, Vicarious Experiences, Verbal Persuasion, Emotional States*). I then created subcategories within each source, distinguishing between instances that seemed to be positive influences on their mathematics self-efficacy or feelings as well as instances that were negative influences on it. I then created tables to keep track of both the number of instances within each source for each participant and brief summaries of the instances described by the participants.

Results

Here I will focus on the results of my qualitative analysis that differ in interesting ways from prior mathematics self-efficacy research.

Mastery Experiences

Of the 20 responses coded *mastery experiences*, 13 were negatively influential, with Julia and Kyle having the most instances (n=4). Julia reported receiving A's throughout elementary and high school, yet reported a low self-efficacy level. She even said, "I think that even if I got a lower grade but still had better understanding of it, a better grasp, I think that I would feel more successful.” Julia, Elissa, and Kyle all noted grades as indicators of their own failure in mathematics. A grade of a C in Geometry for Julia, a B+ in Geometry and B- in PreCalculus for Elissa, and a C in high-school Calculus and D in college Calculus II for Kyle evoked the words “lack of understanding”, “not good”, and “failure” by the three participants, respectively.

Vicarious Experiences

Of the 18 responses coded *vicarious experiences*, 12 were negative instances, with Julia and Elissa each having the most (n=4). All four participants mentioned falling behind peers they saw as “equals” as detrimental to their confidence. Kayla, Julia, and Elissa each mentioned negative mathematics teacher models. Kayla had a mathematics teacher who taught from a piece of paper and struggled to answer her questions if they were not already on his notes. Julia’s Geometry teacher showed a willingness to help certain students, but not her. Elissa’s PreCalculus teacher was described as “convoluted” in how she taught and presented mathematics.

Verbal Persuasion

Of the 16 replies coded *verbal persuasion*, 11 were negatively influential, with Kayla and Elissa having the most negative instances (n=4). Julia once overheard her parents saying that she was not good at math and that she was “not a math person”, while her high-school guidance counselor discouraged her from taking any more mathematics than the minimum requirement. Kayla’s mom affirmed her lack of confidence by saying things like, “we don’t understand this” or “we just don’t do this” while Kayla struggled with her mathematics homework. Kayla indicated her friends’ attempts to boost her confidence verbally would in turn lower her confidence by “putting her on the spot.” Kayla had a teacher tell her that due to her success in the statistics portion of a class he taught, she should take AP Statistics the following year with him. She did not perform well in AP Statistics, however, and indicated that her failure to live up to his expectations was devastating to her remaining confidence in her mathematical capability. Kyle overheard his suite mate telling someone that Kyle was “just getting through” Calculus and told Kyle directly, “You might not do too hot but you might be able to pass.” Elissa’s PreCalculus teacher would tell the class “how bad they were.”

Emotional States

Of the 16 replies coded *emotional states*, 12 were negatively impactful, with Kayla (n=6) having the most. In elementary school, Kayla would panic, not knowing why she was being a diligent note-taker and hard worker yet not understanding the concepts. She surmised that some elementary concepts “would probably have made sense if I wasn’t in a tailspin of anxiety already, if I wasn’t sitting there crying and hyperventilating.” She mentioned shutting down when put on the spot (as mentioned previously). She even mentioned feeling anxiety when I asked her in the interview about her confidence to perform a mathematical task.

Julia used the word “stressful” to describe her experiences – including elementary math race games where she was slower than her peers and finishing her tests last. She also mentioned feeling shame in her high-school Geometry course when she realized she was cheating to pass the class because she did not understand the mathematics. Elissa mentioned her experience in PreCalculus was boring and gave her a lot of anxiety. She wanted to give up because it would be so “frustrating”. Kyle’s lone occurrence focused on his frustration when he would get stuck on mathematical tasks while his peers (especially those about whom he felt smarter) solved them.

Discussion and Concluding Remarks

Taken together, the analyses of participants’ responses regarding the sources of mathematics self-efficacy suggest that a qualitative approach (whether semi-structured interviews or other methods) afforded participants an opportunity to author *how* their experiences informed their efficacy beliefs, and how those sources were interpreted by the participants was not so predictable. For instance, positive verbal encouragement from Kayla's teacher only temporarily increased her confidence, and later debilitated it when she could not succeed in her AP Statistics course. Grades were not indicators of mastery for Julia. She indicated understanding as more important than the grades she received. Elissa saw B's as indicators of failure. Teacher models, whether by making it seem like there's only "one correct way" to "do mathematics" or by not being able to relate to or understand where some students might be in their understandings, negatively impacted participants' efficacy.

This study also differed from prior research (e.g. Usher, 2009) in that students with high achievement did not necessarily exhibit high efficacy. Julia, Elissa, and Kyle all reported successful mathematics experiences (high grades, advanced placement), but Julia had low self-efficacy whereas Elissa and Kyle had moderately high self-efficacy to complete a mathematical task. Also, there seemed to be different kinds of mastery evident in the results of this study. Participants discussed mastery as decided by others (e.g. grades, placement into advanced mathematics classes or not) and mastery perceived by one's self (e.g. Julia's self-perceived lack of understanding). Prior research only using one's grade as an indication of mastery (or not) fail to give evidence to the different types of mastery that can be influential.

Another key difference from prior studies is the prevalence of and types of emotional states in my participants' experiences. Many of the quantitative studies discussed a "lack of significance" when looking at the correlation between participants' emotional states and level of self-efficacy. Perhaps that is due to an over-simplification of emotional and physiological states to only feelings of illness, anxiety, or stress while taking exams. This study revealed there are other activities (e.g. math races, doing math homework, calculating tips) and other emotions (e.g. boredom, shame) that can bring about emotional and physiological reactions. Although this was a small-scale study with only four participants, their recollections of their past mathematical experiences point to the shortcomings of using forced-choice and Likert-scale indices to measure the sources of mathematics self-efficacy.

STUDENTS' FRAMING OF MATHEMATICAL TASKS IN CLINICAL INTERVIEWS

Monica Anthony
University of Maryland
mrd@umd.edu

Janet Walkoe
University of Maryland
jwalkoe@umd.edu

Keywords: Cognition, Affect, Emotion, Beliefs, and Attitudes, Research Methods

Clinical interviews are used in mathematics education research to discover cognitive processes, identify cognitive activities, and evaluate levels of competence. Yet, interviewees' understanding of the interview impacts both how they participate and subsequently the claims we can make about their cognitive processes (Russ, Lee, & Sherin, 2012). *Framing* has been used in science education research to attend to how students understand tasks, and how that understanding impacts their performance on the task and their interactions with others. Russ, Lee and Sherin (2012) posit that students will interpret clinical interviews in "ways that will affect and be evident in how they respond and behave in the interaction" (p. 12). Thus, researchers can infer students' framing of the situation from their verbal, nonverbal, and paraverbal behaviors (Russ, Lee, & Sherin, 2012).

This study describes the framing employed by two college-Algebra students during clinical interviews. The clinical interviews analyzed were originally conducted as part of an investigation of college-level Algebra students' concept images of parabolas. The interview protocol was intended to stimulate different representations and understandings of parabolas and cue participants to move between representations. Interviews were analyzed using the three phase analysis described in Russ, Lee and Sherin (2012). Students' behaviors were compared to the three framings identified in Russ, Lee and Sherin (2012): the inquiry frame, oral examination frame, and expert interview frame.

Preliminary results suggest both participants framed the interviews as oral examinations. Unlike the students in Russ, Lee and Sherin (2012), who moved between lenses depending on the task and interviewer cues, participants in this study maintained their lenses across tasks. One possibility for the pervasion of the oral examination lens is the nature of the mathematical tasks, which may be too similar to what students experienced in their coursework (not novel) and thus they frame the tasks as an assessment of their understanding. Interestingly, when the interview shifts from mathematical tasks to questions about their experiences as mathematics learners, the college students shift to the expert interview frame. Changes in framing are indicated by the reduction in hedging language and laughter, and increased volume and confidence of tone when responding to questions. The shift in frame from oral examination to expert interview could indicate that students do not see themselves as owners of mathematical knowledge. Future analysis seeks to consider the potential influences on participants' framing, beyond interviewer cues and the specific tasks. For example, does the discipline of school mathematics constrain or facilitate how students' frame tasks, both in research settings and in classrooms?

DEVELOPMENTAL DIFFERENCES IN LEARNING MATH BY EXAMPLE IN ELEMENTARY SCHOOL

Julie L. Booth
Temple University
julie.booth@temple.edu

Keywords: Cognition, Elementary School Education

Empirical evidence has amassed supporting the effectiveness of having students explain why correct problem solutions are correct (e.g., Hilbert, Renkl, Kessler, & Reiss, 2008) as well as why incorrect problem solutions are incorrect (e.g., Durkin & Rittle-Johnson, 2012), particularly for students in middle school and above (e.g., Adams et al., 2014). However, research is only beginning to investigate how this approach impacts learning in elementary school mathematics classroom and whether effects are age-dependent. The purpose of the present study was to compare the effectiveness of worked-example worksheets in fourth vs. fifth grades.

We worked closely with elementary school teachers and mathematics coaches to construct worked-example assignments for fourth and fifth grade Common Core Content Standards. We collected data in elementary classrooms (14 5th grade, N = 300 students; 12 4th grade, N = 257 students) where students took a paper- and-pencil pretest and posttest surrounding their unit. The test contained two types of questions: isomorphic procedural items (e.g., procedural items that had the same structure and difficulty level as those trained) and items that measured conceptual understanding of the content. During the unit, teachers instructed as usual, but replaced student practice activities with study assignments where appropriate; experimental group classrooms used the worked-example assignments, while control classrooms used assignments that contained identical problems but did not include worked-examples or self-explanation prompts.

Quantitative analyses were conducted to determine whether posttest scores (controlling for pretest performance) differed for students in the experimental vs. control condition as well as to compare whether the impact of condition varied with grade level. Results indicate that while the worked-example assignments did have benefit for both fourth and fifth grade students, the pattern of results differed by grade. Fifth graders' benefit manifested mostly in gains on conceptual items, which is consistent with extant findings for middle and high-school students. In contrast, fourth graders' benefit was greater on the procedural items, which is more consistent with findings for older students when they study, but don't explain, worked examples. Grade level differences in how students approached and completed their assignments—and how those process data help illuminate findings on differential benefits—will also be discussed.

NEGOTIATING FRAMES IN AN INFORMAL MATH SPACE

Katherine C. Chapman
Vanderbilt University
k.chapman@vanderbilt.edu

Keywords: Classroom Discourse, Equity and Diversity, Gender, Informal Education

According to dominant cultural narratives in the United States—including those instantiated in testing mandates—mathematics is a highly valued discipline, and mathematical competence is reserved for a select few. Despite this rhetoric about mathematical aptitude, research in the sociocultural tradition (Vygotsky, 1978) has shown that these notions of competence are inherently bound to cultural practices, and systematically exclude students from marginalized communities. Furthermore, work to correct this systemic imbalance has taken many forms. Funds of Knowledge research (e.g. Civil, 2007) identifies and draws on specific competencies of students' home communities in order to promote in-school academic achievement, while work on Third Space (Gutiérrez, 2008) promotes a more even-handed synthesis of home- and school-based practices. Relatedly, work using constructs such as Figured Worlds (Holland, 2001) has begun to specify some of the mechanisms by which students negotiate roles and responsibilities in the classroom, as well as the social power that goes along with them (e.g. Esmonde & Langer-Osuna, 2013).

Despite their different approaches and arguably different goals, each of these strands of research makes contact with a fundamental question: What happens when two or more cultural modes come into contact and must be negotiated in situ by participants? In order to begin to address this question more explicitly, this analysis draws on Positioning Theory (van Langenhove & Harré, 1999) and Framing (Goffman, 1974) to address a more circumscribed corrolary: How do students in an informal learning space negotiate answers to the question "What is going on here?" In their work to refine Positioning Theory as it applies to mathematics education research, Herbel-Eisenmann et al (2015) specifically call for attention to timescales in discussions of the storylines that students recruit, as well as more explicit empirical grounding for claims. Drawing on interactional analysis of a single pair of students within a single week of data collection at a math-focused knitting camp, initial findings suggest that 1) specific tools and constraints tend to re-Frame an interaction as being "school math", and 2) student-initiated questions are more likely to subsume mathematics instrumentally into the current Frame.

MATH MATTERS: FIGURING MATHEMATICS LEARNING SPACES AROUND IMPORTANCE, UTILITY, AND SMARTNESS

Missy D. Cosby
Michigan State University
mcosby@msu.edu

Oyemolade Osibodu
Michigan State University
mosibodu@msu.edu

Keywords: Affect, Emotion, Beliefs, and Attitudes

Perceived mathematics ability is a valuable commodity. Those perceived to possess it are more positively positioned in mathematics learning spaces than those who do not which has implications for equity in access to mathematical ideas and participation. We know from research that perceived smartness has consequences for teacher expectations and academic identity development, among other things (Hatt, 2012). Using figured worlds (Holland, Lachicotte, Skinner, & Cain, 1998), we examine the as-if world of two groups of elementary grade students to understand their notions of smartness, mathematics utility, and mathematics importance. To further explicate the collective mathematics identity at play in this figured world, we utilize the first two components of Martin's (2000) framework of mathematics identity: beliefs about their ability and beliefs about its instrumental importance. Not much is known about elementary age student beliefs about ability or smartness in mathematics or the utility of mathematics. In this study, we employ stanzas to analyze the presence and deployment in these mathematics learning spaces of smartness and utility through cultural artifacts, actors in the space, and valued outcomes (Holland et al., 1998). We ask: How do elementary grade students figure their mathematics learning spaces in ways that demonstrate their beliefs about smartness, utility, importance, and demonstrations of mathematical competence?

Several focus groups of approximately five to six students were conducted across two urban elementary school classrooms, one second grade and one fourth grade, as part of a larger, ongoing research project. The focus group interviews contained three segments: 1) students drew diagrams of their happy places, 2) students used improvisation to act out what happens in their math classroom, and 3) students answered questions about their mathematics classroom learning. We used theoretical framing related to situated meanings, social languages, figured worlds, and Discourses (Gee, 2014; Rogers, 2011), coupled with a critical approach to discourse analysis of the focus group transcripts for our investigation. Preliminary findings reveal that teacher actions, various student behaviors, and summative assessment grades play a major role in students meaning-making about mathematical competence. These young mathematics learners overwhelmingly expressed the importance of mathematics, yet this emphasis on importance was restricted to school mathematics learning and practical uses such as counting money or use in future occupations.

STEM RETENTION FOR DEVELOPMENTAL MATHEMATICS STUDENTS: AFFECTIVE TRAITS AND A PEER-MENTORING INTERVENTION

Edgar Fuller
West Virginia University
ef@math.wvu.edu

Jessica Deshler
West Virginia University
deshler@math.wvu.edu

Marjorie Darrah
West Virginia University
mdarrah@math.wvu.edu

Keywords: Affect, Emotion, Beliefs, and Attitudes; Learning Theory, Post-Secondary Education

Students beginning their mathematical studies prior to calculus must master several areas of mathematics in order to reach the level expected for a STEM degree. Yet, nationally, 42% of students enter college at a mathematical level below what is needed for science, technology, engineering and mathematics (STEM) degrees (Radford, Pearson, Ho, Chambers & Ferlazzo, 2012). From 2015-2017, we studied the success and persistence of college students not yet ready for college-level mathematics. We specifically examine mathematics anxiety of students in a pre-college algebra course and the effects of a peer-mentoring program on their success.

The potential for experiencing mathematics anxiety that will impact performance is high (Ashcraft & Krause, 2007; Hembree, 1990) and can create a barrier to entry into STEM disciplines. To examine how affective states such as anxiety impact student success and persistence, we collected survey data from 404 students and compared responses to outcomes and to persistence in their majors. We found that anxiety impacts student success in measureable ways. A one-unit increase in anxiety on our scale (Alexander & Martray, 1989) showed a 1.30% decrease in success likelihood (p=.0003), and a greater decrease in female students (2.08%, p<.0001). Additionally, we found the impact to be more significant for non-STEM intending students (1.52% decrease per unit, p=.0004) than for STEM intending (0.70% with p=.324).

To further support these students, we implemented a peer-mentoring program in the second year of this study. We found the program supported success in STEM coursework but that its impact on STEM intending students was mixed. In a one-semester implementation with N=54 students completing the mentoring process, we observed success rates in the course of 83.3% for the mentored group compared to 75% for the non-mentored population. On the other hand, we found that STEM majors in the mentored group persisted to the subsequent term at a rate of 68.8% while in the non-mentored group 80.4% continued.

Our initial conclusions indicated that as previously observed at other levels of mathematics, anxiety plays an inhibitory role in student performance, and that its impact is more pronounced in our female population and in non-STEM intending students. We find that peer-mentoring supports student success, but that its impact on STEM persistence was not as clear, suggesting that we should more pointedly target these students in the mentoring work.

STUDENT DISENGAGEMENT IN CALCULUS: IMPLICATIONS FOR MEASUREMENT AND QUANTITATIVE RESEARCH

Daria Gerasimova
George Mason University
dgerasim@gmu.edu

Margret Hjalmarson
George Mason University
mhjalmar@gmu.edu

Substantial research has shown that student engagement and disengagement with academic work predict student learning outcomes (Fredricks, Blumenfeld, & Paris, 2004; Skinner, Furrer, Marchand, & Kindermann, 2008). However, less attention has been paid to the ways in which students disengage and to the reasons for their disengagement. Nevertheless, understanding that may help advance the knowledge of quantitative relationships. Thus, the following question guided this exploratory study: How and why do students disengage in a Calculus classroom?

Data for this study were collected via semi-structured interviews. Participants were five demographically diverse students enrolled in the same section of the first calculus course in a three-course sequence. This section was chosen because it was taught via multiple instructional methods. Specifically, instruction included both lecturing and group work, thus allowing us to interview students about their engagement during instructionally different parts of the class.

The analysis revealed three types of student disengagement. The first type is disengagement that may be potentially detrimental for student success in the course. It can be selective when students decide to disengage in response to a particular activity (e.g., a student may stop listening to the instructor if explanations are perceived to be unnecessary long or complex). Potentially detrimental disengagement can also be non-selective when a decision to disengage does not have a specific trigger (e.g., a student may stop listening because s/he got tired or distracted). The second type is alternative engagement, which may or may not have negative implications for student success in the course. This type occurs when a student disengages from one activity but engages in a different (yet relevant) activity instead. For example, a student may decide not to answer instructor's questions out loud but, alternatively, answer them in his/her head. The third type is disengagement that may be potentially non-detrimental for student success in the course. This type can occur when engagement is perceived to be unnecessary (e.g., when a student already knows the material), unproductive (e.g., when listening leads to confusion), or not cost-effective (e.g., when asking a question outside of class is easier). Potentially non-detrimental disengagement can also occur when disengagement is perceived to be unavoidable (e.g., not working on a task because of being stuck).

The presence of these disengagement types suggests that the relationship between students' engagement and their success in the course may differ depending on how and why students disengage. In other words, the types of student disengagement may moderate this relationship. Thus, exploring it without considering the types of disengagement may not provide a full picture.

INFLUENCING FACTORS THAT APPEAR IN THE TRANSITION FROM MONTESSORI MATHEMATICS TO TRADITIONAL METHODS

Zachariah B. Hurdle
Southern Arkansas University
ZBHurdle@saumag.edu

Keywords: Affect, Emotions, Beliefs, and Attitudes; Curriculum Analysis; Elementary School Education; Metacognition

The purpose of this study is to investigate three particular aspects that could affect the transition between a third grade Montessori style and a fourth grade non-Montessori style classroom, specifically within the context of teaching and learning mathematics. These aspects are (a) the change in pacing and structure of the classroom, (b) the removal of manipulatives from the learning experience in favor of handwriting methods, and (c) the reversal of roles that teachers and students occupy. While post-transition effects are well documented, research is limited in analyzing learning during the transitional phase *out* of Montessori programs. The Montessori method relies on self-regulated young learners taking advantage of themselves, their environment, and their experiences—therefore metacognition is used as the theoretical framework for the research. Commonly found in Montessori classrooms, manipulatives (tangible objects used to "manipulate" and physically represent mathematical situations) are often used in three main stages: concrete, representational, and abstract—a gradual shift that maintains student understanding. This qualitative study is guided by the following research questions:

1. To what teaching practices and learning opportunities are third and fourth grade students exposed? To what extent are these practices and learning opportunities related to the Montessori approach?
2. How are three particular aspects of current teaching practices and learning opportunities in fourth grade mathematics perceived by students and teachers compared to previous exposure in the Montessori style?
3. How, and to what extent, does changing these teaching practices and learning opportunities affect the problem-solving strategies of students?

The effect of this transition on problem-solving skills is analyzed through a series of Cognitively Guided Instruction problem-solving exercises to determine mathematical understanding about key concepts within the curriculum; other tools are modified for observations and interviews related to curriculum exposure lined up to theory. Results show that students identify alternative strategies when uncertain how to proceed in a problem. Students revert to previous object-centered methods when a problem is perceived as too difficult. Documents and dialogue show that students use the concept of manipulatives in unfamiliar situations, even if they do not recognize the process. Students also need more exposure with materials for difficult and alternative topics during the Montessori ages. The use of manipulatives is one of the most influential aspects of the transition, followed by the shift in defining student and teacher roles. The pacing and structure of the classroom has minimal effect on the transition.

POWERFUL KNOWLEDGE: LANGUAGES AND IDENTITY IN CHILDREN'S MATHEMATICS LEARNING THROUGH FAMILY WORKSHOPS

Cristina Valencia Mazzanti
University of Georgia
crisvm6@uga.edu

Martha Allexsaht-Snider
University of Georgia
marthaas@uga.edu

Keywords: Equity and Diversity, Early Childhood Education, Informal Education

Educators and researchers concerned with equity in mathematics education have argued the need to view mathematics and schooling through parents' eyes, and in particular, to consider Latino and other immigrant parents as intellectual resources, recognizing their knowledge and experience as important resources in mathematics teaching and learning (Civil, 2007). The goal of this study was to consider what we learned from a series of family workshops in light of the following research question: How can we create diverse spaces for family engagement that support mathematics learning and draw on the wide range of knowledge and experiences that immigrant families bring to their young children's education?

The family workshops took place over a semester and were designed for Latino families with children in elementary school; six families participated regularly (6 adults, 11 children). Instruction was provided in Spanish and focused on mathematics and language acquisition. Researchers and volunteers recorded data during and after the workshops through note taking; photographs of activities and completed work were also collected. We drew on hermeneutics to understand and analyze the data. We worked together to identify significant events and then to interpret and understand them. A hermeneutic perspective allowed us to look closely at the data and to disrupt it through purposeful interpretation, questioning assumptions about the knowledge and languages Latino families bring to their children's mathematics learning.

In the family sessions, we created a space where parents and children worked together on enjoyable mathematical activities that were new and unfamiliar and that required them to draw on previous experiences. The activities were constructed so that parents and children were positioned as experts, teaching one another. For instance, during a game board construction activity parents relied on the knowledge their children had gained at school while children relied on their parents to implement complex rules and mathematical concepts in their games in both Spanish and English. As parents and children were positioned as experts, they created a space in which they were reflected in each other but also saw each other as a new reality to be learned. This process began with the understanding that constructing diverse mathematics learning spaces that support and draw on a wide range of knowledge starts with seeing families and children as people who have rich knowledge and experiences. When conceptualizing the workshops, we also considered education as an issue of equity and identity. We positioned Spanish as the dominant language in the learning space, allowing parents and children to draw on different knowledge and experiences. This challenged everyone in the workshops to explore tensions inherent to speaking Spanish in the U.S., as well as to make experiences with languages powerful knowledge in the context of mathematics learning.

EXPLORING THE RELATIONSHIP BETWEEN PEDAGOGICAL APPROACHES AND STUDENTS' MATHEMATICS IDENTITY DEVELOPMENT

Paran R. Norton
Clemson University
pfisch@clemson.edu

Karen A. High
Clemson University
khigh@clemson.edu

Keywords: Affect, Emotion, Beliefs, and Attitudes, Instructional Activities and Practices

Introductory college calculus has been shown to be gatekeeper course for STEM majors (Suresh 2006), and research continues to show that Calculus I "lowers students' confidence, enjoyment of mathematics, and desire to continue in a field that requires further mathematics" (Bressoud 2015). One possible reason for this continued problem is a lack of research pertaining to the relationship between instructional practices and students' mathematics identity development. Cobb (2004) calls for more research on how students are developing identities in their mathematics classroom since, "mathematics as it is realized in the classroom appears to function as a powerful filter in terms of identity" (pg. 333). This is important since students' mathematics identity strongly predicts their career choice in a STEM field (Cribbs 2012).

This study will report the qualitative piece of a larger mixed methods study aimed at comparing students' mathematics identity in a traditional lecture and an active learning calculus classroom. Twelve semi-structured interviews were conducted to explore students' perceptions of the pedagogy used in their introductory calculus class. We will use the interpretive scheme developed by Cobb and Hodge (2011) to explore the normative identity established by the pedagogical methods as well as students' personal identities which are "concerned with who students are becoming in particular mathematics classrooms" (pg. 190).

Another theoretical framework that will be used to explain students' personal identities is self-determination theory (SDT). Deci and Ryan (2000) state, "human beings can be proactive and engaged or, alternatively, passive and alienated, largely as a function of the social conditions in which they develop and function" (pg. 68). They stress the importance of doing research on the design of social environments (such as a classroom) in order to determine the best conditions for optimizing "people's development, performance, and well-being" (pg. 68). Deci and Ryan identified three needs that are essential in fostering people's development: competence, autonomy, and relatedness. Preliminary analysis revealed that the active learning environment provided more opportunities that promoted students' feelings of competence, autonomy, and relatedness than students in the traditional lecture classroom described.

COGNITIVE AGENCY AND COMPUTER-BASED TASKS

Meghan Riling

mriling@bu.edu

Keywords: High School Education, Cognition, Technology

As computer-focused policies and trends become more popular in schools, more students access math curriculum online. While computer-based programs may be responsive to some student input, their algorithmic basis can make it more difficult for them to be prepared for divergent student thinking, especially in comparison to a teacher. Consider programs that assess student work by judging how well it matches pre-set answers. Unless designed and enacted in classrooms with care, computer-based curriculum materials might encourage students to think about mathematics in pre-determined ways. How do students approach the process of mathematics while using online materials, especially in terms of engaging in original thought?

Drawing on Pickering's (1995) dance of agency and Sinclair's (2001) conception of students as path-finders or track-takers, I define two modes of mathematical behavior: trail-taking and bushwhacking. While trail-taking, students follow an established approach, often relying on Pickering's (1995) *disciplinary agency*, wherein the mathematics "leads [them] through a series of manipulations" (p. 115). The series of manipulations can be seen as a trail that a student may choose to follow. Bushwhacking, on the other hand, refers to actions a student takes of their own invention. It is possible that, unknown to the student, these actions have been taken before by others. In bushwhacking, the student possesses agency, which Pickering (1995) describes as active (rather than passive) and as hallmarked by "choice and discretion" (p. 117).

In this study, students worked in several dynamic geometric environments (DGEs) during a geometry lesson about the midline theorem. The lesson was originally recorded as part of a larger study designing mathematically captivating lessons. Students accessed both problems and online addresses for corresponding DGEs via a printed packet. Students interacted with the DGEs on individual laptops, but were seated in groups of three or four. Passages of group conversations in which students transitioned between trail-taking and bushwhacking were selected for closer analysis, which involved identifying evidence of each mode and highlighting the curricular or social forces that may have contributed to shifts between modes.

Of particular interest were episodes in which students asked one another to share results, which led to students reconsidering previously set approaches, and episodes in which students interacted with DGEs containing a relatively high proportion of drag-able components, which corresponded to some students working in bushwhacking mode, spontaneously suggesting and revising approaches for manipulating the DGE (e.g., "unless you make this parallel to the bottom, but I don't think you… yes you can."). Both types of episodes were found in multiple groups' conversations. Further analysis of student interactions with tasks, especially with varying levels of student control and sharing, could serve to inform future computer-based task design aimed to encourage students to productively engage in bushwhacking while problem-solving.

Why do secondary students in the US consistently and increasingly report a lack of interest in mathematics? Lack of interest in mathematics has been well documented by the TIMSS studies; students' dissatisfaction with mathematics more than doubled by 2011, when 40% of 8th graders reported not liking math, up from 18% as 4th graders in 2007. And, sadly, the trend appears to be worsening. In 2015, 47% of 8th graders indicated not liking math, up from 22% as 4th graders. In order to positively impact student attitudes towards mathematics, it is important to understand factors that may influence secondary students' relationship with the discipline. This poster presents findings from an exploratory study of student disposition toward mathematics.

We designed an online survey to learn about students' relationship with mathematics, including experiences and settings that contribute to both positive and negative feelings about the subject. We surveyed 275 students, grades 9 to 12, in 11 classes in three schools in three New England districts. Though not randomly chosen, this sample allows us to examine student attitudes across a variety of contexts. We asked students about their feelings towards mathematics over the years, as well as which aspects of class they most enjoyed or disliked. Finally, we included items from the TRIPOD survey (Wallace et al., 2016) and the 2015 NAEP survey, which allows us to compare our sample with the national sample.

Initial results indicate that student view their teachers and the topics of study as the central factors influencing their enjoyment of mathematics class. We found a correlation between responses that math is boring and that it is not relevant. Students who like math and those who do not reported different class activity preferences. For example, students who like math reported disliking watching a video in class, while students who dislike math reported disliking learning something new. Both groups of students (those who like math and those who do not) dislike math class when they have to present work to classmates, but hold positive views of solving puzzles and working with other students. Technology seems to appeal equally to both groups. Students who reported disliking math also look forward to playing competitive games. We saw no evidence that gender or race corresponded to students' level of appreciation math. Finally, students reported liking math class less in high school than in middle school.

Identifying factors that influence secondary student mathematical dispositions can inform curriculum designers seeking to improve mathematical attitudes. Future studies can learn if new curricular designs can change student relationships with mathematics to reverse recent trends.

CHARACTERIZING ABSTRACT ALGEBRA STUDENTS' EPISTEMOLOGICAL BELIEFS ABOUT MATHEMATICS

Rachel L. Rupnow
Virginia Tech
rachr15@vt.edu

Keywords: Affect, Emotions, Beliefs, and Attitudes; Post-Secondary Education

Epistemological beliefs about mathematics focus on students' views of the nature of mathematics. Researchers have asked K-12 students, non-math major freshmen, math majors, and faculty members to describe their views of mathematics directly or through metaphors (e.g. Markovits & Forgasz, 2017; Schinck, Neale, Pugalee, & Cifarelli, 2008; Szydlik, 2013; Ward et al., 2010). Students' beliefs about the nature of mathematics can affect their beliefs about what math classes should look like, including the forms of classroom and sociomathematical norms (e.g. Boaler, 1999; Cobb, Gresalfi, & Hodge, 2009). Although established classroom norms can influence students' beliefs, how students' beliefs are affected is not well understood.

This poster examines the beliefs of abstract algebra students from two classrooms, one taught using Inquiry-Oriented materials and another taught via two days of lecture and one day of "lab" in which students discussed problems in groups. Students' beliefs were analyzed through thematic analysis (Braun & Clarke, 2006) based on their responses to survey questions and open-ended questions in follow-up interviews with selected students.

Students' views of the nature of mathematics varied, but included being the study of numbers, the study of logic, and a practical problem-solving tool. Asking students to provide animal metaphors for their views of mathematics highlighted more affective views of mathematics than asking what mathematics is. (For example, "Math is like a cat because everyone either loves cats, or hates them. Everyone loves math, or never wants to touch it in their life.") Although differences between students' beliefs were expected in the two classes based on differing instructional approaches, clearer differences in responses have emerged based on students' backgrounds, such as the number of previous math classes taken, grades in previous classes, and students' majors. Reasons for such differences will be explored.

"EXPLICAME TU ESTRATEGIA": EMERGING BILINGUAL'S DEVELOPMENT OF MATHEMATICAL AGENCY IN PROBLEM SOLVING DISCUSSIONS

Juanita M Silva	Gladys Krause	Luz Maldonado

jsilva@txstate.edu	gladyshrueda@utexas.edu	l.maldonado@txstate.edu

Participating in mathematical practices supports children's conceptual development and increases achievement in the classroom (Bodovski & Farkas, 2007). However, emergent bilingual children often have limited exposure to these mathematical practices, and instead instruction promotes rote memorization and procedural knowledge without conceptual connections, or a focus on English vocabulary (Moschkovich, 2015). The term "emergent bilingual" (García & Kleifgen, 2010) identifies students not as lacking language, but instead indicates the *potential* to become bilingual over time, through schooling, and while still functioning with the home language. We build on Turner's (2003) construct of mathematical agency, defined as a moment in which a child has the power to make sense of mathematics and take ownership of their mathematical thinking. This study investigated emergent bilingual children's opportunities to exhibit mathematical agency when engaging in multilingual mathematical discussions.

Using a teaching experiment methodology (Cobb, 2000), we designed a 5-week after school program for seven third grade emergent bilingual students. All sessions were video-audio recorded and transcribed. These students were recommended by their teachers for additional support due to low scores on district exams. The afterschool math sessions focused on base ten story problems, sessions consisted of understanding the story context, solving the problem using prior knowledge, and sharing students' mathematical strategies in group discussion. The instructors specifically drew upon mathematical practices and positioning moves to engage the emergent bilingual students throughout the sessions.

We uncovered three mathematical agency categories, *limited, developing and enacting*. The *limited* category describes children using procedures without connections and little to none ownership of their thinking; the *developing* category describes children sharing their own thinking with others and trying to make sense of their math ideas; and the *enacting* category describes children making sense of their strategies used and taking ownership of their ideas. Children mostly showed *limited mathematical agency* in the initial sessions and *developing mathematical agency* throughout the rest of the study. *Enacting mathematical agency* was absent in the early sessions, but visible towards the end of the sessions. Among others, a key finding was the benefit of allowing flexibility in language choice for discussion of strategies. Our study highlights the need for further analysis of classroom instruction that builds mathematical agency of emergent bilingual students by positioning them as competent learners.

Keywords: Informal Learning Environment; Maker Education; Mathematical Practices

Making is defined as a "class of activities focused on designing, building, modifying, and/or repurposing material objects, for play or useful ends, oriented toward making a 'product' of some sort that can be used, interacted with, or demonstrated," (Vossoughi & Bevan, 2014, p. 3). Making is often pitched as a means to increase students' engagement in transdisciplinary STEM learning and career pathways (e.g., Simpson et al., 2017). In terms of mathematics, one could argue that less is known about student learning of concepts and practices in making-related environments as the majority of mathematics education and scholarship is grounded in formal learning environments (Pattison et al., 2016). This research addresses this gap in the literature.

This study was conducted in partnership with a local science museum that provided an afterschool program for six Title 1 elementary schools and set within each school. The data source from this study was video data from youths who volunteered to wear a chest-mounted Go-Pro camera. We randomly selected two videos from each day of data collection that were at least 30 minutes in length. This amounted to 44 videos. Using the work of O'Connell and SanGiovanni (2013), we developed an initial coding scheme for each mathematical practice as defined by the Common Core State Standards (CCSS, 2017; e.g., *Problem Articulation* – Determine and articulate what the problem or task is questioning).

In general, youth were more often engaged in "mathematical" practices void of mathematics. Engagement in Practice 1, *make sense of problems and persevere in solving them*, was the most common; specifically, *self-monitoring.* However, monitoring one's process and making changes when necessary (i.e., self-monitoring) looked different as youth were not engaged in doing this through mathematics. Conversely, youths were frequently engaged in doing mathematics through indirect measurement and spatial reasoning, which are not captured within the practices. Our findings highlight how the practices are not conducive to settings outside the formal classroom. This raises the question of what and whose mathematics do we privilege – school mathematics or everyday mathematics (see Civil, 2017).

In this study, we investigate the relationship between teachers' noticing and the quality of their mathematics instruction. We analyzed the conversation of seven elementary teachers around five coaching cycles and scored their level of noticing and the mathematical quality of the instruction of the lesson. We compared teachers' noticing levels with their MQI scores for each coaching cycle. One case showed discrepancy between the level of noticing and the MQI scores. In this proposal, we discuss the cognitive and psychological constructs that seemed to influence teacher's noticing including mathematical knowledge for teaching (MKT), beliefs, teaching efficacy, and emotions. Results show that each of the constructs influenced the teacher's noticing to varying degrees. Implications for professional development are discussed.

Keywords: Coaching; Mathematical Knowledge for Teaching; Teacher Efficacy, Teacher Emotion; Noticing

Effective mathematics teaching requires foregrounding students' thinking (Ball & Cohen, 1999). This requires teachers to attend to and identify how students think and use their observations to make informed decisions about how to effectively respond. Recently, a significant amount of research (e.g. Sherin & van Es, 2009) has focused on investigating teacher noticing in order to understand what and how teachers observe, how they interpret the gathered information to respond to what they observe, and how this process can be influenced. These efforts have been focused on gaining a deeper understanding of how teacher noticing supports teacher learning in efforts to improve their instructional practices (Sherin, Jacobs & Philipp, 2010).

Professional noticing of children's mathematical thinking comprises a set of interrelated skills including (a) attending to students' strategies, (b) interpreting students' understandings, and (c) determining how to respond based on these understandings (Jacobs et al., 2010). Some of the work on teacher noticing has focused on the differences in what and how teachers' notice concluding that expert teachers tend to interpret and recall classroom events with greater detail and insight than novice teachers (Sherin, Jacobs & Philipp, 2010). We also acknowledge that teachers' abilities to notice may be impacted by the nature and quality of the instruction they are observing. For example, if a teacher is lecturing with minimal input from students, which is considered to be one indicator of low quality instruction, opportunities for noticing students' thinking will be limited. In this regard, we contend that evaluations of teachers' abilities to notice should be qualified based on the opportunities the teaching event affords for high-level noticing. Thus, we were interested in examining the alignment between teachers' levels of noticing and their quality of instruction, and the factors that influence this alignment. We considered mathematical knowledge for teaching (MKT), emotions, beliefs and teaching efficacy (TE) as possible factors. We targeted the following research questions:

- Do teachers' mathematical quality of instruction align with their level of noticing?
    - If there is alignment, what factors seem to support alignment?
    - If there is misalignment, what factors seem to influence this misalignment?

Theoretical Framework

Teachers' mental lives have a significant impact on their teaching experiences (Schutz, Hong, Cross & Osbon, 2006). Surprisingly, the ways in which specific cognitive and psychological constructs, such as MKT, emotions, beliefs and TE collectively influence teachers' instructional activity including noticing, has not been investigated broadly. In what follows, we provide a brief overview of each of these constructs with a specific focus on how each may inform teachers' instructional practices.

Mathematical knowledge for teaching (MKT) encompasses deep knowledge of math concepts and the knowledge and skills to attend to students' thinking during the act of teaching, and make in-the-moment decisions about the best ways to respond to what they observe (Ball, Thame & Phelps, 2008; Hill et al., 2008.). There is also a high correlation between mathematics knowledge for teaching and the mathematics quality of instruction (Hill et al., 2008). Teaching is emotional work (Schutz, Hong, Cross & Osbon, 2006). Emotions play a significant role in teachers' relationships, instructional decision-making and overall professional well-being. According to Trigwell (2012), "there are systematic relations between the ways teachers emotionally experience the context of teaching and the ways they approach their teaching." (p. 617). In this regard, we consider that the emotions teachers experience as they engage in instructional activity, including noticing, may influence what and how they notice. Beliefs are defined as "embodied conscious and unconscious ideas and thoughts about oneself, the world, and one's position in it developed through membership in various social groups, which are considered by the individual to be true".(Cross, 2009, p. 4) They are considered precursors to actions (Pajares, 1992). Research has shown that teachers' beliefs about mathematics, learning and teaching greatly influence their practices (e.g. Cross Francis**,** 2015; Ernest, 1989). We also know that beliefs can serve as filters, orienting an individual's thoughts and ideas through a particular lens. For example, a teacher who believes that students are able to build knowledge through meaningful cognitive engagement in activity would perhaps organize her classroom activities to support inquiry and problem solving. Lastly, teacher efficacy (TE) is defined as teachers' beliefs about their capacity to affect how students learn and their perception of overall performance (Tsachannen-Moran, Woolfolk-Hoy & Hoy, 1998). It influences teachers' willingness to learn, adopt and enact particular instructional practices. TE has two components---knowledge and personal efficacy. Knowledge efficacy refers to a person's confidence in her understanding of mathematics content (Roberts & Henson, 2000), while personal efficacy describes a person's confidence in her ability to support students' learning through teaching. Teachers with strong TE tend to be flexible in their approach to teaching and are more focused in planning and organizing instructional activity.

Methods

Seven elementary teachers participated in this study. The teachers were each involved in a PD program involving five coaching cycles. Coaching involved (i) preparing teachers' for their upcoming coaching session (pre-coaching), (ii) supporting teachers during instruction (coaching) and, (iii) debriefing instruction after the coaching session (post-coaching). All conversations were audio-recorded and the coaching sessions were video-recorded. Data sources included (i) audio and videorecordings from the coaching cycle, (ii) scores on mathematical quality of instruction instrument (MQI) (see Hill et. al, 2008), (iii) interviews prior to the start of the coaching that provided data about the core constructs described, and (iv) quantitative results of their teaching efficacy and emotions. Pre-coaching conversations were analyzed to determine teachers' knowledge (about the topic to be taught in the coaching session), efficacy and emotions related to the upcoming coaching session. Coaching session videos were analyzed using the MQI instrument to determine the quality of instruction along four core dimensions. A second round of analysis of the coaching video was done to determine the MKT (specifically common content knowledge (CCK), knowledge of content and students (KCS), specialized content knowledge (SCK) and knowledge of content and teaching (KCT) – (see Ball, Thames and Phelps (2008) for full descriptions) specifically focusing on their knowledge of mathematics being taught in the lesson, instructional strategies and students' thinking and the ways they enacted this knowledge during instruction.

In preparation for the coaching conversations, teachers were asked to identify three instances during the lesson that they found interesting or significant. Post coaching conversations were used to identify the clips the teachers selected which were analyzed for their noticing levels using Van Es' (2011) framework. Then we examined both the MQI scores and noticing levels per coaching cycle (Table 1) to determine the degree of alignment. Analyses of pre- and post coaching interviews determined the emotions, knowledge and beliefs related to the coaching session. Teachers also completed the adapted SETAKIST (Self-Efficacy Teaching and Knowledge Instrument for Teachers of Mathematics) (see Roberts & Henson (2000) for description of the instrument) to determine their knowledge and personal efficacy.

Findings & Discussion

The corpus of data were examined for the seven teachers and presented in Tables 1 and 2. In Table 1, we show the data from the coaching video where they have the highest MQI score and the accompanying noticing level for that instructional video.

