Abstract

Objectives To ensure the cross-national comparability of the set of questions addressing physical and sexual intimate partner violence against women (IPVAW) included in the European Union (EU) Agency for Fundamental Rights (FRA) survey. Once the measurement invariance of these measures is established, we aim to make appropriate and valid comparisons of the physical and sexual IPVAW levels across the EU countries.

Design Cross-sectional, population-based study.

Participants Data were drawn from the survey conducted by the FRA on violence against women, including the responses of 42,002 adult women from the 28 countries of the EU.

Main outcome measures The set of questions addressing life-time prevalence of physical and sexual IPVAW used in the FRA survey. The psychometric properties (i.e., reliability and validity) of these measures were examined, as well as their latent structure and their measurement invariance across the 28 EU countries.

Results The physical and sexual IPVAW measures presented an adequate internal consistency and validity evidence based on their relations to other variables in all countries. A latent structure of two factors was supported and the scalar invariance was established across countries. Our results showed that the average levels of physical and sexual IPVAW were higher in countries like Denmark, Finland, Sweden and United Kingdom compared to the rest of the EU countries. In many of the other countries the levels of these types of violence were overlapped, especially in the case of sexual IPVAW.

Conclusions The findings of this study underlined the importance of using appropriate statistical methods to make valid cross-national comparisons in large socio-

demographical surveys. The measurement invariance approach allowed us to conduct a more robust and refined analysis of how the physical and sexual IPVAW levels were distributed across all the EU.

Strengths and limitations of this study

- This paper is the first to examine the cross-national comparability of survey data addressing physical and sexual intimate partner violence against women (IPVAW) in all European Union (EU) countries
- The application of appropriate analyses to examine the psychometric properties, latent structure, and the measurement invariance of the measures included in a large socio-demographical survey on IPVAW
- A latent means analysis was conducted to compare the levels of physical and sexual IPVAW across all EU countries, an approach that takes into account the latent structure of the IPVAW measures and the magnitude of the contribution of each item to the measured construct
- The cross-sectional design of the survey did not allow for testing measurement invariance across different periods of time

Intimate partner violence against women (IPVAW) has been globally recognized as a major public health problem of epidemic proportions. [1] IPVAW is the form of violence most commonly suffered by women, [2-4] and it has severe physical and psychological consequences not only for the victims and the well-being of their children, but for the entire society. [5-9]

According to the survey conducted by the European Union (EU) Agency for Fundamental Rights (FRA), the estimated prevalence of physical and sexual IPVAW in the EU is 22%, varying across countries from 13% to 32%. [10] One of the main strengths of this survey is that women from the 28 EU countries answered the same set of questions assessing different types of IPVAW. However, the measurement equivalence of these questions across the EU countries has not been tested yet. This hamper the generalizability of these cross-national comparisons, as it not possible to ascertain whether the differences on IPVAW prevalence across all EU member states reflects actual differences between countries, or are the result of cultural expectations or beliefs about intimate partner violence that may affect the interpretation of the questions included in the FRA survey.

IPVAW can be a culturally sensitive issue, and how it is perceived, conceptualized and interpreted may vary across countries. Thus, to make valid cross-national comparisons based on survey data addressing IPVAW, it is important to test their measurement invariance. [11-13] Measurement invariance is a crucial prerequisite in cross-national research, since it allows meaningful comparisons across countries discarding the possibility of cultural bias in the respondents' answers. [14] When measurement invariance is not hold, it means that respondents from different countries interpret and respond differentially to the questions, and thus their scores cannot be directly compared. [15 16] If that is the case, it cannot be assumed that IPVAW is

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies. Erasmushogeschool .

interpreted in the same way in all EU member states, since the same score in one country may reflect a different construct or yield different levels of IPVAW in another. Therefore, computing prevalence rates to compare samples from different countries without ensuring first measurement invariance could lead to unreliable and distorted conclusions, as the validity of such comparisons may become questionable. [17]

The main objective of this study is to ensure the cross-national comparability of the set of questions addressing physical and sexual IPVAW included in the FRA survey, assessing whether respondents of each country conceptualize and interpret these questions in the same manner. Once the measurement invariance of these measures is established, we aim to make appropriate and valid comparisons of the physical and sexual IPVAW levels across the EU countries.

Method

Participants

The data were drawn from the FRA survey on violence against women. [10] This survey includes the responses of 42,002 adult women who were currently or had previously been in an intimate relationship across the 28 countries of the EU. The responses were collected in-person through structured interviews and self-reports, following a two-stage clustered stratified sampling design with equal probability of selection of households within clusters. Additional information on sample collection and procedures can be found in the FRA survey technical report. [18] A special license for secondary data analysis was requested and granted from FRA (Reference No. 102577).

The sample used in this study was selected using the answers of those respondents who have not omitted any of the questions of the survey addressing physical and sexual intimate parte violence. The final sample is composed of 39,403

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

Erasmushogeschool . Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies.

women, aged from 18 to 74 years old, from the different EU countries. Socio-demographical information of the sample by each country is showed on Table 1.

Patient Involvement. No patient involved.

[Insert Table 1 around here]

Measures

Physical violence. Intimate partner physical violence is addressed in the FRA survey with 10 items describing episodes of physical violence perpetrated by either the current or any previous partner (e.g., "Your current/previous partner has slapped you?"). Respondents have to indicate how often have they experienced that episode in a 4-point Likert-type scale (1: "Never", 2: "Once", 3: "2-5 times", 4: "6 or more times"). The responses to these items were dichotomized (0: "Never", 1: "Once or more times"), as in some countries the frequencies of the upper categories were very low (i.e., less than a 2% collapsing the responses to the "2-5 times" and "6 or more times" categories in Austria, Cyprus, Greece, Italy, Latvia, Malta, Slovakia, and Slovenia).

Sexual Violence. The FRA survey included 4 items addressing sexual violence committed by the current or any previous partner (e.g., "Your current/previous partner has made you take part in any form of sexual activity when you did not want to or you were unable to refuse?"). The response format of the items was a 4-point Likert-type scale indicating frequency (1: "Never", 2: "Once", 3: "2-5 times", 4: "6 or more times"). The responses to these items were also dichotomized (0: "Never", 1: "Once or more times").

Validity evidence based on relations to other variables

To test validity evidence of the physical and sexual IPVAW measures based on relations to other variables, [19] the following variables were used:

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies. Erasmushogeschool .

Self-perceived health. The respondents were asked about their health in general at the beginning of the interview, and they have to answer using a 5-point Likert-type graded scale (from 1 = "Very Bad" to 5 = "Very Good").

Experiences of child abuse. The FRA survey included a set of 11 questions addressing experiences of childhood physical and sexual abuse before the age 15 (e.g., "has an adult who was 18 years or over hit you very hard so that it hurt?", "has an adult who was 18 years or over expose their genitals to you?"). If any of these questions were answered affirmatively, we considered that the respondent has experienced child abuse during their childhood.

Income. Reported income was measured in each country as rent quartiles (i.e., "under lowest quartile", "between lowest quartile and median", "between median and highest quartile", "above highest quartile").

Statistical Analyses

The main purpose of this study was to ensure the measurement equivalence of the physical and sexual violence measures of the FRA survey across the 28 EU member states to made appropriate and valid comparisons between these countries. To this end, the psychometric properties (i.e., reliability and validity) and the latent structure of these measures was assessed, and then measurement invariance was tested across the 28 EU countries.

First, the mean, standard deviation, skew, and kurtosis statistics were obtained. The internal consistency of both measures in each country was evaluated computing the Cronbach's α, McDonald's ω, and using the correlation of each item with the rest of their set of questions (i.e., item-test corrected correlation).