Table 1: Alignment between teachers' instructional quality and their noticing level

Teacher	**Noticing Level**	**MQI** (for items that align with noticing framework)	**Alignment/Misalignment**
Bill	3.7	2.5	H/H - alignment
Laura	3	3	H/H - alignment
Anthony	1.5	1	L/L - alignment
Wilma	1.6	3	L/H - misalignment
Katie	1.3	3	L/H - misalignment
Jessica	1.8	3	L/H - misalignment
Sarah	1.7	2.5	L/H - misalignment

L - low; H - high

In the cases of Bill, Laura and Anthony, there was alignment between the quality of their instruction and the level of noticing. We have discussed these findings elsewhere (Cross Francis, Eker, Lloyd, Lui & Alhaayan, 2017). In this proposal, we will focus on the cases where there was misalignment between the teachers' quality of instruction and their level of noticing. For the purposes of this proposal, we present the analyses of the case of Katie. We considered this misalignment particularly noteworthy as we expected that a teacher who was able to produce relatively high quality instruction would foreground students' thinking which would be visible in how and what she noticed. To better understand the factors that may have influenced this misalignment, we examined her MKT, efficacy, beliefs and emotions.

Table 2. Results of analyses of Katie's noticing, MKT, TE and emotions

	Noticing		MQI	Emotions			Efficacy	
	What	How	Students' Productions	Before (Coaching)	During	After	KE	PE
Katie	Level 1	Level 1	3	Indifferent/Excited	Calm	Calm	High	High

MKT

The focus of the lesson was addition and subtraction of single-digit numbers. As with all of Katie's classes she began with the daily math review which consisted of questions aligned with the instructional goal of the lesson in addition to other questions related to concepts they had previously covered (e.g., number sequences). We determined her localized MKT by rating her knowledge as low, medium or high on four of the MKT dimensions – CCK, SCK, KCS and KCT. We considered both her CCK and her SCK to be strong with respect to single-digit addition and subtraction as she made no errors in solving the problems, supporting students in solving the problems or in discussing students' solutions about the problems. Katie was cognizant of the different types of subtraction problems (total unknown, initial unknown and change unknown) and their levels of complexity. Specifically, that total unknown problems are the least complex of the three and that addition can be used to verify the solution. Subtraction was a new concept for the students so Katie began with total unknown problems. She also discussed with the students the different ways of solving addition and subtraction problems – counting one by one, counting on and making items (drawing circles) to count. We considered her KCS and KCT to be low based on specific interactions with students during the instructional video and her responses to our questions referring to her thinking during those instances. In the first instance, the students were asked to solve the following problem:

Kenneth had 6 balloons. His sister popped 2. How many does he have left?
A student solved the problem and wrote:

$6 - 2 = 4$ (student put this on the board first)
$6 - 2 \neq 4$ (Student changes to this but Katie doesn't correct the student)

When asked about the student's thinking in the post-coaching conversation, Katie says he put the slash to show that he was saying that the left side is not equal to the right side. Although Katie knew the difference between both signs, she didn't think she needed to correct it. She was then shown a clip of what was written on the board for an earlier problem.

$$7 + 8 = 12 + 7$$
$$15 \neq 17$$

After seeing these two contrasting uses of the not equal sign, Katie was better able to understand how this could lead to misunderstandings for her students.

We also observed Katie's difficulties in supporting students to solve the following:

Macy had 6 cookies and she gave 2 away. How much does she have now?

Students were supplied with manipulatives to represent the problem. However, instead of being given a set of individual manipulatives (e.g., cubes) from which to select and manipulate to solve the problem, they were given a connected stack of 6 cubes to start. One student, Macy, kept adding two cubes instead of taking two away from the stack. There were several strategies that could have been employed to identify the struggle Macy was having and then to help move her thinking forward, some of which Katie employed. For example, asking a student to show how he would add some more cookies and if that is the same as taking away some cookies. However, although Macy continued to struggle, Katie essentially kept repeating the same strategy. Katie struggled to utilize other teaching approaches that would support Macy. After several minutes the coach asked Macy to show her six cookies, then suggested that she go ahead and eat two of the cookies. Macy took two of the cookies and put them in her lap. She was then able to tell the coach that she would have four cookies left. Katie commented that she didn't think of having Macy model the story. She also didn't consider having Macy separate the stack of cubes so she could represent each cookie with a cube. It's possible that Macy was not able to conceptualize the connected stack of cubes as six cubes (indication that she is not a numeric thinker/counter (Van de Walle, Karp, & Bay-Williams, 2016) but saw the stack as one unit. If Macy was not numeric, she would need individual cubes to count and solve the problem. Based on these observations in the lesson and Katie's interpretations of the events, we considered her KCS and KCT as low.

We considered this low KCS and KCT as a possible influential factor in her noticing. If Katie was not able to recognizing the range of possible reasons why Macy may have struggled to answer the question, she may not have considered this instance of students' thinking significant. Therefore, she would not have thought of it as a particularly interesting or pertinent event to discuss in the post-coaching conversation. Considering she stated that several students were struggling with subtraction, she perhaps categorized it as a part of the normal struggle students have with subtraction problems. As such, she wouldn't have *noticed* this incident as one to unpack independent of the struggles of the class more generally. Additionally, not being aware that allowing students to use the equal sign and not equal sign interchangeably may lead to a misconception would not have been significant, and therefore unlikely she would have identified it as meaningful for discussion.

Beliefs. Katie described math as problem solving and stated that math involved quantity and exploration. She believes there is always a "right" answer, but there are multiple ways to think about and solve problems. Regarding the learning of content, Katie believes that concepts need to be understood first through concrete work and manipulatives and that real contexts are important to use when teaching. She thought math can be applied to everything and that it allowed students to be creative, referencing the approaches of her first grade students. Katie stated that students are learning when they are engaged, when they ask for more, and when they can explain a concept. Katie believes students have varied abilities and learn concepts differently and as such should be allowed to talk about their thinking and make choices about tasks and activities, and the kinds of manipulatives that would support their thinking best. She considers productive struggle to be good and that students should be able to ask questions that lead to deep thinking and good conversation. Regarding her role as a teacher, she believes that when a student doesn't understand a concept, it is her responsibility and not the child's "problem." She also believes that teaching should be thought of as a learning process and teachers should be open to learning along with his/her students. Katie thinks that "teachers don't need to know every single thing" - they should start with what they know and build on their knowledge through a range of teaching experiences; similar to the way we should engage students in learning. Mistakes are okay so teachers should model how one can reason through and struggle with a problem, as reasoning is an important part of the process to developing understanding. Although Katie thinks flexibility is important, she also thinks that consistency in routines and procedures is crucial to creating a classroom that supports learning.

We observed that in providing students with manipulatives to model the problem of giving away six cookies, Katie was adhering to her beliefs that students should use manipulatives (concrete objects) to build their understanding of new concepts. As well, starting with a total unknown problem in a context that she believed reflected their own experience allowed for students to build knowledge and develop reasoning of new concepts (in this case, subtraction). These practices aligned with what she indicates are some of her beliefs about teaching and how children learn. One belief that we considered particularly salient in this instance is Katie's belief that teachers don't need to know every single thing. Similar to the way we approach students' learning, she believes that teachers can start with what they know and continue to build on that. Katie believes that mathematics embodies a way of thinking and learning for both students and teachers. She believes that learning can be spontaneous and unplanned and that lessons should be designed to reflect this. However, while this belief aligns with what the mathematics education community would regard as healthy beliefs (NCTM, 2014) they can be problematic if the teacher does not have the MKT needed to attend to this spontaneity as learning unfolds. When working on the cookies task, Katie struggled to find a teaching approach that would benefit Macy. When the coach suggested an alternate strategy to develop understanding, Katie appreciated this step and acknowledged she didn't think of that possibility. There were a range of challenges that Macy was faced with that Katie didn't appear to know how to address. Katie saw this as a teachable moment for her – one where she learned a strategy for supporting students struggling to solve single-digit subtraction problems. However, she didn't go further into investigating why this approach worked – what was it about Macy's existing mental constructions of number, addition and subtraction that caused her to struggle when Katie posed the task? Katie also didn't see it as a shortcoming that she wasn't able to support Macy in the moment; rather, for Katie this was an opportunity to learn.

Teaching Efficacy. Katie's confidence in her mathematical knowledge, accessed shortly before the coaching experience, is relatively high with a 3.875 (5 is the highest). In the follow-up interview she stated that although she was fairly confident in her mathematical knowledge she still felt that she had "room for growth and improvement." The use of the words "growth" and "improvement" can be interpreted as indicators that Katie may be more open for learning new mathematics and expanding her knowledge of mathematics, however she was not specific about what aspects of mathematics she still needed to improve but spoke more generally. This may suggest that Katie did not have a clear idea of what she did not know or should know as a math teacher and where exactly she needed to improve her knowledge.

With respect to her personal teaching efficacy, Katie was less confident in her ability to support her students' math learning through her teaching. Her score on the survey was 2.25, which is lower than mid-range based on the scale. During the interview, she explained that: "I guess I feel like since I didn't have very strong math instruction [as a student], that I'm still trying to learn structure as a teacher. And I just question it [my teaching ability] because I know that my [own] math instruction wasn't very strong." Katie was not as confident about her teaching ability as she felt she didn't have very good teacher role models when she was a student. As such, she is still trying to develop structure as a teacher, which for her refers to classroom management, grouping strategies and lesson implementation format. It's notable that she did not include analyzing and effectively utilizing students' thinking as a core concern of teaching. In this regard, if classroom features are of primary concern, this may explain her noticing score as she would be more focused on classroom-related issues and how the students are functioning as a group.

Emotions. During the pre-coaching conversation, Kim mentioned that the score of 4 on the anger scale was because the time allotted for math was limited and she was generally displeased with the misbehavior of the students. Her concern with students' misbehavior was also raised in a subsequent pre-coaching conversation where she stated that "Oh, I'm always a bit anxious about the students' behavior." As a result, she finds that she often spends a significant amount of time dealing with disciplinary issues which leaves less time to focus on the students' mathematical ability. A third factor that contributes to this score is that fact that the expectation of the administration, according to Katie, is unreasonable. She stated that the administration expects all the schools in the school district to teach a specific number of mathematics topics within a specific time period, although the students at the respective schools are at different levels of mathematical ability.

With respect to pride (which is 2.5), Katie noted that the reason this score is mid-way is because she tends to set a high standard for students in terms of their mathematics proficiency. Therefore, if after teaching a particular lesson, there is still a gap in their understanding, then she takes full responsibility for such outcome. So, she gave that score because at this point her students tend to have more gaps than she is satisfied with. When describing her emotions with respect to the teaching of the lesson, Katie notes that she feels indifferent. She states that "teaching is what I do for a living", so there is nothing special about teaching this upcoming lesson to her students. However, she mentions that she is excited that someone is going to observe her teaching. This is because even though she has been teaching a long while, she believes that there is always room for improvement and she thinks the feedback would be useful. Moreover, she is willing to learn new ways of teaching different mathematical concepts.

During the post coaching conversation, Katie noted that she felt good about the lesson as students were more engaged and they were able to work more independently in exploring mathematical ideas. She mentioned that she was expecting this type of outcome and so she was not overly excited by the successes or challenges the students demonstrated during the lesson. It didn't appear that she had any curiosity, excitement or disappointed related to Macy's struggle. She seemed not to consider it significant so for her it seemed not to warrant any increased pleasant or unpleasant emotion. We considered her emotional response noteworthy for two reasons, (i) if she had anticipated the outcome, why was she not better prepared to support Macy, and (ii) she did appear to have some excitement and interest in the approach that worked with Macy however, the heightened emotional response did not later deem the event significant for discussion.

Implications

Our analyses showed that although a teacher is able to orchestrate instruction that is of fairly high quality, that doesn't guarantee that he/she will readily identify meaningful instances of students' thinking as significant. This may indicate that teachers may enact high-quality teacher moves drawing on knowledge that is more tacit than explicit. We also observed that there were several factors that seemed to influence Katie's ability to notice students' mathematical thinking to some degree. They seemed to serve as filters focusing attention on more general aspects of classroom activity and not on students' mathematical thinking. As such, they are important factors that need to be considered in teacher development work on noticing specifically, and on instruction broadly. This also underscores the notion that teaching is complex and multi-layered, and that there are a range of factors that influence what a teacher identifies as meaningful or worthwhile instructional events to varying degrees. Although our study focused on the factors that influenced Katie's ability to notice, we believe that the research literature supports that these factors would be influential on other core aspects of teachers' work. We suspect that across teachers the degree of influence varies which would suggest that professional development work be more individualized, first building knowledge of how these constructs influence a teacher's instructional activity, then drawing on this knowledge to inform the approach to be used to support the teacher. Coaching is one professional development model that can support this kind of work.

Using mixed-effects regression, we analyzed teachers' responses to a multimedia survey of instructional practices in posing proof problems in geometry. Teachers described and rated for appropriateness three different ways of involving students in deciding what to prove, including one in which the teacher chooses the givens and the conclusion to prove, and two others that expand the students' role in different degrees. While teachers recognized the former as normative, their ratings identified an alternative as more appropriate, having more positive value, and less negative value than the normative one. This alternative has students propose the givens or the conclusion to prove, and it allows the teacher to control the complexity of instruction by endorsing one proposal before students are to write the proof.

Keywords: Instructional activities and practices, Reasoning and proof, Research methods

Proof plays many roles in mathematics; among them is that of being a method for the discovery of new knowledge (de Villiers, 1990; Lakatos, 1976). Inasmuch as mathematical knowledge is usually represented in the form of conditional propositions (i.e., a conclusion is claimed as necessarily true if certain conditions or hypotheses are taken to be true), the creation of this mathematical knowledge involves both conjecturing a conclusion that can be asserted as true and hypothesizing the conditions that need to be assumed for that conclusion to be necessitated. A conclusion may be intuited as something that is only sometimes true, and one might search for what conditions might make the conclusion is necessarily true. At times, less conditions might also be sufficient to claim the same conclusion, while at other times less conditions may only allow one to make a weaker claim. In all of that, one exercises logical deduction as the process of making a valid inference based on two or more true premises, yet one does more than that: As Lakatos (1976) explained, one engages in a heuristic process of finding out what could be reasonably true. But, while this is part and parcel of mathematical work and quite relevant to making and critiquing mathematical arguments and modeling with mathematics as expected by the Standards for Mathematical Practice (Common Core State Standards Initiative, 2010), students rarely have opportunities to engage in such work in school (Stylianides, 2009). Why would those opportunities be scarce? How could such opportunities be created?

Our work examines those questions from the perspective of the teacher's management of the complex work of having students do proofs. Our goal in this to show that, from the teacher's perspective, there is a way in which the students' share of work could be expanded without compromising the teacher's capacity to manage the work. We document below how the literature has taken care of both curricular and learning perspectives on this matter. Yet, understanding whether opportunities like that are viable also requires consideration of the demands that such work places on the teacher.

Review of Literature

The mathematical work that students do in classrooms can be understood using frameworks associated with the instructional triangle (Cohen, Raudenbush, & Ball, 2003; Herbst & Chazan, 2012). Students' interaction with content happens especially in the context of problems and tasks. The choice of such problems is made by the teacher, whose work involves having students do work that puts them in interaction with target content.

Prior research has looked at the nature of the proof tasks that are afforded to students. Herbst's (2002) historical research showed that while a wide variety of opportunities for students to do original proofs emerged in the third quarter of the 19th century, some including the search for reasoned conjectures described above, the proof exercises in use by the early 1910's already consisted of separated sets of *given* and *prove* statements provided to students. Though efforts have increased to provide more opportunities to reason and prove in a variety of ways, such as with reform-based curricula, studying one such project Stylianides (2009) found that opportunities to find patterns and pose conjectures were low compared to opportunities to engage students in providing rationales. In an analysis of six secondary geometry textbooks, Otten, Gilbertson, Males, and Clark (2014) found that only between 5% and 20% of problems involved the construction of a proof, and most of those involved proving general or particular claims rather than constructing conjectures. In contrast, in a study of grade 8 Japanese geometry textbooks, Fujita and Jones (2014) found a significant portion of exercises providing opportunities for students to conjecture and discover properties. These exploratory problems typically came at the beginning of a lesson, so that by the time students prove or justify at the end of the lesson, they had already explored and investigated the facts on their own. Cirillo and Herbst (2012) have proposed some alternative problems that could be used to engage students in an expanded scope of work, where they could either produce the conclusion of a set of givens, or the givens needed to prove a particular conclusion. We surmise that the viability of these proof problems hinges on more than having such proof problems though. In particular, one might wonder whether students are able to do such work.

The second vertex in the instructional triangle is the student whose interactions with the content happen particularly in the context of their work on tasks. The literature on students thinking and learning reveals students' potential but also their difficulties with proof. Investigations on students' thinking have revealed that students, even at the elementary level, are capable of constructing arguments and proofs (Ball & Bass, 2003; Lampert, 1992; Reid, 2002). Teaching experiments (Norton, 2008) and classroom observations (Ellis, 2007) suggest students can be engaged in making reasoned conjectures. Yet, research has also shown that students sometimes take properties to be true on account of intuition and experience, not seeing the need for proof (Chazan, 1993). This might suggest that problems in which students have to figure out what might be true, might not so easily lend themselves to engaging them in proving.

The third vertex in the instructional triangle is the teacher. One way to inquire on the viability of engaging students in better proof problems might hinge on inspecting what teachers know about proof. Knuth (2002a) found that while secondary teachers acknowledged different important purposes of proof, they failed to recognize proof as a tool for learning mathematics. They also had difficulty knowing what constitutes a robust proof, failing to recognizing non-proofs and making judgements based on the form of an argument instead of the soundness of the reasoning. In a study of the mathematical knowledge for teaching (MKT) needed to teach proof, Steele & Rogers (2012) illustrated how secondary teachers' understanding of proof affected the way the teacher positioned students - namely as creators, "but only in the sense that they provided reasons for a set of predetermined steps" (p. 175). Teachers' attitudes towards students' ability to do proofs also play a role in what proving opportunities are presented to students. We aim to investigate ways to promote the creation of these opportunities for students in a way that teachers deem appropriate.

While the literature has been progressively relying on more classroom data, it has been common to frame issues of proving in the classroom in terms of having or not having resources, be those resources curricula, abilities, attitudes, or knowledge. In our work we have been interested in addressing the problem of students' share of work from a perspective centered on the complexity of the management of classroom instruction. While a teacher may or may not have resources with which to deal with such complexity, they are likely to have means to appraise that complexity and to relate to different practices that might differ amongst themselves by the amount of such complexity. We identify one complexity associated with expanding the work of students in proving here, then we describe how we studied it.

If we start from the nature of the task, we could wonder how teachers might relate to the possibility that students might come up with the proposition to be proved. One first complexity has to do with framing the problem. A teacher is likely to need to do more than identifying the goal of the task (to prove a proposition); some specifics of the thematic territory for the proposition to be proved may need to be identified. For this reason, Cirillo & Herbst (2012) proposed problems that expected students to provide the givens or the conclusion, but providing some of those resources. A second complexity draws on Doyle's (1986) characterization of classrooms as complex environments partly on account of the simultaneity of events. This complexity points to the number of possible responses that could ensue if the teacher asked students to propose what could be the givens or the conclusion to prove: If students had to come up with givens, many students could come up with many different sets of givens. A discussion of which set of givens makes the proposition stronger could be desirable; but managing such discussion might make the work of the teacher harder, especially if students invested themselves in proving different propositions that ended up not all being equally valuable. This work might be especially difficult to manage in classrooms where the norm may be one of accepting a variety of solutions to problems.

Based on prior exploratory work (e.g., Aaron & Herbst, 2017), we conjectured that teachers can appreciate having problems in which the students' scope of work on proofs extends beyond deductive reasoning, to conjecturing a conclusion or hypothesizing the givens. We also conjectured that teachers would perceive the need to manage the complexity of the multiple responses and would appreciate the opportunity to collect the students' thoughts and endorse the proposition whose proof will be written. While such work may still maintain something of a separation between conjecturing and proving (Aaron & Herbst, 2017), it may make it manageable for a teacher to engage students in doing work that is more authentic than current work on proof.

Method

We studied this question using three sets of scenario-based instruments, all related to the hypothesized norm that in proof problems the teacher is responsible for providing the givens and the prove statement, for which we had collected empirical evidence in a pilot study (Herbst, Aaron, Dimmel, & Erickson, 2013). Each instrument consisted of four item sets and each item set included a scenario of instruction, represented using a storyboard, and questions about the actions in the scenario: Participants were asked to describe what they saw happening, then to rate the appropriateness of the teaching they saw. One set of scenarios (DP-C) included only episodes of doing proofs in which the teacher took responsibility for providing the givens and prove statement (as expected by the hypothesized norm). A second set of scenarios (DP-GP) included only episodes where the teacher allowed the students to come up with the givens or the prove statement (a breach of the hypothesized norm). And a third set of scenarios (DP-TSGP) where the teacher again allowed students to propose the givens or the prove statement but also endorsed one of those proposals as the proposition for the whole class to prove.

Open responses to all scenarios were coded in two different ways. On the one hand, they were coded for whether or not they contained evidence that the respondent recognized the teacher's enactment of the norm (in the DP-C case) or its breach (in the DP-GP and DP-TSGP cases). On the other hand, each of those descriptions were coded for the presence of positive appraisals as well as negative appraisals of what the teacher was doing in the scenario (relying on Martin & White's, 2005, appraisal theory). All those coding operations had moderate interrater reliability. Three measures were derived from such codes, which we call *norm recognition* (INR), *positive appraisal* (PA), and *negative appraisal* (NA), all of them ranging from 0 to 4 in each instrument. Additionally, participants rated each scenario for appropriateness (AT) on a scale 1-6, with 1 being very inappropriate and 6 very appropriate.

Our conjectures included that (1) scores on INR(GP) and INR(TSGP) would both be larger than INR (C), indicating that participants noticed that both sets of scenarios breached the norm, but (2) AT(TSGP) would be larger than both AT(GP) and AT(C), which would be consistent with the conjecture that teachers preferred to expand the students' scope of work if the diversity of student proposals could be made more manageable. Appraisal scores were predicted to provide additional evidence: We conjectured that (3) PA(TSGP) would be larger than PA(GP) and PA(C) while (4) NA (TSGP) would be smaller than NA(GP) and NA(C). These conjectures would align with the interpretation that teachers would see value in expanding the students' share of labor in proof problems if the complexities that ensued from such expansion could be managed. We tested these conjectures running mixed effects regression models.

Data

Data comes from a nationally distributed sample of U.S. high school mathematics teachers. Instruments were administered in 2015-2016 through the LessonSketch (www.lessonsketch.org) online platform, where they could peruse scenarios and answer questions. There were 525 participants who completed at least one of the three instruments, and 347 participants who completed all three instruments. Most of the participants who completed all three instruments were white (86%) and female (61%), which is similar to the demographics of secondary high school teachers in the US. On average, participants had been teaching secondary mathematics for 14.7 years (SD = 8.69, min = 1, max = 40).

Results

Descriptives are shown in Table 1. Of the 525 participants who completed the DP-C instrument, 83.4% ($n = 438$) recognized the compliance of the norm at least in one scenario. Of those recognizers 40.4% ($n = 177$) provided at least one positive appraisal for this compliance, while 33.3% ($n = 146$) provided at least one negative appraisal of the compliance (both groups are not necessarily disjoint as any one recognition statement could be accompanied both by positive and negative appraisals). The mean positive appraisal scores was 1.24 (SD = 0.53) and the mean negative appraisal score was 1.17 (0.43), where both measures have a possible range 0-4. In comparison, of the 395 participants who completed the DP-GP instrument, 363 (91.9%) recognized a breach of the norm. Of those recognizers 53.2% ($n = 193$) positively appraised this breach, yielding a mean positive appraisal of the breach score of 1.51 (0.75); also 53.2 % (n = 193) of recognizers appraised the breach of the norm negatively, yielding a mean negative appraisal of the breach score of 1.83 (0.98). Finally, of the 495 participants who completed the DP-TSGP, 444 (89.7%) recognized a breach of the norm. Of those recognizers, 53.2% (n = 236) positively appraised the breach, yielding a mean positive appraisal of the breach score of 1.61 (0.82); of the recognizers, also 30.6% negatively appraised the breach, yielding a mean negative appraisal score of 1.53 (0.75). These descriptives suggest that people noticed the breach of the norm more saliently than its compliance (DP-C:83.4% < DP-GP:91.9%, DP-TSGP: 89.7%), they saw more positive as well as more negative issues with merely expanding the scope of work of the students. But when considering the possibility that the teacher might control that expansion by sanctioning the proposition to be proved, positive appraisals increased and negative appraisals decreased to a level comparable to the negative appraisals of complying with the norm.

A similar tendency could be observed with the appropriateness rating scores. We examined differences in how participants responded to a breach or compliance scenario with ratings toward the low or high end of the appropriateness scale with participants who completed all three instruments and recognized the DP-GP norm (n = 343). When asked to rate the appropriateness of the teaching showed in the DP-C scenarios, average scores were 4.42(SD = 0.65, n = 343), while those average appropriateness scores were 4.56 (SD = 0.94, n = 343) for the scenarios that breached the norm by asking students to provide the givens or the prove statement. The average appropriateness score went up to 4.83 (SD = 0.70, n = 343) in the case of the DP-TSGP scenarios where in addition to expanding the students' share of work, the teacher at some point sanctioned the proposition that students would prove.

Table 1. Descriptive statistics of recognizers and appraisers for each instrument

Instrument	Obs	Recognizers	Appraisers	Mean	SD	Min	Max	% Appraisers
DP-C	525	438	POS: 177	1.24	0.53	1	4	40.41%
			NEG: 146	1.17	0.43	1	3	33.33%
DP-GP	395	363	POS: 193	1.51	0.75	1	4	53.17%
			NEG: 193	1.83	0.98	1	4	53.17%
DP-TSGP	495	444	POS: 236	1.61	0.82	1	4	53.15%
			NEG: 136	1.53	0.75	1	4	30.63%

To ascertain the significance of the differences in AT, PA, and NA scores across different instruments, we calculated a set of mixed effect regression models. Given that each participant responded to multiple instruments, average appropriateness (AT), positive appraisal (PA), and negative appraisal (NA) that come from the same participant are not independent. Therefore, we conducted mixed effect linear regression models that could account for this non-independence among the scores. In the models, the categorical variable indicating a type of instrument was entered as a fixed effect and the variable indicating a participant's ID was entered as a random effect. The analyses were conducted using the STATA statistical software with the sample of participants who responded all three instruments and recognized the DP-GP norm (n = 343).

Table 2. Mixed effects linear regressions of scores on a type of instrument

	Appropriateness (AT) B(SE)	Positive Appraisal (PA) B(SE)	Negative Appraisal (NA) B(SE)
Fixed effects			
DP-C	-0.41 (0.05)***	-0.24 (0.07)**	0.17 (0.07)*
DP-GP	-0.27 (0.05)***	-0.38 (0.071)***	-0.03 (0.07)
Constant	4.83 (0.042)***	2.84 (0.06)***	2.04 (0.06)***
Random effects			
Constant	0.19 (0.03)	0.52 (0.065)	0.37 (0.06)
Residual	0.40 (0.02)	0.86 (0.05)	0.90 (0.05)
N	343	343	343

Standard errors in parentheses; $^{*}p < 0.05$, $^{**}p < 0.01$, $^{***}p < 0.001$
*reference instrument group: DP-TSGP

As shown in Table 2 (the reference group is DP-TSGP), results generally support our conjectures. AT (appropriateness) for TSGP is higher than both AT(DP-GP) and AT(DP-C), AT is significantly lower for DP-C by about 0.41 and DP-GP by about 0.27 (in a scale 0 ~ 6). In addition, the variation associated with the participants explains about 32% of the total deviations from the predicted AT that are not due to a type of instrument. Similarly, PA is significantly lower for DP-C and DP-GP by about 0.24 and 0.38 (in a scale 0 ~ 4) than for TSGP, respectively. The participants random effect comprise about 38% of the total residual variance. NA for DP-TSGP yields significantly higher score than NA for DP-C, but it is not significantly different from NA for DP-GP. For the NA score, the participants random effect explains approximately 29% of the total residual variance.

Conclusion

The data suggests that teachers do recognize the norm that the teacher will provide the givens and the prove for proof problems, yet they do not appraise it as better than some of the alternatives presented. Instead, alternatives in which the teacher expands students' role by inviting them to propose the givens or the statement to prove are appraised as more highly positive. Apprehension for these kinds of proof problems is apparent in the fact that negative appraisals of these alternative kinds of problems are still higher than for the habitual proof problems and not significantly higher than the negative appraisals for instances of doing proofs in which students are free to prove whatever they decide. An important implication for practice of these results is that it suggests that inservice teacher education could focus on helping teachers anticipate what students could propose in response to problems such as those proposed by Cirillo and Herbst (2012) and in practicing how to bring the class to a consensus on what statement they all should be working on.

THE IN-THE-MOMENT NOTICING OF THE NOVICE MATHEMATICS TEACHER

Michael Jarry-Shore
Stanford University
mjarrysh@stanford.edu

Recent reforms urge teachers to support students in pursuing their own mathematical strategies. Yet, to support a student in pursuing a strategy that they themselves devise, teachers must first notice details in the student's mathematical thinking, often in-the-midst of instruction. In this study, I examined four novice teachers' noticing of students' thinking in-the-moment, as well as the types of knowledge teachers called upon to support them with this noticing. Teachers took part in a post-lesson interview, in which they discussed moments from a preceding lesson of theirs caught on video. Findings indicate that novice teachers relied most on knowledge they developed in their own classrooms (e.g., knowledge of their individual students) to support their in-the-moment noticing. These findings align with calls to prepare teachers to view their classrooms as rich sources of knowledge supportive of their instructional practice.

Introduction

Today's mathematics classroom looks quite unlike the mathematics classroom of old. While in the past, teachers typically modeled a single strategy for students to apply in solving a series of practice problems, today, teachers are to encourage students to author their own strategies (NCTM, 2014). Existing research has demonstrated that, when teachers teach in this way, student learning benefits (e.g., Fennema et al., 1996).

To support students in pursuing their own mathematical strategies, however, teachers must be keen observers, capable of noticing important details in students' strategies (Jacobs, Lamb & Philipp, 2010). Only after noticing what a student did and understands in using some strategy, can a teacher then respond in an informed manner (e.g., by suggesting an appropriate next step). In the absence of prior noticing, a teacher might lack an adequate understanding of the student's strategy and could thus respond by asking the student to abandon their chosen approach in favor of one recommended by the teacher.

A number of studies have examined what teachers notice. These studies, however, have typically focused on what teachers notice when watching classroom video (e.g., Sherin & van Es, 2005), and not the sort of live, in-the-moment noticing that helps teachers support students in pursuing their chosen strategies. Of the few studies that have examined teachers' in-the-moment noticing, most have involved teachers in possession of several, if not many, years of experience (Jacobs & Empson, 2016; Sherin, Russ, & Colestock, 2011). While some recent work (e.g., Dyer, 2013) has examined the in-the-moment noticing of more novice teachers, this remains an under-examined area in need of further study.

In the absence of a more refined understanding of the novice teacher's in-the-moment noticing, current programs of professional development focused on this important aspect of practice may fail to address the unique needs of the novice. Accordingly, this study examined the in-the-moment noticing of the novice mathematics teacher.

Theoretical Framework

Teacher Noticing

Framing "noticing." Teachers have likened the process of noticing to having something prick the senses, alerting one to the fact that something important and worthy of attention is occurring (Sherin, Russ, & Colestock, 2011). Some scholars have adopted a similar framing, focusing on what captures teachers' attention in their studies of noticing. For example, in their work on the noticing of pre-service teachers, Star, Lynch, and Perova (2011) examined what teachers identified as important or noteworthy when watching classroom video. Others have included not just what a teacher identifies as noteworthy in their description of noticing, but how teachers make sense of what they deem noteworthy, as well (Sherin & van Es, 2009).

A focus for noticing. While some have studied teachers' noticing of any and all "salient features of classroom instruction" (Star, Lynch, & Perova, 2011, p. 117), others have examined teachers' noticing of students' mathematical thinking, in particular. For example, in their research program, Jacobs. Lamb, Philipp, and Schappelle (2011) acknowledged being "less interested in identifying the variety of what teachers notice and more interested in how and the extent to which teachers notice children's mathematical thinking" (p. 99). To Jacobs, Lamb, and Philipp (2010), noticing children's mathematical thinking consists of three component parts: a) attending, b) interpreting, and c) deciding how to respond. "Attending" refers to the extent to which a teacher pays attention to what a student did in solving some mathematics problem. "Interpreting," on the other hand, refers to the extent to which a teacher pays attention to what a student understood in solving a problem. Finally, "deciding how to respond" refers to a teacher's intended response to a given student. Attending, interpreting, and deciding how to respond occur almost simultaneously, "as if constituting a single, integrated [act]" (p. 173).

In-the-moment noticing. In recent years, scholars have begun to focus less on what teachers notice when watching classroom video and more on what teachers notice in-the-midst of instruction. This shift appears motivated by an acknowledgement that noticing "in the classroom is quite complex – more so than [when watching video] … when teachers [are] given only a small slice of instruction to consider and extended time to do so" (Sherin & van Es, 2009, p. 33).

Jacobs and Empson (2016) developed a framework for teachers' in-the-moment noticing of children's mathematical thinking (Figure 1). According to this framework, what a teacher notices in children's mathematical thinking in-the-moment is dependent upon that teacher's knowledge of children's developmental understandings of key mathematics concepts.

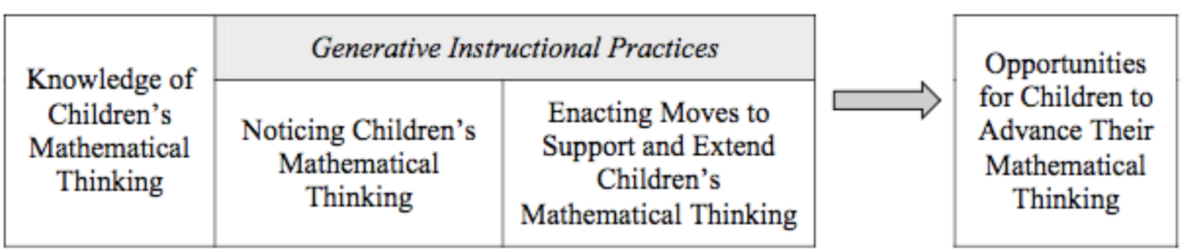

Figure 1: Framework for In-the-moment Noticing of Children's Mathematical Thinking

A significant volume of research has described this knowledge, identifying what students of a given age tend to know, think, and do when working on particular mathematics concepts. For instance, Fennema et al. (1996) identified a developmental trajectory that students in the primary grades tend to follow as they solve arithmetic problems.

Even if they have not studied such developmental trajectories explicitly, veteran teachers are likely to be familiar with what children of a given age tend to know, think, and do. For novice teachers, however, this knowledge it is likely to be less well-developed. As novices have had "the least experience with children's thinking" (Jacobs et al., 2011, p. 100), they are likely less aware of what is typical for children of a given age to know, think, and do mathematically. This raises some important questions. If novice teachers are lacking knowledge of children's developmental understandings of key mathematics concepts, are they capable of noticing students' mathematical thinking in-the-moment? And if so, what knowledge do they draw upon to support this noticing? The present study sought to answer the following:

1. To what extent do novice teachers notice students' mathematical thinking in-the-moment?
2. What knowledge do novice teachers draw upon to support them in noticing students' mathematical thinking in-the-moment?

Method

Setting and Participants

For this study, I recruited four early-career teachers from a public school serving students in grades 4-9. One teacher, Kerry, taught 4th-grade, while Taylor taught 5th-grade, Hannah taught 6th-grade, and Caroline taught 9th-grade (all names are pseudonyms). Kerry and Hannah were first-year teachers at the time of the study, while Taylor and Caroline were in their third year in the classroom. I purposefully selected these teachers because of their school's commitment to student-centered instruction. As opportunities to notice students' mathematical thinking in-the-moment arise as teachers interact with students, I sought to work with teachers in a student-centered school, where significant instructional time would be spent interacting with students.

Data Collection

Capturing video for discussion. Similar to Sherin, Russ, and Colestock (2011), I examined teachers' in-the-moment noticing by first capturing video of teachers' lessons then having them discuss moments from this video shortly afterwards. I used two cameras, a Drift Stealth™ and a GoPro Hero 4™. Teachers mounted the Stealth to the side of their head using a headband and triggered the camera to capture clips of their interactions with students in two of their lessons. I collected a second source of video using a GoPro mounted at the back of the room, as I was worried that teachers might forget to capture clips using the Stealth. Using an app, I viewed a livestream of teachers' lessons recorded using the GoPro and listened to audio of their conversations with students captured using a wireless mic that the teachers wore. As I watched the GoPro video, I tagged moments when the teacher interacted with students.

Post-lesson interview. Consistent with the procedure used by Sherin and colleagues, I asked teachers to discuss their videos in an interview shortly after their second lesson; the first lesson was solely for piloting camera gear. Between each teacher's second lesson and their post-lesson interview, I watched as many of the teacher's Stealth clips as possible, selecting those in which there was some evidence of students' mathematical thinking. I also referenced notes I had taken for the tagged GoPro moments, choosing those in which some mathematical thinking was on display. I chose Stealth clips and GoPro moments in this manner, as I worried that a more random selection would have resulted in a lack of noticing of student thinking, not because teachers were not capable of such noticing, but because there simply would have been less mathematical thinking to notice in a random selection of clips/moments.

In the interviews, I showed the teacher a still image from the start of each clip/moment then asked them the following: "can you walk me through what was happening at this point in the lesson?" When a teacher was not able to respond to this prompt, I played the video until they could. As soon as teachers were able to respond to the prompt, I stopped the video. This procedure was followed as it limited the amount of video teachers were shown, thereby reducing the likelihood that what they went on to describe was based on what they noticed in watching the video and not what they had noticed when the moment actually happened in the preceding lesson. I collected audio- and video-recordings of these interviews.

Data Analysis

Creating instances. I parsed the video of each teacher's post-lesson interview into instances, which consisted of all discussion by the teacher of a given Stealth clip or tagged GoPro moment.

Teachers' noticing. I next created two coding schemes: one for teachers' "attending" and a second for teachers' "interpreting" (Jacobs, Lamb, & Philipp, 2010). Every instance was assigned one of three codes for "attending": (1) evidence of attending provided, (2) lack of evidence of attending provided, or (3) not applicable. If a coder could describe the mathematical strategy of a student or group of students in some clip/moment based on what the teacher said, a level 1 code was assigned. When the teacher did not provide enough detail to make this possible, a level 2 code was assigned. When the teacher did not mention any mathematical strategy in a given instance, a level 3 code was assigned. A similar process was followed when coding "interpreting." Specifically, each instance was assigned one of three codes for interpreting: (1) evidence of interpreting provided, (2) lack of evidence of interpreting provided, or (3) not applicable. If in discussing a given clip/moment, a teacher mentioned what in particular a student or group of students understood (e.g., the student knows how to count by 5's), coders assigned a level 1 code. When the teacher instead made a broad claim (e.g., the student understands addition), a level 2 code was assigned. Finally, if the teacher made no mention of what a student or group of students understood mathematically, a level 3 code was assigned.

Teachers' knowledge. As teachers discussed clips/moments from their lessons, they not only attended to and interpreted students' thinking, but also referenced their knowledge of a range of things. I created a third coding-scheme describing the nine different types of knowledge that teachers referenced in their interviews.

Looking for associations between attending, interpreting, and knowledge. After all instances had been assigned a code for attending, a code for interpreting, and up to nine codes for knowledge, I looked for associations between the attending, interpreting, and knowledge codes. Specifically, I looked to see which types of knowledge were referenced most when "attending" was coded level 1, when "interpreting" was coded level 1, and when both were coded level 1.

Results

Novice Teachers' In-the-moment Noticing

Overall, the four teachers in this study were asked to discuss 49 instances of instruction. In 19 of these 49 instances, teachers provided evidence of attending (i.e., level 1 attending). Similarly, in 18 of these 49 instances, teachers provided evidence of interpreting (i.e., level 1 interpreting). Though evidence of attending was not always accompanied by evidence of interpreting, in 10 of 49 instances, teachers provided evidence of both attending and interpreting.

As an example of level 1 attending, consider the following comment made by one teacher, Kerry, in discussing an interaction she had with a student trying to solve 6×9: "So, I think what [she's] doing here is talking about ten groups of six, does that sound right? Or seven. One of the two. Like, [she's] doing ten groups then subtracting a group to get nine." Based on this comment, coders were able to describe the strategy of the student being discussed, a compensation strategy for multiplication (i.e., $6 \times 9 = 6 \times 10$, subtract 6). As such, coders determined that Kerry had provided evidence here of attending to the substantive details in the student's strategy.

Turning to interpreting, consider Taylor's comment below about an interaction she had with several students trying to place the fractions 4/5 and 3/4 on the number line:

> And, so, I think he was just … using that visual in his head, like, the four, four-fifths versus three-quarters. And then I asked them about if they were missing, they were both missing one piece and what that means, and they were able to say that the, obviously the one that's missing a fifth is a much smaller piece than the one missing a quarter … because it's split into smaller pieces.

Here, Taylor made a specific claim about the understanding of a group of students. Specifically, Taylor claimed that the students in this particular moment knew that 1/5 was a smaller piece than 1/4. As such, coders assigned a level 1 code for interpreting here.

Although teachers provided evidence of either attending or interpreting in a number of instances, this was not always the case. Indeed, in 8 of 49 instances, teachers made no mention of what a student or group of students did in solving a given mathematics problem, while in 18 of 49 instances, they made no mention of what students understood mathematically. In these instances, teachers instead discussed things like students being off-task, even though students' mathematical thinking was on display.

Knowledge Referenced When Discussing Moments of Instruction

Teachers referenced nine types of knowledge in discussing moments from their lessons. *Knowledge of an individual student* was displayed anytime a teacher referenced something in general that they knew about a student. As this knowledge was either mathematical or not, there were actually two codes for knowledge of an individual student. For example, in discussing a student in one moment from her lesson, Kerry commented, "she usually struggles in math, so she'll find the easiest way possible." As another example, when discussing a moment from her lesson, Taylor stated, "well, this one, … she's kind of a perfectionist." While Kerry's comment was focused on mathematics, Taylor's was not.

Knowledge of a group of students was displayed whenever a teacher referenced something they knew about a group of students. As an example, in discussing a moment from her lesson, Taylor stated, "this is the group that I went to first because, I, they're, they're the lowest…they're still really struggling with fractions." While Taylor here referenced knowledge of a group of students that was mathematical in nature, Hannah provided an example of this type of knowledge that was not mathematical, stating, "and the usual ones raised their hands."

Knowledge of the class was displayed anytime a teacher referenced something they knew about their class. As an example, consider the following comment made by Kerry when discussing a moment from her lesson on patterns in multiplication: "So, lots of them I noticed in their patterns, and in everything they do, assume that I can read their minds because they only put, like, half of what they're thinking and it's not enough information for me." Conversely, consider the following comment made by Hannah: "I have, like, a really gifted group and so, they tend to move very fast and they jump right ahead of many others, there's a large gap." The comment here by Kerry focused on the lack of detail her students provide in their mathematical work, so was deemed mathematical in nature, while the comment made by Hannah was not.

Knowledge of students was observed whenever a teacher mentioned something they knew about students in general. For example, consider the following comment made by Kerry in discussing her lesson: "'Cause some kids with subtraction just get, like, really stuck up, even though it is a smaller subtraction, they're like, 'muhhh,' and they get overwhelmed, so the addition really would be faster for them." By contrast, Kerry also discussed how she likes to let students work in the hallway because, "some kids really do need that quiet to focus." Hence, the first comment here was related to mathematics, but the second one was not.