Secondly, a confirmatory factor analysis (CFA) was conducted to determine the latent structure of both IPVAW measures in each country. Two models were compared:

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies.
Erasmushogeschool .

a one-factor model, in which all the items loaded onto a single intimate partner violence factor, and a two-factor model, setting one factor for the physical violence items and another one for the sexual violence items. Given the categorical nature of the items, weighted least squares with adjusted means and variances (WLSMV) was used as estimation method. [20] Model fit was evaluated using a combination of fit indices: CFI, TLI, and RMSEA. CFI and TLI values ≥ .95, and RMSEA values ≤ .06 are indicative of good fit. [21 22]

After establishing the factorial model, a series of multi-group confirmatory factor analysis (MG-CFA) were carried out, testing three different levels of measurement invariance: configural, metric, and scalar. [12 23] Configural invariance applies the same factorial model to all groups (i.e., countries), with no equality constraints for any parameters, ensuring that the same conceptualization of the construct is supported across countries. Metric invariance specifies that the values of the factor loadings are equal across countries, implying that each item is contributing equally and having a similar degree of importance on the factor in all the countries. Scalar invariance holds both factor loadings and item thresholds to be invariant, ensuring that respondents from different countries with the same response pattern on the items will yield the same factor score. If scalar invariance is supported, then the scores on the physical and sexual IPVAW measures can be compared across countries.

To assess which of these invariance levels was better supported by the data, the change in the CFI (ΔCFI) and RMSEA (ΔRMSEA) fit indices was computed, following the general guidelines of Cheung and Rensvold. [24] These guidelines, however, were developed for continuous data, and as Saas, Schmidt and Marsh noted, [25] the interpretation of these fit indices should be taken with caution in the case of categorical data. For this reason, instead of Chen's usual cut-off values for the changes in CFI and

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies. Erasmushogeschool .

RMSEA (i.e., ΔCFI ≤ .010 and ΔRMSEA ≤ .015), [26] we used the cut-offs values proposed by Meade, Johnson, and Brady: ΔCFI ≤ .002 and ΔRMSEA ≥ -.007. [27] These cut-offs are more restrictive and tend to perform as well as maximum-likelihood based procedures when the sample size is large and the items are not normally distributed. [25]

Once an invariant factorial model was established, validity evidence based on relations to other variables was tested using the invariant factor scores of the IPVAW items. A one-way ANOVA was computed for both physical and sexual violence measures of the FRA survey, testing differences by self-perceived health, experiences of child abuse, and income. The size effect of the variables was assessed with the partial eta-squared statistic, using values above .01, .06, and .14, as indicative of small, medium, and large size effects, respectively. [28]

Finally, after determining that both physical and sexual IPVAW measures were psychometrically sound and share an invariant latent structure in all EU countries, the factor means of physical and sexual IPVAW were compared across countries conducting a latent means analysis. This procedure is more appropriate and statistically sophisticated than simply computing the average prevalence for each country, as it does not assume that all the items has the same relevance to assess the construct and, moreover, it takes into account all the constraints for the invariant measurement model. [16 17 23] The magnitude of these cross-national comparisons were evaluated using Cohen's *d* statistic, indicating *d* values above .20, .50, and .80, small, medium and large size effects, respectively. [29] This statistic can be used to obtain the Cohen U_3 statistic, which indicates the percentage of cases of one country that is higher than the average of another. [30-32] The Cohen's *d* and U_3 statistics of the comparisons between each pair of countries can be found in the supplementary material.

Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies.
Erasmushogeschool .

Descriptive analyses, internal consistency, and validity analyses were conducted using the statistical package R and the *psych* library. [33 34] CFA and MG-CFA analyses were computed using *Mplus 7*. [35]

Results

Descriptive Analysis and Internal Consistency

Descriptive statistics of the physical and sexual violence measures are presented on Table 2. All the items showed mean values close to zero, and high skew and kurtosis values—especially in the sexual violence measure—, indicating that most of the respondents reported that the episodes described by the items never happened to them. The corrected item-test correlations were in general high, pointing out a strong relationship between the items and the rest of questions. Regarding the internal consistency, both measures showed an adequate internal consistency in the complete dataset, with alpha and omega values above.70. Separating the sample by countries yield similar results in both the physical violence and sexual violence measures (ranging, respectively, from α=. 84 in Sweden to α=. 90 in Ireland and Lithuania, and from α = .69 in Slovenia to α = .91 in the Netherlands).

[Insert Table 2]

The items 7 and 9 of the physical violence measure presented an extremely low variance (i.e., "being burned", and "being cut, stabbed or shot"), below 0.01. Given this lack of variability, we decided to remove these items from this measure. As a result, the Cronbach's alpha of the physical violence measure was increased to.89 (ranging from α = .84 in Slovenia to α = .92 in Romania and Lithuania), as well as McDonald's omega to .92.

Confirmatory Factor Analysis

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies.
Erasmushogeschool .

Two CFA solutions were tested separately in each country: a one-factor model, assuming that all the items load onto a single IPVAW factor, and a two-factor model, setting one separate factor for the physical and sexual violence items. The CFI and TLI indices were excellent for both the one- and two-factor models, with values around .98 y .99 in all 28 EU countries, respectively. However, the residuals for the one-factor model were above the RMSEA ≤ .06 cut-off criterion for a well fitted model in Belgium, Demark, Finland, France, Germany, Latvia, the Netherlands, Portugal, Sweden, and United Kingdom (being the highest Denmark, with .077, and the closest to the cut-off Portugal with .061), whereas in the two-factor the RMSEA were below this cut-off (being the highest .031 in Denmark and the lowest .011 in Poland). For this reason, we kept the two-factor model as the latent structure of the physical and sexual IPVAW measures.

Measurement Invariance

The analysis of measurement invariance supported the configural, metric, and scalar invariance levels for the physical and sexual violence measures across all EU countries (Table 3). Attending to the fit indices, fixing the loadings to have the same value across all countries did not differ substantially from the configural model (ΔCFI = .002, ΔRMSEA = -.006), supporting the metric invariance level. In the same direction, constraining the item thresholds as well as the item loadings did not reduce substantially the fit of the model (ΔCFI = .002, ΔRMSEA = -.006), indicating that the scalar invariance level could be hold.

[Insert Table 3]

The resulting item parameters are displayed on Figure 1. All the items presented high standardized loadings, indicating a strong relationship of the items to the factor. The correlation between factors vary across countries, as the factor covariance matrix

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies.
Erasmushogeschool .

was freed in each country. The value for this correlation was around .75 in most of the countries, ranging from .56 in Denmark to .91 in Croatia.

[Insert Figure 1]

Validity evidence based on relations to other variables

The factor scores of the invariant model were used for the validity analyses in all countries. Significant and substantive differences were found in the physical IPVAW scores when self-perceived health ($F(4) = 94.0$, $p < .001$, $\eta^2 = .01$), experiences of child abuse ($F(1) = 984.7$, $p < .001$, $\eta^2 = .03$), and income ($F(1) = 127.3$, $p < .001$, $\eta^2 = .01$) are taken into account, showing those women with higher scores on the physical IPVAW factor lower self-perceived health levels, lower income and experiences of child abuse.

In the case of the sexual IPVAW factor scores, substantive differences were also found in self-perceived health ($F(4) = 82.6$, $p < .001$, $\eta^2 = .01$), experiences of child abuse ($F(1) = 311.4$, $p < .001$, $\eta^2 = .03$), and income ($F(1) = 113.4$, $p < .001$, $\eta^2 = .01$). These differences were in the same direction as in the physical IPVAW, presenting those women with higher scores on the sexual IPVAW factor lower self-perceived health levels, lower income, and experiences of child abuse.