Finally, *knowledge of a prior lesson or moment* was observed anytime the teacher referenced either a prior lesson or some moment that had occurred earlier in the lesson being discussed in their interview. For example, when discussing a strategy one of her students was using, Kerry, as if speaking to the actual student, said: "'I'm pretty sure you're using this strategy we talked about in class and that's really cool.'" Conversely, when discussing an interaction with a student about a lack of detail in his work, Kerry referenced knowledge of a similar moment from earlier in the lesson, stating: "Zack, when I was talking to him, … we were looking at his patterns, same thing, where I was just like, 'I don't, this isn't enough information, can you expand on that for me?'" In all cases when a teacher referenced knowledge of a prior lesson or moment, this knowledge was mathematical in nature.

Knowledge and In-the-moment Noticing

When teachers provided evidence of in-the-moment noticing, they referenced certain types of knowledge more so than others. Specifically, in 10 of the 19 instances when teachers' attending was coded level 1, teachers referenced *knowledge of individual students,* while in 9 of these 19 instances, they referenced *knowledge of a prior lesson or moment*. Similarly, in 6 of the 18 instances when teachers' interpreting was coded level 1, teachers referenced *knowledge of individual students,* while in 9 of these 18 instances, teachers referenced *knowledge of a prior lesson or moment.* In 3 of the 10 instances where both attending and interpreting were coded level 1, teachers referenced *knowledge of individual students*, while in 4 of these 10 instances, teachers referenced *knowledge of a prior lesson or moment*.

To illustrate how the knowledge teachers referenced seemed to support their in-the-moment noticing, consider the following comment made by Taylor in discussing an interaction she had with a group of students:

> This one, she's very, um, particular, like, she's, she's kind of a perfectionist, she wants to make sure everything's done well. And I think she was, she was, so, they had figured out which of the fractions, which were big–, larger than one, they had figured out which order they should go in, but they were trying to figure out where to place it on the number line. Um, and I think she was wanting to be, like, pretty exact of where it went.

In this comment, Taylor referenced non-mathematical knowledge she had of an individual student, specifically, that the student was "kind of a perfectionist." This knowledge seemed to set an expectation in Taylor's mind for what to then notice in the group's mathematical work, specifically, that this group would be quite precise in placing fractions on the number line. Indeed, shortly after providing the quote above, Taylor attended to the mathematical strategy used by the group of students being discussed, explaining that, rather than place the fractions 8/7 and 1 & 3/14 just anywhere to the right of 1 on the number line, the students converted 8/7 into a mixed number, thereby allowing for a more precise placement of these fractions:

> The, it was, like, one and two-four, they had figured out, they had, they had already found an equivalent fraction and converted it to a mixed number fraction, so I think it was 1 & 2/14 and 1 & 3/14 … I think there was 8/7, I think that they changed 8/7 to, so they figured out that it was 1 & 1/7, and then they changed it to 1 & 2/14. Yeah.

Discussion

Better Than Expected

As this study demonstrates, novice teachers are certainly capable of noticing salient details in students' mathematical thinking in-the-moment. Existing literature, however, might suggest otherwise. Studies of novice teachers' noticing have found that, at least initially, early-career teachers tend to notice things like classroom management and behavioral issues more so than the substance of students' mathematical thinking (Star, Lynch, & Perova, 2011). Similarly, research examining teachers' noticing of students' mathematical thinking in particular has found that novice teachers tend to focus on the general features of students' strategies (e.g., that a student's work lacks organization) more so than the "mathematical essence of the [strategies]" (Jacobs, Lamb, & Philipp, 2010, p. 183). And yet, in 19 of 49 instances in the present study, teachers provided evidence of attending to students' mathematical thinking, while in 18 of 49 instances, teachers provided evidence of interpreting students' thinking.

These results are particularly compelling for two reasons. First, unlike previous studies of teacher noticing (Jacobs, Lamb, & Philipp, 2010), in the present study, teachers were not asked to describe what students did or understood mathematically, yet still spoke of such things in discussing their lessons. Second, this was a study of teachers' *in-the-moment* noticing, which scholars have both theorized (Sherin & van Es, 2009) and found (Dyer, 2013) to be particularly challenging for teachers. Given this, the task presented to the novice teachers in this study was quite demanding, making the extent to which they noticed student thinking all the more impressive.

So, what could explain why the novice teachers in this study did better than might have been expected in noticing students' mathematical thinking? In previous work examining novice teachers' noticing, teachers were asked to observe students who were not their own and who they had not actually taught themselves (Jacobs, Lamb, & Philipp, 2010; Star, Lynch, & Perova, 2011). As such, teachers in these studies had no knowledge of the students they were observing, the class they were in, or the prior lessons in which they had taken part. As a result, these teachers simply could not leverage such knowledge, knowledge that the present study suggests may be critical in supporting novice teachers' noticing of student thinking.

Mine Your Experience, There Is Knowledge There

This study aligns with existing literature that suggests that teachers' own classrooms are a rich source of knowledge. At present, significant efforts are being made in teacher education programs to prepare novice teachers for the many demands of the classroom. However, scholars have cautioned that no amount of such training can adequately prepare prospective teachers for these many demands (e.g., Ball, Sleep, Boerst, & Bass, 2009). Almost two decades ago, Ball and Cohen (1999) spoke of how "much of what [teachers] … have to learn must be learned in and from practice rather than in preparing to practice" (p. 10). The findings of the present study suggest that some of the knowledge that supports novice teachers' in-the-moment noticing is acquired in teachers' very own classrooms, with their very own students.

This is not meant to suggest that all teacher learning should be postponed until the novice teacher is in their own classroom. Rather, these results suggest that, with regards to in-the-moment noticing, it may be fruitful to prepare teachers to inquire into and acquire knowledge from the spaces in which they teach (Hiebert, Morris, Berk, & Jansen, 2007).

Concluding Thoughts

There were several exceptions to the "knowledge informs noticing" story told above. Indeed, in 2 of the 10 instances in which teachers provided evidence of both attending and interpreting, none of the knowledge types in my coding scheme were referenced. Also, there were instances when teachers called upon what seemed to be the most helpful sources of knowledge (i.e., knowledge of individual students, knowledge of a prior lesson or moment), yet did not provide evidence of in-the-moment attending or interpreting. While I present these cases here as counter-examples, they could also be regarded merely as evidence that the relationship between noticing and knowledge is simply not that straightforward.

Finally, it is important to note that the teachers in this study could well have relied on other, more tacit knowledge (Eraut, 2000) to support their noticing that they simply did not, or could not, share explicitly in their interviews.

INVESTIGATING MTE QUESTIONING AS A RELATIONAL TEACHING PRACTICE

As mathematics teacher educators (MTEs), we enact teaching practices in our mathematics methods courses as instantiations of practice for PTs. Questioning is a core practice in teaching (and learning to teach) mathematics that interacts with relationships between MTEs and prospective teachers (PTs). We engaged in a collaborative self-study to interrogate our questioning practice as part of relational teacher education with a goal of improving our questioning to reach all PTs. Observation and recordings of our questions during mathematics methods classes, collaborative conversations, and narratives were analyzed to describe characteristics of our questioning practice (Dillon, 1990) and determine how it is relational (Kitchen 2005b). We found commonalities in our questioning practice and identified ways to improve it. This serves as an exemplar for MTEs to inquire about their own questioning practice.

Keywords: Instructional activities and practices; Teacher Education-Preservice

As mathematics teacher educators (MTEs), our teaching practice centers on the development of ambitious teaching practices (Kazemi, Franke, & Lampert, 2009) of the prospective teachers (PTs) with whom we work. We view our practice as relational in that it is complex and dependent on the strength of relationships developed between the participants (PTs and MTEs) involved (Bieda, 2016; Grossman et al., 2009a; Noddings, 2003). We extend our definition of relational practice beyond attending only to the mathematical or pedagogical thinking of the PT to include attending to the whole person (Kitchen, 2005a, 2005b; Noddings, 2003). Therefore, we strive to incorporate the experiences of our PTs as learners in our classes and interrogate our own practice as related to those experiences, thus valuing all learners.

Practices we enact in our mathematics methods courses become instantiations for PTs to experience and take up in formulating their own practices (LaBoskey, 2007). We promote the development of ambitious teaching practices by focusing on core practices (Grossman, Hammerness, & McDonald, 2009b). Asking questions of learners is one such core practice, as it occurs frequently in teaching mathematics, provides opportunities to find out about students' thinking, and is accessible to PTs learning to implement mathematics instruction. Although current research on questioning in the teaching of mathematics is available (e.g., Davis, 1997; Nicol, 1998; Parks, 2010), little research has focused on the instantiations of a questioning practice PTs experience in methods courses that prepare them to enact this practice. Yet, the form and function of questions asked in methods courses has potential for influencing PTs' views of questioning practices. We argue that the process of interrogating one's questioning practice as part of relational mathematics teacher education can inform ways to improve that practice as an instantiation which can be taken up by PTs.

Objectives of the Study

We interrogated our questioning practices as MTEs teaching mathematics methods courses to more fully understand the experiences of our PTs in these courses. The following research questions guided our self-study inquiry (LaBoskey, 2007): What are characteristics of our questioning practice? and, How is our questioning practice relational? Initial examination of our questions through the lens of Dillon (1981, 1990) illuminated tractable characteristics of our practice. To explore the relational nature of our questions, we viewed them through Kitchen's lens of relational teacher education (2005a, 2005b, 2016). This lens afforded a view of our questions as drawing from our personal histories, experiences as MTEs, and our understandings of the PTs' histories and experiences and provided us a perspective which informed improvement of this practice.

Theoretical Framework

We define practice following Pinnegar and Hamilton (2009) as "engaging with others in ways that lead to the accomplishment of goals through the use of the knowledge, theories, and understandings" (p. 16). For us, questioning as a relational practice was always a goal directed activity informed by knowledge, theories, and understanding. We sought to build "knowledge from practice" (p. 17) as a way of "knowing to" (p. 18) question as a practice. In our inquiry we were driven to become aware of what informs our questions and ways we use questioning to build our relationships with PTs.

Relationships have consistently been identified as critical in teaching and learning (Russell & Loughran, 2007). Exploration of relationships in self-study has revealed the complexity of coming to know a PT and be known by a PT (Kitchen, 2009). The significance of relationships in teaching and learning gave rise to descriptions of relational practice. Grossman et al. (2009a), drawing from the work of Fletcher (1998), described teaching as relational practice in which relationship is used as a lever in teaching. This description highlighted the utility of relationships for PTs, but not ways in which teacher educators' practices could be characterized as relational. Kitchen's (2005a, 2005b) description of *relational teacher education* as teacher educators "knowing in relationship" (2005a, p. 18) illuminated how a relational practice is constructed through knowing: knowing oneself and knowing PTs. Like Fletcher (1998), Kitchen drew from notions of empathy (Rodgers, 1961) and vulnerability to describe relational practice. Kitchen identified seven defining characteristics of relational teacher education: understanding one's own personal practical knowledge, improving one's practice in teacher education, understanding the landscape of teacher education, respecting and empathizing with PTs, conveying respect and empathy, helping PTs face problems, and receptivity to growing in relationship. We hypothesize that core practices can be viewed as contributing to an MTE's relational practice. In particular, looking at questions an MTE poses through the lens of relational teacher education has the potential to unearth factors that influence the construction and posing of questions.

Questioning can be viewed as a strand of relational practice, since questions communicate the MTE's interests and aims to PTs and provide an opportunity to elicit PT's ideas. Each strand of one's practice contributes to the development of a relational practice, but one could question whether a single strand can be seen as relational. We suggest that one strand of practice can be viewed through a relational teacher education (Kitchen, 2005a) lens to gain insight into ways understandings of self and others are drawn upon in questioning. It is from this perspective that we can label questioning practice as relational. Research points to the complexity of questioning in mathematics classrooms (Davis, 1997; Parks, 2010), particularly when moving beyond evaluative questioning, and suggests that understanding the underlying influences on questioning can inform improvements in the practice. Questioning in a methods course introduces an additional level of complexity as MTEs use questioning to understand the mathematical thinking of PTs and their views of teaching and learning. Examination of MTEs' use of the core practice of questioning in teaching is then warranted as we strive to provide instantiations of effective questioning practice for PTs to draw upon, tacitly or explicitly, as they develop their own questioning practices (Mewborn & Tyminski, 2006).

Exploring questioning with self-study methodology (LaBoskey, 2008) created space for understanding questioning as a practice informed by philosophy (Berci & Griffith, 2005; Gadamer, 1975/2004) and empirical research (Dillon, 1982) with the goal of improving questioning. Our study of questioning, like that of Olsher and Kantor (2012), focused on question-asking and characterizing our questioning practice. We draw from Dillon's (1981, 1990) definition of questions as "interrogative utterances" which are "followed by answers" (Dillon, 1981, p. 51). Dillon (1990) described two sources of assumptions: assumptions in the logic of the question (question-sentences) called *presuppositions*, and assumptions about the context in which the question is asked (question-situations) called *presumptions*. Identifying our assumptions allowed us to identify characteristics of our questioning practices.

Methodology

LaBoskey (2007) described self-study methodology as interactive and improvement aimed. Drawing from LaBoskey's view, our interactions are best described as open, collaborative, and oriented toward reframing (Samaras & Freese, 2009). We opened our questioning practices to each other for scrutiny and engaged in collaborative conversations that created opportunities for constructing new perspectives on or reframing our questioning practice. These conversations further unearthed tensions underlying our questioning practice including ways that relationships informed our practice.

Data collection and analysis occurred in multiple ways as we studied our questioning practices. First, we observed each other teaching at least one class. In-person observations allowed us to situate discussions of questioning in particular contexts and teaching practice. In addition, each of us audio-recorded at least one class session. We then each catalogued questions we posed to PTs during at least one class session. What counted as a question was informed by our view of PTs' engagement. When PTs were exploring, whether prompted by a question or a directive, we considered the activity a question. Examples of questions from the transcripts illustrate differences in the content and approach (See Table 1).

Analysis of our questioning took place in three phases. First, we each identified questions, presuppositions, presumptions, purpose, and roles for PTs associated with questions from one class session and created a table (see Table 1). *Presuppositions* are assumptions conveyed in the logic of the sentence. *Presumptions* are beliefs conveyed in the question-situations (Dillon, 1990). *Purposes* refer to the reasons the MTE posed the question. *Roles* describe the ways in which PTs are positioned in responding to the question. We then summarized our findings, describing insights and remaining dilemmas about our questions, presuppositions, presumptions, purpose, and roles. We each read the summaries in preparation for our discussions of findings in four recorded online conversations (August 10 & 29 and September, 5 & 19, 2017).

Table 1: Examples of Questions

Alyson: The hat you are going to put on is that of the students that wrote the work. And you are going to look at the feedback that the other group wrote. And you are going to decide as the student who wrote that, that is the feedback that you got, what would you do next? (9/13/2016)

<table>
<tr><td>Presuppositions:
There is a next step to which mathematics-learners can reply.</td><td>Presumptions:
PTs can pretend to be someone else and get into another person’s thinking.</td><td>Purpose:
To mimic the act of receiving feedback with a chance to critically examine it after.</td><td>Role:
Mathematics-learner receiving feedback</td></tr>
<tr><td colspan="4">Alyson: What I want you looking at now is what was the feedback and how did the math learner respond to it? Use your observations of those pairs to think about – do we have a complete list of what makes effective feedback? Are there some things you would suggest that we should not do? Are there some things you would suggest that we absolutely should do in responding? Can we use the feedback and student responses to that feedback to make some observations about, adding to or taking off of our list about feedback? (1 minute pause.) Are there some finer points that we need to add to this list about things we should consider when we are writing feedback to the students in the letter writing exchange? (9/13/2016)</td></tr>
<tr><td>Presuppositions:
Our list of characteristics of feedback is incorrect and too generic.</td><td>Presumptions:
PTs can draw conclusions from a mock example of feedback.</td><td>Purpose:
To examine instincts on providing feedback and position PTs to provide appropriate feedback in the actual activity with students.</td><td>Role:
Teacher-researchers</td></tr>
<tr><td colspan="4">Susan: So, the text on this page [reads text on a page of a counting book]. So, what I want you to do is, if this were the question and you were reading this with a group of kids, I want to know what level of cognitive demand, based on the criteria for these levels of cognitive demand, where do you think this would fall? Is it a lower cognitive demand like memorization, or is it a procedure without a connection or is it more of a higher cognitive demand where it might be something related to a procedure with a connection or something that’s more like doing mathematics, … [elaborates by continuing to rephrase the questions] … so think about that, and then of course I want you to think about how to justify your claim, there may be more than one answer here, ok, so, um I’ll give you two or three minutes to work with your group or your partner, and see what you think. (9/12/16)</td></tr>
<tr><td>Presuppositions:
Features of questions or tasks allow for classification according to cognitive demand. Depending on the question, the type of thinking is different.</td><td>Presumptions:
PTs will use the chart describing the levels of cognitive demand to classify a task posed in a children’s book.</td><td>Purpose:
Practice applying the levels of cognitive demand to questions or tasks and consider the type of thinking required in the task. Knowing the type of thinking required in a task is important in selecting tasks or questions for lesson planning.</td><td>Role:
PTs analyze tasks for thinking</td></tr>
<tr><td colspan="4">Signe: What is a confusion you have seen out in the field? (3/6/17)</td></tr>
<tr><td>Presuppositions:
Confusions can be seen in the field and are revealed through analysis of student thinking.</td><td>Presumptions:
PTs are developmentally ready to identify confusions</td><td>Purpose:
Link lesson planning and insights about children’s mathematics.</td><td>Role:
PTs conduct informal research to inform lessons</td></tr>
</table>

Our collaborative conversations served as a second phase of analysis. During this phase we focused on understanding the relational nature of our questions. We identified commonalities and differences in our presuppositions, presumptions, purposes, and roles for PTs. Our discussions focused on ways our questioning was influenced by our view of our own histories as learners and MTEs. For example, we recognized that our love of mathematics and interest in discussing mathematics learning and thinking with PTs influenced our questions. We further focused on ways our questions were influenced by the PTs, what we knew about them as people and learners. In particular, we pressed each other to explore how PTs' problems of practice were taken up or how empathy was conveyed (Kitchen, 2005b) in our questions. For example, Signe consistently wondered if the questions she was posing situated the PTs to respond from their own experiences rather than hypothesizing about the experiences of other teachers or mathematics learners. Discussions of these commonalities resulted in changes (or what we later called *fixes*) to the characteristics identified by the coding according to Dillon (1990). However, discussions of our fixes and the changes themselves provoked additional dilemmas about our questioning as a relational practice.

The third phase of analysis included writing narratives describing fixes we implemented in our questioning practice and dilemmas that remained. We read and discussed these narratives focusing on questioning as a relational practice. These discussions (December 12 & 19, 2017) were recorded and reviewed. From these discussions, we identified dilemmas, made sense of our questioning as relational, and developed assertions for action (Pinnegar & Hamilton, 2009).

Findings

We first present the common characteristics in our question practice as viewed through the lens of Dillon (1990). We then discuss the fixes applied individually in our practice as assertions for actions and highlight the dilemmas that remained relevant to our vision of relational practice.

Presuppositions and purposes

Presuppositions and purposes revealed reference to knowledge we consciously held and wanted to bring to PTs' attention. For example, Susan believed a teacher's awareness of the cognitive demand of mathematics tasks was important. The logic of her questions included the assumption that analyzing the demand of tasks is an essential part of planning lessons. For example: "I want to know what level of cognitive demand, based on the criteria for these levels of cognitive demand, where do you think this would fall?" (September 12, 2016). This example illustrates that, our questions contained expectations that PTs should accept our views of teaching and learning rather than developing views from their own experiences, including from their experiences in our courses.

Presumptions and roles

Presumptions and roles involved intent, contexts, and PTs. We consistently asked questions with the intent of learning what PTs knew. Signe asked about confusions PTs noticed in their work with children. "What is a confusion you have seen out in the field?" (March 6, 2017). Her intent was to gain insight into PTs' experiences. We wondered if we used PTs' responses in our teaching. We collected PTs' experiences with a desire to understand their insecurities and problems of practice (Kitchen, 2005b), yet our planned lessons played out without drawing from the issues PTs raised. We had empathy and respect (Kitchen, 2005b) for PTs, but struggled to convey it or help PTs face problems they described. Instead our questions focused on moving toward goals and implementing instructional activities we had planned before we knew the PTs. In this way we viewed our questions as "information-seeking" (Davis, 1997, p. 363) in that we wanted to understand PTs' thinking, but that thinking did not influence our teaching.

Additionally, our questions positioned PTs to take on a variety of roles during a single lesson. Alyson noticed that her questions positioned PTs in many different roles during one class meeting, roles such as reflective practitioner, researcher, teacher, and learner. She thought of *Whose Line is It Anyway?,* a television show where actors change roles or themes after a minute or two, generating chaos and comic situations. She felt she expected too much of PTs and wondered: What messages about teaching as reflective practice, might PTs gain through shifting roles so quickly and frequently?

Assertions for action and understanding (Pinnegar & Hamilton, 2009)

The analysis of our assumptions (Dillon, 1990) motivated fixes that improved our questioning practice. We eliminated long introductions, multiple roles, and identified the PTs as actors in questions. Dilemmas that remained focused on the relational nature of our questioning practice. Next, we describe the fixes each MTE made, improvements that resulted, and dilemmas that remained in terms of relational teacher education (Kitchen, 2005b).

Susan. Susan fixed her long introduction to questions by consciously posing planned questions. This fix unearthed a significant tension. Reducing the introduction to questions freed up time for PTs' interests and concerns. Their responses in whole class discussion surfaced their concerns and dilemmas or insecurities with teaching mathematics related to their experiences in their field classrooms. These interests and concerns turned the discussion in directions Susan had not anticipated, making it difficult to cover planned content. In addition, Susan wondered if she was listening to the PTs with empathy. Was she participating mindfully and thoughtfully, respecting PTs' contributions to the discussion (Kitchen, 2005a, 2005b)?

Susan found a dilemma between providing time and space for PTs to articulate their experiences, concerns, and insecurities about teaching mathematics (i.e., helping PTs face problems; Kitchen, 2005b) and being able to acknowledge and build on their ideas, while also trying to cover course content. Susan felt most comfortable when the discussions remained anchored around the mathematics content, and less so when the class discussions drifted into more general issues of pedagogical moves. Yet, teaching about mathematics teaching requires facility with the blending of mathematics content and teaching practices (Perks & Prestage, 2008). What is an appropriate balance and blend of content and methods that provides time and space for PTs to connect through sharing and raising their interests, concerns, dilemmas, and insecurities?

Alyson. Alyson began using a new planning method that provided for more concise questioning and positioned PTs consistently either as teachers or learners of teaching. Yet Alyson was left wondering if she was truly conveying empathy (Kitchen, 2005b) through those questions and positionings. Through the roles employed, Alyson was seeing PTs' thinking more clearly and better understanding their struggles but was left with questions about the relational characteristic of conveying empathy. Some PTs responded with favorable comments about Alyson's teaching during the semester, yet others struggled to find their way and began to doubt themselves as teachers. Alyson was left wondering whether the changes she had made had allowed her to convey empathy to *all* PTs?

Signe. Signe wondered if she was actually curious about learning about teaching. Raising this issue unearthed tensions for Signe about her receptivity to growing in relationship (Kitchen, 2005b). Signe felt that she wanted to learn from PTs, but perhaps her curiosity had a different focus than that of PTs. Wondering about her curiosity about teaching was difficult to admit and left Signe feeling distanced from her colleagues. Signe sincerely loved thinking about children's mathematics and teachers' insights about and use of this mathematics, while Signe viewed PTs as focused on improving pedagogical techniques. Neither seemed right or wrong, Signe simply worried. As she tried to enact a questioning practice aligned with Dillon's (1981) suggestion that questions should be asked only when the teacher is actually curious about a learner's thinking, she was faced with her limits. How could she be curious about the more general practices and holistic views of learners PTs shared?

Discussion

Despite significant differences in our context, we identified common characteristics in our questioning practice when we applied Dillon's (1990) framework and examined our presuppositions, presumptions, purposes, and roles. Even though we work in different institutional contexts and programs (e.g., Signe and Susan work with elementary PTs and Alyson with secondary PTs), we could describe common characteristics in our questions, allowing us to answer the first research question. We saw our own histories and experiences reflected in the presuppositions and purposes of our questions. Presumptions and roles provided insight into our exploration of PTs' histories and experiences and how we engage PTs in drawing from those experiences to inform and inspire their practice. With surface level commonalities identified and fixes applied, we could then see the different ways these factors influenced the relational nature of our practice as we developed and posed our questions (Kitchen, 2005a, b).

The examination of our questioning practice in methods courses afforded each of us the opportunity to consider ways in which we were relating to our PTs through questioning and the types of instantiations of practice PTs were experiencing. Both Alyson and Signe found issues with the ways in which they positioned PTs during class sessions. Alyson was positioning PTs in a great variety of roles and Signe was positioning PTs to draw on experiences other than their own. For each, this inappropriate positioning of PTs could hinder their relational practice. The core practice of questioning as relational, assumes that the questioner draws insights from the learner and makes use of those insights to move the lesson forward. Davis (1997) has described the reciprocal relationship involved in such questioning in the domain of mathematics. In mathematics teacher education, feedback PTs provided that is not used may suggest the MTE is not listening, thereby introducing an unintended barrier between the MTE and the PT. As a result of this finding, both MTEs have introduced more careful positioning of PTs into their courses.

All three MTEs have found the results to indicate a need for clearer communication and purposeful word choice with PTs. Signe identified a need to phrase questions differently so as to position PTs to respond from their own perspectives. She accomplished this by attending carefully to the choice of words used in her questions. Susan and Alyson identified a tendency to ask a series of related questions in quick succession rather than one purposefully chosen question. They each addressed this issue in ways that ensured one clear question is asked and then time is provided for PTs to contemplate and respond. Improving the clarity of communication with PTs removes another unintended barrier to relational practice.

Through inspection of the core practice (Grossman et al., 2009b) of questioning in a mathematics methods course, we found ways to improve that practice so that it more closely aligns with our goals of relational teacher education (Kitchen, 2005a, b) and includes more opportunities to draw on our PTs' experiences hermeneutically (Davis, 1997) during class activities. Building public exemplars of practice such as this for instructors of mathematics methods courses provides much needed opportunity for MTEs to engage in inquiry about those practices in order to seek improvements in our work.

CAPTURING VARIABILITY IN FLIPPED MATHEMATICS INSTRUCTION

Samuel Otten

Drake University
milan.sherman@drake.edu

Flipped instruction is being implemented in an increasing number of mathematics classes but the research base is not yet well developed. Many studies of flipped instruction involve a small number of flipped classes being compared to non-flipped classes, but this methodology fails to account for variations in implementations. To aid in the systematic attention to variation, this article presents a framework for flipped mathematics instruction that identifies key features of the videos assigned as homework as well as features of the in-class activities. The components of the framework are accompanied by proposed quality indicators to further distinguish between flipped implementations that are structurally similar but different in enactment

Keywords: Flipped Instruction; Lesson Observations; Classroom Research; Frameworks

In recent years there has been an increase in flipped instruction (Smith, 2014). Flipped instruction is characterized by teachers "flipping" the settings in which lecture and homework occur. Instead of being presented with new material in class and then completing homework problems outside of class, students in flipped classes watch videos or read new material outside of class and then complete the problem sets in class (Bergmann & Sams, 2012). Although the flipped instructional model has a single overarching label, there are a wide variety of learning opportunities it can encompass. On one hand, flipped instruction has the potential to be innovative with regard to differentiation (e.g., students can rewatch videos at their own pace and with technology-based supports) and collaboration (e.g., students can work together because of the increased time in class to solve problems). On the other hand, flipped instruction can be non-innovative, such as when students watch lecture videos at home and then work individually to complete procedural exercises in class (de Araujo, Otten, & Birisci, 2017a).

Because of the variation in flipped implementations, this theoretical article presents a research-based framework that moves beyond a general definition of flipped instruction and provides specific analytic tools that allow for meaningful distinctions to be drawn with respect to the learning opportunities afforded. In particular, the framework considers the components of flipped mathematics lessons and the quality indicators for each component.

Why a Framework is Needed

Although flipped instruction can vary in its implementation (de Araujo, Otten, & Birisci, 2017a), much of the early literature on flipped instruction seems to presume that it is a unified approach that can be directly contrasted with non-flipped instruction. For example, DeSantis, Van Curen, and Putsch (2015) investigated flipped and non-flipped geometry instruction in two high school classes. They found no differences in geometry learning, although students in the flipped class were less satisfied with the unit than students in the non-flipped class. But the flipped lessons in the study involved using the same activities as in the non-flipped lesson, so the implicit assumption was that the act of flipping itself—not the manner of flipping—is of central importance. Moreover, DeSantis and colleagues did not provide substantial detail about the non-flipped instruction, so with regard to the finding of no difference, the basis of comparison is under-specified. A similar example is Clark (2015), who compared his flipped Algebra 1 classes' year-end student outcomes with non-flipped Algebra 1 classes taught by others in the same school. Clark found, like DeSantis and colleagues (2015), no difference between flipped and non-flipped learning measures. Unlike DeSantis et al., however, Clark's students expressed a preference for flipped instruction because of the range of teaching practices it allowed. Again, because of the simplistic and small-scale comparison, the underlying assumption in Clark's study is that it is meaningful to compare flipped instruction with non-flipped instruction of the same content, without substantial regard for the variations that are possible within each category.

The fact that these studies found no difference with regard to content learning, and contradictory results with regard to student attitudes about flipped instruction, is unsurprising. Such results are to be expected if it is true that, as we argue, flipped mathematics instruction can vary widely along important dimensions of instruction, just as non-flipped instruction also varies. Nevertheless, these studies provide a positive first step with regard to empirically documenting the phenomena of flipped instruction in mathematics by showing that, in certain situations, flipping alone does not seem to influence student learning. Yet there are substantial limitations to the accumulated knowledge that can be generated from these studies because there is not yet a structural framework for identifying and interpreting the various features of flipped instruction in the cited studies. With such a framework in hand, patterns could be discerned across grade levels and even across articles that include empirical descriptions of flipped instruction without comparisons to non-flipped instruction (e.g., Talbert, 2014; Zack et al., 2015).

It should be noted that other frameworks for flipped instruction exist, but they serve different functions than ours. For example, Chen and colleagues (2014) introduced the FLIPPED model (Flexible environments, Learner-centered approach, Intentional content, Professional educators, Progressive networking, Engaging and effective learning experiences, Diversified and seamless learning platforms) but theirs is a prescriptive model meant to guide the design and implementation of a flipped course. It is not designed to capture the variability across preexisting flipped courses. Furthermore, it is not specific to mathematics instruction and it functions at the course level whereas our framework is applied at the lesson level. DeLozier and Rhodes (2017) provided a more descriptive framework, parsing the out-of-class lectures from the in-class activities and specifying different types of the latter (quizzes, pair-and-share activities, student presentations). In our work, however, we have seen that not all flipped instructors use strictly lecture videos (de Araujo, Otten, & Birisci, 2017b), and DeLozier and Rhodes do not account for the quality of the enacted in-class activities, nor is their work specific to mathematics. Yet we do incorporate their top-level distinction between out-of-class and in-class lesson phases.

To assess the quality of the flipped lessons in a mathematics-specific manner, we draw on existing instruments for lesson observations but make some key modifications. Observation protocols such as the M-SCAN (Walkowiak et al., 2014) and IQA (Boston & Wolff, 2006) presume a certain form of instruction, with cognitively demanding tasks and student discussions, and thus may not be widely applicable to all forms of mathematics instruction. Moreover, these instruments combine various sub-scores into an overall score for the quality of the lesson, even though there is scholarly disagreement about the ideal nature of some of the sub-scores. In other words, although some aspects are universally regarded as indicators of quality instruction (e.g., coherent development of ideas, effective use of multiple representations), other aspects are not universally accepted (e.g., the value of shared mathematical authority, student discussions) (Munter, Stein, & Smith, 2015). Thus, in order to capture the full range of flipped instruction variability in an even-handed way, it would be wise to separate the universally-accepted indicators of quality from those that simply mark different instructional paradigms. We represent this separation in the in-class component of our framework.

A Framework for Flipped Mathematics Instruction

Adapting the overall structure of the Mathematical Task Framework (Stein, Grover, & Henningsen, 1996), our framework (Figure 1) includes the assignment given to students to be completed outside of class (left) and the activity that takes place in class (center), which collectively produce various student outcomes (right). We distinguish between different types of videos (lecture and set-up) and between different interaction formats in class (whole-class and non-whole-class). These distinctions are rooted in our perspective on students' mathematical learning as a sociocultural process through which students are coming to participate actively in a mathematical community (Vygotsky, 1980). This process is an integration of social and individual dimensions and, mathematically, it involves becoming an active participant both in individual meaning-making through thinking or writing, for example, as well as collaborative meaning-making through listening to or interacting with the teacher and peers, for example. In other words, we view the learning of mathematics as not simply the development of an ability to solve certain kinds of problems but the development of the ability to participate in various forms of mathematical discourse and activity, and our framework distinguishes between some of these forms at a structural level. We also attend to the nature of discourse (Staples & Colonis, 2007) and the cognitive demand of tasks (Stein, Grover, & Henningsen, 1996) because these relate to the kinds of activities students have opportunities to participate in.

This framework is based on pilot analyses of flipped classes at several different academic levels and consultation with experts in specific domains (e.g., video design, classroom discourse, mathematical tasks). Due to space limitations, details on the development process are not shared.

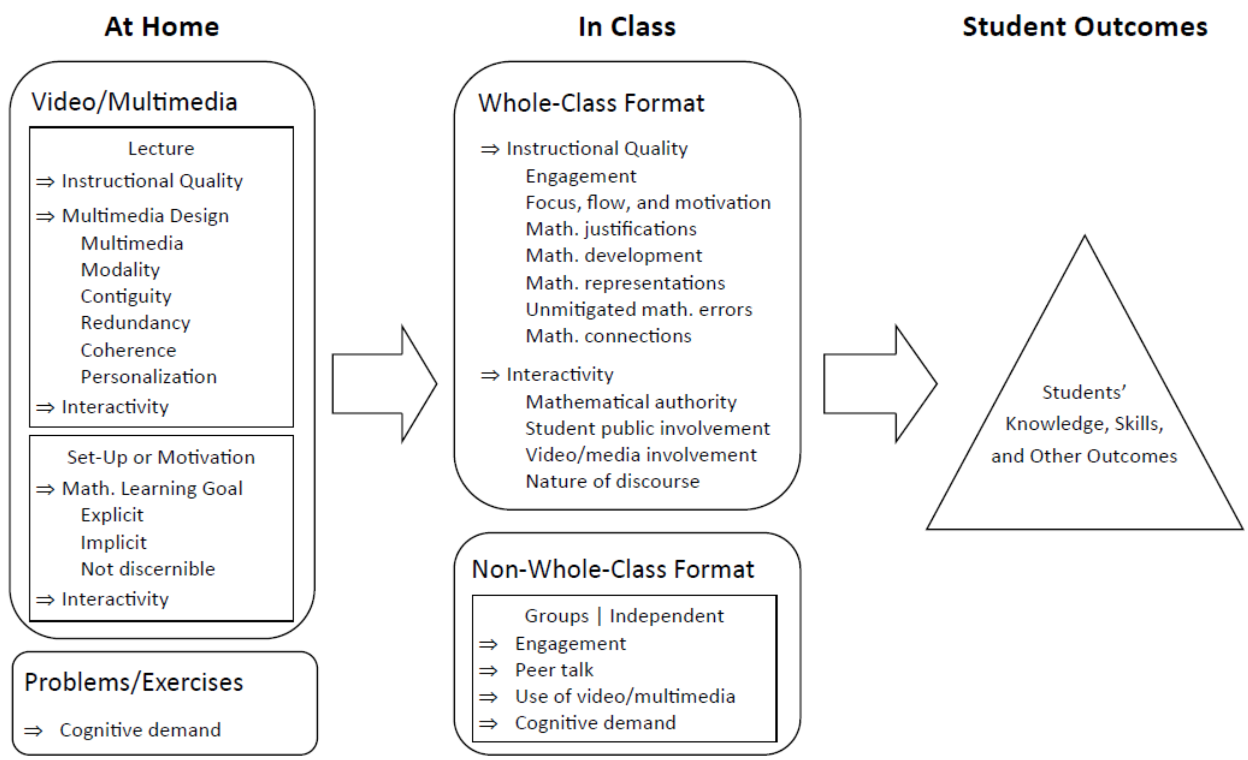

Figure 1. A framework for flipped mathematics instruction

At-Home Components

Looking more closely at the *at-home* components, the framework identifies *video or multimedia* homework in which students are assigned multimedia content to watch, read, or listen to. Although this type of homework is the definitive category for flipped lessons, teachers implementing flipped instruction are not bound to it exclusively. Teachers may, on occasion, also assign *problems or exercises* to be completed outside of class, in which case the framework could be used to show that both or either type of homework was assigned. Also, it is possible that a particular lesson has no homework assigned. Non-flipped lessons, by definition, will have only problems/exercises homework or no homework.

Videos or multimedia. Although we often use the term 'video' because flipped mathematics homework commonly takes this form, we acknowledge that some teachers might use written text, podcasts, animations, or multimedia resources such as iBooks. For video homework, the framework distinguishes between *lecture* videos, which present expository information or worked examples, and *set-up or motivation* videos, which establish a context or pose a problem that will be addressed in class. Within these two types, the framework then specifies normative quality criteria. By normative quality, we mean that instruction satisfying the criteria is hypothesized to be more predictive of positive student outcomes than instruction that does not satisfy the criteria, which could be empirically tested in future studies.

The normative quality criteria for lecture videos address three aspects: instructional quality, multimedia design, and interactivity. *Instructional quality* captures the clarity and flow of the ideas as well as features specific to mathematics, such as mathematical justifications, multiple mathematical representations, the absence of unmitigated errors, and connections to mathematical content that the students may have already learned or will learn in the future. Most of these particular aspects can be operationalized by drawing on existing instruments in the mathematics education literature. In particular, the clarity of the lecture *foci* relates to research on explicit lesson objectives (Wiggins & McTighe, 2005), and the *coherent flow* of ideas relates to all of the video content being connected to that foci. We can also attend to whether there is an intellectual or "real-world" *motivation* for the foci. With regard to mathematics-specific features, we draw on the Studying Teacher Expertise and Assignment in Mathematics (STEAM) project (Tarr et al., 2016), which provides a lesson observation coding scheme for *mathematical justifications*, the *meaningful development of mathematical ideas*, and the *integration of multiple representations*. In addition to these aspects from STEAM, we also include a dimension from the mathematical quality of instruction (MQI) instrument (Learning Mathematics for Teaching Project, 2011), namely, the *absence of unmitigated mathematical errors*. Finally, we attend to whether the video's particular mathematical foci is explicitly *connected to the mathematical ideas* of prior or subsequent lessons.

These features of instructional quality not only apply to the videos but are also used to characterize whole-class discourse in the in-class portion of lessons (see below). Aspects that are specific to videos, however, are multimedia design and interactivity. For *multimedia design* quality, we drew on Clark and Mayer's (2007) six principles of digital material design. The *multimedia principle* states that graphics (not words alone) help students learn the information in question. The *modality principle* states that the graphics should be described or explained with spoken words rather than on-screen text. The *contiguity principle* states that, if some brief on-screen text is used, it should be placed spatially near the relevant graphics. The *redundancy principle* states that the on-screen text should be minimal and should not be a full transcription of the audio narration. The *coherence principle* states that irrelevant graphics and audio should be excluded. Finally, the *personalization principle* states that audio narration should be in a conversational style and it is preferable for the speaker to be visible.

Interactivity captures the extent to which students are expected to be more than passive viewers of the video. Interactivity can be achieved in a variety of ways. For example, Webel, Sheffel, and Conner (2018) studied a teacher whose videos for flipped instruction contained embedded questions that provided the teacher with formative assessment data she could use to inform in-class activities. These embedded questions within the video are one possible form of interactivity. Other forms include requiring students to post a comment or submit a reflection after watching the video or incorporating a virtual manipulative (Moyer-Packenham & Westenskow, 2013) that the students can interact with as part of the homework.

The aspects described above apply to a lecture video, which is the most common type of video in flipped lessons (de Araujo, Otten, & Birisci, 2017b). Our framework, however, also includes *set-up or motivation videos*. Because of a lack of prior research on set-up videos, we drew on practical resources for setting up mathematical work such as the three-act tasks promoted by Meyer (2011) often involving what we call a set-up video that presents a situation and leads to a mathematical question. Our framework distinguishes between different ways in which the set-up videos connect to the mathematical goals of the remainder of the lesson. Specifically, we distinguish between three possibilities: an *explicit connection* to the mathematical goal of the in-class activity that follows (i.e., it is clear from watching the video what the specific mathematical question or problem is, even though its solution is not explicated); an *implicit connection* (i.e., it presents a context that allows for mathematical explorations but it is not clear which mathematical question or problem is intended to be pursued until it is specified later); or *no discernible connection* (i.e., it has a contextual connection or some other association with the in-class activity but does not contain the *mathematical* ideas of the lesson). We do not presume a priori that one of these is more beneficial than the others, but that could be determined empirically through applications of the framework.

Problems/exercises. If students are assigned a problem set to complete outside of class, then the framework attends to the cognitive demand (Stein, Grover, & Henningsen, 1996) of those problems. After coding each item for cognitive demand, the assignment overall can be characterized as *low* (nearly all items at a low level), *moderate* (predominantly low but a substantial minority of items at a high level), or *high* (a majority of the items at a high level). Note that if problems are begun in class and students are then expected to complete any unfinished problems at home, this would fall under the in-class component of group or independent work rather than strictly homework.

Moving on, the arrow between the at-home section of the framework and the in-class section represents the fact that what occurs outside of class potentially influences what occurs in class. For example, if students do not watch the video, the lesson will likely play out differently in class than if they had watched the video attentively. Note that, although videos are typically assigned to be watched prior to the in-class portion of the lesson, some flipped lessons may use a video as a way to summarize ideas after the in-class activity. Thus the arrow is not necessarily chronological and the left-to-right order visible in Figure 1 is not absolute.

In-Class Components

Moving to the *in-class* components, the framework first distinguishes between the interaction format the teacher employs—a *whole-class format* in which the entire class is expected to be attending to the public discourse whether that be the teacher addressing the entire class or students sharing out or asking questions, and a *non-whole-class format* which includes the expectation that students work together in *groups* or *independently*.

Whole-class format. As noted above, this framework differs from others because we separate instructional quality indicators from markers of a particular pedagogical model. For instructional quality we use the same aspects defined above (focus, flow, motivation, mathematical justifications, mathematical development of ideas, multiple mathematical representations, absence of unmitigated mathematical errors, and connections to other mathematical topics) plus an engagement (i.e., on-task) measure to gain a normative sense of the lesson flow and development of mathematical ideas. Additionally, the framework distinguishes between several descriptive aspects of the lesson. These aspects relate to the interactivity of the whole-class segments of the lesson. With regard to *mathematical authority*, we distinguish between teacher/textbook authority and shared/community authority. We also note the extent to which *students are publicly involved* in the whole-class discourse, and if they are, we attend to whether the *nature of discourse* was sharing or collaborative (Staples & Colonis, 2007). Finally, considering flipped lessons in particular, we note whether the *videos are referenced or incorporated* into the discourse (e.g., by reviewing the key ideas from the video homework).