Latent Means Analysis

After determining that the physical and sexual IPVAW measures are psychometrically sound, and after ensuring their measurement equivalence across all EU countries, the means of the physical and sexual violence factors can now be compared conducting a MG-CFA. Denmark was used as the reference group, as it was one of the countries that presented higher levels of physical and sexual IPVAW. The factor means in this country were fixed to zero and their variances fixed to one. In the rest of the countries these parameters were freely estimated. This way, the estimated

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies. Erasmushogeschool .

mean parameter of the standardized solution represents the difference in factor means of each country with Denmark. The resulting model fitted very well to the data (CFI = .997, TLI = .997, RMSEA = .027 [.026 - .029]). The standardized factor means for each country are displayed on Figures 2 and 3.

[Insert Figure 2]

Although Denmark was the country with higher levels of physical IPVAW, the differences between this country and Latvia (z = -0.01, p = .850, d = 0.01), Finland (z = -0.04, p = .587, d = 0.04), United Kingdom (z = -0.12, p = .059, d = 0.13), and Sweden (z = -0.12, p = .115, d = 0.12) were negligible, with Cohen's d values below .20. Substantive and large differences were found between Denmark and Ireland (z = -0.70, p < .001, d = 0.85), Slovenia (z = -0.75, p < .001, d = 0.84), Spain (z = -0.75, p < .001, d = 0.86), Cyprus (z = -0.77, p < .001, d = 0.94), and Poland (z = -0.79, p < .001, d = 0.96).

It should be noted that the confidence intervals (CI) of the physical IPVAW factor means were overlapped between many of the EU countries, indicating no significant differences between them. However, the countries could be grouped using these intervals. This way, countries whose factor mean is comprised within the CI of Latvia showed on average higher levels of physical IPVAW (Denmark, Finland, United Kingdom, and Sweden). On the other hand, countries with factor means comprised within the CI of Poland—the country with the lowest factor mean—presented lower levels of physical IPVAW (Ireland, Slovenia, Spain, and Cyprus). The rest of the countries laid somewhere in between, with some countries like Lithuania or the Netherlands more proximate to the countries with higher levels of physical IPVAW, and others like Greece or Italy closer to the countries with lower levels of this type of violence.

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies.
Erasmushogeschool .

Regarding the sexual IPVAW measure, the countries with higher latent means in this factor were, along with Denmark, Finland (z = 0.00, p = .986, d = 0.00), Sweden (z = -0.10, p = .537, d = 0.10), Luxembourg (z = -0.31, p = .082, d = 0.34), Bulgaria (z = -0.32, p = .072, d = 0.34), and Slovenia (z = -0.34, p = .130, d = 0.32). Large differences in the sexual IPVAW factor were found between Denmark and Lithuania (z = -0.87, p < .001, d = 1.06), Croatia (z = -0.88, p < .001, d = 1.04), Austria (z = -0.90, p < .001, d = 1.13), Ireland (z = -0.97, p < .001, d = 1.29), Romania (z = -0.98, p < .001, d = 1.24), Poland (z = -1.04, p < .001, d = 1.31), Spain (z = -1.07, p < .001, d = 1.32), Greece (z = -1.08, p < .001, d = 1.39), Portugal (z = -1.12, p < .001, d = 1.43), and Cyprus (z = -1.97, p < .001, d = 1.71).

[Insert Figure 3]

The CI of the sexual IPVAW factor means were, however, much wider than in the case of physical IPVAW, as this measure is comprised only by four items. As a result, most of the countries' factor means CI were highly overlapped. In this case the CI of Finland was used to group the countries that tend to present higher levels of sexual IPVAW (Denmark, Sweden, Belgium, Luxembourg, United Kingdom, and Slovenia), whereas the CI of Cyprus was used to delimit those countries with lower levels in this factor (Portugal, Greece, Spain, and Poland). The rest of the countries are in a middle area, with some countries like France and Germany nearer to the countries with higher levels of sexual IPVAW, and others like Romania and Ireland more proximate to the countries with lower levels of this type of violence. Italy was in the middle of the distribution, being the only country whose CI was not overlapped with neither the Finland nor the Cyprus intervals.

The comparisons of both physical and sexual IPVAW factor scores can also be made between each pair of countries. For instance, we could compare Finland—one of

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

Erasmushogeschool . Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies.

the countries with higher levels of physical and sexual IPVAW—with the Netherlands and Spain —countries with moderate and low levels of both types of IPVAW, respectively. The differences between Finland and the Netherlands were small in the case of physical IPVAW, showing the 59.9% of the Finish sample higher values in this factor than the average of the Dutch sample ($d = 0.24$, $U_3 = .595$). Medium differences were found in the case of sexual IPVAW, presenting the 72.6% of the Finish sample higher scores in the sexual IPVAW factor than the average of the Dutch sample ($d = 0.60$, $U_3 = .726$). When Finland is compared to Spain, large differences were found in both factors, showing the 79.1% of the Finish sample higher values in the physical IPVAW factor than the average of the Spanish sample ($d = 0.81$, $U_3 = .791$), and the 90.7% in the case of sexual IPVAW ($d = 1.32$, $U_3 = .907$). The comparisons between each pair of countries, as well as its associated size effect, can be found in the supplementary material.

Discussion

In this measurement invariance study, we conducted a set of analyses to ensure the cross-national comparability of the set of questions addressing physical and sexual IPVAW used in the FRA survey, and examined how physical and sexual IPVAW levels were distributed across all EU countries.

The first set of analyses aimed to study the psychometric properties (i.e., reliability and validity) of the set of questions addressing physical and sexual IPVAW across the EU. Our results showed that the measures of the FRA survey were measuring two different constructs: physical and sexual IPVAW. Both factors were related and showed an adequate internal consistency in all EU countries (with α and ω values above .70 in almost all countries). Regarding the validity evidence based on relations with

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

Erasmushogeschool . Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies.

other variables, we found, as expected, that women who reported having experiences of child abuse were more likely to show higher levels of physical and sexual IPVAW. This finding is consistent with previous research pointing out that women who have been victimized in childhood have higher risk of being victimized during adulthood. [36-41] In addition, we found that the women presenting higher levels of physical and sexual IPVAW also reported lower levels of self-perceived health and income, a finding well consolidated in the IPVAW literature. [42-46]

The second set of analyses aimed to address the comparability of the physical and sexual IPVAW measures across the 28 EU countries, discarding the possibility of measurement bias. To do so, a series of MG-CFA analyses were conducted to test and establish measurement invariance. Although previous studies have acknowledged the difficulties to establish the metric or scalar invariance levels when several groups are used, [14 47 48] we were able to hold scalar invariance (i.e., equal factor loadings and thresholds) across the 28 EU countries. This may be due to the type of questions included on the FRA survey, as they are mostly behavioral oriented (e.g., being stabbed, cut, slapped, or being forced into sexual intercourse).