Group or independent work. With regard to group or independent work, the framework includes *engagement* (i.e., on-task behavior), *peer talk* (i.e., the extent to which students verbally interact with one another), and the *use of video/multimedia* from the lesson homework. For example, while solving a problem in class, do students use their phones or tablets to view videos and rewatch explanations of worked examples? We also use the well-known construct of *cognitive demand* (Stein, Grover, & Henningsen, 1996) to characterize the written tasks students work on during group or independent work. Because flipped instruction can provide more in-class time for problem solving, it is plausible that teachers may feel more freedom to enact cognitively demanding tasks in their flipped lessons.

Student Outcomes

The framework does not predetermine the student outcomes of interest because those will largely depend upon the specific context in which the framework is employed, especially with regard to specific mathematical content. However, the framework does acknowledge that several different student outcomes may be of interest in studies of flipped instruction. In addition to measures of students' mathematical knowledge, one may also be interested in their skills with various mathematical practices and their attitudes or affective dispositions toward mathematics. Furthermore, researchers may wish to use multiple measures of a single outcome to increase the robustness of findings. In any event, the specification of these outcomes is somewhat independent of the enactment of lessons through the at-home and in-class phases of the lesson.

Discussion

In presenting this framework, we hope to provide a structure that can support the accumulation of empirical findings related to flipped instruction, inform the design of future studies, and facilitate connections between research and practice. This framework is needed because empirical research on the effectiveness of flipped instruction must move beyond simple flipped/non-flipped comparisons (e.g., Clark, 2015; DeSantis et al., 2015) toward an investigation of the specific features of flipped instruction and the complex interactions of those features as they relate to student outcomes.

Although the framework is built around structural components of flipped lessons, it also goes further by focusing attention on the quality with which certain structural activities occur. In particular, the framework includes quality criteria for lecture videos, set-up videos, whole-class discourse, and it incorporates the levels of cognitive demand (Stein, Grover, & Henningsen, 1996) for the independent or group tasks. This attention to quality will not only allow researchers to distinguish between different structural implementations of flipped instruction (e.g., those who use lecture videos and independent work versus those who use set-up videos and whole-class discussions) but also between different qualities of implementation within the same structure (e.g., productive whole-class discussions versus unproductive ones). To be clear, we do not mean to imply that the quality criteria specified in this article are the only sets of criteria that could be used, nor do we necessarily think they are ideal. Rather, we have proposed some characteristics that, according to our theoretical perspective, are worth considering, but those with different perspectives would likely identify different characteristics, and ultimately we hope that future research can empirically test the benefits of various implementations of flipped instruction.

With regard to empirical studies, the framework can be valuable in formulating testable hypotheses. For example, one can consider whether video features are more predictive of student learning than in-class features. (We hypothesize that the reverse is true.) Additionally, the framework can be used to aggregate across lessons rather than remain at the scope of an individual lesson. Future research could include multiple observations of a flipped class over time and compile the proportional allotments and the quality indicators for the components of flipped instruction. For instance, a teacher may 80% of the time assign lecture videos that satisfy only some of the quality criteria and may assign the other 20% of the time set-up videos that explicitly connect to the lesson's learning goals, and 50% of the in-class time may be spent solving high cognitive demand tasks in groups while the other 50% of the time is spent having high quality whole-class discussions. In this way, multiple class aggregations could be formed (for flipped and non-flipped classes) and then analyzed with respect to student outcome measures. Such work has potential to contribute to our theoretical understanding of mathematics instruction and to inform the efforts of practitioners who are implementing flipped instruction.

Conclusion

Many of the expositional and anecdotal works related to flipped instruction are written in ways that suggest flipped instruction is a unified teaching model. Even the few empirical studies that exist involved research designs that presume flipped instruction is a *singular approach* that can be meaningfully compared to non-flipped instruction. We have instead found that wide variation exists in flipped implementation (de Araujo, Otten, & Birisci, 2017b; Otten, Zhao, de Araujo, & Sherman, in press). Although it is possible that flipped instruction frees up class time for rich whole-class discussions and the enactment of cognitively demanding tasks, we know that there are secondary mathematics teachers using flipped instruction in ways that differ little from conventional non-flipped instruction aside from the change in instructional environment. As a field we do not yet know the prevalence of either of these implementations nor do we have compelling empirical evidence of the implications that either has for student learning. It is our hope that this framework will guide feature endeavors to gather this evidence.

ON TEACHING ACTIONS IN MATHEMATICAL PROBLEM-SOLVING CONTEXTS

Jérôme Proulx
Laboratoire Épistémologie et Activité Mathématique, Université du Québec à Montréal
proulx.jerome@uqam.ca

In this research report, the question of the role of the teacher in problem-solving contexts is addressed, particularly in relation to the development of mathematical concepts. Data extracts from a problem-solving session are used to draw out three sorts of teaching actions that aim to push forward the mathematics in the classroom. These teaching actions are discussed in light of verbatim extracts and of available theoretical constructs from the research literature.

Keywords: Mathematics, Problem-solving, Teaching Actions, Analytical Geometry

Introduction

The literature abounds with work conducted on mathematical problem-solving from a variety of perspectives, illustrating the beneficial outcomes for students of a sustained practice of solving problems in classrooms: on the meaning given to mathematical concepts and their relevance for everyday life; on the development of critical, logical and autonomous thinking; on the active engagement in doing mathematics; on the development of positive relationships with mathematics, and so on (Boaler, 1998; Borasi, 1992, 1996; English & Gainsburg, 2015). Through this literature, one dimension that appears in need of further research concerns the role of the teacher in problem-solving contexts. As Stein, Boaler and Silver (2004) explain, problem-solving work is mostly focused on students – who are plunged into authentic mathematical practices as are mathematicians – hence the problem-solving literature says little about teachers, their role, and classroom events or actions in which teachers interact. This leads to wonder about *What is the role of the teacher in problem-solving contexts?* In parallel, another salient issue that remains little studied, as English and Gainsburg (2015) illustrate, concerns the development of content in problem-solving contexts. There is a need to investigate the interplay of mathematical concept development and problem-solving endeavors in the classroom, and *How is problem-solving used as a powerful means to develop mathematical concepts*? It is these two issues that orient this research report, namely teachers' actions in problem-solving contexts that aim at covering content and developing concepts, that is, at pushing forward mathematics in the classroom. As Jaworski (e.g., 2011) often noted, we have numerous theories about students' learning and mathematical activity, but the same is not true for teaching and the teacher's role. There is thus an important need to conduct studies that aim to develop conceptualisations of the teacher's roles *in the action* of teaching in problem-solving contexts: this research report aims to contribute to reflections and conceptualizations on these teacher's roles.

In order to do this, an analysis is conducted on an extract taken from a session in a Grade-10 classroom. Once aspects of the research are grounded both theoretically and methodologically, the extract is presented and then analyzed in relation to three kinds of teaching actions that contributed to concept development – that is, that pushed forward the mathematics of the classroom – using theoretical concepts and verbatim extract as supporting illustrations to clarify the nature of these teaching actions.

Theoretical Grounding – Problem Solving as Engaging in a Dynamic Process

Grounded in the enactivist theory of cognition for conceptualizing problem-solving environments as non-linear endeavors (Proulx & Simmt, 2016), the research is also strongly inspired by the work of Borasi (1992) and Lampert (1990) on inquiry and problem-solving, who aim to place students in authentic problem-solving situations. In their work, mathematical problem-solving is conceived of as a process that does not follow a pre-specified thread of events – analogous to the development of mathematics itself as a discipline – where numerous questions and ideas arise amid problem-solving endeavors, these often becoming central issues that can redirect the inquiry being undertaken (see also Cobb et al., 1994).

Remillard and Kaye Geist (2003) termed these "emergent" events as openings in the curriculum, where occasions offer themselves to inquiry and (can) redirect the flow of classroom events; something akin to Van Zoest et al. (2015) notion of building on ideas unfolding in the classroom. Borasi (1992, p. 202) addressed these matters in terms of flexibility, where authentic mathematical problem-solving spaces are conceived for tackling unanticipated events:

> The open-endedness that characterizes inquiry requires extreme flexibility in terms of curriculum content and choices. A teacher will often need to deviate from the original lesson plan in order to follow a new lead, pursue valuable questions raised by the students, or let the class fully engage in a debate stimulated by difference in opinion or different solutions.

Mathematics teaching is thus here conceived as a dynamic process that emerges amid interactions between teacher and students. As Curcio and Artzt (2004) assert, teachers are themselves engaged in problem-solving when they teach through problem-solving, deploying an expertise in action, while teaching, in reaction to the events of the classroom. Teachers navigate through the "material" of the classroom, act with what happens, and attempt to push the mathematics of the classroom forward through analyzing and synthesizing on-the-spot the mathematical ideas shared and produced. It is in this sense that, in Bednarz and Proulx (2009), teachers' actions are conceived along three interconnected dimensions. *First*, following work on mathematics teachers' practices (e.g., Roditi, 2005), teaching is conceived of as an event that happens in the action of, in relation to, the task in which the teacher is engaged: *teaching is enacted in action*. *Second*, along a situated cognition perspective (Lave, 1988), teaching is conceived of as situated, deployed in relation to a specific context. As Roditi (2005) insists, teaching actions are not independent of students' learning or the classroom environment, a context that plays an immense role in the kinds of actions deployed in the act of teaching: *teaching is a situated practice*. *Third*, aligned with Mason and Spence's (1999) knowing-to act in the moment, teaching is conceived of as a practice adapted in real time to events of the classroom. Teachers constantly need to adapt their responses to the dynamics of the classroom as situations often drift from the planned script: *teaching is a practice deployed in the moment*, while it is enacted. Along these dimensions, teachers are seen as continually reflecting on possibilities, offering and inventing new avenues and representations in relation to students, thinking of additional explanations to clarify or resituate the tasks offered, choosing to emphasize some aspects and not others, knowing that an explanation or a representation may eventually benefit students' understanding, and so on. Teaching practice can thus hardly be considered as a preestablished practice designed in advance for reacting to situations, but rather an expertise enacted in context, in action, as a knowing-to act adapted to situations and deployed on-the-spot in (inter)relation to classroom events. It is along this theoretical perspective that teachers' actions for pushing forward the mathematics of the classroom, are considered.

Methodological Considerations

This research report is part of a wider research program focused on studying the teaching of mathematics through problem-solving in elementary and secondary classrooms. We collaborate with groups of teachers who regularly invite us into their classrooms to experiment various kinds of problem-solving approaches and to interact, assess and reflect with us on the teaching that goes on in these sessions. Because it inserts itself in regular classrooms, the research does not want to be disruptive and follows the teachers' teaching plans, with the tasks given in class to students being chosen by and with teachers (often coming from their teaching materials and workbooks). The problem-solving sessions usually follow the same trend, starting with a task presented to students, written on the board or handed on paper, where students are given relative amounts of time to address it. After this, in a plenary manner, students are asked to share their strategies/solutions and thoughts with the group, while making sure that these are clearly explained and justified for other students to understand and ask additional questions if necessary. Students are also invited to interact between each other in relation to the ideas shared, to question or challenge them, add to them, etc., thus aiming to create a community of inquiry (Borasi, 1992; Lampert, 1990). These various interactions in turn often provoke new inquiries, where students can be asked to explore new issues or additional questions (Cobb et al., 1994).

Data-collection focuses on classroom discussions and interactions, as well as traces left on the board, all chronologically recorded as field notes by a research assistant (RA) or videotaped. Data analysis is carried out in two phases. The *first phase* consists of on-the-spot meetings (PI, RA, and teachers) to discuss teaching events that occurred during the sessions that stood out and deserved attention (in this case, on teaching actions that pushed the mathematics forward). These meetings offer a first level of analysis, which also affords interpretations of teaching events from the teachers' perspectives and permits refinement of, and adds to, the observational notes. This first level of analysis revealed salient issues about three explicit teaching actions that succeeded in pushing forward the mathematics of the classroom, that is, actions that enabled mathematical concept development: validation practices, reformulation practices, and summarizing practices. This three-pronged orientation toward teaching actions was used to orient the subsequent data analysis. This *second phase* consisted of attending to the data in relation to Desgagné's (1998) notion of available constructs from the mathematics education literature, which could give these teaching actions deeper theoretical meaning: here, e.g., Forman and Ansell's (2001) revoicing, Shimuru's (2004) *yamada*, Lampert's (1990) establishment of a community of validation.

Data Extract from the Problem-Solving Session

The extract is taken from a session in a Grade-10 classroom of about 30 students, who were working on analytical geometry in relation to distances (points, midpoints, lines, etc.) and had been initiated to usual algebraic formulas. This extract was chosen for its capacity to illustrate patterns of teacher and student interactions that were common to almost every session conducted/experimented in classrooms. For this precise session, the teacher wished to experiment with tasks along a mental computation context (following our work on mental computation, e.g., Proulx, 2014), with the intention to see how students would engage in it. One task given to students was "*Find the distance between (0,0) and (4,3) in the plane*" (given orally, with points drawn on a Cartesian plane on the front board), who had 15 seconds to answer without recourse to paper and pencil or any other material. When time was up, students were invited to share and justify their solutions to the group. The following is a synthesis of the strategies engaged in and the discussions, questions, and explorations that ensued.

The first strategy referred to applying the usual distance formula (D=$\sqrt{(x_1-x_2)^2+\ (y_1-y_2)^2}$), leading to 5 as a distance. A second strategy suggested drawing a triangle in the plane, with sides 3 and 4, for then finding the hypotenuse by using Pythagoras (Figure 1a).

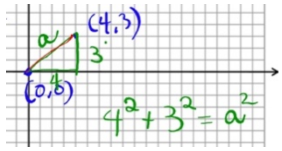

Figure 1a – Drawing the right triangle

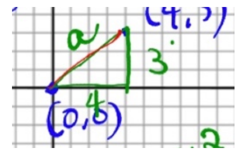

Figure 1b – Close-up on the triangle

Another student then suggested a third strategy: coming to the board to trace a red segment to count directly on it from (0,0) to (4,3) as in Figure 1b. Starting from (0,0), she counted "the number of points" to arrive at (4,3), counting the number of whole-number coordinate points from (0,0) to (4,3). While doing this at the board, she suddenly stopped and mentioned that her red segment did not go through the points she envisaged, which made the counting difficult. The teacher then traced another segment going through square diagonals linking two separate points, which could enable counting the number of (whole-number) coordinate points from one point to the next (giving 4 as a distance, Figure 2). The student agreed that for this case, it would work.

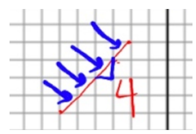

Figure 2 – Line drawn through square diagonals

The teacher then asked if the measure obtained with square diagonal lengths was identical to that obtained with the side of the square (drawing  on the board).

> One student asserted that both lengths were not identical, because the diagonal of the square was not of the same length as the square's side. Another explained that both lengths were different, because the hypotenuse is always the longer side in a triangle. Finally, a student claimed that the diagonal was longer, because it faces the wider angle.

The teacher then asked if that last assertion about facing the wider angle was always true, and if so why (drawing on the board a random right triangle ).

> One student, pointing at the triangle, stated that it was indeed the case in this drawn triangle. Another student explained that, in a triangle, the bigger the angle the longer the opposite side, mentioning that if the side-hypotenuse had been longer, the opposite angle would have been wider. And, because the sum of the (measures of the) angles in a triangle is 180º, then the 90º angle is always the wider one, the other 90º being shared between the remaining two angles.

Using the drawing of the triangle, the teacher simulated the variation of the right angle toward an obtuse one and traced the resulting side obtained, showing how it would become longer (drawing  on the board). He then moved it toward producing an acute angle, asking students if their "theory" about opposite side of the angle worked for any angle, like acute ones.

> One student asserted that it works for isosceles triangles, with equal sides facing equal angles, and another mentioned that it is the same for the equilateral triangle, since it is "everywhere the same" with same angles and same side lengths.

The teacher explained that these ideas about the diagonals being longer than the side underlined the fact that this initial strategy amounted to counting diagonals, that is, the number of diagonals of a unit square. And, that this offered a different sort of measure for the (same) distance between the two points: one in terms of units and one in terms of diagonals. A student added that if one knows the value of the diagonal, then one could find the number of unit squares for the diagonal-segment by multiplying by that factor.

One student offered a fourth strategy to find the distance, suggesting to use the sine law with angles of 45°. The teacher asked the student how he knew that both angles were 45° in the triangle. As skepticism grew in the classroom, the teacher suggested that students inquire, in small groups or individually, if the triangle's angle were 45° or not, and to be able to convince others. After 5-6 minutes of exploration, students were invited to share their findings.

> One student explained that on her exam checklist there is an isosceles right triangle with 45° angles. Thus with this triangle of side length of 4 and 3, one cannot directly assert that it is 45° because it is not an isosceles triangle as its sides are not of equal measure. Another student illustrated at the board that if one "completes" the initial triangle into a rectangle ( , see Figure 3a), then the hypotenuses of both triangles are the rectangle's diagonal which cuts it in two equal parts and thus cuts its angle in two equal 45° parts.

As the teacher highlighted that the two arguments were opposed, one student replied not in agreement with the last argument, drawing on the board a random rectangle with its diagonal (Figure 3b), and asserting that in this rectangle *it was not certain* that the angle was divided into two equal parts. Another student added that because the sides of the triangle were not identical (of 3 and 4), then the diagonal would not necessarily cut the 90° angle in two equal parts of 45°.

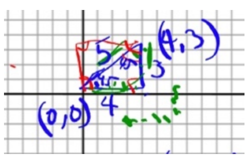

Figure 3a – The "completed" rectangle

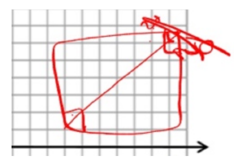

Figure 3b – The "counter" rectangle

The teacher highlighted that this last argument reused aspects of the precedent "theory" that the longer side faces the wider angle in the triangle. Hence, following this, a longer side needed to face a wider angle. Then a counter-example was offered to the group.

> The student who made reference to the checklist asserted that it happens in their exams that right triangles don't have 45° angles, for example, one with 32° and 58°; coming to the board to draw it (Figure 4). She completed her drawing to create a rectangle, explaining that the diagonal cuts as well this rectangle in two parts, but that the angles obtained are not of 45°.

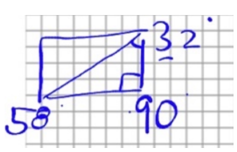

Figure 4 – The triangle counter-example with angles of 32° and 58°, and the rectangle

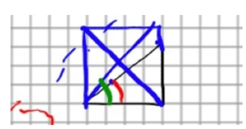

Figure 5 – Comparing triangles within a square

The teacher asserted that this offered a counter-example, with a type of right triangle frequently met that did not have angles of 45°. One student added that because all sides were different, then their associated angles would be different, the longer side needed to face a wider angle, leading to different angles. The teacher then highlighted the work of one student who drew a square in his notebook to assess the 45º situation. Drawing a triangle of sides 3-4-5, he extended the cathetus of 3 toward one of 4 to create a 4x4 square. Then, because in the previous unit-square the angles were of 45º, in this 4x4 they were 45º as well (Figure 5). Comparing hypotenuses of both triangles, it illustrated that in the initial 3-4-5 right triangle the angle is smaller than the right triangle of side 4 and 4. All this led students to appear to agree with the fact that the angle was not 45º, ending the explorations (and leading to offer another task to be solved by the students).

Pushing Forward the Mathematics: Validating Practices

One kind of teaching actions enacted in the session are validation practices. These, in problem-solving contexts, are related to the consideration of the classroom as a mathematical community of validation as Boaler (1998), Borasi (1992) and Lampert (1990) call it. In this community, members are encouraged to generate ideas, questions, and problems, to solve them, to share their understanding, to negotiate meaning, to develop explanations and justifications to support their solutions, to question others' solutions, and so on. As Lampert (1990) explains it is the teacher's role to makes sure that students' justifications are adequate, that arguments are clearly stated, that solutions are expressed in an intelligible manner and are accessible; essential conditions for the mathematical community to take shape and flourish. In sum, it is the teacher's role to create and sustain this mathematical community. As a way of example, when Max mentioned that the triangle's angle was 45º for using the sine law, the following interaction led to a request for validation from the classroom community:

Teacher: And, how do you know that the angle is 45º? [some students appeared opposed]
Max: Because it is 45º for both angles [some students agree, others express disagreement]
Teacher: Ok, so maybe 45º maybe not. We are not sure. But we need to arrive at something, we need to agree, we need to know if it is or not 45º. So, I will ask you to take a couple of minutes, alone or in small groups, to see if it is or not 45º, and to be able to explain it and even be able to convince others of it. You can use all you have, workbooks, textbooks, notes, whatever. After that, we will share your findings. Ok, go! [students start to work]

For Cobb et al. (1994) and Lampert (1990), a community of validation develops, analyzes, questions, and argues for what is or not mathematically acceptable. Hence the mathematics produced within the classroom community is validated by the community itself (in which the teacher takes part). The teacher's requirement for and establishment of these validation practices aim to give status to the mathematical productions of the classroom, to make official the ideas shared by making them accessible and reusable in the future as they are justified and argued for. These validation practices contribute to the advancement of mathematical ideas in the classroom.

Pushing Forward the Mathematics: Reformulating Practices

Another sort of teaching actions relates to the reformulation of students' ideas. While students share their strategies, as Cobb and Yackel (1998) underline, the teacher can re-describe students' reasoning and reformulate it in different terms: one in which they would not necessarily have used but that are aligned with the meaning they are making. As an example, when Sandra explained her strategy of counting the points on the red segment, the teacher not only asked her to clarify what she did, but also re-explained and reformulated the underlying idea.

Sandra: Well, I just counted the points.
Teacher: What do you mean exactly by this?
Sandra: (coming to the board) Well, if you draw a line from here to here, it gives 1, 2, 3…

Teacher: Ah, OK, you trace a segment from one point to the other, so from (0,0) to (4,3).
Sandra: Yes. But, finally, this thing does not work as I thought.
Teacher: Ok, it is difficult to count directly on the plane. So, Sandra, you wanted to count the number of coordinate points that your segment crosses from (0,0) to (4,3). And it's difficult because it does not cross them directly. But it could work! If you take this segment and link these two other points (Figure 2). Then, here, it goes though the square diagonals and we can directly count the points crossed on the plane.

The teacher here resumed and reformulated Sandra's explanations, not to correct them (even if some adjustments could be made), but mostly to clarify them, deepening them, drawing out its key elements for all to see. This is aligned with what Forman and Ansell (2001) call *revoicing*:

> there is a greater tendency for students to provide the explanations […] and for the teacher to repeat, expand, recast, or translate students' explanations for the speaker and the rest of the class. The teacher revoices students' contributions to the conversation so as to articulate presupposed information, emphasize particular aspects of the explanation. (p. 119)

These reformulating practices are a way for the teacher to insert him or herself into students' explanations and work with the mathematical ideas produced in the moment. It is also a way to make ideas accessible to the classroom community for engaging in subsequent validation practices, since some ideas are not always mathematically adequate (like numerous arguments made around the 45^o angle). These are then also clarified and reformulated for students to understand and validate as a community. By making the mathematical ideas accessible to all and highlighting them, the teacher is making the mathematics of the classroom advance.

Pushing Forward the Mathematics: Summarizing Practices

A third sort of teaching action is about summarizing practices. At different moments in the classroom, when ideas are shared in the problem-solving process, the teacher underlines explicitly some ideas produced that have important mathematical potential and to which students need to pay attention: those that will be useful or reused in the future. Hence in problem-solving contexts, the teacher has an important role to play in underlying the important mathematical ideas produced and making sure that these are clear and accessible, as Stein et al. (2004) mention. These summarizing practices can happen at varying moments during a problem-solving session, and the teacher at any moment can opt to underline, validate, put forth, thus summarize, the mathematical ideas shared for leaving traces about the mathematical productions of the classroom. For example, in relation to the query about the square diagonal, after arguments and ideas were shared, the teacher summed up the ideas and came back on Sandra's strategy, extending it to the calculation of distances:

Teacher: Let's go back to the square diagonal. It is longer than the side. In Sandra's strategy, we count the number of diagonals, the ones from one point to the other, from (0,0) to (4,3). We talked about points crossing. We would here have 4 diagonals, which is also a possible measure of the distance between (0,0) and (4,3). We would thus have two measures: one of 5 in terms of square-sides and one of 4 in terms of square-diagonals. Same distance, measured in two different ways, hence offering two different measures.

When it is done at the end of the inquiry, as Shimizu (2004) mentions, this summing up is an occasion to conclude by highlighting the mathematical ideas worked on during that inquiry, what is called in Japanese the *yamada* of the activity. For example, the strategy offered for concluding the 45^o exploration was a way of summing up most ideas shared in class and of settling the issue.

Summarizing practices in problem-solving contexts are essential acts that contributes to leaving mathematical traces of what was covered in the classroom, enabling students to pay attention to important mathematical concepts, hence pushing the mathematics forward.

Final Remarks

These three teaching actions succeeded in pushing the mathematics forward in the classroom, highlighting the important role of the teacher in the evolution of the classroom and how mathematics is tackled and develops in it. The analysis of these teaching actions offers an initial way, albeit preliminary, to address the questions that triggered this research report, namely, about the possible teacher actions that aim to contribute to the development of mathematical concepts in problem-solving contexts. Much more needs to be studied in terms of the outcomes of these practices, for example, on student's personal concept-development and how they operationalize these in various situations. But, at this point, this initial analysis offers promise for better understanding and conceptualization of teachers' roles in problem-solving contexts.

EMERGENT BILINGUALS AS TEACHERS: CONSTRUCTING STORYLINES IN AN ELEMENTARY MATHEMATICS CLASSROOM

Erin Smith
The University of Southern Mississippi
erin.marie.smith@usm.edu

Stereotypes and storylines for emergent bilinguals (EBs) permeate U.S. culture, have been historically deficit-oriented, and determine ways teachers and students interact with each other in classroom contexts. As a way to disrupt and challenge such narratives, one elementary teacher, Courtney, leveraged her authority to construct and foster the storyline of mathematical competence for EBs across multiple school years. One of the most frequent ways Courtney did this was to interactively position EBs as teachers in whole class mathematical interactions.

Keywords: Equity and Diversity, Classroom Discourse

Stereotypes and storylines of mathematical competence permeate U.S. culture (Nasir, 2016). For emergent bilinguals (EBs), their stereotype and storyline has historically been deficit-oriented, focusing solely on their linguistic deficiencies, need of remediation, and ill-preparedness for school, and the added challenges they pose to over-worked teachers. Such stereotypes and storylines can circulate in classrooms and determine ways teachers and students interact with EBs (de Araujo, Smith, & Sakow, 2016; Turner, Dominguez, Maldonado, & Empson, 2013; Wood, 2013; Yoon, 2008). For instance, if teachers position EBs in deficit storylines, EBs opportunities to learn, have access to, and achieve success in mathematics are restricted. In contrast, when teachers position EBs in ways that call attention to and value their mathematical and linguistic competencies and diverse cultural assets and experiences, a storyline of mathematical competence can be fostered. Too frequently, however, EBs are shut out of such storylines. Thus, it is critical for productive storylines be established and fostered for EBs in classrooms. Yet, to do this, teachers must be strategic in their use of classroom discourse to interactively position EBs in identified and desired storylines.

One theoretical lens to examine the creation of storylines for EBs via classroom discourse is positioning theory (van Langenhove & Harré, 1999). Positioning theory foregrounds discourse and proffers a way to critically analyze how language-in-use can construct and foster storylines for groups of students through moment-to-moment interactions. More specifically, positioning theory enables the researcher to examine how teachers' interactive positions of EBs individually acts to establish and foster different storylines for EBs collectively over time.

Positioning Theory and the Role of the Teacher

Positioning theory (van Langenhove & Harré, 1999) is composed of three central components: acts, storylines, and positions. *Acts* refer to the social meaning(s) of people's intended actions, (Harré, Moghaddam, Cairnie, Rothbart, & Sabat, 2009). *Storylines* are "strips of life [that] unfold according to local narrative conventions" (Harré, 2012, p. 198) that are constituted and reconstituted through social interactions. Oftentimes, these refer to the multiple categories, stereotypes, or cultural values (e.g., teacher/student, reform/traditional instruction, correct/incorrect) people draw on in social situations that are used to define the expectations and conventions of interactions in that setting (Herbel-Eisenmann, Wagner, Johnson, Suh, & Figueras, 2015). For example, a teacher in a classroom may draw on the storylines of teacher/student, reform/traditional instruction, and correct/incorrect mathematics answers simultaneously to motivate his/her interactions with students. Hence, within each social interaction there are multiple storylines at play, all drawn from and on participants' cultural, historical, and political backgrounds and experiences. Additionally, the ways individuals enact storylines are or become socially recognizable. For instance, if a teacher employs a storyline that contradicts historical or culturally shared narratives (e.g., incorrect answers are just as valuable as correct answers), the acts may not initially be conceived as socially recognizable, however, over time they become socially recognizable as the storyline is taken up.

The ways people enact storylines are referred to as *positions*. Within storylines, people assume a position, called reflexive positioning, and are positioned by others, called interactive positioning. These positions are metaphorical and determine the social expectations and range of available acts of speakers and listeners. In this way, each position is relational and the range of acts that are available is contingent upon each given situation. Some situations can further restrict the range of available positions. For example, in institutional settings, such as schools, individuals' rights and duties are socially prescribed.

Role of the Teacher

Given their position in the classroom, teachers' discursive practices represent a powerful tool that can be leveraged to create, foster, or shift storylines for groups of students in mathematics. The storylines established and fostered by the teacher can expand or restrict students' ability to exercise agency, participate, and learn. For example, if a teacher constructs a storyline of mathematical competence for an EB that is supported through her/his positioning moves (e.g., calls on student to share her/his mathematical thinking, invites student to take on the role of teacher, allows student to control the mathematical tools), the social expectations, opportunities to co-construct mathematics, and range of available positions would be different compared to a student whose storyline was of mathematical incompetence. The consequences of teacher positioning are further magnified by the appropriation of positions and storylines by peers (Turner et al., 2013; Yoon, 2008). Thus, teachers' interactive positions and storylines of EBs can affect EBs' ability to participate, contribute, and learn.

When teachers' discursive practices are employed in whole class settings, the interactive positions and subsequent storylines for EBs are made visible to everyone. Consequently, research (Turner et al., 2013; Wood, 2013) has found that these public displays affect how peers interactively position EBs in the future. Moreover, the storylines constructed by teachers can act to counter or reinforce storylines for individuals through group associations. For instance, storylines constructed for individual EBs can act to counter deficit-oriented stereotypes of EBs as a whole. In order to better understand the ways teachers' interactive positions can create and foster storylines for EBs that can counter deficit-oriented storylines, this study was guided by the question, *What storylines for EBs does an elementary teacher construct and foster through her acts in whole-class mathematical interactions?*

Methodology

Data for this study were drawn from a three-year longitudinal professional development intervention focused on EBs development of mathematic and linguistic competencies, the enhancement of mathematics curriculum for EBs, and the facilitation of productive classroom interactions for EBs (see Chval, Pinnow, & Thomas, 2014 for more information). Data collected included classroom video and audio recordings.

To answer the research question, a case study design (Stake, 1995) was used to examine the discursive practices of Courtney, a white female, monolingual third-grade teacher. Courtney taught at a school that was predominately white (>70%) with less than 10% of the student population Latinx. In addition, over half of students received free and reduced lunch. Prior to Courtney's participation in the intervention, she had taught for two years and had received no formal education in pedagogy for EBs or had opportunities to teach EBs. Consequently, Courtney's participation in the intervention coincided with her first opportunity to teach EBs. Thereafter, in each year of the study Courtney taught 1-3 Latinx EBs.

Data Selection and analysis

To identify the storylines Courtney constructed and fostered for EBs through her interactive positions, a subset of the data was analyzed. Data was restricted to the first two years of the study due to the number and retention of EBs. In each of the first two years, Courtney had three Latinx EBs (see Table 1 for a summary of student demographics). Each student was classified as an English language learner by the school district based on their scores on the Assessing Comprehension and Communication in English State-to-State for English Language Learners (ACCESS) assessment. Based on their ACCESS composite scores, the EBs in this study can be considered to be at an "intermediate" level of English language proficiency.

Table 1: Summary of student demographics

Year	Student	Birthplace	ACCESS Composite Score
1	Alonzo	Mexico	4.6*
1	Yasmin	USA	3.8*
1	Ignacio	Mexico	3.9*
2	Samuel	USA	4
2	Bryce	USA	3.8
2	Lea	USA	Not available

*ACCESS scores were only available for the following school year.

Across the two years, there were a total of 45 lessons, each approximately one hour long, that were video and audio recorded. To identify the storylines created and fostered for EBs related to mathematics, only those interactions where an EB participated, was asked to participate, or was interactively positioned by the teacher or peers in whole class settings were transcribed and analyzed. In my analysis, I first identified the Courtney's acts at the utterance and turn taking levels in MAXQDA (see Figure 1). Then, I open coded (Strauss & Corbin, 1990) the acts to identify Courtney's interactive positions of EBs and the storylines that were told via the acts.

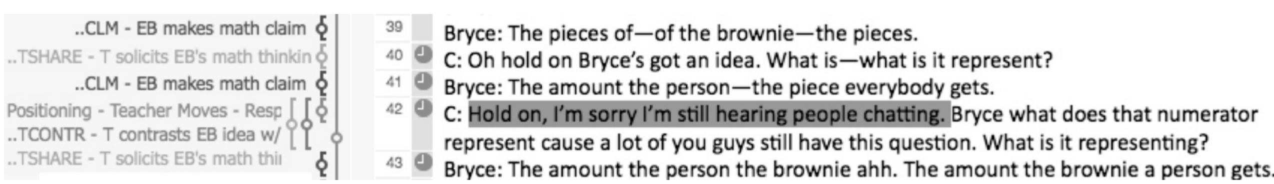

Figure 1. Example of a coded classroom transcript in MAXQDA.

Findings

Across the two years, Courtney constructed and fostered multiple storylines for EBs via her interactive positions. One of the most frequent storylines she promoted was EBs as teachers. Courtney cultivated this storyline in numerous ways, such as asking or allowing EBs to: share problem-solving strategies, control the classroom conversation, assign work, revoice a peer's thinking, and correct peers' mathematical errors. In this way, Courtney positioned EBs physically or metaphorically as teachers, which was a privileged role in the institutional space (of the classroom). To illustrate the several ways this storyline was advanced in classroom interactions, representative classroom excerpts are presented below.

Share a Problem-Solving Strategy

Courtney leveraged problem-solving sharing opportunities as a chance to position EBs as teachers. Frequently, these sharing opportunities occurred at the conclusion of the lesson and were used as a way to share different student approaches to a single problem or highlight specific aspects of a problem-solving strategy (e.g., how to draw efficient pictures). As students worked individually or in small groups on mathematics tasks, Courtney circulated and traditionally selected three students to share who represented a range of strategies. Often, each student's work was scanned, which served as a visual referent as the student shared at the board. This was a particularly useful tool for EBs since they could gesture and point while explaining in English. When students presented, they were physically and metaphorically positioned as a teacher. In this way, the student was physically located in the space routinely reserved for the teacher (i.e., standing at the front of the classroom while peers sat on the carpet) that acted to garner the attention of the class. As a result, the student was positioned as an expert who had ideas worthy of consideration and could explain those ideas to peers.

The following transcript from Oct. 22 illustrates this practice. At the close of the lesson, Courtney selected three students to share their strategy to the problem, "Clayton rolled 8 dice. Each landed on 4. What was Clayton's total? How do you know that is Clayton's total?" Lea (EB) was the second student to share and her work was shown on board (see Figure 2).

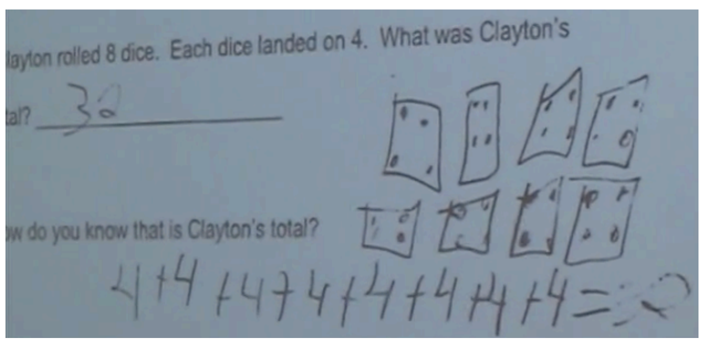

Figure 2. Lea's written work to solve the problem of calculating the sum for eight die each showing a value of four.

1 Courtney: Alright the next person to share is Lea. Lea will you get up. [Administrative talk]
2 Lea: (gets up and comes to board) First um I added four and then um I added four plus four plus four plus four. First I drew a picture of eight dice and then added four plus four plus four plus four plus four plus four plus four plus four equals 32.
3 Courtney: So why did you—how many four—how many times did you need to count up by four?
4 Lea: Well I needed to count um I needed to count eight times so I could get (inaudible)
5 Courtney: Ok so when she—when she—what'd um—any comments about Lea's strategy?
6 Lea: Janie.
7 Janie: Nice work and I like your strategy.
8 Lea: Carl
9 Carl: I like the way how you like, drew a picture of this stuff (gestures across work)—numbers.
10 Lea: Ok. Laura

11 Laura: Um I think the way that you drew your picture of the four plus four plus four kind of (inaudible) but I still think you did a great job.
12 Courtney: Alright so she wrote a number sentence and she wrote up a picture to go along with that. I like—I like your strategy a lot. Nice job Lea. (clapping and cheers)

In this excerpt, we see how Courtney invited Lea to the front of the room to share her strategy with the class with her written work as a visual referent. This act physically positioned Lea in the role of the teacher (at the board), metaphorically positioned her as an expert who had a problem-solving she could explain and peers could learn from, and provided an opportunity to be an active classroom participant. At the board, Lea described her strategy for calculating the sum of 32 (turn 2), which included drawing a representation of the dice rolled (Figure 2). Next, Courtney asked Lea for clarification of the number of times she added four (turn 3), which enabled Lea extended talk time and to maintain control of the conversational floor.
In sum, interactions such as this illustrate the ways Courtney interactively positioned EBs as teachers by allowing EBs to physically assume the space of the teacher, explain problem-solving strategies to peers, and control the classroom conversation.

Control Classroom Conversation

Another way Courtney interactively positioned EBs as teachers was to allow EBs to control the classroom conversation around their mathematical ideas, which occurred after EBs had shared their problem-solving strategies. Frequently, Courtney would ask classmates if they had any comments, questions, or compliments for the presenter, which the speaker would then field. Not only did this practice provide opportunities for EBs to retain the conversational floor but also reinforced the expectation that peers will consider and respond to EBs' mathematical ideas.

The transcript above illustrates a common way Courtney employed this practice. After Lea shared her problem-solving strategy, Courtney invited peers to comment (turn 5). This act reinforced the classroom norm that students would attend to and think about each other's mathematical thinking, signaled that Lea's ideas were worthy of further consideration, and kept Lea's mathematical thinking at the center of the conversation. Courtney then allowed Lea to control the conversation of peer comments on her problem-solving strategy, a practice that is often reserved for the teacher (Mehan, 1979). Lea fielded comments on her mathematical thinking from Janie, Carl, and Laura (turns 7, 9, and 11). Lea's peers had many comments they could make, however, in each comment there is evidence of their attention to Lea's mathematical thinking, particularly her problem-solving strategy and representation. Moreover, each peer comment included praise (e.g., "I like your strategy"), although Laura's was back-handed (turn 11). Courtney did not allow the conversation around Lea's ideas to end on this note, but concluded with a positive evaluation, "I like your strategy a lot."

Overall, this excerpt illustrates another way Courtney interactively positioned EBs in the role of the teacher, both physically and metaphorically, which advanced the storyline of EBs as teachers. These interactive positions also allowed opportunities for EBs to use mathematical discourse, have extended talk time, and control the conversational floor.

Assign Work

Assigning work to the class is a practice often reserved for the teacher, however, there were instances in the data where Courtney would allow EBs to do just this. For example, on Nov. 11, Courtney walked through a task with the class at the carpet. In the task, each student was to create their own book of stamps. To do this, they would determine the face value of a stamp, the total number of stamps in their book (shaped in an array), and the total value of the book. In the demonstration, Courtney asked Alonzo to select the face value of the stamp and then calculate the total value of the book. After Alonzo did this, Courtney asked the class what she must do next according to the checklist of instructions.

1 Courtney: So all of these altogether is 75, (writes 75 on board) 75 what, dollars?
2 Choral: 75 cents
3 Courtney: Ok, so should I just write that [the total value of the book] or
4 Student: No
5 Courtney: What's the next step that I have on my checklist, Clark what's the next step I have on my checklist?
6 Clark: Um explain, explain your strategy.
7 Courtney: Oh, I have to explain my strategy. Ok so how can I explain what Alonzo had asked us to do? Yasmin, how can I explain it?

What is important in this interaction is the way Courtney framed the next step of the instructions to "explain your strategy." Although the checklist specified students should do this, Courtney reframed this task as something Alonzo had asked them to do (turn 7). With this act, Courtney interactively positioned Alonzo as someone who asked the class to do mathematical work—acts traditionally reserved for teachers in instructional spaces. Thus, Courtney's interactive position promoted the storyline of EBs as teachers.

Revoice Peers' Mathematical Contributions

Courtney frequently revoiced students' mathematical explanations in whole class discussions. Less commonly, were explicit requests from Courtney for students to take on this practice. For instance, on Oct. 27, Courtney asked the class if someone could revoice Emily's strategy to calculate the total value of her book of stamps (see Figure 3).

Figure 3. Emily's book of stamps and her written work.

1 Emily: I counted by 5s and 10 and (inaudible) instead of going like this (gestures across a row), I got, and then I did 5 times 18.
2 Courtney: Ok um, can someone else explain her strategy?
3 Lea: (hand raised)
4 Courtney: Lea can you go up there and explain what Emily did?
5 Lea: She did like (gets up and moves to board) (5.0 second pause)
6 Courtney: Shhh.
7 Lea: She did like, she counted by fives and go like 5, like 10, 15, all the way to 90 (points to 90).

8 Courtney: Alright. Laura. Thank you Lea for explaining her strategy you must've been paying close attention.

In this excerpt, Courtney interactively positioned Lea as a student who could revoice a peer's problem-solving strategy, attended to and thought about a peer's mathematical ideas, and could articulate those thoughts publicly (turn 4). Lea paused in her explanation (turn 5) and Courtney moved to silence the class (turn 6), which positioned Lea as a student who should be respected, had an idea everyone should hear, and had the conversational floor. Lea continued (turn 7) and supported her explanation with gestures to the written work. Lea's explanation evidenced she understood Emily's strategy of repeated addition. Next, Courtney thanked Lea for her explanation and then positioned her as a student who followed the classroom norms of paying attention, stating "you must've been paying close attention" (turn 8).

Overall, this interaction represents another way Courtney interactively positioned EBs as teachers. In this case specifically, Lea was positioned physically and metaphorically as a teacher when she described Emily's strategy. As with the previous excerpt, Courtney allowed Lea to control the space in the front of the room and did not approach her.

Correct Peer Mathematical Errors

A final way Courtney interactively positioned EBs as teachers was through invitations to correct a peer's work at the board. For example, on Apr. 26, the class discussed two representations of 97 cents, "$0.97" and "¢97," written on the board and agreed "¢" was to be written on the right-hand side of the value (e.g., 97¢). Courtney then stated,

> Alright so the 97 cents, oh instead of having the 97 cents at the back of the cents sign it's in the front of this one isn't it. Alright, so how can we fix that? So, who can fix that up for me? Who can fix it? Who wants to? You want to fix it Samuel? Yeah go fix it, fix somebody's work for me. You're their editor. You're going to fix up what somebody did.

In her turn, Courtney invited an EB to come to the board to correct the error, a practice often reserved for the teacher. Courtney picked Samuel, an EB, who was asked to be an "editor" for the peer. Courtney's act invited Samuel to take up the physical space of the teacher (by coming to the board) and situated him as a person who can correct peers' mathematical work. Courtney went further by calling Samuel an "editor"—a powerful title for him in a class full of native English-speaking peers. In short, this interaction represented another way Courtney interactively positioned EBs in the role of a teacher—a person who can correct others' work.

Discussion and Conclusion

Courtney, a white female, monolingual elementary teacher presents a case of a teacher who leveraged her authority in the classroom to interactively position EBs in ways that fostered the storyline of EBs as teachers–a privileged role in the institutional space of the classroom. An examination of the data revealed that Courtney did this through interactive positions that asked or allowed EBs to: share problem-solving strategies, control the classroom conversation, assign work, revoice a peer's thinking, and correct peers' mathematical errors. As a result, Courtney employed interactive positions at the individual level, which advanced the storyline of EBs as teachers for the collective. In this way, Courtney promoted a storyline for EBs in mathematics that challenged dominant narratives that EBs require remediation and extensive mathematical support (Chval & Pinnow, 2010; de Araujo et al., 2016; Polat & Mahalingappa, 2013).

Courtney characteristically represents many elementary teachers in the U.S. As such, her case is common, yet unique. She not only represents the majority of elementary teachers in the

U.S., but her success in advancing productive storylines for EBs in mathematics situates her in the unique position to offer insight into the ways teachers can use their discursive practices to put forth storylines for EBs in mathematics that challenge dominant narratives. Thus, there is much to learn from Courtney that other monolingual teachers can integrate into their practice. Most notably, the interactive positions identified can be implemented by other teachers to advance the storyline of EBs as teachers of mathematics. For example, a teacher may begin to reflect on the storylines they construct for EBs through their acts. Alternatively, a teacher may ask EBs to take on roles and responsibilities that are typically reserved for teachers (e.g., assigning work, control the classroom conversation, teaching peers). Given the growth of EBs in the U.S., it is essential that teachers understand how their interactive positions can be used to promote storylines individually and collectively to create change in public perceptions of mathematical ability.

We investigated teachers' responses to a common set of varied-potential instances of student mathematical thinking to better understand how a teacher can shape meaningful mathematical discourse. Teacher responses were coded using a scheme that both disentangles and coordinates the teacher move, who it is directed to, and the degree to which student thinking is honored. Teachers tended to direct responses to the same student, use a limited number of moves, and explicitly incorporate students' thinking. We consider the productivity of teacher responses in relation to frameworks related to the productive use of student mathematical thinking.

Keywords: Classroom Discourse, Instructional Activities and Practices

Recommendations for ambitious mathematics teaching have identified the importance of instruction that honors and incorporates student thinking (e.g., National Council of Teachers of Mathematics [NCTM], 2014). Such instruction involves the teacher facilitating meaningful mathematical discourse by eliciting and making public student thinking, as well as appropriately *responding* to that thinking. Research has shown that the way in which teachers respond to student mathematical thinking (SMT) affects student learning in the classroom. For example, research has found that teacher responses that press students to further engage in thinking about the mathematics in their contributions provide students with increased learning opportunities (Kazemi & Stipek, 2001). More recently, Ing et al. (2015) found that responses that encourage students to engage with each other around mathematics correlate with increased student participation and higher student achievement.

Since SMT varies in the degree to which it provides leverage for accomplishing mathematical goals (Leatham, Peterson, Stockero, & Van Zoest, 2015), it follows that not all thinking should be responded to in the same way. Research examining teachers' responses to different types of SMT has produced mixed findings. Franke et al. (2009) found that the types of questions teachers asked did not vary depending on the clarity, correctness or completeness of a student's initial explanation, but other studies have found that teachers' responses do vary based on different types of SMT. For example, Bishop, Hardison, and Przybyla-Kuchek (2016) found that short or routine student contributions were related to teacher actions that were not responsive to SMT, whereas those that included strategies or reasoning were related to responses that engaged students in conversations about the SMT. Similarly, Drageset (2015) reported that brief answers to non-complex questions were typically responded to with a recall or procedural question, whereas unexplained answers were typically followed by responses that focused on an elaboration or rationale. Although prior research provides a foundation for understanding teachers' responses to instances of SMT, more work is required to fully understand variations in such responses, including whether particular responses might be more or less productive in supporting student learning in particular situations. Fortunately, scholars have developed a number of constructs for characterizing teacher responses that support this line of research.

Researchers have characterized teacher responses in various ways based on the focus of their studies. Brodie (2011) developed a coding scheme for teacher responses that captured two key aspects of responses—responsiveness to student ideas and student engagement. Schleppenbach, Flavares, Sims, and Perry (2007) analyzed teachers' responses to student errors using a scheme that captured two additional aspects of responses—the form of the response (statements or questions) and who questions were directed towards (the same student or other student(s)). Peterson et al. (2017) aimed to develop a comprehensive coding scheme that foregrounded responsiveness while also capturing other important ideas included in existing teacher response constructs. These researchers developed the Teacher Response Coding Scheme (TRC) to both disentangle and coordinate a number of components important in a teacher response, including the actors invited to respond, the type of action, and responsiveness to the SMT. Such a scheme provides a way to study teacher responses to student contributions that simultaneously addresses components of responses valued by other scholars working in this area.

Our study extends earlier research on teacher responses by using the TRC (Peterson et al., 2017) to examine teachers' responses to a common set of SMT with varied potential to support student mathematical learning. In particular, this study focuses on answering the question: *How do teachers' responses vary depending on the potential of an instance of SMT to support student mathematical learning?* We use these findings to discuss the extent to which various teacher responses are productive given the mathematical potential of an instance of SMT.

Theoretical Framework

Our work draws on two distinct, but related theoretical constructs. To make sense of the potential of an instance of SMT to support student mathematical learning, we use the MOST Analytical Framework (Leatham et al., 2015). To interpret the productivity of teachers' responses to these instances of varying potential, we use a set of principles drawn from the literature that underlie productive use of SMT. Descriptions of these constructs follow.

Leatham et al. (2015) characterized particular high potential instances of SMT as MOSTs—**M**athematically Significant Pedagogical **O**pportunities to Build on **S**tudent **T**hinking. The MOST Analytic Framework defines three characteristics of these instances—student mathematical thinking, significant mathematics, and pedagogical opportunity—each having two criteria that are used to determine whether an instance of SMT embodies that characteristic. For student mathematical thinking the criteria are that the *student mathematics* is inferable and that one can articulate a closely related *mathematical point* that the contribution could be used to better understand. For the significant mathematics characteristic, the criteria are that the mathematical point is *appropriate* for the students in the class—not too easy or too hard—and *central* to mathematical goals for their learning. To satisfy the pedagogical opportunity characteristic, the instance must create an *opening* to build on the SMT and the pedagogical *timing* must be right to take advantage of the opening when it occurs. The six criteria are considered linearly and an instance of SMT is classified according to the last criteria it satisfies (Student Mathematics, Mathematical Point, Appropriate, Central, Opening). Instances that meet all six criteria are classified as MOSTs. Those instances that appear mathematical, but for which the student mathematics cannot be inferred, are designated *cannot infer* (CNI).

To determine whether a teacher response to an instance of SMT is likely to be productive, we focus on the extent to which it coordinates core ideas about effective teaching and learning of mathematics drawn from the literature (e.g., NCTM, 2014)—what we refer to as principles underlying productive use of SMT (see Figure 1). We see these four principles as simultaneously coordinated in the teaching practice of *building* on SMT—making student thinking "the object of consideration by the class in order to engage the class in making sense of that thinking to better understand an important mathematical idea" (Van Zoest et al., 2017, p. 36). Further, we see MOSTs as instances of SMT that are prime opportunities for a teacher to engage in building.

1. The mathematics of the instance is at the forefront. (Mathematics Principle)
2. Students are positioned as legitimate mathematical thinkers. (Legitimacy Principle)
3. Students are engaged in sense making. (Sense-Making Principle)
4. Students are working collaboratively. (Collaboration Principle)

Figure 1. Principles underlying productive use of student mathematical thinking.

Methodology

The Scenario Interview

The Scenario Interview (Stockero et al., 2015) is a tool to investigate how teachers respond to SMT during instruction and their reasoning underlying those responses. Teachers are presented with eight instances of SMT—four each from geometry and algebra contexts. The instances represent a range of SMT that satisfy different sets of MOST criteria, including those for which the SMT cannot be inferred and those that are mathematically significant but have poor timing. Four instances—two from each context—are MOSTs. Figure 2 provides four sample instances, their contexts and the last criteria they met on the MOST Analytic Framework.

Scenario	Context	Instance	Criteria
G1	Students were sharing their solutions to the following task (a corresponding picture was on the board). *Given two concentric circles, radii 5cm and 3cm, what is the area of the band between the circles?*	Chris shared his solution: "The radius of the big circle is 5 and the radius of the little circle is 3, so the gap is 2, so the area of the band is 4π cm^2."	MOST
G2		Before the teacher had a chance to respond to Chris, Pat says, "I also got 4π cm^2, but I did it a different way."	SM
A1	Students had been discussing the following task and had come up with the equation y = 10x + 25. Task: *Jenny received $25 for her birthday that she deposited into a savings account. She has a babysitting job that pays $10 per week, which she deposits into her account each week. Write an equation that she can use to predict how much she will have saved after any number of weeks.*	Terry says, "If you deposit $20 per week instead of $10 per week, the number in front of the x in the equation would change, but the number that is added would stay the same."	Central
A2		Casey said, "You could also change the story so the number in front of the x is negative."	MOST

Figure 2. Sample Scenario Interview instances, contexts and the last MOST criteria met.

The Scenario Interview situates the interviewee as the teacher in the context presented. They are asked to describe what they might do next were the instance to occur in their classroom and to explain why they would respond in that way. The interviewee may ask for contextual information they feel is needed before giving their initial response and is later provided common contextual information, after which they can revise their response if desired. If they did so revise, the revised response was used for this analysis. Using a common set of instances of SMT and providing common contextual information allowed for direct comparisons among teacher responses to a collection of instances that satisfy different subsets of the MOST criteria. This comparison allowed us to determine whether teachers seem to differentiate their responses based on the type of SMT to which they are responding.

Data Collection and Analysis

Data consisted of video-recorded Scenario Interviews conducted with 25 grade 6-12 mathematics teachers from across the United States. We segmented each interview into the 8 instances of SMT and the 25 teachers' responses to each individual instance. A *teacher response* was defined as *the collection of actions that a teacher describes they would take immediately following an instance of SMT*. There were a total of 198 teacher responses because one teacher was not able to envision one of the instances occurring in their classroom, and another teacher's interview was cut short before the last scenario was completed.

To begin to understand teachers' responses, we focused on teachers' initial responses to the instances in the Scenario Interview. Thus, preparing data for coding required making inferences about how the teacher would respond *in the moment* to each instance by considering both the teacher's description of their initial response and their rationale. Three coders individually analyzed each instance for a participating teacher, distilled the teacher's response to its essence, and met to discuss their inferred responses until a final teacher response was agreed upon. Any disagreements were brought to the larger research team for further discussion.

The teacher responses were coded using the TRC (Peterson et al., 2017), a scheme that disentangles the teacher move (Move) from other aspects of the teacher response, including who is publicly given the opportunity to consider the SMT (Actor) and the degree to which the SMT is honored (Recognition-Student Action and Recognition-Student Ideas). Figure 3 provides the TRC coding categories and codes discussed in this paper. Note that the TRC allows for multiple moves to be present in a teacher response. To facilitate our analysis, in cases of multiple actions in a given teacher response we identified the *predominate code* for each category—*the code that the students are most likely to experience as the instructional intent of the response*. The analysis used the predominate codes for each of the 198 teacher responses.

Category	Coding Category Description	Codes
Actor	Those who are publicly given the opportunity to consider the instance of SMT	teacher, same student(s), whole class
Recognition-Action	The degree to which the teacher response (either verbal or non-verbal) uses the student action	explicit, implicit, not
Recognition-Ideas	The extent to which the student who contributed the instance of SMT is likely to recognize their idea(s) in the teacher response	core, peripheral, other, not applicable
Move	What the actor is doing or being asked to do with respect to the instance of SMT	adjourn, clarify, collect, connect, develop, dismiss, justify

Figure 3. Subset of the *Teacher Response Coding Scheme* (*TRC*) discussed in this paper.

We use two teachers' responses to Scenario G1 (see Figure 1) to illustrate our application of the TRC. T1's response, "I would just ask [Chris] to explain by using pictures and words how he came up with the 4 pi," asks the *same student* a question that is a *develop* move in that the student is asked to explain how he arrived at the answer. T1 uses the student's words so Action is coded *explicit*, and the question stays *core* to the student's Ideas because it focuses on how Chris arrived at his answer. In T2's response, "Who else has another answer? Did everybody get that? Give me some more answers," Actor is coded as *whole class* because all students are invited to participate. Move is *collect* as T2 requests that other students share their answers. The student's words are not used, but referred to (by "that"), so Action is *implicit.* Asking other students to share their answers to the same task is *peripheral* to the contributing student's Ideas.

Results and Discussion

To understand how teachers' responses vary depending on the potential of an instance of SMT to support student mathematical learning, we begin by comparing results related to the Actor, Move, and Recognition categories for MOSTs and non-MOSTs. Then, we discuss how particular responses might be more or less productive in particular situations by considering how they adhere to the principles underlying productive use of SMT. Note that there were 99 MOSTs and 99 non-MOSTs in the data set; since the frequencies and percentages are essentially equivalent, we report only the frequencies.

Comparison of Teacher Responses

Actor. Responses coded *same student* were the most prevalent in the data and occurred at about the same frequency for MOSTs (65 of 99) and non-MOSTs (63 of 99). This even distribution among MOSTs and non-MOSTs did not occur for instances with a *whole class* or *teacher* actor. More MOSTs (26) than non-MOSTs (6) were coded whole class, while the opposite was true for instances coded teacher (4 MOSTs; 30 non-MOSTs). This suggests that teachers may distinguish, at least to some extent, instances that have potential to be discussed by the class from those that the teacher might just quickly deal with and move on.

Moves. Two dominant moves in the data, *develop* and *justify*, occurred more frequently in response to MOSTs than non-MOSTs (Table 1). Develop moves accounted for 37 MOST responses and only 25 non-MOST responses, while justify moves accounted for 18 MOST and 11 non-MOST responses. Together these two moves accounted for over half of responses to MOSTs. Two other dominant moves, *adjourn* and *clarify*, occurred more frequently in response to non-MOSTs. These moves accounted for 21 and 23 non-MOST responses, respectively, and for only 3 and 5 MOST responses, respectively. Thus, adjourn and clarify moves accounted for nearly half of non-MOST responses. As with Actor, the differences in Move for MOSTs versus non-MOSTs suggest the teacher actions differ depending on the type of SMT.

Table 1: Actor and Move Totals for MOSTs and non-MOSTs

	Actor			Move			
	Same Student	Whole Class	Teacher	Develop	Justify	Adjourn	Clarify
MOST	65	26	4	37	18	3	5
non-MOST	63	6	30	25	11	21	23

Actor/Move interactions. We also considered the distribution of Moves by Actor. Three moves—*develop, clarify* and *justify*—accounted for 111 of the 128 responses with a *same student* actor. We found that the distribution of these moves between MOSTs and non-MOSTs paralleled that for the data set overall; develop and justify moves occurred more frequently in response to MOSTs and clarify moves occurred more frequently in response to non-MOSTs. The predominant moves directed to the *whole class*—*collect* and *connect*—each occurred twice as often for MOSTs as non-MOSTs (although the numbers are small). Still different moves were the most common when the *teacher* was the actor, with *adjourn* being the most common move, followed by *dismiss*. Adjourn and dismiss moves necessarily had a teacher actor since when a teacher uses these moves, they do not provide an opportunity for students to publicly consider the instance. The majority of both of these moves were in response to non-MOSTs.

Recognition of Student Actions and Ideas. The Recognition codes operationalize the extent to which the student who provided the instance would recognize their thinking in the teacher's response. More responses to MOSTs than to non-MOSTs were classified as *explicit* or *implicit* for Student Action (86 MOSTs; 65 non-MOSTs), while more responses to non-MOSTs were classified as *not* aligning with student actions (13 MOSTs; 34 non-MOSTs). In terms of Student Ideas, 139 of the 198 total responses remained *core* to the SMT, and 19 of 198 were *peripheral*. As with the student actions, more responses to MOSTs than non-MOSTs were classified as core or peripheral (89 MOST; 69 non-MOST), while more responses to non-MOSTs were classified as *other* and *not applicable* (10 MOSTs; 30 non-MOSTs). These findings suggest that teachers' responses generally valued students' contributions by incorporating their actions and ideas.

Discussion of Productivity of Responses

We consider the productivity of teacher responses by examining the extent to which a response adheres to the four principles for productive use of student mathematical thinking (see Figure 1). We discuss several instances, including both MOSTs and non-MOSTs, to illustrate how responses with different coding can be more or less productive given the type of SMT to which the response is given.

The majority of *adjourn* moves (21 of the 24) occurred in response to two particular non-MOSTs instances. The productivity of this move is not the same for each instance, however. The first instance, classified as Opening, involved a student, Sam, giving an answer before other students had time to think about the task. Here, the common response, "Let's give everyone a chance to work it out and see what everyone else gets" (T10) is productive because of the poor timing of Sam blurting out his answer. Adjourning Sam's response provides all of the students in the class sufficient time to engage in sense making. In scenario G2 (where Pat claims to have arrived at the same answer in a different way; classified as Student Mathematics), a similar adjourning response to "address Chris's [the previous student's] comment first" (T3) might be less productive. Because we do not know Pat's "different way," making a move to *develop* his idea (as 12 teachers did) could lead to an opportunity to compare and contrast two different solution methods. Thus, develop responses, such as, "Talk to us Pat. What did you do?" (T9) seem more productive than adjourning this instance. T9's develop move would position Pat as a legitimate mathematical thinker and provide an opportunity for *all* students to make sense of the relationship between Pat's and Chris's contributions.

Develop moves with a *same student* actor were common for MOSTs. However, because MOSTs are opportunities for *building* on SMT—making student thinking the object of consideration by the class—asking the same student to develop or justify their idea may not always be necessary and may actually limit other students' opportunities to jointly participate in making sense of mathematical ideas. For example, consider scenario A2 (Figure 2), for which nearly half of the develop move responses with same student actor for MOSTs occurred. The most common teacher response in this instance was to ask Casey, the student who made the suggestion, to explain how they would change the story (e.g., "Well what do you mean? What sort of an equation, or what sort of a real-life situation can you think of where that would be a negative?" (T6)). Contrast this response with a similar response directed instead to the whole class: "Interesting comment; who can come up with a story, a situation that would match what Casey is saying?" (T7). In this case, directing the response to the whole class might be more productive, as it would engage all of the students in trying to come up with a situation where the coefficient is negative, increasing the likelihood of advancing the entire class's understanding of the mathematics of linear equations. This type of response aligns with all four core principles underlying productive use of a MOST, as it positions the students as capable of collaboratively making sense of the SMT.

Sometimes it is productive, however, to direct a response back to the same student. Consider an instance in which the student, Jesse, said, "It would have to be divided by x," an imprecise statement that needs clarification because "it" is unclear. The most common move in response to this instance was *clarify*, typically by asking Jesse, "what do you want to divide by x?" (T8). This response might be quite productive in helping members of the class figure out what Jesse was saying, and in doing so, would position Jesse's statement as legitimate mathematical thinking. Although the collaboration principle for productive use of SMT (Figure 1) privileges turning SMT over to the whole class whenever appropriate, cases like this one illustrate instances where directing the teacher response to the same student may be a productive first step. Productivity also depends on the recognition of student actions and ideas. A large percentage of the responses in our data were both *explicit* and *core*, meaning that the teachers in this study honored the SMT by incorporating the student's verbal or non-verbal actions and staying focused on the student's core ideas. For example, T8's response to Jesse discussed above is *explicit* and *core* as it incorporates both the student's words (divide by x) and his ideas (what he wanted to divide). A response such as this positions the student as a legitimate mathematical thinker by keeping the students' mathematics at the forefront, important aspects of productively using SMT.

Conclusion and Implications

By studying teachers' responses to a common set of instances of SMT with varying potential for incorporation into instruction, this study contributes to the teacher response literature by illuminating (a) how teachers' responses vary depending on the potential the SMT that is shared has to support student mathematical learning and (b) why some teacher responses are more productive than others in particular situations.

The results revealed that the teachers were generally able to distinguish when different moves might be more productive, as different moves were often employed in response to MOSTs and non-MOSTs. For example, most *whole class* actor responses occurred with MOSTs and most *teacher* actor responses occurred with non-MOSTs. However, our finding that the majority of teacher responses to both MOSTs and non-MOSTs were directed to the *same student* raises some concerns, as MOSTs are prime opportunities for teachers to engage in the teaching practice of *building* on SMT. Thus, directing responses to such instances to a single student results in a missed opportunity. In terms of responsiveness, we found that teacher responses to both MOSTs and non-MOSTs often stayed *core* to the ideas in the SMT and *explicitly* incorporated the students' actions, signaling that these teachers valued students' contributions and often positioned students as legitimate mathematical thinkers who can make valid contributions to the development of the mathematics in the classroom.

Our findings have the potential to help teacher educators develop a more nuanced understanding of what teachers are doing well and where they may need support, thus providing more focus to their teacher development efforts. For example, suppose the majority of a teacher's responses honor SMT, but engage only the contributing student. Professional development work could focus specifically on expanding the ways that they honor SMT by studying the potential in directing a response to the whole class, and when it would and would not be appropriate to do so. Such focused efforts would allow teacher educators to leverage teachers' strengths and thus develop teachers' practice more effectively.

This study examines how a PD program to promote teachers' shift toward a student-adaptive pedagogy impacts students' multiplicative reasoning. We describe the underpinnings of this pedagogy and main components of the PD program. Then, we present key features of participants, data collection/analysis methods, and the written assessment used to measure students' multiplicative reasoning (MR). We found a significant increase in students' MR, between (a) year-ends for different classes and (b) year-start to year-end for the same groups of students. We also found students of participating ("treatment") teachers outperformed those of non-participating ("control") teachers. We discuss the importance of these findings for theory, for teacher education, and for students' mathematical future.

Introduction

In the context of NCTM (2000) reform efforts, we promote students' mathematics by fostering teachers' focus on students' reasoning. Here, we examine the impact of a professional development (PD) program to foster grade-3 teachers' shift to a constructivist-based, *student-adaptive pedagogy* (Tzur, 2013) on their students' multiplicative reasoning. We stress our focus is on students' reasoning, not on their observable solutions to problems (Tzur et al., 2013). In our study, we use students' work to infer reasoning in terms of mental operations on units that could explain a *child's underlying sense* of the problem and its solution. Our study contributes to the body of research that links teacher learning to identify and build on students' mathematics with students' learning and outcomes (Visnovska & Cobb, 2009).

Conceptual framework

We explicate two components of our conceptual framework: student-adaptive pedagogy and numerical reasoning—particularly the difference between additive and multiplicative reasoning. Extending Steffe's (1990) notion of adaptive teaching, Tzur (2008, 2013) proposed student-adaptive pedagogy as a comprehensive approach rooted in a conception-based perspective on knowing and learning. Simon et al. (2000) distinguished this perspective from traditional ("show-and-tell") and perception-based perspectives identified in teachers' transition to reform-oriented practices. Perception-based perspectives differ from traditional in emphasizing the active nature of learning mathematics. However, common to both perspectives is a stance that depicts mathematical knowing as existing outside the learner.

In contrast, a conception-based perspective builds on two implications of the core constructivist notion of assimilation (Piaget, 1985). First, one's available ways of operating afford and constrain what and how one may "see" and do mathematically. Second, conceptual learning entails bringing forth available ways of operating mathematically and transforming those into more advanced ones. These implications compel pedagogical practices that adapt goals and activities for students' learning based on students' available mathematics. Tzur (2008) depicted student-adaptive pedagogy as a reflective cycle (triad) of teaching rooted in hypothetical learning trajectories (HLT; see Simon, 1995; Simon & Tzur, 2004). It begins with inferring students' available mathematics, proceeds to setting the goals for their next learning, and then to selecting tasks that can be assimilated into available schemes and help transform those into the intended mathematics. For example, a teacher may infer two different strengths of her third graders' conception of whole numbers based on the strategy they use to add two single-digit numbers: weak (count-on) or strong (break-apart-make-ten, or BAMT) (Tzur et al., 2017). Thus, she would not set the same goals and engage all of them in the same tasks. Rather, she can engage those who used count-on in tasks to strengthen their conception of number and those who used BAMT in tasks to foster transition to multiplicative reasoning.

As for numerical reasoning, we explain it in terms of mental units and operations inferred to underlie students' problem solving (Steffe, 1992; Ulrich, 2016). Two types of units inform our inferences, *singletons (1s) and composite units* (i.e., units composed of smaller units). For example, the number "8" is a unit composed of eight 1s, or of five 1s and three 1s, etc. We infer *additive reasoning* when one's operations involve no unit change—she operates on one kind of unit (e.g., 2 *keys* + 2 *keys* + 2 *keys* = 6 *keys*). Conversely, we infer the first of six *multiplicative reasoning* schemes, which Tzur et al. (2013) termed *multiplicative double counting* (mDC), when one's operations involve a change of unit (Simon et al., in press). Such a change takes place when items of one kind of unit are distributed over (and coordinated with) items of another kind of unit to yield a different kind of unit (e.g., 2 *keys-per-box*, placed in 3 *boxes*, yield 6 *keys*). To find the total, a simultaneous count of accrual of composite units and 1s takes place (e.g., first-box-is-2-keys, second-is-4, third-is-6).

Methods

Settings and Participants

For two years, eleven grade-3 teachers and their students (age ~9) in two schools in a large USA city participated in the study. School A (7 teachers) is located in a small district and School B (4 teachers) in another, large district. In School A, 3 teachers participated in the PD program (treatment) and 4 teachers did not (control). Of the participating students, ~85% identified as students of colour and ~70% were learning English as an additional language (we detail student numbers in Data Collection).

Concept-Sensitive Assessment of the mDC Scheme

To assess students' mDC scheme, we used a 5-item written measure that our team developed and validated. Validation included correlating students' written responses with an interviewer's inferences of their mDC scheme (Ktb=0.883, $p<.0005$). The first item assesses additive reasoning; the following four assess the mDC scheme (Table 1). Cronbach's α (0.91) and Rasch (0.98) indicated inter-item reliability.

Table 1: Five Word Problems Comprising the mDC Written Assessment

#	Word Problem
1	For breakfast Ana ate 8 grapes. For lunch, Ana ate 7 grapes. How many grapes did Ana eat in all? Ana ate _______ grapes in all.
2	The picture shows towers made of **3** cubes, **5** cubes, **12** cubes, and **24** cubes. In this problem, Pat only has towers with **3 cubes**. Pat cannot break apart any tower. Can Pat build a tower of **24** cubes using only towers of **3 cubes**? (If Yes, fill in the blank): Pat CAN use _____ **towers** of **3** cubes to build a tower of **24** cubes.
3	The picture to the right shows a box. Alex put **6** towers in the box. Alex made each tower with **3** cubes. The numbers on the picture show this. How many **cubes in all** did Alex use to make **6** towers? (fill in the blank): ______
4	There are **4 teams** in a school. Each team has **5 players**. The picture shows the name of each team. Joy said there are **35 players in all**, because she skip-counted by 5 (Joy started 5, 10, and kept going to 35). Is Joy Correct? (circle one): Yes No. How many teams did Joy count? (circle one): 4 5 7 20 35 Another number ______
5	Sam baked **28** smiley **cookies**. He put all of them in boxes. Sam put **4 cookies in each box**. The picture shows only **one of the boxes**. How many boxes did Sam use for all 28 cookies? (fill in the blank): ________

Job-embedded PD Program

Focusing on multiplicative and fractional reasoning enacted within the teaching triad, we engaged participating teachers in a PD program to promote their: (a) own mathematical reasoning, (b) understanding of progressions in students' reasoning, (c) use of tasks to foster such progressions, and (d) attention to language and actions used by them and by students. To these ends, we used three, job-embedded PD experiences: Two, week-long *Summer Institutes* (Sis; total ~70 hours), *Buddy-Pairs* (total ~24 hours), and School/Grade-based workshops (total ~16 hours).

In both Sis, we engaged teachers in whole groups, small group, or individual work while using tasks they could later enact in their classrooms. We frequently involved them in observing conceptually-selected videos and analysing students' reasoning, In SI-2, the segments were selected from teachers' own classrooms. Using that analysis, they would discuss goals and tailor/justify tasks to promote the next learning.

During the school year (2016-17), we worked with teachers in their own classrooms, mingling *buddy-pair* experiences and grade-based workshops. In the former, teachers teamed up to visit a buddy's classroom, while a member of our team co-taught with the hosting teacher. Then, our team member and buddy teachers reflected on: (a) what students seemed to understand, (b) what serves as evidence for such claims, (c) how tasks could foster that learning, and (d) what/why/how to teach next. In the workshops, we focused on concepts from the buddy-pair experiences to promote teachers' own mathematics, to situate the concept(s) within progressions, and to select tasks that can promote differentiated learning based on where students seemed to be conceptually. A particular emphasis was on the strength of a student's conception of number and/or on the mDC scheme, which teachers learned to glean from students' strategies when solving problems in the classroom.

Data Collection and Analysis

Collection

Five graduate research assistants (GRAs) administered the written assessment in a whole-class setting (~40 minutes). The GRA read out loud each item to enhance comprehension, monitored students' work on all sub-questions, and, before starting Problem 2, guided them to build a tower of 7 cubes to ascertain they recognized this object. We administered the mDC assessment three times: Spring '16 (pre-PD, year-end, N=81), Fall '16 (pre-PD, year-start, N=177), and Spring '17 (post-PD, N=113). The GRAs entered student responses to the mDC assessment in pairs; one read the responses out loud and another entered them into a spreadsheet.

Analysis

Scoring correct responses as 1 and incorrect as 0, we tested two main hypotheses about participating students: (a) post-PD, year-end outcomes will be better than pre-PD year-end and (b) post-PD, year-end outcomes will be better than pre-PD, year-start. We also tested a hypothesis that treatment students in School A will outperform their control counterparts. For each hypothesis, we analysed the mean of responses to all four mDC questions (ranging 0-4) and to Problem 3 alone (0 or 1). We chose Problem 3 because it is a typical multiplicative situation taught in schools that proved the hardest, and thus distinguishes teaching "multiplication as repeated addition" vs. as coordination of composite units and 1s. For the total mean on Problems 2-5 we used an independent sample t-test, a one-way ANOVA, a repeated-measure ANOVA, and Cohen's-d effect size (ES); for the non-parametric variable of responses to Problem 3 we used the Mann-Whitney test (MWz values).

Results

Three analyses show the PD impact on 3rd graders' reasoning: pre/post between two year-ends (Sp-16, Sp-17), pre/post growth between year-start and year-end (Fa-16, Sp-17), and pre/post between treatment and control students in School A.

Pre/Post PD: Year-Ends (Sp-16 vs. Sp-17)

Table 3 shows that, overall, 3rd graders at year-end of post-PD (39%) outperformed their year-end, pre-PD counterparts (28%), though this did *not* reach statistical significance (t=1.38, df=89, p=.17). For Problem #3, students in post-PD (43%) outperformed pre-PD (32%; MWz=1.02, N=91, p=.31). These results differ for each school. In School A (treatment only), a minimal change is indicated for all mDC problems, from pre-PD (25%) to post-PD (28%), with a larger (non-significant) difference on Problem #3 (22% to 36%, respectively). These non-significant results are highlighted differently when compared with changes in School A's control group. In School B, the pre-post PD increase on all four mDC problems (29% to 56%) was statistically significant (t=2.15, df=47, p=.037), but the increase on Problem #3 (36% to 52%) was not (MWz=1.07, N=49, p=.28).

Table 2: Percentages of students' correct solution (all mDC problems; Problem 3).

	All mDC Problems		mDC Problem **3**	
	Pre (Sp-16)	Post (Sp-17)	Pre (Sp-16)	Post (Sp-17)
All AdPed	28%	39%	32%	43%
School A	25%	28%	22%	36%
School B	29%	52%	36%	52%

Pre/Post PD: Year-Start (Fa-16) vs. Year-End (Sp-17)

Table 4 shows growth, from year-start (Fa-16) to year-end (Sp-17), for all students, then separately for each school. Growth in mDC reasoning, from year-start (14%) to year-end (39%), was statistically significant (t=4.91, df=147, p<.0005), with *large effect-size* (Cohen-d's ES=0.83). Similarly, results for Problem #3 show the growth from year-start (18%) to year-end (43%) was statistically significant (MWz= 3.36, N=149, p=.001), with *moderate effect-size* (Cohen-r's ES=0.58).

In School A, the growth on all four mDC problems, from pre-PD (mere 8%) to post-PD (28%), was statistically significant (t=2.96, df=62, p=.004), with *near-large effect-size* (Cohen-d's ES=0.75). Similarly, for Problem #3 the growth from year-start (6%) to year-end (36%) was statistically significant (MWz=2.87, N=64, p=.004), with *intermediate effect-size* (Cohen-r's ES=0.3). In School B, the growth on all four problems was remarkable, from pre-PD (18%) to post-PD (52%) (t=4.88, df=83, p<.0005), with a *very large effect-size* (Cohen-d's ES=1.15). Growth on Problem 3, from pre-PD (24%) to post-PD (52%), was statistically significant (MWz=2.5, N=85, p=.012), with a *moderate effect-size* (Cohen-r's ES=0.62).

Table 3: Percentages of students' correct solution (all mDC problems; Problem 3).

	All mDC Problems		mDC Problem **3**	
	Pre (Fa-16)	Post (Sp-17)	Pre (Fa-16)	Post (Sp-17)
All AdPed	14%	39%	18%	43%
School A	8%	28%	6%	36%
School B	18%	52%	24%	52%

Treatment vs. Comparison

Table 5 (Sp-16 vs. S-17) and Table 6 (Fa-16 vs. Sp-17) compare outcomes of 3rd graders' mDC reasoning, between treatment and comparison groups (School A only). In both tables, a two-way ANOVA (shown in the post-PD cells of the treatment group) is statistically significant in favour of the treatment group.

Table 4: Sp-16 vs. Sp-17 – percentages of treatment/control student correct solutions.

	All mDC Problems		mDC Problem **3**	
School A	Pre (Sp-16)	Post (Sp-17)	Pre (Sp-16)	Post (Sp-17)
Treatment	25%	28% ($F_{1,142}$=4.42, p<.037)	22%	36% (Friedman's $Q_{1,145}$=26.6, p<.0005)
Control	36%	20%	39%	15%

Table 5: Fa-16 vs. Sp-17 – percentages of treatment/control student correct solutions.

	All mDC Problems		mDC Problem **3**	
School A	Pre (Fa-16)	Post (Sp-17)	Pre (Fa-16)	Post (Sp-17)
Treatment	8%	28% ($F_{1,203}$=6.26, p=.013)	10%	36% (Friedman's $Q_{1,54}$=38, p<.0005)
Control	19%	20%	23%	22%

Summary of Analysis

We analysed third graders' responses to four, concept-sensitive items that, combined, indicate students' reasoning with the mDC scheme. We showed PD impact on that reasoning using three major comparisons: (a) pre-post increase between two consecutive *year-ends* within the same student population, (b) pre-post growth from *year-start to year-end* in the same schools within the PD year, and (c) interaction between outcomes of students of teachers in treatment and control groups within the same, single school. Those comparisons support our claim: PD to foster teachers' shift toward student-adaptive pedagogy (focus on multiplicative reasoning) can bring about desired growth in their students' multiplicative reasoning and problem solving.

A question arises of causes for between-school differences. While more data are needed, we note two plausible factors. First, teacher practices in each school reflected a different starting-point: mostly traditional at School A and mostly reform-oriented, perception-based perspective at school B (Simon et al., 2004). Second, teachers differed in their learning, and thus enactment, of assessing and using their students' conception of number, including how this conception predicts mDC (Tzur et al., 2017). Specifically, School B teachers reorganized instruction to (a) foster conception of number in students who seemed to lack it and (b) strengthen it in students with a weak conception of number. That is, they focused more on fostering students' construction of mDC by capitalizing on the strength of their conception of number.

Discussion

We found impact of a PD program to foster teachers' shift toward student-adaptive pedagogy on growth in their students' multiplicative reasoning. The scope of this paper precludes detailing the job-embedded PD. Yet, it shows that fostering teachers' initial adoption of this constructivist-based pedagogy supports the crucial conceptual advance in students' reasoning—from additive to multiplicative. Moreover, it shows the benefits of helping teachers to first conceptualize multiplication themselves, and then teach it, not as repeated addition (as did Control teachers), but rather as coordination of three different units, which we fostered in treatment teachers.

Implications for Practice

We note two main implications of this study for practice. First, our findings stress the benefits of changing teachers' understanding of multiplication, and then of teaching it, away from "repeated addition" and toward units coordination. Arguably, the most telling evidence is found in students' solutions to the *typical multiplication Problem 3*—markedly students of treatment teachers outperforming their control counterparts. Second, for mathematics teacher education, our study highlights the benefits of a dual focus on the necessary growth in teachers' own mathematical reasoning and their ability to tailor learning goals and activities to the students' available conceptions. Specifically, in this study we demonstrate the possibility of increasing students' multiplicative reasoning and problem solving by promoting teacher development as professionals who can understand, and apply, theory and research findings to alter their practice. We note that, in both schools, the principal and other instructional leaders provided constant, enthusiastic support for the intended teacher change.

Implications for Research and Theory

We note five main foci implied by this study. First, for theory building, this study implies the possibility, and need, to corroborate, statistically, the theoretically sound progression in students' schemes for whole number multiplicative reasoning (Tzur et al., 2013). In this study, we found the impact on students' mDC, an introductory level of multiplicative reasoning. Collecting and analysing data from a large sample of students would allow corroboration to more advanced schemes of multiplicative reasoning. Second, it seems important to also link the impact of our constructivist-based, job-embedded PD on students' mDC reasoning with their outcomes on district and/or state tests, as well as studying this impact for different student populations. Third, in our data analysis we grouped teachers uniformly, although they started their individual journeys toward student-adaptive pedagogy at different points and progressed in rather different paces. Linking differentiations in teacher practices to student learning and outcomes could further understandings of how the impact found in this study is related to teacher learning. Fourth, further attribution of PD impact to parts of the intervention is needed, that is, to changes in teachers': own mathematics, understanding of conceptual progressions in students' mathematics, selection and enactment of instructional activities tailored to fostering particular students' learning, and use of language as an additional focus of the intervention. Fifth, the differentiated support by school principals and coaches we witnessed indicates the importance of considering an extended-level unit of analysis (beyond teachers), namely, schools as systems. All five foci can build on the findings reported here about the promising impact that a constructivist-based PD can have on teachers and thus on students' mathematics.

This study investigates whether the use of Physics Education Technology (PhET) interactive simulations (sims) supported teachers' instructional quality depending on in enacting and maintaining cognitive demand of mathematical tasks. We report findings from two middle-school mathematics teachers who each used parallel module lesson plans across two of their sections, with one section following a sim-based lesson plan and the other following a non-sim-based lesson plan. Data collection was comprised of the teacher's tasks as planned and our classroom observations. Each lesson was analyzed in terms of instructional quality assessment framework (IQA). Preliminary findings suggest that the students using PhET sims had more opportunities for higher academic rigor and accountable talk through the engagement with cognitively demanding work, rather than focusing on procedures and reproducing knowledge.

Keywords: Instructional Quality, Interactive Simulations, Instructional Practice

In recent years, researchers have accentuated mathematical instruction that engages students as explorers in a dynamic disciplinary space (Langer-Osuna, 2017), rather than a static and structured system of facts and procedures. The Common Core State Standards in Mathematics places a high emphasis on cognitively demanding thinking skills and a more in-depth understanding of mathematical concepts (National Council of Teachers of Mathematics [NCTM], 2010; Stein, Correnti, Moore, Russell, & Kelly, 2017). However, minimal research exists on how teachers can transform their practice to help students engage with mathematics while also being faithful to the content standards they are tasked to teach (Stein et al., 2017).

The development of new technology has advanced the instructional capabilities of mathematics teachers (Goldenberg, 2000), resulting in increased use of technology in K-12 classrooms (Rehn, Moore, Podolefsky, & Finkelstein, 2013). Technology has the potential to empower teachers to transform their practice in new ways that position students to develop deeper cognitive and conceptual understanding (NCTM, 2000). The National Research Council (NRC) (2011) has highlighted simulations as among several tools that may help teachers transform their practice to meet challenges associated with recent reform efforts. Interactive simulations use dynamic visualizations to model representations and functions that lead students to sense-make about a phenomenon of interest (Hensberry, Moore, & Perkins, 2015).

For this study, we concentrate on PhET sims, which show promise as an effective tool for improving student engagement and learning in science and mathematics (Hensberry, et al., 2015). While the use of simulations provides great opportunity for students' conceptual understanding of science and mathematics, the use of computer technology cannot guarantee increased learning gains on its own (Lei, 2010). Learning to use classroom tools in tandem with reform-oriented teaching practices can assist teachers to consider the "importance of learning with technology rather than learning about technology" (Drier, 2001, p. 170). While there is some evidence indicating the use of simulations supports higher levels of student mathematical thinking (Brown, 2017), we instead consider the influence of simulations on teaching practices and its potential to push teachers to deliver a higher quality of instruction. By using instructional quality assessment (IQA) framework (Boston, 2012), we aimed to capture observable indicators of high-quality mathematics instruction. This framework included two main categories based on academic rigor and accountable talk happened during the instruction. Academic rigor included rubrics for the potential cognitive demand of the task, implementation of the task, student discussion following the task, and rigor of teachers' questions. Accountable talk included scoring of participation, teacher's linking contribution, student's linking contribution, teachers' press for knowledge or thinking, and students providing knowledge or thinking based on rubrics. Within this study, we examine the following research question: In what ways, if any, does the use of PhET sims influence each teachers' instructional quality in middle school mathematics classrooms?