Once an invariant model was established for the physical and sexual IPVAW measures, proper comparisons could be made between the countries. Instead of computing the prevalence using the set of questions of the FRA survey, an approach that ignores the latent structure of the IPVAW measures and the magnitude of the contribution of each item to the construct, we conducted a latent means analysis, comparing the factor means of each country. [12 15 16] This is one of the mains strengths of this study, and our findings suggest that there were almost no differences between many of the EU countries, since their confidence intervals were highly overlapped, implying that the levels of sexual and physical IPVAW were fairly similar between them. There

Erasmushogeschool .

were, however, substantial differences between the countries with higher levels of physical and sexual IPVAW and those with lower levels of these types of violence. In particular, countries such as Denmark, Finland, Sweden, and United Kingdom, showed on average higher levels than countries like Cyprus, Poland, and Spain. These findings are in line with the idea of the Nordic paradox, as Denmark, Finland, and Sweden—countries with the highest levels of gender equality in the EU—were among the countries with higher levels of physical and sexual IPVAW. [49 50]

This study has some limitations. First, we used WLSMV as estimation method for the measurement invariance analysis due to the asymmetrical distribution of the responses to the set of questions included on the FRA survey. According to Sass, Schmitt, and Marsh, [25] the use of fit indices with this method to test measurement invariance could lead to higher rates of Type I errors, assuming an invariant model when actually the instrument is non-invariant. To address this issue, we decided to use the cut-offs proposed by Meade et al. for the CFI and RMSEA, [27] as they are more restrictive than Chen's cut-offs. [26] Second, in this case, chi-squared based tests to compare the different levels of measurement invariance could not be used in conjunction with the fit indices, since this statistic is known to be sensible to large sample sizes. Third, the cross-sectional design of the survey did not allow for testing measurement invariance across different periods of time. Fourth, the wide range of the confidence intervals of the physical and sexual IPVAW factor means, suggest that the measures included in the FRA survey could be improved in order to obtain more accurate and reliable estimations of the IPVAW levels, especially in the case of sexual IPVAW.

Taken together, the results of this study underlined the importance of using appropriate statistical methods to account for the cross-national comparability of the

Erasmushogeschool .

measures included in large socio-demographical surveys. The measurement invariance approach allowed us to conduct a more appropriate and refined analysis of how the physical and sexual IPVAW levels are distributed across the EU. This study is an important step towards a rigorous assessment of cross-national differences in physical and sexual IPVAW, and further research is needed to evaluate the role that the country has, if any, to account for the differences across EU countries.

Contributors. MM-F designed the analytic strategy, conducted the statistical analysis and wrote the manuscript. BMJ Open

Ensuring the comparability of cross-national survey data on intimate partner violence against women: A measurement invariance study in the European Union

Journal:	*BMJ Open*
Manuscript ID	bmjopen-2019-032231.R1
Article Type:	Original research
Date Submitted by the Author:	14-Oct-2019
Complete List of Authors:	Martín-Fernández, Manuel; University of Valencia, Department of Social Psychology Gracia, Enrique; University of Valencia, Social Psychology Lila, Marisol; University of Valencia, Social Psychology
Primary Subject Heading:	Global health
Secondary Subject Heading:	Public health
Keywords:	Intimate partner violence, Measurement Invariance, European Union, PUBLIC HEALTH, Psychometrics, Cross-national research

Abstract

Objectives To ensure the cross-national comparability of the set of questions addressing physical and sexual intimate partner violence against women (IPVAW) included in the European Union (EU) Agency for Fundamental Rights (FRA) survey. Once the measurement invariance of these measures is established, we aim to make appropriate and valid comparisons of the levels of physical and sexual IPVAW across the EU countries.

Design Cross-sectional, population-based study.

Participants Data were drawn from the survey conducted by the FRA on violence against women, including the responses of 42,002 adult women from the 28 countries of the EU.

Main outcome measures The set of questions addressing life-time prevalence of physical and sexual IPVAW used in the FRA survey. The psychometric properties (i.e., reliability and validity) of these measures were examined, as well as their latent structure and their measurement invariance across the 28 EU countries.

Results The physical and sexual IPVAW measures presented adequate internal consistency and validity evidence based on their relations to other variables in all countries. A latent two-factor structure was supported and scalar invariance was established across countries. Our results showed that the average levels of physical and sexual IPVAW were higher in countries like Denmark, Finland, Sweden and United Kingdom compared to the rest of the EU countries. In many of the other countries the levels of these types of violence overlapped, especially in the case of sexual IPVAW.

Conclusions The findings of this study underline the importance of using appropriate statistical methods to make valid cross-national comparisons in large socio-demographic surveys. The measurement invariance approach allowed us to conduct a

more robust and refined analysis of how levels of physical and sexual IPVAW were distributed across all EU countries.

Strengths and limitations of this study

- This paper is the first to examine the cross-national comparability of survey data addressing physical and sexual intimate partner violence against women (IPVAW) in all European Union (EU) countries
- Appropriate analyses were applied to examine the psychometric properties, latent structure, and the measurement invariance of the measures included in a large socio-demographic survey on IPVAW
- A latent means analysis was conducted to compare the levels of physical and sexual IPVAW across all EU countries, an approach that takes into account the latent structure of the IPVAW measures and the magnitude of the contribution of each item to the measured construct
- The cross-sectional design of the survey did not allow for testing measurement invariance across different periods of time

Intimate partner violence against women (IPVAW) has been globally recognized as a major public health problem of epidemic proportions.[1] IPVAW is the form of violence most commonly suffered by women,[2-4] and it has severe physical and psychological consequences not only for the well-being of victims and their children, but for society as a whole.[5-9]

According to the survey conducted by the European Union (EU) Agency for Fundamental Rights (FRA), the estimated prevalence of physical and sexual IPVAW in the EU is 22%, varying across countries from 13% to 32%.[10] One of the main strengths of this survey is that women from the 28 EU countries answered the same set of questions assessing different types of IPVAW. However, the measurement equivalence of these questions across the EU countries has not yet been tested. This hampers the generalizability of these cross-national comparisons, as it not possible to ascertain whether the differences in IPVAW prevalence across all EU member states reflect actual differences between countries, or whether they are the result of cultural expectations or beliefs about intimate partner violence that may affect the interpretation of the FRA survey questions.

IPVAW can be a culturally sensitive issue, and how it is perceived, conceptualized and interpreted may vary across countries. Thus, to make valid cross-national comparisons based on survey data addressing IPVAW, it is important to test their measurement invariance.[11-13] Measurement invariance is a crucial prerequisite in cross-national research, since it allows meaningful comparisons across countries ruling out the possibility of cultural bias in the respondents' answers.[14] When measurement invariance is not supported, it means that respondents from different countries interpret and respond differently to the questions, and thus their scores cannot be directly compared.[15 16] If that is the case, it cannot be assumed that IPVAW is interpreted in the

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies. Erasmushogeschool .

same way in all EU member states, since the same score in one country may reflect a different construct or yield different levels of IPVAW in another. Therefore, computing prevalence rates to compare samples from different countries without first ensuring measurement invariance could lead to unreliable and distorted conclusions, as the validity of such comparisons may be questionable.[17]

The main objective of this study is to ensure the cross-national comparability of the set of questions addressing physical and sexual IPVAW included in the FRA survey, by assessing whether respondents of each country conceptualize and interpret these questions in the same manner. For validity purposes, the relationship of physical and sexual IPVAW to related sociodemographic and background variables (i.e., as self-perceived health, household income, and experiences of child abuse) were tested.[18-20] Once the measurement invariance of these measures is established, we aim to make appropriate and valid comparisons of the physical and sexual IPVAW levels across the EU countries.

Method

Participants

The data were drawn from the FRA survey on violence against women.[10] This survey includes the responses of 42,002 adult women from the 28 EU countries who were currently or had previously been in an intimate relationship. The responses were collected in person through structured interviews and self-reports, following a two-stage clustered stratified sampling design with equal probability of selection of households within clusters. The average response rate to the survey was 42.1%, ranging from 18.5% in Luxembourg to 84.0% in Hungary. Additional information on sample collection and

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies.
Erasmushogeschool .

procedures can be found in the FRA survey technical report.[21] A special license for secondary data analysis was requested and granted from FRA (Reference No. 102577).

The sample used in this study was selected using the answers from respondents who did not omit any of the survey questions addressing physical and sexual intimate partner violence. The final sample is composed of 39,403 women, aged from 18 to 74 years old, from the 28 EU countries. Socio-demographic information of the sample by country is shown in Table 1.

Patient Involvement. No patient involved.

[Insert Table 1 around here]

Measures

The measures used in this study were developed by FRA in collaboration with research experts, survey experts, policy makers, practitioners, nongovernmental organizations. All the items included in the questionnaire were translated by experts in the field of IPVAW from English into other languages of the 28 EU member states.[21]

Physical violence. Intimate partner physical violence is addressed in the FRA survey with 10 items describing episodes of physical violence perpetrated by either the current or any previous partner (e.g., "Has your current/previous partner ever slapped you?"). Respondents were asked to indicate how often they had experienced that episode on a 4-point Likert-type scale (1: "Never", 2: "Once", 3: "2-5 times", 4: "6 or more times"). The responses to these items were dichotomized (0: "Never", 1: "Once or more times"), as in some countries the frequencies of the upper categories were very low (i.e., less than 2% when the responses to the "2-5 times" and "6 or more times" categories are collapsed in Austria, Cyprus, Greece, Italy, Latvia, Malta, Slovakia, and Slovenia).

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies. Erasmushogeschool .

Sexual Violence. The FRA survey included four items addressing sexual violence committed by the current or any previous partner (e.g., "Has your current/previous partner made you take part in any form of sexual activity when you did not want to or you were unable to refuse?"). The response format of the items was a 4-point Likert-type scale indicating frequency (1: "Never", 2: "Once", 3: "2-5 times", 4: "6 or more times"). The responses to these items were also dichotomized (0: "Never", 1: "Once or more times").

Validity evidence based on relations to other variables

To test validity evidence of the physical and sexual IPVAW measures based on relations to other variables,[22] the following variables were used:

Self-perceived health. The respondents were asked to respond about their health in general at the beginning of the interview using a 5-point Likert-type graded scale (from 1 = "Very Bad" to 5 = "Very Good").

Experiences of child abuse. The FRA survey included a set of 11 questions addressing experiences of childhood physical and sexual abuse before the age of 15 (e.g., "did an adult who was 18 years or over hit you very hard so that it hurt?", "did an adult who was 18 years or over expose their genitals to you?"). If any of these questions were answered affirmatively, we considered that the respondent has experienced child abuse during their childhood.

Income. Reported income was measured in each country as household income quartiles (i.e., "below lowest quartile", "between lowest quartile and median", "between median and highest quartile", "above highest quartile").

Statistical Analyses

The main purpose of this study was to ensure the measurement equivalence of the physical and sexual violence measures of the FRA survey across the 28 EU member

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies.
Erasmushogeschool .

states in order to make appropriate and valid comparisons between these countries. To this end, the psychometric properties (i.e., reliability and validity) and the latent structure of these measures was assessed, and then measurement invariance was tested across the 28 EU countries.

First, the mean, standard deviation, skew, and kurtosis statistics were obtained. The internal consistency of the physical and sexual violence measures in each country was evaluated by computing the Cronbach's α and McDonald's ω, and using the correlation of each item with the rest of its set of questions (i.e., item-test corrected correlation).

Secondly, a confirmatory factor analysis (CFA) was conducted to determine the latent structure of the two IPVAW measures in each country. Two models were compared: a one-factor model, in which all the items loaded onto a single intimate partner violence factor, and a two-factor model, setting one factor for the physical violence items and another one for the sexual violence items. Given the categorical nature of the items, weighted least squares with adjusted means and variances (WLSMV) was used as estimation method.[23] Model fit was evaluated using a combination of fit indices: CFI, TLI, and RMSEA. CFI and TLI values ≥ .95, and RMSEA values ≤ .06 are indicative of good fit.[24 25]

After establishing the factor model, a series of multi-group confirmatory factor analyses (MG-CFA) were carried out, testing three different levels of measurement invariance: configural, metric, and scalar.[12 26] Configural invariance applies the same factor model to all groups (i.e., countries), with no equality constraints for any parameters, ensuring that the same conceptualization of the construct is supported across countries. Metric invariance specifies that the values of the factor loadings are equal across countries, implying that each item is contributing equally and having a

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies. Erasmushogeschool .

similar degree of importance on the factor in all the countries. Scalar invariance holds both factor loadings and item thresholds to be invariant, ensuring that respondents from different countries with the same response pattern on the items will yield the same factor score. If scalar invariance is supported, then the scores on the physical and sexual IPVAW measures can be compared across countries.

To assess which of these invariance levels was best supported by the data, the change in the CFI (ΔCFI) and RMSEA (ΔRMSEA) fit indices was computed, following the general guidelines of Cheung and Rensvold.[27] These guidelines, however, were developed for continuous data, and as Saas, Schmidt and Marsh noted,[28] the interpretation of these fit indices should be taken with caution in the case of categorical data. For this reason, instead of Chen's usual cut-off values for the changes in CFI and RMSEA (i.e., $\Delta CFI \leq .010$ and $\Delta RMSEA \leq .015$),[29] we used the cut-offs values proposed by Meade, Johnson, and Brady: $\Delta CFI \leq .002$ and $\Delta RMSEA \geq -.007$.[30] These cut-offs are more restrictive and tend to perform as well as maximum-likelihood based procedures when the sample size is large and the items are not normally distributed.[28]

Having established an invariant factor model, validity evidence based on relations to other variables was tested using the invariant factor scores of the IPVAW measures. A one-way ANOVA was computed for both physical and sexual violence measures of the FRA survey, testing differences by self-perceived health, experiences of child abuse, and income. These analyses were conducted for the total sample to avoid type I errors. The size effect of the variables was assessed with the partial eta-squared statistic, using values above .01, .06, and .14, as indicative of small, medium, and large size effects, respectively.[31]

Finally, after determining that both physical and sexual IPVAW measures were psychometrically sound and share an invariant latent structure in all EU countries, the

Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies.
Erasmushogeschool .

factor means of physical and sexual IPVAW were compared across countries conducting a latent means analysis. This procedure is more appropriate and statistically sophisticated than simply computing the average prevalence for each country, as it does not assume that all the items have the same relevance to assess the construct and, moreover, it takes into account all the constraints for the invariant measurement model.[16 17 26] The magnitude of these cross-national comparisons was evaluated using Cohen's *d* statistic, indicating *d* values above .20, .50, and .80, small, medium and large size effects, respectively.[32] This statistic can be used to obtain the Cohen U_3 statistic, which indicates the percentage of cases of one country that is higher than the average of another.[33-35] The Cohen's *d* and U_3 statistics of the comparisons between each pair of countries can be found in the supplementary material (file 1).

Descriptive analyses, internal consistency, and validity analyses were conducted using the statistical package R and the *psych* library.[36 37] CFA and MG-CFA analyses were computed using *Mplus 7*.[38]

Results

Descriptive Analysis and Internal Consistency

Descriptive statistics of the physical and sexual violence measures are presented in Table 2. All the items showed mean values close to zero, and high skew and kurtosis values, especially in the sexual violence measure, indicating that most of the respondents reported having no experience of the episodes described by the items. The corrected item-test correlations were in general high, pointing to a strong relationship between the items and the rest of the questions. Regarding the internal consistency, both measures showed an adequate internal consistency in the complete dataset, with alpha and omega values above.70. Separating the sample by countries yields similar results in

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

Erasmushogeschool . Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies.

both the physical violence and sexual violence measures (ranging, respectively, from α=. 84 in Sweden to α=. 90 in Ireland and Lithuania, and from α = .69 in Slovenia to α = .91 in the Netherlands).