Methods

Setting

This study involves two middle-school mathematics teachers in U.S. public schools, Elise and Kathy (both names are pseudonyms). Elise taught three lesson modules for sim and corresponding modules without the use of sims for grade 7 involving the topics of unit rates, scale, and probability. With the same number of modules for sim and non-sim versions, Kathy taught 6th grades on data analysis, ratio and proportion, and algebraic expressions. The non-sim lessons had the same learning goals. Each teacher had access to the lesson plans and tasks at the PhET website (https://phet.colorado.edu) and were free in deciding which sim and task they preferred to use in their lessons. For the non-sim lesson plans, the teachers each created their own sequence of tasks.

Data Collection and Analysis

Data include video recordings of both the sim and non-sim class periods, which were transcribed for ease of coding. Instructional quality was analyzed using the frameworks described previously. In IQA, academic rigor score is calculated by four rubrics AR1 (potential of the task), AR2 (implementation of the task), AR3 (student discussion following the task), and AR-Q (rigor of teachers' questions) with a scoring scale from 0 to 4. For accountable talk score, we used four rubrics named as AT1 (participation), AT2 (teacher's linking contribution), AT3 (student's linking contribution), AT4 (teacher's press for knowledge or thinking), AT5 (student's providing knowledge or thinking) with the same scoring scale from 0 to 4.

Findings

The dimensions of the IQA framework revealed some qualitative differences in the cognitive demand of tasks as planned and enacted, the quality of discussion during the whole class discussions, rigor of teacher questioning, the opportunities in making connections, teacher's press for knowledge and thinking, and students' responses to that press. Findings suggest that in sim lessons, both teachers created more opportunities for students to develop mathematical meaning, share their ideas, and justify their thinking, rather than focusing on procedures and reproducing knowledge. These findings provide a motivation to explore the role of interactive simulations in creating opportunities for some teachers to leave their comfort zone, which comprised of relatively traditional and teacher-centered practices and attempt to improve the quality of their instruction (Lampert, Boerst, & Graziani, 2008).

Conclusion

This report aimed to start an exploration of how teachers' instructional practices might be transformed by the use of tasks with cognitive demand and use of interactive simulations. Although each teacher taught the same grade level and the same content in their two classes, their moves seem to show some increase in attending student thinking and creating opportunities for students to share their ideas, justify their thinking. Despite its exploratory nature, this study offers some insight into how the use of interactive simulations might create opportunities for teachers to adopt new teaching practices that support students' mathematical understanding and reasoning.

Using active learning strategies in a large undergraduate mathematics classroom can be challenging. Minimal results from recent research on active-learning indicate that more investigation of how instructors are being effective using these strategies in these classrooms is still needed. Results from this study indicate that students who participated in Team Activities and other learner-centered activities in a large scale precalculus undergraduate classroom report a good experience and are more positive in their attitudes towards mathematics. Particularly, students valued the collaborative efforts in this mathematics classroom, something they do not often have the opportunity to do in a traditional mathematics course. This report has implications for large universities where many of the classes are taught at a large scale while instructors are focused on bringing in more active learning to improve instruction.

Keywords: Post-Secondary Mathematics; Affect, Emotions, Beliefs, and Attitudes; Instructional Activities and Practices

The number of students in the United States entering and completing undergraduate and graduate science, technology, engineering, and mathematics (STEM) programs is declining, and this decline has been connected to the nature and quality of instruction in undergraduate STEM courses (Carnevale, Smith, & Melton, 2011; PCAST, 2012). The President's Council of Advisors on Science and Technology estimates that an additional 1,000,000 STEM graduates are needed in the next decade to meet workplace demands (PCAST, 2012), with these demands being both in STEM careers and broader STEM competencies (Carnevale, Smith, & Melton, 2011). Freeman and colleagues (2014) published the results of a meta-analysis that addressed articles about using active learning in STEM and the student outcomes. The results were significant. Performance outcomes showed on average a .5 standard deviation increase when active learning strategies are used. Additionally, persistence and attitudes towards math and confidence in doing mathematics is higher when such strategies are.

This research aimed to introduce a few active learning practices in a large size Precalculus classroom and conduct a mixed method study to understand how they are perceived and affect student outcomes. Pre-calculus is a gateway course for upper level mathematics courses for students and other STEM courses, thus it should be researched to help in its implementation. Conducting this research will add to the literature as possible corroboration for the continued use for active learning strategies in mathematics courses specifically in large-scaled classrooms where direct instruction has been overused. For this study, outcomes were defined as students' attitudes towards mathematics and themselves as mathematics learners, interest in mathematics, and self-efficacy. Research questions are: (1) What are students' perceptions of active learning strategies in a large-scale pre-calculus course? And (2) How are students' self-efficacy and attitudes towards mathematics different after participation in an active learning course?

Literature Review

Student attitudes and self-efficacy are two important facets to study in mathematics education today. Núñez-Peña, Suárez-Pellicioni, and Bono (2013) found that poor success rates in mathematics course are related to negative attitudes towards mathematics in general. In addition, both student attitudes and self-efficacy play an integral part in perceived usefulness of mathematics, in choosing careers involving mathematics, and in opting to take more mathematics courses beyond those required for their degree (Sheldrake, Mujtaba, & Reiss, 2015).

There have been studies focused on ways to improve student attitudes and self-efficacy in these courses to help combat the negative repercussions as described above (Wilkins & Ma, 2003). Wilkins and Ma (2003) report on the importance of social influence, challenging curricula, and engaging activities as ways to help students see the importance of mathematics in their own lives and to see that mathematics can be engaging as well. The choices instructors make on the activities presented in class can make a big difference in how students view mathematics in general (Wilkins & Ma, 2003). As retention rates in STEM fields remain a difficult feat still today, it is important to help improve the attitudes and self-efficacy of students in undergraduate mathematics courses for the future.

Theoretical support for our work was taken from higher education research and adds a new perspective to traditional mathematics education frameworks. Fraser (1989) stated that "the strongest tradition in past classroom environment research has involved investigation of associations between students' cognitive and affective learning outcomes and their perceptions of psychosocial characteristics of their classrooms" (p. 315). So, we use this tradition of studying the associations as our research base. We overlay that plan to investigate students' outcomes and perceptions onto learner-centered classroom environments as we see this as a particularly crucial factor in the students learning as well as their self-efficacy (Peters,2013). Therefore, our investigation is of learner-centered instruction (and we define environment as part of this) which has been shown to be effective in increasing both cognitive and affective outcomes. Students' perceptions will influence the affective outcomes and we will study this relationship.

Methods

This research was carried out at a large, public university located in the southeast area of the United States. During Summer 2016, 94 students were enrolled in a four-credit hour Precalculus/Trigonometry course. Throughout the course, a total of five Team Activities were assigned to the students to complete in small groups. An entire class period was dedicated for the completion of each Team Activity. These frequently consisted of real-world scenarios, and were intended to help students develop a deeper understanding of the mathematics. Students worked in teams of 3-4 in order to solve application problems and write out complete solutions.

Participation in both pre- and post-surveys were online, voluntary, and open to all students in the course. In total, 18 students completed both pre- and post-surveys (results are in the following section). The surveys contained were Likert-scale statements where participants were instructed to select the number that best expressed their feelings as to what extent did they agreed or disagreed with each statement. Survey questions addressed mathematical self-efficacy, students perceived mathematical ability/work ethic, and students' interest in the field of mathematics in the future.

The purpose of the interview was to collect qualitative data on student perceptions of the class and the mathematics they had learned throughout the duration of the course. Fourteen students volunteered to be interviewed to share their experiences at the end of the semester. Interview participants included seven women and seven men.

The interview was split into two parts: student views on the course and student mathematical thinking.

Results

A close look at that individual responses showed that: (1) of all the changes that occurred from pre- to post-survey, 57.69% were increases, while 42.31% were decreases; (2) 11 of the 18 students increased on average from pre- to post-survey; and (3) On average, each student increased by +0.119.

Looking at the collective responses on the individual questions, 15 of the questions (65%) showed positive agreement increases, while 6 of the questions (26%) showed decreases in agreement, and 2 of the questions (9%) remained constant with regards to agreement. The questions that showed the biggest mean positive increases were: *Math is easy for me to understand* and *I am not nervous when I am in math class*, *I would like an occupation in math,* and *I am able to do the math in my class*. The questions that had the biggest decreases in mean responses were: *I have a lot of math skills*, *I work hard with math in school,* and *I don't give up even if I have a difficult math problem*.

The questions specifically centered around three distinct categories of questions. They included questions related to students' mathematics self-efficacy (Group 1), questions gauging how students' think about their own work ethic in mathematics (Group 2), and how mathematics relates to students' futures (Group 3). Participants' responses were averaged within each group to create a students' overall Group Score for that group. Paired t-tests were run using statistical software within these group averages.

Of the three groups of questions, the first was the found to be statistically significant. Just as with some findings described above, the mean values from pre- to post-survey were not practically different, only increasing from 3.07 to 3.28. The mean values in Group 2: Work Ethic in Math decreased from a 4.30 to 4.25. Group 3: Math in the Future showed an overall increase in the means from pre- to post-survey having showed a 0.24 increase.

In the interviews, students were asked if they believed that Team Activities were helpful for their learning and then were encouraged to explain their response. Several codes that emerged from this section of the interview, and will be discussed in the presentation. Overall feelings for Team Activities were very mixed. There was a similar number of students who felt positively toward Team Activities and who felt negatively.

Discussion and Conclusion

Various course components provided the students the opportunity to work with other students to aid their learning (including other aspects not discussed in this paper). The Team Activities provided this unique experience that is often not found in a typical large populated mathematics course taught at universities. By breaking away from entire class periods filled solely with lecture, this course afforded students the opportunity to benefit from active learning through these Team Activities. With the Team Activities, students had to work together in groups of 3-5 people to complete the mathematical tasks that were assigned to them. All the Team Activities got the student to get up out of their seats and find their groups. Some of the Team Activities allowed students to get out of the lecture hall, altogether. During this time, students had the opportunity to work with one another in order to strengthen and reaffirm what they should have learned. These had the students go outside and interact with their surroundings in order to solve a mathematical task. An overwhelming majority of students enjoyed this active learning aspect of the course (along with others not discussed in this paper).

An interesting aspect that came up after analysis, is that seeing the mathematics working in a "real world" context did not seem to be as an important factor to most students. We thought that this concerted effort to bring an applicable view into how mathematics in this classroom is actually used in the field is what these students wanted, but it seemed as if this was not as important to these students. The Team Activities were designed to elicit a connection between the mathematics and its applicability in the real world, yet students failed to mention how the two were connected. Potentially, the design of the Team Activities needs to be revisited to make more explicit (when appropriate) how these are real scenarios seen by professionals.

The teaching assistants (TAs) in this course were very essential to the success for many of the students. Students were able to interact with the five TAs in multiple facets of the course. TAs had a huge role in the implementation of the Team Activities. Students also lamented the fact that during the Team Activities, there were never enough of them.

In this paper, we chose to discuss just a small portion of the entire work due to lack of space. The results are significant as we are finding that it makes a difference even to include just a few instructional strategies that are considered learner-centered. As related to Fraser's (1989) work, we found evidence to support his contention that perceptions affect outcomes. This result opens up a significant question: How important is it to include learner centered instruction fully implemented or can a partial implementation work? More research has been and will be conducted to see what (if any) effect that these active learning components that were used in this course have affected students' perceptions, self-efficacy, and attitudes on learning mathematics.

STUDENT PARTICIPATION, AUTHORITY AND TOGETHERNESS IN A COLLABORATIVE MATH TASK: WITH AND WITHOUT THE TEACHER

Heather Fink
University of California, Berkeley
hfink@berkeley.edu

Anna Zarkh
University of California, Berkeley
annazarkh@berkeley.edu

To support equitable learning opportunities during group work, it is important that teachers notice participation and authority imbalances among students. We analyze two seemingly productive student-pairs working on a math task to understand what is made available to notice about participation and positioning on two levels: (1) what a teacher can observe during teacher-group interactions, and (2) what is noticeable during group work without the teacher present. We found that while mathematical participation was imbalanced during group work for both student-pairs, for one pair, "togetherness" and balanced authority during teacher-group interaction did not reflect, and thus potentially masked, participation imbalance.

Keywords: Classroom Discourse, Equity and Diversity, Instructional Activities and Practices

Collaboration is seen as a promising approach to support equity. However, it is also recognized that group work does not always play out equitably in classrooms (Esmonde, 2009). It has long been argued that successful implementation of collaborative learning depends on strategic facilitation of learning environments and that, in particular, teacher-group interactions during small-group work are means to shift inequitable group dynamics (Cohen & Lotan, 2014). What teachers notice about students' equity-related experiences during complex collaborative learning interactions is important for such support to be possible (van Es, Hand, & Mercado, 2017; Wager, 2014). There is a need to better understand what equity-related aspects of students' collaboration are not easily available for teachers to notice during small-group check-ins.

Some aspects of group work are easier to notice than others. When student-groups are off task or silent during group work, it may be easy for a teacher to notice that collaboration is not ideal. However, even if students stay on task and talk to each other, inequitable processes such as imbalances in participation and authority can still occur (Esmonde, 2009; Langer-Osuna, 2017). Since imbalances are often subtle and evolve over time, they may not be easily observable during short teacher-group interactions. To shed more light on this issue we examine two seemingly productive student-pairs working on a collaborative math task, and compare processes consequential for equity across two settings: teacher-group interactions and group work.

Theoretical Perspectives

Esmonde (2009) draws on sociocultural theories of learning to define equity as the fair distribution of: (a) access to mathematical content and practices and (b) access to productive positional identities. In this study, we use the metaphor of participation to identify students' access to mathematical ideas and practices, and positioning theory to identify processes by which students make sense of themselves and their peers as mathematics learners.

Learning happens through participation in disciplinary practices (Lave, 1996). In collaborative settings, this means active participation in the task and mathematical discourse practices of the group, such as asking questions and providing explanations (Reinholz & Shah, 2018).

Positioning theory (van Langenhove & Harré, 1999) illuminates ways in which narratives at various scales influence and get constituted by small-scale interactions in classrooms (Herbel-

Eisenmann, Wagner, Johnson, Suh, & Figueras, 2015). During interaction, communicational acts evoke *positions*, expectations about interlocutors' rights and obligations in a given situation. For example, if one student asks another "Is this answer correct?", he creates a "right" for evaluation, positioning his partner as an *expert* and himself as a *novice*. Such interpretation of utterances in terms of rights and obligations relies on interlocutors' past experiences and familiarity with the same *storylines* (e.g. "math experts know the answers").

We draw on these analytical lenses to address the following research question: *How do student participation in mathematical practices and positioning manifest: (a) during teacher-group interaction, and (b) during group work interaction?*

Methods

Data analyzed in this study was collected at a mid-size city in central England. It is part of a large corpus of video data of students working on "Formative Assessment Lessons" (FALs; see Burkhardt & Schoenfeld, 2018) developed by the Mathematics Assessment Project (http://map.mathshell.org/). The video corpus of FAL classroom enactments was collected to support development of tablet-based versions of the FALs by the FACT project (Formative Assessment with Computational Technologies: http://fact.engineering.asu.edu/). The analyses presented in this paper emerged from a larger study within the FACT project, in which the same video data supported the development of a collaboration coding scheme for learning analytics (VanLehn, Burkhardt, Cheema, Kang, Pead, Schoenfeld, & Wetzel, submitted).

Since the purpose of our study was to analyze groups that do not exhibit easy-to-notice, undesirable small-group behaviors, we searched the data corpus for groups that seemed to be working together productively. We selected two such groups and present analyses of four episodes: two TGI episodes and two corresponding group work episodes. These episodes feature a teacher, Mr.B, and two student-pairs, Abby & Ben and Chris & Diana.

The task is part of a 7th grade FAL. Students are given four cards with printed money amounts: $100, $150, $200, $160 (to be positioned as four vertices of a square) and 12 arrow cards with a specified percent increase or decrease, e.g., "up by 50%". The task entails matching a percent increase or decrease arrow card to an appropriate space between money card vertices, e.g., matching the arrow card "down by 25%" to the space between $200 and $150.

Data Analysis

Episodes were transcribed and coded for speech and action indicators informed by our theoretical framework and prior work on participation and authority. We started our analysis with these two categories in mind, yet found that another storyline, which we call "togetherness", was helpful in capturing consequential differences between the two student pairs. Our operationalization of participation, authority and togetherness is elaborated below.

Who suggested the card placement is used as an indicator of mathematical participation in the task. To analyze participation in discourse practices, we draw on Reinholz and Shah (2018) and focus on two discourse forms: explanations and questioning. We coded *who explains* and *explanation length* (brief or extended), in addition to *who asks a question* and *question type* (a "why/how" question or a "what" question).

Our analysis focuses on two storylines and related positions: (a) *authority* storyline (experts vs. novices) and (b) *togetherness* storyline (partners vs. individual contributors). In the *authority* storyline, *experts* answer other students' questions, evaluate contributions, and explain why answers are correct. *Novices* ask questions, seek approval of experts, and defer to experts for decisions. To identify *expert* or *novice* positions we look at: Who asks and who answers "why/how", "what", and "approval" questions. The *togetherness* storyline is about how students perceive their rights and obligations as groupmates. *Partners* are expected to seek and maintain joint attention, share control over decisions, and solicit contributions from each other. For *individual contributors* joint attention and joint decisions are not expected. Though they can ask each other questions, each student is responsible for his or her contribution to the task. To identify *partner* or *individual contributor* positions we look at: the percent of card placement decisions that were made jointly, the acceptance rate of students' focus initiation moves, and the total number of questions students asked each other.

Findings

First, we present our analyses of Teacher-Group Interactions (TGIs) and Group Work focusing on mathematical participation, authority, and togetherness. We then discuss similarities and differences between what was noticeable about the two student-pairs in the two settings.

Teacher-Group Interactions

TGIs with both pairs involved one of the students explaining a card placement to the teacher. The two exchanges were different, however, in the ways authority and togetherness storylines were evoked. In the first group, Ben was positioned as an expert and as an individual contributor. In the second group, Chris and Diana positioned themselves as novices and as partners. Chris and Diana's greater similarity in authority and higher degree of togetherness give an overall impression of more balance in learning opportunities than between Abby and Ben.

Group Work

Summary of Participation, Authority, and Togetherness

	Participation						Authority			Togetherness			
	Suggestions (rejected)	Explanations		Questions Asked by			Questions Answered by			Total Number of	Focus Initiations		Joint
		Extended	Brief	Why/How	What	Approval	Why/How	What	Approval	Questions Asked	Number	Acceptance	Decision Rate
Abby	4(3)	0	2	3	1	3	0	1	0	7	16	59%	17%
Ben	9	5	2	0	2	0	4	1	3	2	11		
Chris	3(1)	1	1	2	2	3	0	1	4	8	8	76%	55%
Diana	10	2	4	0	4	4	5	6	3	10	13		

Figure 1. Summary of participation, authority, and togetherness during groupwork.

Groupwork participation was imbalanced in favor of one student in both pairs; Ben and Diana made considerably more placement suggestions and explanations than their partners. The imbalance in explaining mirrors the imbalance in asking "why/how" questions. Abby and Chris's questioning created opportunities for Ben and Diana to explain, but, since Abby and Chris were not asked "why/how" questions, they did not have similar opportunities to learn by explaining.

Authority was distributed differently in the two pairs. With Abby and Ben, imbalanced authority was stable and enduring; Ben was positioned as *expert* and Abby as *novice*. In the other pair, Chris was consistently positioned as *novice*, but Diana's position was negotiated in contrasting directions. Diana positioned herself as *novice* by repeatedly asking for approval from Chris, yet, Chris also positioned her as *expert* by asking her several "why/how" questions.

Togetherness was also different in the two pairs. Ben and Abby did not share a clearly agreed upon togetherness storyline. While Ben consistently positioned himself as an *individual contributor*, Abby made repeated moves to position them as *partners*. These ongoing negotiations were reflected in the way Ben and Abby went back and forth between having shared focus and not. In contrast, Chris and Diana accepted each other as *partners*. They maintained joint focus and joint ownership over different parts of the task by attending to each other's activity and consistently checking-in with each other to make decisions together.

Comparison between TGIs and group work

Abby and Ben's participation and authority imbalance and their overall lack of togetherness during Group Work manifested similarly during their TGI. In contrast, Chris and Diana's participation imbalance was not clearly reflected in their TGI. When interacting with Mr. B, both students positioned themselves as similarly uncertain about the math and demonstrated a high degree of togetherness. Though the pair consistently worked together and authority was relatively balanced, close examination of their work revealed that opportunities to learn were inequitably distributed as Diana suggested and explained significantly more than Chris did.

Discussion

Our study reveals that togetherness and balance in authority, salient during teacher-group interactions, does not reflect imbalances in mathematical participation that are detrimental to equitable learning opportunities. This finding has implications for teacher noticing of student collaboration for equity and the design of technology to support that noticing. Recognition that togetherness and balanced authority have the potential to mask enduring participation imbalances can help teachers critically examine their noticing of seemingly productive groups. Our findings also provide further support for the potential of using learning analytics to track participation imbalances in classrooms (Reinholz & Shah, 2018). Our analysis suggests that capturing who suggests ideas, asks questions, and explains can support noticing for equitable participation.

INVESTIGATING COLLEGE CALCULUS INSTRUCTORS' KNOWLEDGE, DISPOSITION, AND RESPONSIVENESS TO STUDENT THINKING

Jessica R. Gehrtz
Colorado State University
gehrtz@math.colostate.edu

Effective instruction relies on an instructor's knowledge of student thinking and ability to attend and respond to student mathematical strategies. Additionally, their disposition towards student thinking further influences how they respond to students, impacting student learning. A survey and task-based interviews were used to investigate instructors' responsiveness to student thinking. Results from these analyses indicate that responsiveness to student thinking can be present during multiple phases of instruction (planning, assessing, and in-the-moment teaching) and provides specific instructional practices that relate to responsiveness to student thinking.

Keywords: Mathematical Knowledge for Teaching, Post-Secondary Education, Instructional activities and practices

Effective instruction, both in a lecture environment and in an active learning environment, relies on the instructor's ability to attend and respond to student mathematical strategies, which involves drawing on their knowledge of student thinking (Johnson & Larsen, 2012). This ability to attend, or notice, impacts student learning and is influenced by the instructor's disposition towards student thinking (Sherin & Russ, 2014). The purpose of this study is to gain insight into the instructional practices that relate to instructors' responsiveness, and to understand how college calculus instructors incorporate their knowledge of student thinking into instruction.

Research on Instructors' Knowledge with Dispositions and Responsiveness

There has been much research surrounding teachers' knowledge of student thinking, particularly at the K-12 level, by considering this as one component of instructors' mathematical knowledge for teaching (MKT). MKT includes knowledge of content and the pedagogical knowledge needed to facilitate learning and effective instruction (e.g. Ball, Thames, & Phelps, 2008). It influences instructors' decisions, and impacts what they notice and attend to during in-the-moment instruction and when they prepare for instruction (Jacobs, Lamb & Philip, 2010). Jacobs, Lamb, and Philipp (2010) describe this noticing as attending to, interpreting, and deciding how to respond to students' mathematical strategies, and can be leveraged to connect instructors' knowledge and practice with their disposition to student thinking (Hand, 2012).

An instructor's disposition influences what they notice as "significant interactions" during instruction (Goodwin, 1994). Gresalfi and Cobb (2006) describe *disposition* as that which "encompasses ideas about, values of, and ways of participating with a discipline" (p. 50). This stems from a situated cognition learning perspective which points to the importance of context in the development of understanding and knowledge. An instructor's disposition towards student thinking is continually shaped and interacts with their MKT to influence instructor responsiveness to student thinking, further impacting how they elicit and respond to student thinking (van Es & Sherin, 2002). An instructor's responsiveness to student thinking generates opportunities for effective instructional practices (Carpenter et al., 1989). For example, an instructor can support student learning by addressing difficulties, or by eliciting student thinking through purposeful activities or questioning when they attend to student thinking (Jacobs, Lamb, Philipp, & Schappelle, 2011). In this paper I investigate college calculus instructors' responsiveness to student thinking. Specifically, I investigate the following research questions: (1) What instructional practices reflect responsiveness toward student thinking? (2) How does responsiveness show up when instructors discuss their instructional decisions?

Methodology and Results

This study is part of a larger study investigating college mathematics instructor knowledge, dispositions, and responsiveness to student thinking. Quantitative and qualitative data were collected and analyzed separately, and then the results were brought together to provide a more complete picture of how responsiveness relates to instructional practices using a convergent parallel mixed methods study design (Creswell & Plano Clark, 2007).

Quantitative Data Collection and Analysis

To collect data regarding instructional practices and responsiveness to student thinking, the Postsecondary Instructional Practices Survey (PIPS) (Walter et al., 2016) was expanded to include 5 *responsiveness* items (PIPS+) (e.g. R1, listed in Table 1). The survey was distributed to precalculus and calculus I and II instructors at 12 institutions in the United States. These schools were selected as part of a larger study that is studying multiple dimensions of calculus instruction across the US. For this study, I consider results from the calculus I instructors of record, which includes 35 graduate teaching assistants and 57 faculty/lecturers from the 12 institutions.

To answer the first research question, an exploratory factor analysis with varimax rotation was conducted on the PIPS+ items. Three factors were requested, suppressing factors with loadings less than .4. Constructs were summarized considering themes from the items that loaded on each factor. In the results I discuss the two factors where the 5 *responsiveness* items loaded.

Quantitative Results

After rotation, the first factor in the factor analysis accounted for 16.4% of the variance, the second factor accounted for 12.3%, and the third factor (not related to responsiveness) accounted for 8.2%. The first factor indexed instructional practices that include student involvement in class, and had strong loadings on 20 items (including 4 *responsiveness* items). The second factor indexed instructor planning and instructional activities, and loaded highly on 8 items (including 1 *responsiveness* item), as displayed in Table 1.

Table 1. Responsiveness Items Related to Two Factors

Factor	Survey Items
1	**R1:** I use a variety of approaches (e.g., questioning, discussion, formal/informal assessments) to gauge where my students are in their understanding of concepts **R2:** I use student questions and comments to determine the focus and direction of classroom lessons **R3:** I adjust my teaching based upon what students currently do or do not understand **R4:** I use student assessment results to guide the direction of my instruction during the semester **Sample survey item:** I structure class so that students explore or discuss their understanding of concepts before direct instruction
2	**R5:** I consider students' thinking/understanding when planning lessons **Sample survey item:** I explain concepts in this class in a variety of ways

Hodges, T.E., Roy, G. J., & Tyminski, A. M. (Eds.). (2018). *Proceedings of the 40th annual meeting of the North American Chapter of the International Group for the Psychology of Mathematics Education*. Greenville, SC: University of South Carolina & Clemson University.

The exploratory factor analysis illuminates instructional practices that are linked with responsiveness to student thinking since factors are generated by grouping items instructors rated as similarly descriptive of their instruction. For example, instructors who consider student thinking/understandings when planning lessons (R5) also explain concepts in a variety of ways.

Qualitative Data Collection and Analysis

To understand the degrees to which college calculus instructors incorporate their knowledge of student thinking into their instructional practices (answering RQ2), eight instructors (6 graduate teaching assistants and 2 teaching faculty) from one of the 12 institutions surveyed were interviewed three times over one academic year. The interview protocol was adapted from a task-based interview used to examine college instructor MKT (Speer & Frank, 2013).

The interview data were analyzed using thematic analysis (Braun & Clarke, 2006), by first identifying utterances related to instructors' attention to student thinking. These segments were then coded as either related to *responding* to specific student thinking through some action (e.g. "[I would] help him review [how to find] the minimum"), or as *responsiveness* to student thinking, which demonstrated a more general consideration of student thinking (e.g. "I just try to put myself inside [the student's] head as best as I can"). *Responsiveness* segments were coded again, beginning with a priori codes developed from the 5 *responsiveness* survey items. Eight additional codes were created for segments that could not be described by these, including two subcodes related to R5. See Table 2 in the results section for sample coded excerpts.

Qualitative Results

Instructors incorporated their knowledge of student thinking during planning, grading, and in-the-moment teaching. The coding of the interviews highlighted the attention to student thinking captured by the *responsiveness* survey items was present as instructors discussed how they adjusted their instruction in response to their students' understanding (R2, R3) or considered student thinking when planning (R5).

Table 2. Examples of Segments Coded Using A Priori Responsiveness Codes

Code	Interview Excerpt
R2	"If I have a lesson planned, … then in the middle … we'll get derailed and somebody will say 'I have a lot of confusion about this piece'... and we end up covering things that I didn't plan to cover at all."
R3	"I have been tweaking my lectures because I keep thinking, like I should do an example of this because I realize that they really are confused about [it]."
R5	"When I plan a lesson I think about what my students will struggle with and what they will feel very natural, … when I write a lesson I will try to build in examples that I hope address [students'] confusion."
R5/ Use own experience	"Every single time we try to think before the [recitation] … [thinking about] the first time I learned this- what was tough for me, and we write that on the board."

Discussion and Implications

The results from these analyses demonstrate that instructors respond to student thinking and strategies during a variety of instructional practices. The exploratory factor analysis highlights specific practices that instructors use (regardless of instructional format) to attend to students' understandings of mathematical ideas, and is supported by the interviews. These provide specific practices that can be incorporated by instructors interested in being more responsive to student thinking. This is especially relevant due to the findings that encourage the use of active learning strategies in undergraduate instruction (e.g. Freeman, et al., 2014), since this requires a rich knowledge of student thinking and the ability to respond during in-the-moment instruction.

In future work, I will further consider how an instructor's disposition is related to their responsiveness. Gresalfi and Cobb (2006) noted that developing "positive and productive dispositions … will allow us to begin to address the current well-documented gap between who actually has opportunities to be successful in the classroom" (p. 55). Although Gresalfi and Cobb were referring to cultivating students' dispositions, this also can apply to instructors' dispositions towards student thinking; when we better understand how we can foster positive dispositions and responsiveness towards student thinking, then we can better support students by providing opportunities for more effective instruction building off of student understandings (Hand, 2012).

ARGUMENTATION IN THE MATHEMATICS CLASSROOM: SOCIAL, SOCIOMATHEMATICAL, AND MATHEMATICAL ARGUMENTS

Carlos Nicolas Gomez
Clemson University
carlos@clemson.edu

Stacy R. Jones
Clemson University
stacy9@clemson.edu

We argue for the expansion of Krummheuer's conceptualization of argumentation in the mathematics classroom. We use Toulmin's deconstruction of arguments along with studies on social interactions (e.g. Goffman, 1959) to position argumentation as a larger social phenomenon. We provide examples from two lessons conducted by a first year secondary teacher to highlight three different types of arguments: (1) social arguments; (2) sociomathematical arguments; and (3) mathematical arguments. Compartmentalizing classroom arguments in this way provides researchers a way to examine the perpetuation of deficit narratives, construction of sociomathematical norms, and establishment of productive learning environments.

Keywords: Classroom discourse, Instructional activities and practice

In general, argumentation is defined as the attempt to convince someone of the validity of a claim (Toulmin, 2003). Researchers have focused on various aspects of argumentation in the mathematics classroom including understanding classroom events (Whitenack & Knipping, 2002), teacher's support of argumentation (Conner, Singletary, Smith, Wagner, & Francisco, 2014), and students' justification and proof (Staples, Bratlo, & Thanheiser, 2012). All of these studies build on the conceptualization of arguments by Toulmin (2003), but more importantly, on Krummheuer's (1995) ethnography of argumentation in the mathematics classroom.
In this report, we return to Toulmin's (2003) conceptualization of argumentation to describe a framework deconstructing the arguments occurring in the mathematics classroom and, as such, expand the notion of argumentation as a social action. We argue previous research on argumentation has solely focused on mathematical arguments (e.g. Ingles, Meija-Ramos, & Simpson, 2007) and less on the social arguments taking place on a regular basis (Gee, 2001; Goffman, 1959). We focus on episodes from a 1st year teacher's class to emphasize the variety of social and mathematical arguments occurring in the mathematics classroom.

Argumentation in the Mathematics Classroom

Krummheuer (1995) provided a theoretical background of argumentation and conceptualized how argumentation can be considered in the learning of mathematics. There has been, however, few previous attempts to conceptualize argumentation as a broader lens and what new understandings such a lens can provide (see Gomez, 2018). We build on previous investigations into the ways individuals attempt to convince others in the community of his or her membership to particular social groups (e.g. Gee, 2001). In other words, individuals make arguments about how they want to be seen and positioned by others. As Goffman (1959) wrote:

> When an individual plays a part he implicitly requests his observers to take seriously the impression that is fostered before them. They are asked to believe that the character they see actually possesses the attributes he appears to possess, that the task he performs will have the consequences that are implicitly claimed for it, and that, in general, matters are what they appear to be. (p. 17)

The framework we describe in this presentation is meant to bring to the forefront, not just the mathematical arguments made in the classroom, but also the social and sociomathematical arguments. The use of an argumentation lens can provide new understandings of the ways dominant narratives are perpetuated in mathematics education. With the different types of arguments described, in combination with Toulmin's (2003) deconstruction of arguments, researchers can dismantle the ways teachers and students perpetuate deficit narratives and aid in the reconstruction of more productive narratives.

Social, Sociomathematical, and Mathematical Argumentation

In this section, we provide examples of each type of argument with classroom episodes of a first year teacher. We use episodes from two lessons to highlight the three types of arguments: (1) social arguments (i.e. attempts to convince an audience about one's social positioning in the world); (2) sociomathematical arguments (i.e. attempts to convince an audience of the ways individuals do mathematics within the social order); and (3) mathematical arguments (i.e. attempts to convince an audience about the validity of a mathematical claim through the use of implicit and explicit warrants of a mathematical nature (e.g. constructs, ideas, and facts) or other social capital (e.g. authority, status)).

The classroom episodes come from a longitudinal study following a cohort of 16 prospective secondary teachers through their teacher education program. For this report, we focus on Susan (pseudonym), a white cisgender female in her early 20s during her first year of teaching 9th grade Algebra. The objective of the lessons was to have students determine and write the equations of lines. She focused the majority of her time on two tasks. The first task asked students to find the equations of lines representing roads near the school. The second task was a penny pattern task (see Figure 1). The students were asked to use the data from the penny pattern task to construct a graph on a coordinate plane and find the equation of the line.

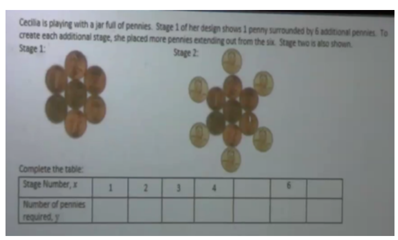

Figure 1. Penny task Susan gave to students

Social Arguments

Social arguments are attempts to convince an audience about one's social positioning in the world. In other words, social arguments are about the kind of person one wants to be seen as by others. One must argue he is the person he believes he is by using specific discourses and presenting himself in particular ways (e.g. what one chooses to wear) (Gee, 2001). We refer to arguments made to demonstrate ownership of characteristic traits or to be legitimized as a member of a community as *identity work* (Gomez, 2018). One needs to make social arguments to be recognized as a certain kind of person.

In the following episode, Susan provides a narrative to her students about her thinking process for making mathematics more interesting for them.

> Okay story time goes like this. Um, yesterday I was thinking to myself - self, how can I make math more interesting for my students because inevitably what happens when I give you guys

> something you say to me, "Ms. S when am I ever going to use this in real life?" And that is a great question. So I'm answering the question. (Susan, Lesson 1)

For this argument, Susan claimed to be attempting to make mathematics more interesting for her students warranted by her answering their questions about the application of mathematics. In the narrative, she positions herself as doing the work of a teacher and taking time outside of class for the students' benefit. She may also have been trying to provide a counter-narrative about mathematics teachers to help students reconstruct their mathematics experiences as more positive.

Sociomathematical Arguments

We define sociomathematical arguments as attempts to convince an audience of the ways individuals do mathematics within the social order. Consequently, the sociomathematical arguments made are directly related to the construction of sociomathematical norms (Yackel & Cobb, 1996), or "normative aspects of mathematics discussions specific to students' mathematical activity" (p. 361). The teacher needs to convince the students to accept, follow, and then maintain the constructed sociomathematical norms. Furthermore, these events help in the development of the students' identities as doers-of-mathematics (Cobb, Greselfi, & Hodge, 2009).

Susan made a number of sociomathematical arguments during the two lessons by attempting to convince the students learning mathematics is collaborative. She did not provide explicit warrants to the whole group during these two lessons, but did find opportunities to continue the argument while monitoring the students' small group work. While monitoring the students' work, for example, she warrants argues the benefits of collaboration:

Susan: Excellent! Yes! Great job!
Student 1: Thanks. Now I just don't know how to do this.
Susan: Yes you do.
Student 2: Yes, it's like -
Student 1: So this would be like 7 and then -
Student 2: See like 1 and 7 like that [points to paper].
Student 1: Oh.
Susan: *This is why I put you guys with each other because you can find the answer with each other.* You don't even need—well you might need me for some stuff.

Mathematical Arguments

Mathematical arguments are the attempt to convince an audience of the validity of a mathematical claim through the use of implicit and explicit warrants of a mathematical nature (e.g. constructs, ideas, and facts) or other social capital (e.g. authority, status). Mathematical arguments have been the main focus of research on argumentation (e.g. Inglis et al., 2007). This is possibly because of the strong focus Krummheuer's (1995) conceptualization of argumentation placed on the mathematical arguments happening in the classroom. These arguments are usually explicit because it is through the construction of mathematical arguments students learn to do mathematics. "Learning how to argue whether an idea or claim is true or false in a mathematically valid way is an essential part of learning to do mathematics" (Koestler, Felton, Bieda, & Otten, 2013, p. 30).

A multitude of mathematical arguments occurred during Susan's two lessons. In this episode, Susan asked a student to contribute a claim to the whole group by asking her how many pennies there are in the first stage of the penny pattern task.

Susan: Okay so this girl is playing with pennies and she's decided, hey how about I start arranging them in a particular order and keeping track of how I arranged them. So the first stage is right there [points to board]. How many pennies total does she have in the first stage? [Susan reaches for cup with popsicle sticks and selects one] Student6?

Student 6: Seven.

Susan: Seven. Yes. [writes 7 in table]. Here is her pennies [points to board; uses marker to write "1" on each penny as she counts them]. One, two, three, four, five, six, seven. She has seven total pennies from stage one.

Susan was the main contributor to this mathematical argument. While the student was providing the claim, the warrant was contributed by Susan. So she was demonstrating her mathematical reasoning and not the student's thinking. Students may infer this as Susan arguing for her authority as well especially if Susan contributes majority of warrants.

Discussion and Conclusion

In this report, we extend and build on Krummheuer's (1995) conceptualization of argumentation in the mathematics classroom. In general, more than just mathematical arguments occur in the classroom. We argue social and sociomathematical arguments need to be explored further because they recognize the complexities of teaching and learning mathematics.

CARING, MALE AFRICAN AMERICANS, AND MATHEMATICS TEACHING AND LEARNING

Jason G. Hunter
DeKalb County School District
Jason_Hunter@dekalbschoolsga.org

David W. Stinson
Georgia State University
dstinson@gsu.edu

In this paper, the authors report on a qualitative study that explored the influence a "successful" African American male mathematics teacher had on three African American male high school students' perceptions of teacher care. This critical ethnography study was guided by an intersection of an eclectic array of theoretical traditions, including care theory, critical race theory, and culturally relevant pedagogy. The study employed ethnographic methods during data collection; data analysis identified six overarching themes that the participants used to describe teacher care. Findings suggest that teachers should reconsider the ways they care for African American male students and that a caring teacher–student relationship has a positive influence on African American male students' descriptions and perceptions of teacher care.

Keywords: Equity and Diversity, High School Education

Introduction

Narratives on the achievement outcomes of Black boys in mathematics are too often negative (see Stinson, 2006). Contrary to these negative narratives, however, research affirms positive outcomes for students, including Black boys, when engaged in caring teacher–student relationships (see, e.g., Bartell, 2011; Roberts, 2009; Steele, 1992). But literature specific to caring teacher−student relationships, African American male students, and mathematics teaching and learning is all but nonexistent. Therefore, in this study, we sought to uncover the definitions that African American male high school students had of teacher care, and how, if at all, an African American male teacher might influence their perceptions of teacher care. We categorized the study as a critical ethnography where the researcher studies an intact cultural group in a natural setting over a prolonged period of time (Madison, 2005). It was guided by an intersection of an eclectic array of theoretical traditions (Stinson, 2009) that included care theory (e.g., Gilligan, 1982; Noddings, 1992), critical race theory (e.g., Tate, 1997), and culturally relevant pedagogy (e.g., Ladson-Billings, 1992).

Theoretical Frameworks

Care theory as an analytic framework has a vast history and has been described from many perspectives from a variety of disciplines. This body of knowledge is a result of contributions from several scholars who have defined care in multiple ways (see, e.g. Agne, 1999; Gilligan, 1982; Kohlberg, 1984; Noddings, 1984, 1992, 2002, 2006; Oakes & Lipton, 1999; Siddle-Walker, 1993). This multiplicity has often created somewhat of a muddled definition of care. Nonetheless, Gilligan's (1982) scholarship provided the foundation in which current research on an ethic of care is established where caring transitioned from being initially rooted in the field of nursing, to being recognized as a framework to base other research.

Noddings's (1984, see also 1992) scholarship is recognized as the first to expand Gilligan's (1982) work on care to education. Noddings believes human interaction was the central theme of care theory, which created a natural fit in education research. Noddings defines a caring relationship as inclusive of components of understanding, inter-subjectivity, and constant activity. She claims that a caring relationship is not complete unless there is some sort of confirmation given by the cared for. Therefore, Noddings argues that the teacher–student relationship should be reciprocal and requires a certain amount of trade. She also reveals concerns of cultural relevance when it comes to care in the classroom. Noddings (2006) states, “Two students in the same class are roughly in the same situation, but they may need very different forms of care from their teacher” (p. 20). The teacher must understand each individual student to better provide the care defined by Noddings’s theory.

Critical race theory (CRT) as a theoretical framework was first derived from the legal field in the 1980s, when scholars such as Derrick Bell, Richard Delgado, and Alan Freeman searched for a way to more directly and adequately address race and racism in the United States (Roberts, 2010). It was initially rooted in critical legal studies (CLS), a movement that critically examined formalism and objectivism (Tate, 1997). CLS offered critiques of the law, but failed to address issues related to race. As a result of the shortcomings of CLS, came the development of CRT. Gloria Ladson-Billings and William Tate were the first scholars to introduced CRT to the field of education (DeCuir & Dixson, 2004). CRT stresses the need to interrogate how the law as well as socio-cultural and -political structures and discourse reproduce, reify, and normalize racism in society.

Throughout the research project, male African American high school students were provided a non-colorblind opportunity to describe teacher care and explain the practices of a caring teacher (see, e.g., Thompson, 1998). This non-color-and-cultural-blind approach made it possible for the descriptions that the students had of caring teachers to include tenets of culturally relevant pedagogy (CRP). CRP is frequently identified with the work of Ladson-Billings (e.g., 1992); she defines CRP as pedagogy that “prepares students to effect change in society, not merely fit into it” (p. 382). She stresses how vital the teacher−student relationship is to CRP, and says it allows teachers to “empower students intellectually, socially, emotionally, and politically” (p. 382). This type of pedagogy views culture as a powerful variable in the success of students, and it acknowledges the importance of high standards and expectations for teachers (Irvine, 2001). Roberts (2009) argues, “CRP is a philosophical construct that discusses a set of pedagogical behaviors that identifies, values, respects, and utilizes the cultural knowledge and performance styles of ethnically diverse students” (p. 16).