[Insert Table 2]

The items 7 and 9 of the physical violence measure presented an extremely low variance (i.e., "being burned", and "being cut, stabbed or shot"), below 0.01. Given this lack of variability, we decided to remove these items from this measure. As a result, the Cronbach's alpha of the physical violence measure increased to.89 (ranging from α = .84 in Slovenia to α = .92 in Romania and Lithuania), and McDonald's omega increased to .92.

Confirmatory Factor Analysis

Two CFA solutions were tested separately in each country: a one-factor model, assuming that all the items load onto a single IPVAW factor, and a two-factor model, setting one separate factor for the physical and sexual violence items (Table 3). The CFI and TLI indices were excellent for both the one- and two-factor models, with values around .98 and .99 in all 28 EU countries, respectively. However, the residuals for the one-factor model were above the RMSEA ≤ .06 cut-off criterion for a well-fitting model in Belgium, Demark, Finland, France, Germany, Latvia, the Netherlands, Portugal, Sweden, and United Kingdom (the highest was Denmark, with .077, and the closest to the cut-off was Portugal, with .061), whereas in the two-factor model the RMSEA were below this cut-off (the highest was .031 in Denmark and the lowest, .011 in Poland). For this reason, we kept the two-factor model as the latent structure of the physical and sexual IPVAW measures.

[Insert Table 3]

Measurement Invariance

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies. Erasmushogeschool .

The analysis of measurement invariance supported the configural, metric, and scalar invariance levels for the physical and sexual violence measures across all EU countries (Table 4). Attending to the fit indices, when the loadings were fixed to have the same value across all countries they did not differ substantially from the configural model (ΔCFI = .002, ΔRMSEA = -.006), supporting the metric invariance level. In the same direction, constraining the item thresholds as well as the item loadings did not substantially reduce the fit of the model (ΔCFI = .002, ΔRMSEA = -.006), indicating that the scalar invariance level could hold.

[Insert Table 4]

The resulting item parameters are displayed in Figure 1. All the items presented high standardized loadings, indicating a strong relationship of the items to the factor. The correlation between factors varies across countries, as the factor covariance matrix was freed in each country. The value for this correlation was around .75 in most of the countries, ranging from .56 in Denmark to .91 in Croatia. The model parameters for all countries can be found in the supplementary material (file 2).

[Insert Figure 1]

Validity evidence based on relations to other variables

The factor scores of the invariant model were used for the validity analyses in all countries. Significant and substantive differences were found in the physical IPVAW scores when self-perceived health ($F(4) = 94.0$, $p < .001$, $\eta^2 = .01$), experiences of child abuse ($F(1) = 984.7$, $p < .001$, $\eta^2 = .03$), and income ($F(1) = 127.3$, $p < .001$, $\eta^2 = .01$) were taken into account, showing that women with higher scores on the physical IPVAW factor had lower self-perceived health levels, lower income and experiences of child abuse.

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies. Erasmushogeschool .

In the case of the sexual IPVAW factor scores, substantive differences were also found in self-perceived health ($F(4) = 82.6$, $p < .001$, $\eta^2 = .01$), experiences of child abuse ($F(1) = 311.4$, $p < .001$, $\eta^2 = .03$), and income ($F(1) = 113.4$, $p < .001$, $\eta^2 = .01$). These differences were in the same direction as in the physical IPVAW, as the women with higher scores on the sexual IPVAW factor presented lower self-perceived health levels, lower income, and experiences of child abuse.

Latent Means Analysis

After determining that the physical and sexual IPVAW measures are psychometrically sound, and after ensuring their measurement equivalence across all EU countries, the means of the physical and sexual violence factors can now be compared by conducting a MG-CFA. Denmark was used as the reference group, as it was one of the countries presenting the highest levels of physical and sexual IPVAW. The factor means for Denmark were fixed to zero and their variances fixed to one. In the rest of the countries these parameters were freely estimated. In this way, the estimated mean parameter of the standardized solution represents the difference in factor means between each country and Denmark. The resulting model presented a very good fit to the data (CFI = .997, TLI = .997, RMSEA = .027 [.026 - .029]). The standardized factor means for each country are displayed in Figures 2 and 3.

[Insert Figure 2]

Although Denmark was the country with the highest levels of physical IPVAW, the differences between this country and Latvia ($z = -0.01$, $p = .850$, $d = 0.01$), Finland ($z = -0.04$, $p = .587$, $d = 0.04$), United Kingdom ($z = -0.12$, $p = .059$, $d = 0.13$), and Sweden ($z = -0.12$, $p = .115$, $d = 0.12$) were negligible, with Cohen's d values below .20. Large substantive differences were found between Denmark and Ireland ($z = -0.70$, $p < .001$, $d = 0.85$), Slovenia ($z = -0.75$, $p < .001$, $d = 0.84$), Spain ($z = -0.75$, $p < .001$, d

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies. Erasmushogeschool .

= 0.86), Cyprus (z = -0.77, p < .001, d = 0.94), and Poland (z = -0.79, p < .001, d = 0.96).

It should be noted that the confidence intervals (CI) of the physical IPVAW factor means overlapped between many of the EU countries, indicating no significant differences between them. However, the countries could be grouped according to the confidence intervals. Thus, countries whose factor mean falls within the CI of Latvia showed on average higher levels of physical IPVAW (Denmark, Finland, United Kingdom, and Sweden). On the other hand, countries with factor means falling within the CI of Poland—the country with the lowest factor mean—presented lower levels of physical IPVAW (Ireland, Slovenia, Spain, and Cyprus). The rest of the countries fell somewhere in between, with some countries like Lithuania or the Netherlands closer to the countries with higher levels of physical IPVAW, and others such as Greece or Italy closer to the countries with lower levels.

Regarding the sexual IPVAW measure, the countries with higher latent means in this factor were, along with Denmark, Finland (z = 0.00, p = .986, d = 0.00), Sweden (z = -0.10, p = .537, d = 0.10), Luxembourg (z = -0.31, p = .082, d = 0.34), Bulgaria (z = -0.32, p = .072, d = 0.34), and Slovenia (z = -0.34, p = .130, d = 0.32). Large differences in the sexual IPVAW factor were found between Denmark and Lithuania (z = -0.87, p < .001, d = 1.06), Croatia (z = -0.88, p < .001, d = 1.04), Austria (z = -0.90, p < .001, d = 1.13), Ireland (z = -0.97, p < .001, d = 1.29), Romania (z = -0.98, p < .001, d = 1.24), Poland (z = -1.04, p < .001, d = 1.31), Spain (z = -1.07, p < .001, d = 1.32), Greece (z = -1.08, p < .001, d = 1.39), Portugal (z = -1.12, p < .001, d = 1.43), and Cyprus (z = -1.97, p < .001, d = 1.71).

[Insert Figure 3]

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

Erasmushogeschool . Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies.

The CI of the sexual IPVAW factor means were, however, much wider than in the case of physical IPVAW, as this measure is comprised of only four items. As a result, most of the countries' factor means CI greatly overlapped. In this case the CI of Finland was used to group the countries that tend to present higher levels of sexual IPVAW (Denmark, Sweden, Belgium, Luxembourg, United Kingdom, and Slovenia), whereas the CI of Cyprus was used to delimit those countries with lower levels in this factor (Portugal, Greece, Spain, and Poland). The rest of the countries fall into the intermediate area, with some countries such as France and Germany nearer to the countries with higher levels of sexual IPVAW, and others like Romania and Ireland closer to the countries with lower levels of this type of violence. Italy was in the middle of the distribution, and was the only country whose CI did not overlap with the intervals for either Finland or Cyprus.