Methodological Considerations

The participants in this study were three high school-aged male African Americans—Kareem, Joshua, and Michael (pseudonyms, as are all proper names)—in a tenth-grade Geometry class at Divine High School, and the African American male teacher of that class. The student body at Divine is composed of all male African Americans; it is a public charter school, located in the “inner city,” in a low socio-economic neighborhood. The three male participants are students of the same “successful” African American male teacher—Mr. Ira—who was selected by the process of “community nomination” (Foster, 1997), whereby members of a community of interest suggest individuals who they believe will be the best subjects for research. Mr. Ira had been teaching for over twenty-two years, working at Divine since it opened. He was a tenth-grade geometry teacher, 54-year-old father of three, originally from the northeastern United States, and identified as an African American man.

Data collection included semester-long, daily participant observations (and accompanying field notes) and three semi-structured interviews with each participant (all observations and interviews were conducted by the first author). The method of participant observation suggests researchers should take part in activities, rituals, interactions, and events of the participants as a means of learning about their lives and culture (DeWalt & DeWalt, 2011), while field notes assists in "constructing the case." The theoretical underpinnings of care theory, critical race theory, and culturally relevant pedagogy (described earlier) provided the lens to ground the logic of the observations. The first author spent almost every day for a school semester (16 weeks) at the research location for participant observations. Participant observation "puts you where the action is and lets you collect data…any kind of data that you want" (Bernard, 2006, p. 343). Field notes were used to record data from the observations. Field notes were crucial to recording the observations, laying a foundation for the contexts for the participant interviews; given that participant observation "is rarely, if ever, the only technique used by a researcher conducting ethnographic research" (DeWalt & DeWalt, 2011, p. 3).

Findings

During data analysis, six overarching themes were identified that the participants used to describe teacher care: (a) motivation, (b) culture, (c) confidence, (d) discipline, (e) concern for futures, and (f) environment (see Table 1). These themes were interpreted from the participants' significant statements, and of these six themes motivation and classroom environment were noted as the most important to the student participants. These African American boys wanted to feel (and be) capable and comfortable in a mathematics classroom. Fortunately for them, they had an African American male teacher, Mr. Ira, who also found these aspects of teacher care important and who would stop at nothing to encourage and create an environment designed for their success in mathematics.

Table 1: Overarching Codes/Themes and Sub Themes – Descriptions of Teacher Care

Motivation	Culture	Confidence	Discipline	Concern for Futures	Environment
Inspirational	Understands struggle	Believes in students	Rules	Will not allow students to cheat themselves	No judging
Leads by example	Fights stereotypes	Gives students hope	Expectations	Future job concern	Safe
Encouragement	Defends students	Teaches self-efficacy	Second chances	Treats students like his children	Comfortable
Makes students feel important	Diversifies lessons		Empathy	Cares about students' lives outside of school	Mistakes okay
Praises students			Patience		Family environment
			Firm but fair		Offset institutional racism

When it comes to the influence an African American male teacher had on the participants' perceptions of teacher care, there was some overlap with how they described teacher care. An African American male teacher simply softened the environment, so to speak, and made the student participants feel more comfortable. Clearly, the students perceived connections to the teacher participant, based on his appearance, and assumptions they made about him. Pursuing this further, and based on the participants' descriptions, we are all but certain that these assumptions were also rooted in their historical interactions with teachers of other races. These interactions helped garner the assumptions and shape the eventual expectations the students had of the teacher participant in the beginning. Mr. Ira called for “empathy and patience as teachers weather the storm, because they will be tested.” But when the storm is over, hindsight reveals that this is a nonissue. Because as intelligent as they are, the student participants, and Black boys in general, eventually crossed reference their pre-expectations with how they define a caring teacher.

MULTILINGUAL PERSPECTIVES AS NEW OPPORTUNITIES FOR SEEING AND LEARNING MATHEMATICS

Cristina Valencia Mazzanti
University of Georgia
crisvm6@uga.edu

Martha Allexsaht-Snider
University of Georgia
marthaas@uga.edu

This research intends to offer multilingual perspectives of the languages in mathematics classrooms and how they can be conceptualized. Through our analysis of the multilingual perspectives of translanguaging and the teachers, children, and researchers in the study we present ways to identify and understand different language practices that emerge as young multilingual children experience and make sense of mathematics.

Keywords: Equity and Diversity, Early Childhood Education, Culturally Relevant Pedagogy

The use of more than one language in mathematics classrooms has been often conceptualized as code-switching or language-switching (e.g., Barwell et al., 2016). However, neither language-switching nor code-switching represents a multilingual perspective of the world, but instead a perspective in which being monolingual is still considered the norm (Garcia & Wei, 2014; Celic & Seltzer, 2011). Although hard to know with precision, it has long been estimated that more than half the world knows more than one language (Stavans & Hoffman, 2015). These perspectives point to the increase of multiple languages in mathematics classrooms across the globe and make it necessary to understand the language practices of multilingual people[1] from a standpoint in which being monolingual is no longer considered the norm.

This paper aims to offer possibilities for the way we identify the languages used by children and educators during mathematics learning from the multilingual perspectives of the authors, children, and translanguaging, drawing on data collected for two school years in two kindergarten classrooms. For this purpose, we understand languages as any medium through which we communicate or make sense of the world. From this perspective, we consider the following questions: (1) What languages are currently being used in mathematics classrooms? (2) How can we conceptualize the languages in mathematics classrooms from multilingual perspectives?

Perspectives and Theoretical Framework

This paper takes an interpretivist approach, using hermeneutics as a way to make sense of the multilingual perspectives of the authors, the children, and translanguaging. A hermeneutic perspective allows us to look closely at the narratives collected as data for this study and disrupts them through purposeful interpretation; it allows us to question taken for granted notions about knowledge and language in the context of mathematics learning. Moules et al. (2015) explain that “hermeneutics is organized around the disruption of the clear narrative, always questioning those things that are taken for granted.” (p. 4). Hermeneutics also allows us to understand our role as researcher in the process of interpretation and to think about the contextual factors that shape understanding as well as what can be understood.

We draw on translanguaging to re-conceptualize the learning and language practices of children taking place in mathematics classrooms because it offers a view of language that is inherently multilingual. The term is used to describe the way multilingual people use language; it refers to “the ability of multilingual speakers to shuttle between languages, treating the diverse languages that form their repertoire as an integrated system” (Canagarajah, 2011, p. 401).

Translanguaging offers a way to conceptualize the language practices of multilingual people as something different than code-switching or language-switching. As explained by Celic & Seltzer (2011) "Notice that translanguaging is not simply going from one language code to another. The notion of code-switching assumes that the two languages of bilinguals are two separate monolingual codes that could be used without reference to each other. Instead, translanguaging posits that bilinguals have one linguistic repertoire from which they select features strategically to communicate effectively. That is, translanguaging takes as a starting point the language practices of bilingual people as the norm, and not the language of monolinguals, as described by traditional usage books and grammars" (p. 1).

We find it particularly helpful to think about the way translanguaging incorporates the idea of languaging, and how this allows us to conceptualize language in a dynamic way. "Language is not a simple system of structures that is independent of human actions with others, of our being with others. The term *languaging* is needed to refer to the simultaneous process of continuous becoming of ourselves and of our language practices, as we interact and make meaning of the world. […] Languaging both shapes and is shaped by context." (Garcia & Wei, 2014, p. 8.) Adopting translanguaging as a framework for understanding the language practices of multilingual people allows us to unveil the ways in which language practices are complex and ingrained in contexts that relate to identity and nationality and carry power dynamics.

Modes of Inquiry

In this paper, we draw on multilingual perspectives as the sources of our analysis and conceptualization of language through the authors, the children, and translanguaging. We also draw on the data collected during mathematics instruction in two kindergarten classrooms in two public schools in Georgia as a part of a larger study to understand the connections between mathematics and language. The focus of the study during the first school year was the bilingual students in a public school in a kindergarten classroom with a large Latino population. The focus of the study in the second school year was the children in an immersion bilingual program (Spanish/English) in a different public school. The children in the bilingual program were taught mathematics in Spanish and were native speakers of Spanish and/or English.

Cristina collected data through the role of a participant observer and volunteer teacher using journal entries to record significant events while also collecting student work. During the second year of the study we introduced audio recordings for data collection as well as periodic field notes taken by Martha through the role of reactive observer. Data was collected and analyzed through an interpretative hermeneutic approach because it provided us with ways to look deeply and understand differently, disrupting current narratives about language use in mathematics classrooms. We conducted in-depth analysis of events rendered into text, interpreting them from multilingual perspectives as a way to bring to light the dynamic, contextualized, and interactive nature of language practices in the lived experiences of multilingual children in the mathematics classroom.

Results and Discussion

In this section, we consider a lesson on word problems implemented by Cristina in the second year of the study as it allows us to see the way languages are being used. During this particular lesson, the class is being introduced to word problems as well as how to represent their mathematical processes and answers. For this purpose, in her role as a volunteer teacher, Cristina worked with the children to create a word problem and how to represent their thinking using a picture book as a common and meaningful context. The complexity of language practices occurring during this lesson is particularly visible in audio-recordings, for instance in the following transcription of the lesson:

Cristina:	Ramón hizo cinco dibujos. Su hermana Marisol encontró tres dibujos ¿Cuantos dibujos hay? [Several students raise their hand] - Kira ¿Cuál es el problema? No me digas la respuesta ¿Cuál es el problema? [*Ramon made five drawings. His sister Marisol found three drawings. How many drawings are there? [Several students raise their hand] -Kira, what is the problem? Don't tell me the answer. What is the problem?*]
Kira:	Um- uh –
Cristina:	¿Qué queremos saber? [*What do we want to know?*]
Kira:	The brother did five drawings. The little sister has three more. How many does both of them have together?

Perhaps the first idea that comes forward about language in this brief interaction is the fact the fact that mathematics is occurring multilingually, that Cristina and Kira are using Spanish and English simultaneously as a way to communicate and learn mathematics. Translanguaging allows us to see this multilingual interaction as a fully complex communicative practice. In other words, instead of seeing the interaction from a perspective in which English and Spanish are working separately to support mathematics learning, translanguaging allows to see how both languages work together to support Kira's and other students' mathematical learning. Kira's restatement of the word problem presented in Spanish not only introduces English as a strategy to support understanding but also incorporates several mathematical clues about what we are trying to know. In her answer, Kira incorporates word clues (i.e., more, both of them, and together) calling attention to the mathematical question and the way the numbers relate to each other. Kira's answer builds understanding from what is being said beyond translation, and it reflects the syntaxes of Cristina's sentences in Spanish (Ramón hizo 5 dibujos, the brother did 5 drawings); this indicates that Kyra is using both languages to understand the mathematics question and the communicative demands within the lesson.

Through the notion of languaging, as explained in the theoretical section, translanguaging also allows us to see how the contextual nature of language plays a role in our ability to communicate and make meaning of an interaction. This is noticeable in the transcription when Cristina restates her question in a different way to elicit Kira's response. In the interaction it is possible to see that the first question Cristina asks does not makes sense to Kira, as the idea of a problem in the way they are often talked about in mathematics classrooms is unfamiliar for the student. This is consistent with the findings of other researchers who have called attention to the issue of naming word problems, problems, when the situation does not appear problematic to students. This also brings attention to the way Cristina was able to identify what Kira needed to understand and to be successful at answering the question. Although Kira is a native English speaker, Cristina understood that the breakdown in communication was because of the meanings that are attributed to the word "problema/problem" in mathematics classrooms, and not because she did not understand Spanish.

The interactions in the transcription also allow us to open questions about the way language can be used symbolically and how this plays a role in the mathematics classroom. The quantities in the word problem (3/5) are originally introduced through the way they are represented by sounds in Spanish (tres/cinco). Kira then connects them to the way they are represented by sounds in English (three/five). Later in the lesson the students worked independently to connect those sounds to a numeral and a model of the quantity, as can be seen in the following examples:

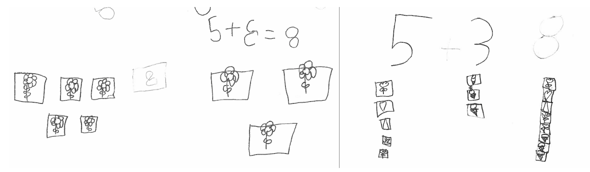

Figure 1. Connections between sounds to a numeral and a model of the quantity.

This way of using languages, to provide multiple complex representations of the same concept through different modalities, allow us to conceptualize the languages being used but also allow us to see how languages catalyze learning and make it visible. In this particular instance it is a way for children to build their number sense, making meaning of the relations that exist between numbers to successfully complete and represent ideas about addition.

This report was designed to highlight the many languages that are used in mathematics classrooms and consider how we might conceptualize them from multilingual perspectives. By offering a brief analysis of a small set of data we show some of the possibilities and richness this kind of analysis can have, particularly for multilingual people. As a final essential remark, we would like to point out that adopting translanguaging as a framework for understanding the language practices of multilingual people in mathematics classrooms is an issue of equity, particularly in a world that is increasingly multilingual. Translanguaging provides us with a way to understand the inherent power dynamics of languages and a way to invert them; this is visible even in the way it takes multilingualism as the norm instead of monolingualism. Setati (2008) makes a powerful argument for the need to focus on the political role of language within multilingual mathematics education research. She calls us to go beyond arguing for the incorporation of students' home language or thinking of language as tool for thinking and communication. In this instance, taking a stance to see language in mathematics instruction through multilingual perspectives allowed us to purposefully interpret data, disrupting taken for granted narratives and opening new and more equitable possibilities to see and understand the mathematics learning of multilingual children.

INVESTIGATING THE RELATIONSHIP BETWEEN THE ENACTED CURRICULUM AND TEACHER CONCERNS IN HIGH SCHOOL MATHEMATICS

Ji-Won Son
University at Buffalo
jiwonson@buffalo.edu

Jeri Diletti
University at Buffalo
jeirdille@buffalo.edu

The purpose of this study is to investigate the relationships among teacher concerns regarding the CCSSM, teachers' intended curriculum and teachers' enacted curriculum. Three high school teachers were intentionally selected as a focus group, based on their different levels of concern. Each teacher was observed during three different lessons on linear/non-linear functions. Pre- and post-observation interviews were conducted both before and after each lesson was taught. Findings suggest a complicated relationship exists between teacher concerns and their intended and enacted curriculum. Regarding teacher concerns, different factors seem to take account for the complicated relationship between teacher concerns and their enacted curricula.

Keywords: Enacted Curriculum, Teacher Concern, High School Mathematics

Introduction

The Common Core State Standards for Mathematics (CCSSM) highlight the importance of students' conceptual understanding, mathematical reasoning, and problem solving in order to prepare students for college and careers. However, the success of this reform effort largely depends on how teachers actually design and implement instruction based on the goals of the new standards (Son & Kim, 2015, 2016). Depending on the concerns teachers have, based on the new standards and curriculum, teachers may or may not consider themselves qualified to implement the desired innovations (Christou, Eliophotou-Menon & Philippou, 2004).While there exists an increasing amount of research on reform efforts, many questions still remain regarding the implementation of the CCSSM and teachers' concerns. The purpose of this study is to investigate the concerns teachers have regarding the implementation of the CCSSM and how those concerns relate to the enactment of their curricula. This study also explores how teachers address the mathematical shift of rigor defined in the CCSSM in connection with the tasks they use and types of questions they pose to their students. The research questions that guide this study include: (1) In what ways do Algebra 1 teachers implement the CCSSM to address the mathematical shift of rigor, as defined by the CCSSM, in their Algebra 1 classes? And (2) In what ways do Algebra 1 teacher concerns connect to their implementations of the CCSSM? Three high school teachers were intentionally selected as a focus group, based on their different levels of concern. In answering the two research questions, this study explored whether the three teachers' intended curricula aligned with their enacted curricula in their teaching of linear and non-linear functions. It was also determined if the tasks provided to students and the teacher questioning during instruction addressed the major shift of rigor emphasized in the CCSM.

Theoretical Perspectives

Remillard (2005) describes multiple meanings of curriculum use: curriculum use as following or subverting the text, curriculum use as drawing on the text, curriculum use as interpretation of text and curriculum use as participation with the text. Building on Remillard's second perspective, this study regards teachers' curriculum use as drawing on the text. With this view, the emphasis is placed on the teacher, and views the text as "one of the many resources in constructing the enacted curriculum" (Remillard, 2005, p. 219). We also build on three different frameworks to explore teacher concerns, mathematical tasks and teacher questions.

In exploring teacher concerns on the CCSSM, six stages of concerns identified based on the Concerns-Based Adoption Model (CBAM): A Model for Change in Individuals (Hall & Hord, 2001) are used. In exploring learning opportunities presented to students, cognitive demand of mathematical tasks was explored based on the framework by Stein, Grover, and Henningsen (1996). The four levels are used to determine the rigor of tasks teachers used in their classrooms, which refer to the thinking processes involved in solving the tasks. The framework involves two levels of low cognitive demand tasks—High cognitive demand (i.e., Procedures with Connections; Doing Mathematics) and low cognitive demand (i.e., Memorization; Procedures without Connections). In order to explore teacher questions, the framework adapted from Boaler and Brodie (2004) was used.

Methods

Table 1shows an overview of the study design. Qualitative research methods (e.g., classroom observations and teacher interviews) were utilized for the study. Three teachers were intentionally selected, based on their concerns, for the case studies in order to analyze teachers' implementation strategies of the CCSSM. Ms. Brimm, Mrs. Doherty, and Mrs. Schilling (all psuedonyms) work in the same school district. Classroom observations and pre and post-lesson interviews with these teachers were used for this study. Prior to analyzing lesson tasks, a problem analysis was conducted on the *Pearson Algebra I Common Core* textbook. Since the observed lessons for this study solely focused on linear and non-linear functions, only the corresponding chapter (chapter 4) of the textbook was analyzed.

Table 1: Overview of Study Design

	Qualitative Research Study
Participants	• 3 teachers from a rural school district in Western New York • Each teacher exhibits a different stage of concern
Data Collection	• 3 video-recorded classroom observations for each teacher • One general interview prior to any lesson enactment • Pre- and post-lesson interviews before and after each of the lessons
Data Analysis	• Relative frequencies completed for task type (application, procedural, conceptual) for (a) each lesson and (b) total across the 3 lessons • Significant patterns in teacher questioning • Differences in intended vs. enacted curriculum

Three sets of data were collected from the three teachers: teachers' planned lesson, three video-recorded observations and field notes and structured interviews. Teachers' guided notes and their taught lessons were analyzed in light of two aspects – (1) mathematical tasks and types used and (2) types and frequencies of teacher questioning. The interview data were analyzed to determine: (a) if the teachers intended curriculum differed from their enacted curriculum, (b) if they were aware of any deviations that occurred between the intended and enacted and (c) why teachers made deviations.

Summary of the Findings

All three teachers in this study used the same resources, had the same professional development opportunities and designed the curriculum collaboratively. However, the enacted curriculum for these teachers was differed based on the level of concern each teacher had.

Alignment Between Rigor of Teachers' Enacted Curriculum and the CCSSM

First, we found that the *Pearson Algebra 1 Common Core* (Charles et al., 2012) the three teachers used provide cognitively low-demand tasks and fail to address the mathematical shift of rigor highlighted in the CCSSM. All sections except section 4.1 had a heavy emphasis on procedural tasks including the sections observed in this study. This analysis suggests that if teachers closely follow the *Pearson Algebra 1 Common Core* textbook as a main resource, their students might not be exposed to a high level of cognitive demand.

Second, we found that the vast majority of tasks and teacher questions for all three teachers were low cognitive demand. Teachers at all stages of concern are not providing cognitively demanding lessons nor are they addressing the mathematical shift of rigor. Ms. Brimm stated in her initial interview that she went on the recommendation of the high school teachers to use the *Pearson Algebra 1 Common Core* textbook. Mrs. Doherty also noted that this textbook was most closely aligned with the CCSSM Algebra standards. Mrs. Schilling's comments were similar. She stated that the textbook was the best one written to address the Common Core Algebra standards. We observed that these three teachers rarely altered textbook problems. In particular, the vast majority of questions for all three teachers were low cognitive demand. Teachers only significantly increased the cognitive demand of the questions when they had students working collaboratively in groups in order to communicate their ideas to others and justify their reasoning.

The Relationship of Teacher Concerns and the CCSSM Enacted Curriculum

First, Ms. Brimm was determined to be at the self-concern level. She felt she was not knowledgeable about the mathematics content and methods she had to teach. She thus followed the textbook very closely in selecting tasks. She stated that at times, she had to learn the content before she could teach it. In addition, she rarely altered the tasks during the enactment of the lessons. Ms. Brimm's lack of content knowledge seems to lead her to have self concerns. This resulted in her following the textbook closely. Her self concerns also led her to focus mainly on content coverage and did not allow her to modify the intended curriculum.

Second, the teacher with management concerns tended to express her students' low abilities in doing mathematics. Ms. Schilling was determined to be at the management concern level. Similar to Ms. Brimm, in the selection and design of her lesson tasks, Mrs. Schilling stated that all her tasks came from the Pearson Algebra 1 Common Core textbook. However, in the enactment of the tasks, Mrs. Schilling did alter her initial plans. Mrs. Schilling's concern over the material she had to cover led her to have management concerns. She was comfortable with the content and methodology and, therefore, was able to slightly modify her intended curriculum. However, she was unable to provide any cognitively demanding lessons since her focus was on content coverage and the ability level of her students.

Third, Mrs. Doherty was found to have impact concerns. Mrs. Doherty's high interest in student understanding, as well as her desire to collaborate frequently with other teachers, led her to have impact concerns. With this higher level of concern, Mrs. Doherty was able to focus her lessons on student understanding, and therefore, was able to modify her intended curriculum. She altered the curriculum based on the needs of her students. However, her tasks and questions remained at a low cognitive level for two of the three lessons.

Discussion and Implications

This study contributes to the current literature because it has shown the relationships between teacher concerns on the CCSSM and their intended and enacted curriculum. Teacher concerns seem to be hindering their ability to provide cognitively demanding lessons, thereby showing limited success for the CCSSM. Therefore, implications of this research exist for textbook publishers, curriculum developers, professional development providers, teacher educators, teachers, administrators and future researchers. For example, textbook publishers, curriculum developers and teachers need to be aware of cognitive demand of tasks used by teachers. Professional development providers and teacher educators can help teachers focus their questioning, and address the concerns teachers have.

MATHEMATICAL MODELING COMPETENCIES ESSENTIAL FOR ELEMENTARY TEACHERS: THE CASE OF TEACHERS IN TRANSITION

Jennifer M. Suh	Kathleen Matson	Padmanabhan Seshaiyer
George Mason University	George Mason University	George Mason University
Jsuh4@gmu.edu	kmatson@gmu.edu	pseshaiy@gmu.edu

This report documents three teachers journeys as they engaged in a Teacher Research Study Group while implementing mathematical modeling in the elementary grades. In detailing three teachers' perspectives, we provide a context and describe each of the teachers' mathematical modeling journeys and their process of adopting the innovation of MM in their classrooms. Four main mathematical modeling competencies emerged as being central to the success of enacting mathematical modeling in the elementary classroom: a) finding relevance, b) identifying MM potential; c)posing MM questions; and d) capitalizing on a useable model.

Keywords: Teacher Education-Inservice/Professional Development, Modeling, Instructional Activities and Practices

Research Literature on Mathematical Modeling

As a reform-oriented initiative, we consider MM to be an **ambitious teaching** practice. Ambitious teaching is teaching that aspires to teach all students academic content and have them apply their knowledge to solve authentic academic problems. MM does exactly this as it moves students through a process of mathematizing a real-world problem and using the mathematics to solve it. MM, as an ambitious teaching practice, builds on student ideas and gives students a role of sense-makers. Our increased dependence on technology together with the complexity and interconnectedness of our society has led to significant changes in the types of mathematical thinking required in today's world (English, 2013). Educational leaders are emphasizing the importance of developing students' abilities to deal with these new demands of our society (e.g. Lesh & Doerr, 2003). These abilities include interdisciplinary problem solving, techno-mathematical literacy, flexibility in applying numerical and algebraic reasoning, thinking critically, and constructing, describing, explaining, manipulating and predicting complex systems (English, 2013). Mathematical modeling (MM) is seen as a powerful tool for advancing students understanding of mathematics and for developing an appreciation of mathematics as a tool for analyzing critical issues in the real-world, that is, the world outside of the mathematics classroom (Greer & Mukhopadhyay, 2012). Traditionally, MM has been implemented primarily in secondary schools, but recent research examines using this approach with elementary students to promote their problem solving and problem-posing abilities (e.g. English, 2010). MM provides the opportunity for students to solve genuine problems and to construct significant mathematical ideas and processes instead of simply executing previously taught procedures and is important in helping students understand the real world (English, 2010).

Method for Our Study

A qualitative case study approach was selected for this study as our intent was to gain insight and understanding of elementary school teachers' adoption of MM . The boundaries of the case were in-service, K-6, mathematics teachers who, following a PD on mathematical modeling, chose to participate in a teacher research study group. This case consisted of three mathematics teachers from our larger research project who continued in our spring teacher research study group. We were interested in gaining insights into how teachers' pedagogical practices and knowledge emerged as they enacted MM in the elementary school and how inquiry into their own practice helped them negotiate the adoption of MM. We were not looking to do a detailed study of the individual teachers as that would entail separate case studies. Instead, our unit of analysis was the similarities and differences across these teachers' experiences in implementing MM. The boundaries of the case were determined by place, time and event.

Participants. Participants were inservice, K-6, mathematics teachers, in a large mid-Atlantic school district, involved in a professional development (PD) initiative focused on mathematical modeling (MM), between August, 2015 and June, 2016. We selected three mathematics teachers from our PD who elected to join our spring teacher research study group (TRSG), demonstrated an understanding of mathematical modeling that was consistent with the project goals, and whom we identified as early adopters of MM (Rogers 2003). Our three participants taught Advanced Academic Program (AAP) students. Anne was an experienced teacher with 28 years of experience and taught sixth grade. 7% of the students in Anne's school participate in a free or reduced lunch program. Lisa, a third grade teacher, had 5 years of teaching experience at the time of our study. Matthew had four years of teaching experience and taught fourth grade and had 26 students in his math class. 4% of the students in Matthew's school participate in a free or reduced lunch program.

Research Questions. In order to understand how teachers enacted mathematical modeling skillfully in the elementary grades, we addressed these research questions: What pedagogical practices and knowledge emerged as teachers enacted MM in the elementary school classroom? How did teachers develop their modeling teaching practices as they continued on their journey as implementers of mathematical modeling in the elementary grades?

Data Sources. Debriefs of individual Lesson Study session and Lesson Study group presentation at a final symposium were captured on video. Sources also included individual teacher reflections, semi-structured researcher memo's for each Lesson Study and symposium presentation, exit passes from the summer institute and the final symposium, and participant Powerpoint presentations from the final symposium. The artifacts collected from the Lesson Study cycle included the planning agendas, actual lesson plans, student work samples, the analysis of student work, and teacher reflections. Each of these factors contributed to compiling a comprehensive picture of teachers' experiences with MM.

Data Analysis. During the first phases of the analysis, we used the observational memos from lessons with analytic researcher memos that allowed us to not only describe our teacher-designers planning and enactment of the mathematical modeling lessons but also summarize our thoughts about potential ways in which certain skills, knowledge and beliefs contributed to the teachers' ability to facilitate learning through mathematical modeling. Interviews, videoclips of classroom episodes and artifacts from lessons including lesson plans, and student artifacts also helped identity the development of the mathematical modeling processes in the elementary classroom and the various models that emerged from the mathematical modeling tasks. We created a chronological timeline for each of the teacher designers with linked data sources allowing us to focus on documenting the generative change that teachers experienced as they continued to implement mathematical modeling during the fall and spring semester of the school year. The story line provided a comprehensive profile for each of our participants for our case study analysis.

For the second phase of our data analysis, we used thematic networks as a tool for our data analysis. We started by identifying specific teacher moves in the transcripts of our interviews, in our researcher memos, and teacher reflections. We used Dedoose Version 7.5.9 to code our data and dissect the text into text segments. These text segment were analyzed qualitatively for emergent themes and patterns. In addition, the text segment were counted and compared within each theme to identify and describe any differences between the three case study participants.

Results

In detailing the teachers' perspectives of the MM lessons and reflections on the MM process using several of the episodes in these cases, we found four main categories of mathematical modeling competencies that emerged as being central to the success of enacting mathematical modeling in the elementary classroom: a) finding relevance, b) identifying MM potential; c)posing MM questions; and d) capitalizing on a useable model.

Finding Relevance. One of the strengths of MM is the authenticity and real-worldness of the problems being solved by students. We noted teachers in the TRSG able to identify engaging contexts, build on student ideas, use authentic problems and make real-life connections for their students. This was one of Anne's strengths. At the beginning of the year, Anne asked her students, "How can we impact our school and community?" With her students, she identified which ideas could be solved with mathematics and used her students' ideas and her knowledge of the curriculum to develop authentic and relevant MM projects for her class."Students are empowered by knowing they can really do something. It is unlike contrived math that comes from a book. I think it is important that they know it is something they can really do."

Identifying Mathematical Modeling Potential. We found that the MM tasks designed and developed by our participants centered around four types of models: descriptive, optimization, predictive and ranking models. This includes the notion of using mathematics to make decisions. Teachers working within their curriculums, Matthew began with his curriculum and worked backwards, for less experienced teachers, this approach supported them in adopting MM, Anne started with a problem, context and then looked at the math. For the school store task, as students compiled their surveys she asked them to predict the first week's sales in their store. This led students to compute unit rates, calculate estimated profit, differentiate between wholesale and retail costs, draw graphs to represent their predictions (predictive); with the dead-stock of pencils, she saw potential to apply linear functions by asking students to find the best sale option to get rid of stock and promote bulk sale. (predictive); with the wait-time dilemma - students computed rate and flow issues and collected data to reduce wait-time in line (optimization).In Lisa's Planning a day trip task, students had to optimize the time they could spend at sites, maximize fun but minimize cost. (optimization)

Posing Mathematical Modeling Questions. An important element of successful MM tasks is asking the right types of questions. Some were planned and spontaneous questions, driving questions while others emerged as MM questions as teachers became more comfortable asking questions. Questions varied from the main driving question of the MM task that kept students focused on the mathematics of the problem to day-to-day questions that preseed students to explain and justify their assumptions, choices and reasoning. Anne focused on questioning pattern for working with large amounts of data. Students overwhelmed by large amounts of data, Anne's focused questions (focus versus funneling, NCTM, 2014) helped them arrive at use of representative samples to process 600+ surveys. Her questioning brought out how this approach could apply to other situations.

Capitalizing on the Usefulness Principle. We found that in elementary school classrooms, not all MM tasks result in a generalizable model. Some of the tasks resulted in one model to solve a particular real-world problem, sometimes students were able to apply the principles to an additional problem and we found that less frequently, students were able to develop a generalizable model. We posit that this is a natural part of mathematical modeling in the elementary grades and that these early experiences with MM serve to develop student understanding of and comfort with MM that will eventually lead them to develop generalizable models. Thus, for elementary grades capitalizing on the useable model looks different than it would in upper grades.

Conclusion

Supporting teachers adopt an innovation as ambitious teaching practices

As shared in the teacher's profile, these teachers were knowledge-seekers, they came with the predisposition to gain knowledge "learn more about creating research-based lessons for modeling real-world mathematics" and "share this approach with other teachers". Each of our teachers sought out this innovative ambitious practice of teaching mathematical modeling as a process to use with their curriculum standards. They gained knowledge and practice by collaborating with a team of teachers during the professional development summer institute and lesson study. While they immersed as math modelers during the institute and a teacher designer and implementer, they weighed the benefits and challenges and made personal decision whether to continue with the innovative practice. This decision led these three teachers to voluntarily join the Spring Teacher Research Study Group. With additional support from the project team, these teachers gained more knowledge and continued to put this innovation into use, sometimes flailing and sometimes, finding the "sweetspot". In their continued pursuit of finding what worked for their students, they continued to evaluate not only their own teaching decisions but the learning outcome of their students.

This exploratory study investigated 164 instances of student mathematical thinking that emerged during whole-class instruction in a high-school geometry course. The MOST Analytic Framework provided a way to categorize these instances according to their building potential—that is, the potential for learning to occur if the student thinking of the instance were made the object of consideration by the class. The variations in the building potential of student thinking revealed in the study highlight the complexity of teaching and the need to support teachers in identifying and appropriately responding to instances with different levels of building potential.

Keywords: Classroom Discourse, Cognition, Instructional Activities and Practices

Reform documents (e.g., NCTM, 2014) advocate for the use of student thinking in instruction, and the benefits of doing so have been highlighted by various studies (e.g., Franke & Kazemi, 2001). Not all student thinking, however, has the same potential to support learning by being incorporated into instruction (Leatham, Peterson, Stockero, & Van Zoest, 2015), particularly if the teacher's goal is to enact the teaching practice of *building—making student thinking the "object of consideration by the class in order to engage the class in making sense of that thinking to better understand an important mathematical idea"* (Van Zoest et al., 2017, p. 36). Better understanding the range of student thinking that is available during instruction could help support the development of practices that provide the most productive response to that thinking. We report here on our characterization of the student mathematical thinking that emerged during whole-class instruction in one teacher's classroom.

Literature Review

We identified research related to three types of characterizations of student thinking: (1) the context in which student thinking emerges during classroom instruction (e.g., Edwards & Marland, 1984); (2) the type of student thinking that occurs in a particular content area (e.g., Carpenter, 1985, for addition); and (3) the potential of the student thinking to further the mathematical understanding of the class if incorporated into instruction (e.g., Stockero & Van Zoest, 2013). The first two groups of studies provided insight into student thinking, but did not provide information on the potential of the student thinking to be used in instruction by a teacher. Drawing on the third group of studies, Leatham et al. (2015) developed a framework for identifying high-potential instances of student thinking that, if made the object of consideration by the class, have the potential to foster learners' understanding of important mathematical ideas.

Such instances of student mathematical thinking are called Mathematically Significant Pedagogical Opportunities to Build on Student Thinking (MOSTs). Van Zoest et al. (2017) investigated the attributes of MOSTs and how those attributes might be used to support teachers' identification and productive use of MOSTs. Their study, however, did not investigate the broader range of student thinking that is available in the classroom. The exploratory study reported in this paper extends the work of Van Zoest et al. (2017) by examining the full range of student mathematical thinking that emerges during whole-class instruction and considering productive teacher responses to instances with different potential for building.

Theoretical Framework

Leatham et al. (2015) proposed six criteria for characterizing and identifying MOSTs (see Figure 1). These criteria create a natural subcategorization of student thinking that might occur in the classroom, a subcategorization that we theorized would differentiate student thinking according to the *building potential* of that thinking—that is, *the potential for learning to occur if the student thinking of the instance were made the object of consideration by the class*. We conceptualize building as a teaching practice that involves making clear the instance of student thinking that the class is to consider, turning that instance over to the class in a way that requires them to make sense of it, orchestrating the conversation that ensues, and ensuring that the mathematical point of the instance is made explicit (Van Zoest, et. al, 2016).

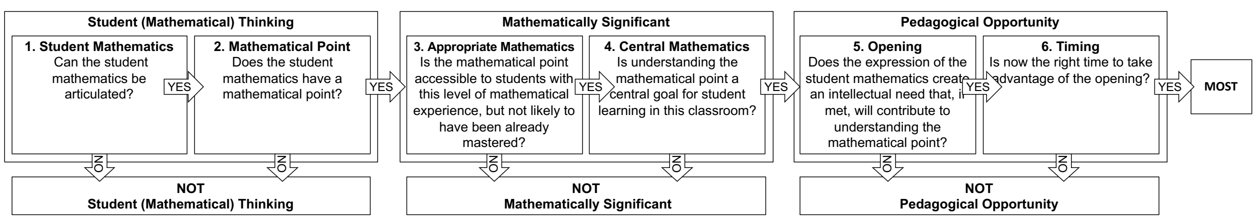

Figure 1. The Six Criteria of the MOST Analytic Framework

Methodology

This study is part of a larger project that included a data set of 11 videotaped mathematics lessons from 6-12th grade classrooms that reflected the diversity of teachers, students, mathematics, and curricula present in US schools (Van Zoest et al., 2017). Based on the analysis reported in Van Zoest et al. (2017), we identified a lesson from this data set whose rates of instances of student thinking per minute and of MOSTs per minute during whole-class instruction were at the medians of the larger data set. We analyzed the 45 minutes of whole-class instruction in this 90-minute, 11th grade geometry lesson about finding the surface area and volume of a sphere. Our unit of analysis was an instance of student thinking—an "observable student action or small collection of connected actions" (Leatham et al., 2015, p. 92)—that is potentially mathematical. Employing analytic processes described elsewhere (Van Zoest et al., 2017) resulted in 164 instances of student thinking that were coded at the last criterion they satisfied according to the MOST Analytic Framework (Figure 1). Instances that appeared mathematical, but for which the student mathematics (criterion 1) could not be inferred, were coded as Cannot Infer (CNI). We then theorized about the relationship between the location of these instances within the MOST Criteria and the potential of these instances for productively enacting the teaching practice of building. We did so by considering the potential advantages and disadvantages of enacting the building practice for such instances.

Results & Discussion

About 17% of the 164 instances were MOSTs (met all six criteria in Figure 1), and thus are, by definition, instances that are worth building on. They have *high building potential* because they are particularly opportune instances that have the potential to result in the class developing a better understanding of mathematics that is both appropriate and central to their learning. Thus, not building on a MOST would be a missed opportunity. The 34.7% of instances that met at least Central Mathematics (criterion 4) but fell short of being MOSTs, were considered to have *some building potential*. These instances are mathematically relevant, but lack pedagogical expediency—they either lack an intellectual need for the students to engage with the thinking (criterion 5) or the pedagogical timing is inappropriate to take full advantage of the thinking (criterion 6). Since these instances do involve mathematics that the students could benefit from considering, a teacher *could* use them to move the students' learning forward, but it would not be a missed opportunity were they not made an object of consideration for the class. To illustrate the difference between instances with high and some building potential, we provide an example of students engaged in sense-making for each of these categories (see Figure 2).

The teacher begins talking about great circles and a student asks a question. **Instance of Student Thinking**: Would it be kind of be like the circumference of a circle? **Mathematical Point**: A great circle is a circle of maximum circumference that can be drawn on a sphere; the great circle is the object (circle) and the circumference is the distance around the circle. **Building Potential:** High **(MOST Coding**: MOST)
The teacher asks if the surface area of a sphere is more like the area or circumference of a circle. **Instance of Student Thinking**: Area, because the circumference is just the outside, like a line [outlines a circle in the air]. And then the area's the whole thing. **Mathematical Point**: Circumference is the distance around a circle and area is the space that circle takes up. **Building Potential:** Some (**MOST Coding**: Central Mathematics)

Figure 2. Sense-Making Examples for High Building Potential and Some Building Potential

We considered the 29.9% of instances that satisfied criterion 1, 2, or 3 but fell short of meeting the criterion for Central Mathematics as having *no building potential*. These instances lack mathematical relevance to learning goals for the students in the class, so pursuing them would seem to be a pedagogical misstep. A productive teacher response to such instances might be to allow the conversation to move on. Being aware of instances that have no building potential might be as important as being aware of instances that have high building potential, since this knowledge would enable teachers to spend time where it is warranted.

The 18.9% of instances that were not inferable (CNI) were considered to have *unknown building potential*. Pursuing these instances as the object of whole-class discussion in their current form would also seem to be a pedagogical misstep. With these instances, if students attempt to infer their peers' mathematical ideas, they may arrive at very different interpretations. Participating in a discussion with different perceptions of what it is that they are discussing could lead to miscommunication and inhibit learning (Peterson et al., 2018). Although often these instances do not seem to warrant further consideration because of their limited nature, in some cases the students' idea might very well be relevant and timely to the discussion (possibly even a MOST). In these cases, a productive teacher move would be to seek clarification.

Conclusion

The results of this exploratory study showed that student thinking available in a high school geometry classroom during whole-class instruction varied substantially, both with regard to the MOST Criteria and with regard to its building potential. We identified and discussed four categories of building potential (high, some, none, and unknown), each of which suggests different types of productive responses from a teacher. The variation in building potential of instances of student thinking revealed in this study highlights the complexity of teaching, and the need to support teachers in identifying and appropriately responding to instances with different levels of building potential. Further work is needed to better understand these various response-related practices and how they might be coordinated into productive use of student mathematical thinking. Knowing more about variations in building potential and associated productive responses informs the design of professional development that supports teachers in implementing instruction that productively incorporates student mathematical thinking.

TEACHER DECISION MAKING IN INSTRUCTIONAL SITUATIONS IN ALGEBRA AND GEOMETRY: DO TEACHERS FOLLOW INSTRUCTIONAL NORMS?

Emanuele Bardelli
University of Michigan
bardelli@umich.edu

Patricio Herbst
University of Michigan
pgherbst@umich.edu

Teaching, as any other social activity, is firmly rooted in the cultural context in which it takes place. Stigler and Hiebert (1999) used the notion of cognitive scripts to describe what happens in a lesson, revealing cross-national differences. Following up on this initial study, Givvin and colleagues (2005) showed that lessons across different countries converge towards common "lesson signatures." These signatures capture the (often tacit) cultural expectations of the components of a typical mathematics lesson. Building upon this idea, Jacobs and Morita (2002) have shown that American and Japanese teachers have different views about their ideal mathematics lesson and suggested that these instructional scripts are cultural in nature. Moreover, they also argued that American teachers do not hold one ideal lesson script but rather have access to multiple "culturally sanctioned options for teaching". A question that arises here is whether choice of those different scripts can be explained by distinctions between the subject matter being taught.

To operationalize the question, we conceive of scripts as being assemblages of norms, and we study whether mathematics teachers' tendency to follow a norm plays a role in teachers' instructional decision making, understood as choosing to act according to the norm. In particular, we focus on two instructional situations that are common in secondary mathematics, doing proofs in geometry and solving linear equations in algebra. The main hypothesis undergirding this poster is that these instructional situations are governed by specific norms. By engaging mathematics teachers in scenarios of classroom instruction, we measure their disposition to attend to these specific instructional norms across different scenarios. We ask: (1) Do instructional norms play a role in teacher's decisions? (2) Is the disposition to comply with norms different from individual resources?

Using multimedia scenarios depicting eight different teaching situations, we surveyed a national sample of secondary mathematics teachers. We find that our hypothesized latent constructs explain part of the variation in the kind of decisions that teachers make. In addition, we provide initial evidence in support to our claim that these dispositions to comply with instructional norms are social resources that are separate from the individual resources that have been studied up to this point in teacher decision making.

This work has raised new questions about the relationship between individual and social resources that mathematics teachers seem to rely upon when making instructional decisions. Our models provide initial evidence suggesting that decision making is subject-specific and acculturation into the norms of the teaching community could explain part of the variation we observe in teacher's decisions.