Comparisons of the physical and sexual IPVAW factor scores can also be made between each pair of countries. For instance, we compare Finland—one of the countries with highest levels of physical and sexual IPVAW—with the Netherlands and Spain—countries with moderate and low levels of both types of IPVAW, respectively. The differences between Finland and the Netherlands were small in the case of physical IPVAW, showing that 59.9% of the Finnish sample had higher values in this factor than the average of the Dutch sample ($d = 0.24$, $U_3 = .595$). Medium differences were found in the case of sexual IPVAW, as 72.6% of the Finnish sample presented higher scores in the sexual IPVAW factor than the average of the Dutch sample ($d = 0.60$, $U_3 = .726$). When Finland is compared to Spain, large differences were found in both factors: 79.1% of the Finnish sample presented higher values in the physical IPVAW factor than the average of the Spanish sample ($d = 0.81$, $U_3 = .791$), and 90.7% in the case of sexual

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies.
Erasmushogeschool .

IPVAW (d = 1.32, U_3 = .907). The comparisons between each pair of countries together with their associated size effect can be found in the supplementary material (file 1).

Discussion

In this measurement invariance study, we conducted a set of analyses to ensure the cross-national comparability of the questions addressing physical and sexual IPVAW used in the FRA survey, and examined how physical and sexual IPVAW levels were distributed across all EU countries.

The first set of analyses aimed to study the psychometric properties (i.e., reliability and validity) of the questions addressing physical and sexual IPVAW across the EU. Our results showed that the measures of the FRA survey were measuring two different constructs: physical and sexual IPVAW. The two factors were related and showed an adequate internal consistency in all EU countries (with α and ω values above .70 in almost all countries). Regarding the validity evidence based on relations with other variables, we found, as expected, that women who reported having experiences of child abuse were more likely to show higher levels of physical and sexual IPVAW. This finding is consistent with previous research showing that women who were victimized in childhood have a higher risk of being victimized during adulthood.[39-44] In addition, we found that the women presenting higher levels of physical and sexual IPVAW also reported lower levels of self-perceived health and income, a well-established finding in the IPVAW literature.[45-49]

The second set of analyses aimed to address the comparability of the physical and sexual IPVAW measures across the 28 EU countries, to rule out the possibility of measurement bias. To do so, a series of MG-CFA analyses were conducted to test and establish measurement invariance. Although previous studies have acknowledged the

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

Erasmushogeschool . Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies.

difficulties in establishing the metric or scalar invariance levels when several groups are used,[14 50 51] we were able to demonstrate scalar invariance (i.e., equal factor loadings and thresholds) across the 28 EU countries. This means that is possible to exclude the country as a biasing variable, which in turn suggest that the respondents conceptualized and interpreted the physical and sexual IPVAW measures included in the FRA survey in a similar way across countries.[52 53] This finding may be due to the type of questions included in the FRA survey, as they are mostly behavioral oriented (e.g., being stabbed, cut, slapped, or being forced into sexual intercourse).

Once an invariant model had been established for the physical and sexual IPVAW measures, we were able to make proper comparisons between countries. Instead of computing the prevalence using the set of questions from the FRA survey, an approach that ignores the latent structure of the IPVAW measures and the magnitude of the contribution of each item to the construct, we conducted a latent means analysis, comparing the factor means of each country.[12 15 16] This is one of the main strengths of this study, and our findings suggest that there were almost no differences between many of the EU countries, since their confidence intervals overlapped considerably, implying that the levels of sexual and physical IPVAW were fairly similar between them. There were, however, substantial differences between the countries with higher levels of physical and sexual IPVAW and those with lower levels. In particular, countries such as Denmark, Finland, Sweden, and United Kingdom showed on average higher levels than countries like Cyprus, Poland, and Spain. These findings are in line with what is known as the Nordic paradox, as Denmark, Finland, and Sweden—countries with the highest levels of gender equality in the EU—were among the countries with highest levels of physical and sexual IPVAW.[54 55]

This study has some limitations. First, we used WLSMV as the estimation method for the measurement invariance analysis due to the asymmetrical distribution of the responses to the set of questions included in the FRA survey. According to Sass, Schmitt, and Marsh,[28] the use of fit indices with this method to test measurement invariance could lead to higher rates of Type I errors, assuming an invariant model when actually the instrument is non-invariant. To address this issue, we decided to use the cut-offs proposed by Meade et al. for the CFI and RMSEA,[30] as they are more restrictive than those of Chen.[29] Second, in this case, chi-squared based tests to compare the different levels of measurement invariance could not be used in conjunction with the fit indices, since this statistic is known to be sensitive to large sample sizes. Third, the cross-sectional design of the survey did not allow for testing measurement invariance across different periods of time. Fourth, the wide range of the confidence intervals of the physical and sexual IPVAW factor means suggest that the measures included in the FRA survey could be improved in order to obtain more accurate and reliable estimations of the IPVAW levels, especially in the case of sexual IPVAW. Fifth, self-selection bias is another potential issue, since only a 42% of the respondents agreed initially to be interviewed. This is also reflected in the wide variability in the response rates across the EU countries, with some countries presenting response rates lower than 30% (e.g., Luxembourg, Netherlands, or Sweden), whereas others showed response rates above 60% (e.g., Cyprus, Hungary, or Latvia).[24] Finally, future research could also examine the relationship of physical and sexual IPVAW to other IPVAW measures included in the survey, such as psychological IPVAW, sexual harassment, or stalking behavior.

Taken together, the results of this study underlined the importance of using appropriate statistical methods to account for the cross-national comparability of the measures included in large socio-demographic surveys. The measurement invariance

approach allowed us to conduct a more appropriate and refined analysis of how physical and sexual IPVAW levels are distributed across the EU. This study is an important step towards a rigorous assessment of cross-national differences in physical and sexual IPVAW, and further research is needed to evaluate the role that the country has, if any, in accounting for the differences across EU countries.

Contributors. MM-F designed the analytic strategy, conducted the statistical analysis and wrote the manuscript. EG conceived the study, supervised the writing of the manuscript, and acquired the funding and the FRA special license. ML supervised the writing of the manuscript, and acquired the funding.

Funding. This research was supported by Grants PSI2017-84764-P (EG, ML), and BES-2015-075576 (MM-F) from the Spanish Ministry of Economy and Competitiveness (http://www.mineco.gob.es).

Table 2. Psychometric properties of the Physical Violence and Sexual Violence measures.

	M	SD	Skew	Kurtosis	$r_{item-test}$
Physical Violence (Cronbach's α= .87, McDonald's ω = .90)					
Threatened to hurt you physically	0.14	0.35	2.05	2.18	0.70
Pushed you or shoved you	0.16	0.36	1.88	1.53	0.73
Slapped you	0.13	0.33	2.23	2.99	0.73
Thrown a hard object at you	0.06	0.24	3.66	11.43	0.65
Grabbed you or pulled your hair	0.08	0.28	3.03	7.18	0.74
Beat you with a fist or a hard object, or kicked you	0.07	0.25	3.50	10.26	0.72
Burned you	0.01	0.09	11.55	131.34	0.27
Tried to suffocate you or strangle you	0.03	0.18	5.25	25.60	0.53
Cut or stabbed you, or shot at you	0.01	0.09	11.37	127.23	0.29
Beat your head against something	0.04	0.18	5.03	23.32	0.60
Sexual Violence (Cronbach's α= .85, McDonald's ω = .88)					
Forced you into sexual intercourse by holding you down or hurting you in some way	0.04	0.19	4.93	22.34	0.73
Attempted to force you into sexual intercourse by holding you down or hurting you in some way	0.04	0.19	4.94	22.44	0.73
Mad you take part in any form of sexual activity when you did not want to or you were unable to refuse	0.04	0.19	4.94	22.42	0.66
Consented to sexual activity because you were afraid of what your current partner might do if you refused	0.05	0.21	4.28	16.35	0.68

Note: M = Mean; SD = Standard Deviation; $r_{item-test}$ = corrected item-test correlation. Skew and kurtosis standard error were below .01.