EXAMINING THE SOCIAL ASPECTS OF GREENHOUSE EFFECT THROUGH MATHEMATICAL MODELING

Debasmita Basu
Montclair State University
basud2@montclair.edu

Nicole Panorkou
Montclair State University
panorkoun@montclair.edu

Keywords: Social justice, Modeling, Greenhouse Effect, Covariational Reasoning

This study focuses on the environmental topic of greenhouse effect for engaging students with issues of social injustice through mathematics. Although mathematics has been previously used by researchers to guide students towards developing an awareness about social justice issues, such as unemployment rate and racial profiling (Gutstein, 2006; Stinson, Bidwell, & Powell, 2012), it has not been used for exploring environmental justice. Environmental change is a serious threat to humanity and unfortunately it bears down disproportionately upon the poor (Agyeman, Bullard, & Evans, 2002). Consequently, any environmental issue can rightfully be considered as a social issue that requires immediate attention.

Our goal is to utilize mathematical thinking to think critically about environmental science, and express and challenge views on this topic. We exploited the power of mathematical modeling (e.g. Lesh & Lehrer, 2003) for helping students interpret and address social issues related to the greenhouse effect and the changing climate. To identify the impact of their daily actions on the greenhouse effect and understand its influence on their lives in future, we engage students in tasks in which they explore quantities that co-vary, such as the amount of carbon-dioxide (CO_2), air temperature, and the sea level rise.

In this poster, we present the three modeling tasks we developed in NetLogo (Wilensky, 1999) and our initial findings from whole class design experiments (Cobb et al., 2003) in middle school classrooms. By engaging with our modeling tasks, students were able to reason about the covariational relationships of the quantities involved, such as recognizing that "as the albedo goes down, temperature goes up" or "when the temperature rises by 0.5 degrees, the sea-level rises by 4 feet." The tasks also helped students distinguish between linear and non-linear relationships of the various quantities. By reasoning through mathematics, students were able to develop an awareness about the significance of the greenhouse effect on their lives. Examples include arguing it is important to take action about the greenhouse effect otherwise "we are gonna live with the damaged planet." In discussing the damages from the rise of sea level, they argued that they are in a worse situation than rich people because even if the rich houses get destroyed rich people "will be able to build it," something that the poor families cannot afford.

DIFFERENTIATING MATH GAMES: MEETING THE NEEDS OF ALL STUDENTS

Diana Tang-En Chang
University of North Georgia
Diana.Chang@ung.edu

This poster focuses on differentiating math games as an instructional strategy to meet the varying academic needs of students. It is common to see both researchers (e.g., Siegler & Ramani, 2008) and curricula, such as Everyday Mathematics, advocating for the use of math games with young children in the school setting. Often, curricula teachers' manuals suggest that all students play the same game, without differentiation. Moreover, they do not provide teachers guidance on how to meet the diverse mathematical needs of students while playing math games. Differentiation in the mathematics classroom is not new (e.g., Murata, 2013), but thus far, very few have explored the application of differentiation within math games. To address this need, my study focused on one question: "How can math games be differentiated to meet the diverse mathematical needs of individual students?"

My study is framed broadly by situated learning theories (e.g., Lave & Wenger, 1991), which allows researchers to examine students' mathematical reasoning and thinking through the lens of participation in the social classroom environment (Cobb & Bowers, 1999). In my study, I use the situated learning theory as a lens to examine the participation that occurs while students play differentiated math games in small groups of two to four. The study was situated in a first-grade classroom of a small rural school, where the majority of students were African American. For eleven sessions, I played a variety of math games that were differentiated for each students' academic level; each session lasted thirty minutes. All sessions were video recorded and later coded and analyzed following traditional methods of ethnographic analysis (Erickson, 1986).

In this study, I found that differentiating math games provided students the opportunity to engage in fun activities while solving math problems that were appropriately leveled. For example, in "The Race Car Game," Clark was able to solve double-digit problems, such as 32+16 and 36+45, while Joseph solved single-digit problems such as 5+7 and 10+9. Though their numbers differed, both students were equally engaged in the game. This was evident through their body language, such as squeals of delight and hand clapping, and the comments they made, such as "I can't wait to get to that shortcut," "I like playing," and "this game is fun."

I acknowledge that this type of differentiation would be difficult in a whole class setting. Rather, this type of differentiation would work best in math centers, when teachers have the time to focus on a small group of students and provide individualized support. By sharing this study, I hope to support teacher educators' work with pre-service and practicing teachers with regards to using games productively in the early childhood mathematics classroom.

WRITING IN MATHEMATICS CLASS: ELEMENTARY MATHEMATICAL WRITING TASK FORCE RECOMMENDATIONS

Madelyn W. Colonnese
University of North Carolina at Charlotte
mcolonn1@uncc.edu

Keywords: Elementary School Education, Classroom Discourse

The National Council of Teachers of Mathematics noted that "writing is another important component of the discourse" (1991, p. 34). Writing can enhance students' learning and foster a deeper understanding (The National Commission on Writing, 2003). In mathematics, writing can offer students an opportunity to personally make sense of ideas and use symbols to convey their mathematical thinking. Yet, descriptions are limited in how elementary teachers should utilize writing to "lay the foundation for future reasoning and proof writing" (Casa et al., 2016, p. 2).

To clarify the purposes for mathematical writing, the Elementary Mathematical Writing Task Force was convened in October 2015. The task force had three primary goals: (1) consider various purposes for writing in mathematics class, (2) reach consensus about the types and purposes for mathematical writing that leverage students' mathematics learning, and (3) account for perspectives from multiple stakeholders, evidence of students' potential for writing productively in mathematics, and multiple sets of curriculum standards. To address these goals the task force was comprised of those with expertise in mathematics, writing, scientific writing, curriculum design, assessment development. Members were also knowledgeable about English language learners, students with learning difficulties, and students identified as gifted.

To begin the meeting, members introduced themselves by sharing an artifact related to mathematical writing. These artifacts helped the task force begin to generate initial ideas. Small groups then analyzed writing-related items including standards from mathematics and writing education and student samples. As the groups worked, they developed descriptions for the types of and purposes for mathematical writing. The descriptions were then presented to the entire task force to discuss and refine; ultimately leading towards consensus about the types of writing.

The task force identified two overarching goals of mathematical writing: to reason and to communicate mathematically. The task force recommended four types with associated purposes for mathematical writing: exploratory writing - to personally make sense of a problem, situation, or one's own ideas; informative/explanatory writing - to describe and to explain; argumentative writing - to construct and to critique an argument; and mathematically creative writing - to document original ideas, problems, and/or solutions, to convey fluency and flexibility in thinking and to elaborate on ideas. The task force also identified considerations for elementary mathematical writing including: writing develops across multiple continua, the audience influences students' mathematical writing, and mathematical writing may take multiple forms.

BEGINNING MATHEMATICS TEACHERS' USES OF INSTRUCTIONAL STRATEGIES AND ORGANIZATION OF STUDENTS FOR LEARNING

Michele Cudd
NC State University
mdcudd@ncsu.edu

Derek Williams
NC State University
daw0731@gmail.com

Karen Hollebrands
NC State University
kfholleb@ncsu.edu

Keywords: High School Education, Instructional Activities and Practices

Reform-based instructional practices (e.g., NCTM, 2014) have been slow to be pervasive. Teachers' uses of whole class organizations, individual work, and small groups in secondary classrooms have shifted from roughly 50%, 30%, and 20% in the 1970s (Fey, 1979) to, more recently, roughly 48%, 22%, and 22% (Banilower et al., 2013). Instructional practices are important to study because of their proximity to students' opportunities to learn (Carroll, 1963).

Methods

We observed 7 beginning teachers a total of 47 times over 3 semesters to explore how they organized students for learning and the instructional strategies utilized. We investigated whether these decisions differ by course level and, when possible, examined changes over time. For every 5-minute interval observed, our dataset notes how teachers organized students and indicates whether instructional activity was teacher directed, student centered, or assessing understanding.

Results and Discussion

Collectively, teachers in this study organized students as a whole class, in small groups, and individually roughly 48%, 29%, and 23% of time. Regarding instructional strategies, teacher directed methods, assessing understanding, and student center strategies occurred during 48%, 26%, and 25% of class time. Student centered strategies occurred most often in small groups. These teachers organized their classes similarly to the collective, regardless of course level; however, teaching strategies differed. Students in intro courses were less likely to experience teacher directed methods and more likely to experience assessing understanding than peers in core or advanced courses. Students in core courses were more likely to experience teacher directed methods and less likely to experience student centered strategies than their peers. Changes in one teacher's practices stand out. She decreased the proportion of time with students organized as a whole class and individually in favor of small group time while also decreasing time using teacher directed strategies for more student centered methods.

Conclusion

Beginning teachers in this study show an alignment with more recent studies (Banilower et al., 2013) by implementing more student centered methods while lessening time students spend learning individually. Our participants are demonstrating reform practices in their classrooms, but perhaps more work needs to be done addressing how they tend to different levels of classes.

COMPARING INTERDISCIPLINARY TEACHING APPROACHES

Katherine Aumer
Hawaii Pacific University
kaumer@hpu.edu

Tara Davis
Hawaii Pacific University
tdavis@hpu.edu

Keywords: Problem Solving; Affect, Emotions, Beliefs and Attitudes; Curriculum

The purpose of this study is to test the synthetic interdisciplinary approach with the informed disciplinary approach in math and psychology (Lattuca, 2001) on its impact on math efficacy, perception of psychology as a science, and mathematics problem solving ability. In accordance with previous literature (e.g., Lattuca, Voight, & Fath, 2004) we argue that the use of a synthetic interdisciplinary approach will increase math efficacy, perceptions of psychology as a science, and academic performance than in classes where an informed disciplinary approach is used.

To test this, we constructed a survey instrument, which included math tasks. We included 10 questions from the PISA survey (OECD, 2013) so that we can make national and international comparisons. The study used a nested model (class nested in instructor) and was taken twice (within subjects approach) at the beginning of the Fall 2017 semester and again at the end of the semester. The classes that were assessed are a team-taught, synthetic interdisciplinary Math and Psychology course, as well as individually taught disciplinary Psychology in Statistics and Proof Writing classes (all classes taught by the authors).

We have preliminary results from analysis of 10 items from the PISA survey. These assessed students' feelings about their personal math performance and contained questions like: "I learn mathematics quickly." and "I am just not good at math." (reverse coded) and answered on a 1 (strongly disagree) to 5 (strongly agree) Likert scale. Students (n = 18) taking the interdisciplinary course felt that their math abilities improved by the end of the semester (M=3.34) compared to when they began the interdisciplinary course (M=3.08) with p = .003. Students (n = 9) taking the math course (without the interdisciplinary element) did not feel like their math abilities improved by the end of the semester. The surveys will be analyzed in greater depth during summer 2018 and the results of this analysis will also be included in the poster.

There is the possibility of a follow up study to this one when the authors teach the class again. Therefore, we would also like feedback on study design, and theoretical aspects. This study has implications for those teaching interdisciplinary classes and what the effects of this kind of teaching are, compared with disciplinary teaching. Because of this, we argue that this study is in line with the theme for this year's PME-NA Conference, in particular, "looking ahead to emerging opportunities in mathematics education research" while noting that "mathematics itself is increasingly interdisciplinary". This study could inform institutional decisions about whether to support instructors in team-teaching or in offering interdisciplinary courses. In this poster we will also describe the teaching methodology used in the classes studied and its potential impacts on the survey outcomes.

EXPLORING FIRST GRADERS' ORAL AND WRITTEN MATHEMATICAL EXPLANATIONS

Nicole Venuto Gearing
Utah Valley University
nicole.gearing@uvu.edu

Keywords: Elementary Education, Classroom Discourse

While communicating mathematical reasoning is difficult for young children (Moyer, 2000), it is a relevant skill to develop. The following study considers the impact of adding written discourse to problem-based lessons on fifty children's ability to talk and write about their mathematical reasoning within the numbers and operations domain in four first-grade classrooms in a suburban Title I school in the southeastern United States. The four classes were randomly assigned to an intervention group or a comparison group. Both groups participated in the same problem-based lesson format that encouraged oral discourse during each of the six lessons. While both groups engaged in oral discourse, the intervention group also wrote about how they solved the problems. As the researcher and students engaged in the lessons, it became clear that it was necessary to establish sociomathematical norms so that students understood what it meant to explain how they solved problems (Cobb, Wood & Yackel, 1993).

Pre and post oral and written mathematical explanations were collected and scored by two independent scorers using a rubric adapted from Project M^3 (Gavin et al., 2007). Intervention effects on oral and written mathematical explanations were evaluated separately using a one-way Analysis of Covariance where groups (comparison and intervention) was the independent variable, post explanation scores were the dependent variable, and the pre-explanation scores were the covariate. Both analyses revealed significant differences between the post *oral* explanation scores and post *written* explanation scores of the intervention and comparison groups, $F(1,43) = 8.992$, $p = .004$ (*oral*) and $F(1,44) = 6.173$, $p = .017$ (*written*). These results suggest that adding written discourse to problem-based mathematics lessons that encourage oral discourse increased the children in intervention group's ability to talk and write about their mathematical thinking. While both groups had increased opportunity for oral discourse, the intervention group's scores were significantly different, indicating that adding written discourse also improves children's ability to talk about their mathematical reasoning. The practical benefits of these results are important. Once children are comfortable talking and writing about their solution strategies, both can be used for formative assessment by classroom teachers. Written explanations can also serve as a permanent record for mathematical thought (Lee, 2006), increasing the teacher's ability to understand each child's thinking, therefore increasing equity within the early childhood classroom.

AN EXPLORATION IN DOING COLLABORATIVE UNSOLVED MATHEMATICS

Cassondra Gendron
UMass - Dartmouth
cgendron1@umassd.edu

Isaac Nichols
Vanderbilt University
isaac.t.nichols@vanderbilt.edu

Corey E. Brady
Vanderbilt University
corey.brady@vanderbilt.edu

Keywords: Advanced Mathematical Thinking, Post-Secondary Education, Reasoning and Proof

Research in the field of mathematics is often done collaboratively and is open-ended, as the purpose of mathematics research is to solve previously unsolved problems. Moreover, mathematics as a field has become increasingly collaborative in recent decades (Grossman, 2002; Gowers & Nielsen, 2009). In contrast, mathematics in k-16 is still overwhelmingly viewed as a closed subject, with answers that are only right or wrong and is viewed as an individual activity. This model leaves only an elite few doing mathematics and mathematics research. Attempts to explore alternative models of learning and doing mathematics in school settings work against strong barriers of perception about what mathematics is and what the role of the learner should be. One component in the effort to overcome these barriers is a series of "existence proofs" showing (a) that collaborative mathematics is possible at a variety of levels, and (b) that working collectively can produce different kinds of mathematical experiences and results. This poster describes one such existence proof, describing collective inquiry into a celebrated problem.

In 1937, Lothar Collatz conceptualized a problem, now known by many names but most often, The Collatz Conjecture or the 3*n*+1 problem. The problem depends on a function *f(n)*, defined for any positive whole integer, *n:*

$$f(n) = \begin{cases} \frac{n}{2}, n \text{ is even} \\ 3n+1, n \text{ is odd} \end{cases}$$

The value of f(*n*) is another integer, and thus a member of the domain of f, enabling one to form f(f(*n*)), or f2(n); f(f(f(n))), or f3(n); and so on. Repeatedly applying f generates a sequence of integers {fi(n)}. The Collatz Conjecture is that for any initial value of n, this sequence reaches 1 in a finite number of iterations. This is a simple problem to state but an extremely difficult problem to solve. Since 1937, mathematicians have taken up the charge to prove the conjecture, most notably, Jeffery Lagarias. In his investigations, he has looked at modular arithmetic and creating visual representations (Lagarias, 2010).

Over a two-week period, we explored what happened when unsolved mathematics (Collatz Conjecture) was given to a group of PhD and Masters students enrolled in a course that specifically focused on inquiry-based, collaborative, open-ended mathematics. The group studied patterns that arose when exploring the 3n+1 problem. The group crafted illuminating representations, examined the problem using modular arithmetic, and explored what happened when the initial number, *n*, was negative. These explorations both recapitulated the work of Lagarias and went off in its own directions. This work describes the processes and products.

GROUPING FOR "DIVERSITY": AN EQUITABLE PRACTICE?

Cara Haines
University of Missouri
carahaines@mail.missouri.edu

Charles Munter
University of Missouri
munterc@missouri.edu

Keywords: Equity and Diversity, Teacher Education, Instructional Activities and Practices

To help meet the well-established need for a more equitable mathematics education in the U.S., it is imperative that researchers attend to teachers' conceptions and enactments of equitable instruction. In this analysis, for example, we were concerned with secondary (grades 6-12) mathematics teachers' instructional visions—or their perceptions of ideal instruction (Munter, 2014)—to understand the development of those visions as teachers engaged in equity-focused professional development.

In analyses of interviews with participating teachers, we noticed that a considerable number of them identified strategies used for assigning students to small groups as indicators of equitable instruction. Among the grouping strategies that teachers described as equitable was a subset that emphasized grouping for "diversity"—a strategy for arranging students so that each small group mirrors the demographics of the whole class. Such cases were the focus of this analysis.

Findings and Discussion

Of the 37 teachers interviewed, 15 referred to students' racial or ethnic identities in discussing equitable grouping strategies. Of those, 9 recommended grouping for "diversity" (GfD) while 6 alluded to the strategy but did not necessarily recommend it. Most teachers who promoted GfD did not provide a rationale for its use (n=6), although a few suggested that it could support students in getting to know peers outside of their own social groups (n=3). The 6 who mentioned but did not promote GfD either explained how district leaders seemed to prefer it (n=3) or defended hypothetical classroom scenarios in which GfD was not used (n=3).

We wonder whether these results are related to the price that Ladson-Billings (2004) argued was paid for the 1954 *Brown v. Board of Education* decision. As she noted, desegregation efforts were never about breaking up racial groups of students, and certainly not about getting children of color into the presence of white children. However, the U.S. Supreme Court's decision to rule in favor of Brown was grounded in the argument that the public school segregation was detrimental to Black children, as it exacerbated "Black inferiority" (p. 5). Given that teachers' GfD descriptions seem related to this narrative (e.g., "If I do see that one group is all African American males then yes, that is an issue…that needs to be broken up"), we wonder whether it might be shaping teachers' conceptions of "diversity" at the level of small-group interactions.

Regarding implications for research, we encourage those interested in teachers' learning as it relates to K-12 (in)equity to be on the lookout for practitioners' conceptions of equity as "diversity" or "desegregation." Future research might also investigate potential ways to disrupt such ideas. Regarding implications for practice, we hope that our results will encourage practitioners to take care as they conceptualize and implement equity-related efforts.

DEVELOPING METHODS TO IMPLEMENT EMBODIED GAME DESIGN FOR MOBILE LEARNING TECHNOLOGIES IN STEM CLASSROOMS

Taylyn Hulse
Worcester Polytechnic Institute
trhulse@wpi.edu

Avery Harrison
Worcester Polytechnic Institute
aeharrison@wpi.edu

Ivon Arroyo
Worcester Polytechnic Institute
iarroyo@wpi.edu

Erin Ottmar
Worcester Polytechnic Institute
erottmar@wpi.edu

Keywords: Instructional activities, Learning theory, Technology, Research methods

In this poster, we present a new way to engage with mathematics and design thinking that invites students to not only *play* games, but to also *create* their own math games supported by mobile technologies. Our priority is to establish a framework that can be used in all STEM classrooms, regardless of computer programming experience or tools. To achieve this goal, our team has designed and implemented an instructional activity and created an extensive coding guide to test the effectiveness of this activity in high school STEM classrooms.

The field of educational games has shown the benefits of playing well-designed games on student motivation, engagement, and performance (Gee, 2003), but only recently has research focused on the benefits of students creating their own games. By positioning students in the role of creators, rather than consumers, they can explore, discover, and construct their own learning, which could lead to deeper conceptual understanding (Papert, 1990). Some have also argued that STEM learning environments should be more embodied and social (Abrahamson, 2009). Embodied learning combines movement with higher-order cognitive activities, such as analyzing and evaluating. By grounding students through physical movement, object manipulation, and gesture, abstract concepts may become more concrete (Koedinger, Alibali, & Nathan, 2008).

Extending this evidence, we propose the Embodied Game Design framework as an instructional activity and a preliminary method for analyzing students' higher-level thinking in STEM classrooms. Our current study explores the *feasibility* of game design for high school students as well as the *pedagogical effectiveness* of the activity designs. Over the course of three days, participants played an established math game, created their own games in small teams, and then modified their games. Results showed that the project is feasible and that particular instructional design elements produce varying outcomes. Ultimately, we aim to develop a complete, instructional design that will be appropriate for K-12 students and can be used as an interdisciplinary, project-based activity that engages students in collaboration, mathematics, active and embodied learning, and technology-based design to promote computational thinking.

THE RELATIONSHIP BETWEEN NOVICE TEACHERS' SELF-EFFICACY AND STUDENTS' OPPORTUNITIES FOR DISCOURSE

Temple A. Walkowiak
NC State University
tawalkow@ncsu.edu

Diane Hunter
NC State University
dchunter@ncsu.edu

Teomara Rutherford
NC State University
taruther@ncsu.edu

Keywords: teaching self-efficacy, discourse, elementary, novice teachers

Documents outlining standards and recommendations for mathematics instruction consistently emphasize the importance of high-quality mathematical discourse. Although quality mathematical discourse is valued, it can be challenging to implement, particularly for novice teachers (Bennett, 2010). Teaching self-efficacy, or one's beliefs about her/his ability to teach, has been linked to effective mathematics instructional practices for more experienced teachers (Enon, 1995); however, little is known about this relationship for *novice* teachers, the focus of the current study. Specifically, this study examines the relationship between mathematics teaching efficacy and mathematical discourse implementation for novice elementary teachers, all in their second year of teaching.

The participants in this study were 118 second-year teachers. The teachers completed a mathematics teaching log (Walkowiak & Lee, 2013) on which they reported the proportion of time that students in their classroom had opportunities to engage in mathematical discourse during a given lesson (with a mean of 38.7 lessons logged per teacher). Teachers responded on a four-point scale about students' opportunities to engage in nine "math talk" behaviors. Teachers also completed the Mathematics Teaching Efficacy Beliefs Instrument (MTEBI; Enochs, Smith, & Huinker, 2000) to measure their self-efficacy to teach mathematics. Rasch scores were computed for each scale: Personal Mathematics Teaching Efficacy (PMTE; belief about ability to teach mathematics) and Mathematics Teaching Outcome Expectancy (MTOE; belief about ability to impact student outcomes). Multiple regression analyses were utilized to assess if mathematics teaching efficacy predicted mathematical discourse, controlling for teachers' high school GPA and SAT scores. Grade band (K-2 vs. 3-5) was examined as a potential moderator. MTOE, or beliefs about ability to impact student outcomes, was a statistically significant predictor of opportunities for discourse within the mathematics lessons, $b = 0.069$, $t(117) = 2.38$, $p = .02$. The results of the regression including all variables explained a statistically significant proportion of the variance in opportunities for classroom discourse ($R^2 = 0.067$, $F(4,113) = 2.02$, $p < .05$). The moderation of grade band was not statistically significant.

Keywords: Classroom Discourse; Instructional activities and practices; Teacher Knowledge

Building on Shulman's (1986) work, researchers have explored different ways of categorizing and investigating teacher knowledge and competency. Our study examines a relatively unknown aspect of teacher competency in mathematics education, which we call discursive capacity. Discursive capacity is defined as the toolkit with which a teacher facilitates mathematical discourse as evident in meaningful interactions and participations with communicative forms in the classroom community as regulated by social and socio-mathematical norms. Using the construct of discursive capacity, we elaborate further the role of maxims and normative knowledge (Shulman, 1986) in teachers' effective teaching practice as an extension of Shuman's conceptualization of different forms of teacher knowledge.

We propose understanding the nature and kinds of *mathematical discourse for teaching* (MDT) as the basis for studying discursive capacity. To that end, we observed, video-recorded, and transcribed lessons of Korean master teachers in which discourse was the primary mode of teaching school mathematics. We analyzed various forms and paths of classroom discourse and discursive patterns in the videos in order to characterize the teacher's discursive practice for teaching mathematics.

Our analysis revealed that student participation is normed and nurtured for learning when the teacher established positive relationships in the classroom community and forged the kinds of connections with students that increase student motivation to learn. Further, we identified the sequential and deeply connected phases of practicing MDT: first, building a classroom community rooted in positive relationships and regulated by socio-mathematical norms; second, launching a lesson with discursive strategies to elicit student thinking and expanding it for further learning; and third, facilitating problem-solving with patterns of discursive practice depending on the nature of tasks and engaging students in collaborative problem-solving and overcoming misconceptions. These three contexts combine to afford the opportunity for us to understand how a teacher and their students co-create a community and engage in mathematics discourse. In our presentation, we will illustrate a teacher's discursive competency found in the process of these sequential phases and discuss the opportunity and challenge of theorizing the practice-based MDT.

TEACHING NORMS FOR THE ORDER OF MULTIPLICATION IN THIRD GRADE

Karl W. Kosko
Kent State University
kkosko1@kent.edu

Keywords: Elementary School Education; Number Concepts and Operations

Numerous different recommendations for the order that multiplication should be taught exist. Woodward (2006) suggested introducing multiplication using 0s, 1s, squares, 5s, 9s and 10s, followed by other operands. Researchers in neuroscience suggest that multiplication with operands 2-5 is simpler and uses different neural processes than operands 6-9 (Jost et al., 2004). Recommendations also vary between different third grade textbooks. Although there are numerous recommendations for the order operands are introduced, there is little to no research on the order that they are introduced. The purpose of this study is to investigate the order that third grade teachers rank introducing specific operands in multiplication. Third grade teachers (n=49) were asked to rank the order they "assign tasks/activities with these multiples [0 to 10]" in a school year. Descriptive data are reported in Table 1. The distribution of ranks was found to be independent from chance ($\chi^2(df=100)=1044.046$, $p<.001$), indicating that, there are certain reported tendencies for the order operands are introduced. Median and mode statistics suggest the most common sequence reported by teachers is in the following order: 0s, 1s, 2s, 5s, 10s, 3s, 4s, 6s, 7s, 8s, and 9s. Approximately a third of teachers reported a similar sequence. There is a large amount of variance in specific sequences reported. Preliminary analysis suggests teachers' rankings are not meaningfully associated with adopted textbook, years of experience, level of education, or other reported background characteristics. Findings suggest a need for further study to explain teachers' rankings of multiplication operands, and the reasoning behind it.

Table 1: Third Grade Teachers' Reported Rankings of Order of Multiplication Operands.

RECOGNIZED MATHEMATICS INSTRUCTORS' BELIEFS ABOUT LEARNING

Valentin A. B. Küchle
Michigan State University
kuechlev@msu.edu

Keywords: Teacher Beliefs, Learning Theories, Post-Secondary Education

Prior research on teachers' beliefs and conceptions suggests a relationship between teachers' instructional practices and their beliefs about learning (Thompson, 1992). The focus of this work, however, has largely been limited to the beliefs of K–12 teachers. Only a few researchers have extended this work to the undergraduate level (e.g., Speer, 2008). In an attempt to further this line of research, this qualitative methods study tackles the question of what beliefs about learning mathematics are being held by university mathematics instructors who—through institutional teaching awards—have been recognized for their teaching excellence. The purposes of the study are to document these beliefs, as they may provide insightful, workable ways of thinking about the learning of mathematics, as well as to compare and contrast these with views espoused by mathematics educators.

The participants were five mathematics instructors at a large Midwestern university. They were randomly chosen from a pool of mathematics instructors who had won at least one of the university's teaching awards. One hour-long, semi-structured interviews were conducted with all participants, with questions seeking to unearth the instructors' conceptions of learning. For instance, questions were asked about the goals of learning, environments for learning, and the roles of teacher and student in the student's learning process. The interviews were audio-recorded and transcribed.

Analysis of the data is ongoing, but preliminary analysis suggests the emergence of a complex picture. The participants were largely able to articulate meaningful replies to the questions but seemed to fuse different viewpoints on learning. To make sense of the data, I use coding methods borrowed from grounded theory, looking for emergent leads. Furthermore, to help with untangling and delineating the mathematics instructors' views, I draw on established views of learning in mathematics education literature, such as Sfard's two metaphors for learning (Sfard, 1998) and Harel's three principles of learning and teaching mathematics (Harel, 2002).

I would like to emphasize that the mathematics instructors' views are not meant to provide a goal or a benchmark for others to attain, as neither the instructors themselves, nor I, claim that they are excellent teachers. Rather, this study is meant to scrutinize the belief systems that have allowed some mathematics instructors to celebrate teaching success and gain recognition by their students and peers. In addition, understanding the mathematics community's appointed role models may provide a greater understanding of—and mirror for—the community as a whole.

Keywords: Instructional Activities and Practices

A majority of the studies scrutinized teacher noticing by having the teachers watch videos of lessons and reflect upon what they have noticed (Sherin & van Es, 2005); however, this is a significantly different task from the more authentic work of engaging in in-the-moment noticing to attend to and respond to student thinking during instruction. In this study, we investigated a teacher's in-the-moment noticing skills and how these supported efforts to provide effective scaffolding during interactions with a group of students.

The teacher participant in this study was a mathematics teacher with experience of 6-10 years of teaching grade 7 and 8. A total of 7 lessons were audio and video recorded and the transcripts were generated for each lesson. Direct and verbal interactions between the teacher and a group of four students in the classroom were identified from the transcripts. Three researchers coded the levels of scaffolding strategies from Anghileri (2006) to identify the frequency and context of instances of "Level 1: Environmental provisions"; "Level 2: Explaining, reviewing and restructuring"; and "Level 3: Developing conceptual thinking" (p.39). The scaffolding strategies were analyzed by examining them in relation to noticing classifications perceived by Jacobs et al. (2010), which were composed of the following components: "Attending to children's strategies", "Interpreting children's mathematical understandings", and "Deciding how to respond on the basis of children's understandings" (p.172).

Preliminary data from the 7-day lesson reveal a total 113 verbal interactions between the group of students and the teacher, many of which incorporated multiple occasions of scaffolding. Out of the 252 scaffolding instances, 58 were classified as Level 1, 180 were Level 2, and 14 were Level 3. It was noted that higher levels of scaffolding strategies, restructuring practices from the Level 2 as well as the Level 3, were mostly coincided with the other two lower strategies from the Level 2, which are explaining and reviewing.

INVESTIGATING GROUP PROBLEM POSING FOR SECONDARY STUDENTS IN A LINEAR FUNCTIONS-BASED LESSON INTERVENTION

Robert A. Mixell
University of Delaware

Keywords: group problem posing, representations, mathematical connections, positioning theory

Rationale and Theory

Looking back, the NCTM (1991) has advocated for instruction that promotes *representations* and *mathematical connections*. Yet, this has been an enduring challenge as U.S. mathematics lessons often lack such opportunities (Hiebert et al., 2005). A more contemporary 21st-century expectation from industry is *collaboration*. However, students may *position* one another in ways that hinder shared intellectual work (Wood, 2013). As problem posing is deemed a valuable mathematical practice (NCTM, 1991) and a tool for representation use (Cai & Hwang, 2002), I used the activity of *group problem posing* to examine how high-school student groups incorporated representations and mathematical connections into their problem scenarios. I also explored how intellectual work was shared as roles were negotiated and renegotiated.

Methods and Analysis

Five groups of Integrated Mathematics 2 students participated in a five-lesson algebra intervention. Groups were heterogeneously formed by race, gender, mathematical disposition, and performance. Each lesson began with a 30-minute review session on linear functions, followed by a 30-minute group problem-posing session. Groups were asked to create problems including lesson mathematics, representations, and cultural artifacts (e.g., fast-food menu prices). Groups also evaluated and re-negotiated their roles each day. Problems were coded using a priori and grounded categories based on representations and mathematical connections. One group's problem-posing sessions were video-recorded. Transcribed videos, field notes, and written reflections about the use of roles were analyzed to understand the negotiation of student roles.

Results and Discussion

Analysis revealed that groups often incorporated one or more representations but struggled to purposefully use them and/or make mathematical connections. Additionally, many problems only focused on finding "total cost." In spite of the focus on roles, the analyzed group typically worked *cooperatively* rather than *collaboratively*. Looking ahead, these findings provide insights into challenges with using representations, making mathematical connections, and sharing in the intellectual work of group problem posing. Understanding such challenges can help identify principles for refining the practice and supporting the effective engagement of student groups.

TRADITIONAL VERSUS STANDARDS-BASED GRADING: A COMPARISON OF THE TEACHING PRACTICES OF SECONDARY MATHEMATICS TEACHERS

Michelle A. Morgan
University of Northern Colorado
Michelle.Morgan@unco.edu

Robert A. Powers
University of Northern Colorado
Robert.Powers@unco.edu

Keywords: Assessment and Evaluation, Standards

There has been a movement in recent years towards developing alternative systems for measurement and evaluation of academic achievement and performance. By using a standards-based grading system, Iamarino (2015) argued that a teacher "is better able to determine a student's grade based on the single most important aspect of education – how well the student comprehends the content of the course" (p. 2). According to Iamarino (2015), implementation of standards-based grading can be difficult and uncomfortable for teachers as well as other stakeholders such as district supervisors, students, and parents. Furthermore, Vatterott (2015) cautioned that standards-based grading is more than a modification to the course grading scheme and many teachers fail to modify all aspects of the learning process.

Methodology

This quantitative survey study sought to determine and describe the impact of standards-based grading practices on instruction in traditional, secondary (Grades 7-12) mathematics classrooms across a state in the Rocky Mountain region of the United States. To answer their research questions, the research team developed an online questionnaire based on sample questions from the TIMSS survey (NCES, 2011; NCES, 2015) and the Math Task Analysis Guide (Smith & Stein, 1998). It included basic demographic questions as well as specific questions focused on how teachers implement and assess instruction as part of their practice as a secondary mathematics teacher. Using information available on publically accessible websites, the research team compiled a list of teachers who were clearly identifiable as teaching secondary mathematics. This process resulted in a sampling frame of 2565 secondary mathematics teachers all of whom were invited via email to participate in the study.

Results and Discussion

The survey received a response rate of 24.9% ($N = 638$). Preliminary data analysis suggests that there was no difference between the practices of secondary mathematics teachers who self-reported utilizing standards-based grading and those who self-reported traditional grading practices. The results of this study suggest a need for follow-up research studies as well as a need for pre-service and in-service teacher preparation and support.

THE EFFECTS OF INQUIRY-BASED PEDAGOGY ON STUDENTS' ATTITUDES IN MATH AND INTENT TO PURSUE STEM

Karisma Morton
The University of Texas at Austin
karisma.morton@utexas.edu

Ursula Nguyen
The University of Texas at Austin
ursulanguyen@utexas.edu

The education research community has long recognized that teachers' pedagogical choices are key to the development of learning environments that can either promote or hinder equity. This is especially evident in mathematics classrooms where inequality between groups of students (i.e., boys and girls and majority and minority racial/ethnic groups) is pronounced. Specifically, we know from prior research that pedagogy in mathematics that is based on traditional modes of direct and lecture-based instruction can actually reproduce and exacerbate current patterns of inequality (Ellis, 2008). As a result, mathematical reform efforts call for more inquiry-based modes of instruction (NCTM, 2000) as they are beneficial for student outcomes and for fostering equitable experiences and outcomes (Boaler & Staples, 2008).

Both quantitative and qualitative studies have provided valuable insight into the positive ways that inquiry-based mathematics instruction can affect not only student achievement but also their attitudes towards mathematics and STEM in general (Boaler, 2006; Goos, 2004). Importantly, qualitative studies often consider the viewpoints of students in their assessment of the processes of classroom instruction as well as the outcomes of that instruction. Yet there is a lack of large-scale quantitative research that captures students' experiences of inquiry-based activities in their mathematics classrooms and examines its potential impact on their math-related attitudes. Furthermore, as female students continue to confront obstacles to their pursuit of math in the form of stereotypes and messages from others about a lack of belonging, it is critical to examine whether and how inquiry-based math classrooms may be particularly important in shaping favorable math attitudes for girls. And while there is some research that examines whether teachers' pedagogical choices may impact girls' attitudes more than boys, it is generally limited in scope, and further does not simultaneously consider differences by race/ethnicity.

Thus, our study seeks to fill current gaps in the literature by investigating whether students' experiences of inquiry-based learning in their mathematics classrooms are related to their attitudes towards math, and whether and how such patterns might vary by gender as well as by race/ethnicity. We utilize data from the U.S. portion of the Trends in International Mathematics and Science Study (TIMSS) of 2007 to conduct our investigation. This dataset is ideal as it includes a nationally representative sample of students at the critical stage of adolescence, and queries them about their math attitudes as well as the range of activities that characterize their math classroom.

CONTEXTUAL PROBLEMS AS CONCEPTUAL ANCHORS?: A STUDY OF TWO CLASSROOMS

Luke Reinke
UNC Charlotte
lreinke@uncc.edu

Rukiye Ayan
Middle East Technical University
rayan@metu.edu.tr

Amanda R. Casto
UNC Charlotte
acasto2@uncc.edu

Michelle Stephan
UNC Charlotte
michelle.stephan@uncc.edu

Mathematics teachers have been advised that contextual problem-solving experiences can be used to develop new mathematical ideas, and can serve as anchors for understanding new mathematical ideas (Meyer, Dekker, & Querelle, 2001). But research suggests students are often conditioned to strip away contextual elements of problems; thus, the contexts are unlikely to serve as anchors for these students. In this study, we ask: *What are the different ways students and teachers make reference to the context or prior contexts to support understanding? When does this occur?*

We conducted a multiple case study of two seventh grade mathematics teachers over the course of six weeks. We analyzed video recordings of the enacted curriculum through the lens of Wernet's (2017) framework for exploring classroom interactions around contexts.

First, the depth of referencing previous contexts varied across teachers. One teacher referenced previous contexts through brief transitional statements; the other teacher prompted students to compare contexts to previous storylines throughout lessons. Second, we identified two subcategories of Wernet's (2017) "references to the context while solving or making sense of the problem" category. Students made *conceptually-oriented contextual references* when reasoning informally or giving contextualized rationales for their reasoning (e.g. grouping infants in fives because in the day care each adult could only watch five infants). When more formal representations were discussed, the teachers and students made p*rocedurally- oriented contextual references* by explaining the contextual meaning of quantities in the tables, but not the conceptual meaning underlying their procedures (e.g. "what you do to the bottom you have to do to the top"). Third, we note implicit references to prior contextualized experiences, in the form of student-generated inscriptions mimicking those developed in response to previous problems.

Our additions to Wernet's (2017) framework add to the theoretical knowledge base of classroom interactions around contextual problems by providing specificity about different ways teachers and students reference contexts, but further research is necessary to understand whether the patterns found within these two classrooms are representative of larger trends in contextual-problem based instruction. Our findings also have practical implications. Teachers should be supported in understanding which types of contextual references support conceptual reasoning and should consider providing opportunities for students to compare various contexts. Reflecting across contexts gives students the opportunity to identify relevant mathematical connections and generalize previously developed strategies.

PROBLEM POSING AND STUDENT ENGAGEMENT IN A UNIVERSITY DEVELOPMENTAL MATHEMATICS COURSE

John Sevier
Appalachian State University
sevierjn@appstate.edu

Anthony Fernandes
University of North Carolina at Charlotte
Anthony.Fernandes@uncc.edu

Keywords: Engagement, Attitudes, Problem Solving, Problem Posing

With the continued increase of enrollment at colleges and universities, students entering college mathematics underprepared is increasing. The National Assessment of Educational Progress, found only 25% of 12 grade students had scored at or above the proficient level on the NAEP math assessment (NAEP, 2015). A portion of these students entering post-secondary institutions, are being required to enroll in developmental mathematics courses to better prepare them for college mathematics coursework (Larnell, 2016).

Developmental mathematics students learn to focus on the outcomes of their problem-solving efforts and often have little or no time to focus on the problem formation where Ellerton (2013) noted that the formulation of the problem is more essential than its solution. Silver (1997) found that instruction involving problem solving and problem posing tasks will assist students in developing more creative approaches to mathematics. With this, problem posing is seen to not only engage students with problem solving but use the individual student interest to help increase the level of engagement, reduce common fears and anxieties, and help students develop improved attitudes towards mathematics (Lavy & Bershadsky, 2003).

The research is guided by the question: *What problems do developmental mathematics students design based on their personal experiences and interests as they engage in problem posing?* The researcher will use Ellerton's (2013) *Active Learning Framework* and categorize problems posed based on Mji & Glencross' (1999) notion of surface and deep approaches to mathematical understanding. Students will be observed and recorded discussing and creating word problems based on their interests and approach. These problems will give instructors insight of types of problems that developmental mathematics students prefer to engage in and create more potential in understanding course content at a higher level and improve attitudes towards mathematics.

The findings of the study will be reported, and student work will be presented at the poster session. Implications of the study will be to observe how to better serve students entering underprepared for post-secondary math. It will also give a training ground for pre service teachers to better prepare themselves for working with students at the K-12 levels.

SECONDARY STRINGS: MATH TALKS IN HIGH SCHOOL

Rob Wieman
Rowan University
gomathman@yahoo.com

Jill Perry
Rowan University
perry@rowan.edu

Keywords: Instructional Activities and Practices, Classroom Discourse, High School Education

Background: The Problem

The authors work closely with a group of K-12 teacher leaders who have become excited about engaging students in reasoning and problem-solving in their classes. Despite this enthusiasm, secondary teachers find it particularly difficult to move beyond occasional problem-solving lessons while teaching their mandated curriculum. Their default has been using guided notes and practice, focusing on procedures.

One support for change is instructional routines that provide structure for norms and interactions (Lampert & Graziani, 2009) We engaged our teacher leaders in number/pattern talks, a widely used structure used by k-8 teachers to engage students in "making sense of mathematics" (Parrish 2011, p.204). For our secondary colleagues, number talks have been pivotal in shifting them towards a student-centered practice. This has led to a new challenge - designing talks that focus on secondary content.

Secondary Strings: A Work in Progress

Together, we are exploring/studying the question: ***What might math talks look like in high school classrooms?*** For us, a secondary math talk (or string) is a series of problems that support the construction of conceptual understanding and procedural fluency. We begin with a problem that all students can do, connected to a fundamental concept. Ensuing problems gradually move students to new ideas, while positioning the students as problem solvers and sense-makers, and prompt them to make connections and generalizations. We will share several prototype secondary strings. We will also identify questions that we still have connected to the structure, design and use of these strings, including:

- What are basic design features of effective secondary strings?
- What skills and knowledge are needed to plan and enact effective secondary strings?
- What factors contribute to successful uptake of secondary strings?

Connection to Conference Theme

Our efforts to extend the work of elementary mathematics teacher educators into secondary classrooms is connected to the conference theme in two ways. First, we are hopeful that secondary strings can provide supports for teachers hoping to respond to "changing mathematical and pedagogical demands" by helping them provide opportunities for students to reason and make sense of secondary curriculum. In so doing, we also hope support equitable teaching by broadening access to opportunities for reasoning and sense-making for all students.