Figure 1. *Multi-group confirmatory factor analysis: scalar invariance model.*
Note: The standardized factor loadings belong to the reference country (i.e., Denmark). As in the standardized solution the factor variances are fixed to 1, there are slight differences in the decimals of the loadings in each country.

Figure 2. *Physical violence latent means across the EU.*

Abstract

Objectives To ensure the cross-national comparability of the set of questions addressing physical and sexual intimate partner violence against women (IPVAW) included in the European Union (EU) Agency for Fundamental Rights (FRA) survey. Once the measurement invariance of these measures is established, we aim to make appropriate and valid comparisons of the levels of physical and sexual IPVAW across the EU countries.

Design Cross-sectional, population-based study.

Participants Data were drawn from the survey conducted by the FRA on violence against women, including the responses of 42,002 adult women from the 28 countries of the EU.

Main outcome measures The set of questions addressing life-time prevalence of physical and sexual IPVAW used in the FRA survey. The psychometric properties (i.e., reliability and validity) of these measures were examined, as well as their latent structure and their measurement invariance across the 28 EU countries.

Results The physical and sexual IPVAW measures presented adequate internal consistency and validity evidence based on their relations to other variables in all countries. A latent two-factor structure was supported and scalar invariance was established across countries. Our results showed that the average levels of physical and sexual IPVAW were highest in Denmark, Finland, Sweden and United Kingdom compared to the rest of the EU countries. In many of the other countries the levels of these types of violence overlapped, especially in the case of sexual IPVAW.

Conclusions The findings of this study the results of this study showed that the set of questions addressing physical and sexual IPVAW included in the FRA survey can be compared across all EU countries, highlighting the importance of testing the

measurement equivalence of the instruments used in large socio-demographic surveys in order to make valid cross-national comparisons.

Strengths and limitations of this study

- This paper is the first to examine the cross-national comparability of survey data addressing physical and sexual intimate partner violence against women (IPVAW) in all European Union (EU) countries
- Appropriate analyses were applied to examine the psychometric properties, latent structure, and the measurement invariance of the measures included in a large socio-demographic survey on IPVAW
- A latent means analysis was conducted to compare the levels of physical and sexual IPVAW across all EU countries, an approach that takes into account the latent structure of the IPVAW measures and the magnitude of the contribution of each item to the measured construct
- The cross-sectional design of the survey did not allow for testing measurement invariance across different periods of time

Intimate partner violence against women (IPVAW) has been globally recognized as a major public health problem of epidemic proportions.[1] IPVAW is the form of violence most commonly suffered by women,[2-4] and it has severe physical and psychological consequences not only for the well-being of victims and their children, but for society as a whole.[5-9]

According to the survey conducted by the European Union (EU) Agency for Fundamental Rights (FRA), the estimated prevalence of physical and sexual IPVAW in the EU is 22%, varying across countries from 13% to 32%.[10] One of the main strengths of this survey is that women from the 28 EU countries answered the same set of questions assessing different types of IPVAW. However, the measurement equivalence of these questions across the EU countries has not yet been tested. This hampers the generalizability of these cross-national comparisons, as it not possible to ascertain whether the differences in IPVAW prevalence across all EU member states reflect actual differences between countries, or whether they are the result of cultural expectations or beliefs about intimate partner violence that may affect the interpretation of the FRA survey questions.

IPVAW can be a culturally sensitive issue, and how it is perceived, conceptualized and interpreted may vary across countries. Thus, to make valid cross-national comparisons based on survey data addressing IPVAW, it is important to test their measurement invariance.[11-13] Measurement invariance is a crucial prerequisite in cross-national research, since it allows meaningful comparisons across countries ruling out the possibility of cultural bias in the respondents' answers.[14] When measurement invariance is not supported, it means that respondents from different countries interpret and respond differently to the questions, and thus their scores cannot be directly compared.[15 16] If that is the case, it cannot be assumed that IPVAW is interpreted in the

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies. Erasmushogeschool .

same way in all EU member states, since the same score in one country may reflect a different construct or yield different levels of IPVAW in another. Therefore, computing prevalence rates to compare samples from different countries without first ensuring measurement invariance could lead to unreliable and distorted conclusions, as the validity of such comparisons may be questionable.[17] Previous research has already assessed and established the cross-national comparability of the psychological IPVAW across the EU, but this issue still remains unexplored for physical and sexual forms of this type of violence.[18]

The main objective of this study is to ensure the cross-national comparability of the set of questions addressing physical and sexual IPVAW included in the FRA survey, by assessing whether respondents of each country conceptualize and interpret these questions in the same manner. For validity purposes, the relationship of physical and sexual IPVAW to related sociodemographic and background variables (i.e., as self-perceived health, household income, and experiences of child abuse) were tested.[19-20] Once the measurement invariance of these measures is established, we aim to make appropriate and valid comparisons of the physical and sexual IPVAW levels across the EU countries.

Method

Participants

The data were drawn from the FRA survey on violence against women.[10] This survey includes the responses of 42,002 adult women from the 28 EU countries who were currently or had previously been in an intimate relationship. The responses were collected in person through structured interviews and self-reports, following a two-stage clustered stratified sampling design with equal probability of selection of households

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies.
Erasmushogeschool .

within clusters. The average response rate to the survey was 42.1%, ranging from 18.5% in Luxembourg to 84.0% in Hungary. Additional information on sample collection and procedures can be found in the FRA survey technical report.[21] A special license for secondary data analysis was requested and granted from FRA (Reference No. 102577).

The sample used in this study was selected using the answers from respondents who did not omit any of the survey questions addressing physical and sexual intimate partner violence. The final sample is composed of 39,403 women, aged from 18 to 74 years old, from the 28 EU countries. Socio-demographic information of the sample by country is shown in Table 1.

Patient Involvement. Participants were not involved in the design, planning and conduct of this study. Participation in this study was anonymous and informed consent was obtained before conducting the interviews.

[Insert Table 1 around here]

Measures

The measures used in this study were developed by FRA in collaboration with research experts, survey experts, policy makers, practitioners, nongovernmental organizations. All the items included in the questionnaire were translated by experts in the field of IPVAW from English into other languages of the 28 EU member states.[21]

Physical violence. Intimate partner physical violence is addressed in the FRA survey with 10 items describing episodes of physical violence perpetrated by either the current or any previous partner (e.g., "Has your current/previous partner ever slapped you?"). Respondents were asked to indicate how often they had experienced that episode on a 4-point Likert-type scale (1: "Never", 2: "Once", 3: "2-5 times", 4: "6 or more times"). The responses to these items were dichotomized (0: "Never", 1: "Once or more times"), as in some countries the frequencies of the upper categories were very

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

Erasmushogeschool . Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies.

low (i.e., less than 2% when the responses to the "2-5 times" and "6 or more times" categories are collapsed in Austria, Cyprus, Greece, Italy, Latvia, Malta, Slovakia, and Slovenia).

Sexual Violence. The FRA survey included four items addressing sexual violence committed by the current or any previous partner (e.g., "Has your current/previous partner made you take part in any form of sexual activity when you did not want to or you were unable to refuse?"). The response format of the items was a 4-point Likert-type scale indicating frequency (1: "Never", 2: "Once", 3: "2-5 times", 4: "6 or more times"). The responses to these items were also dichotomized (0: "Never", 1: "Once or more times").

Validity evidence based on relations to other variables

To test validity evidence of the physical and sexual IPVAW measures based on relations to other variables,[22] the following variables were used:

Self-perceived health. The respondents were asked to respond about their health in general at the beginning of the interview using a 5-point Likert-type graded scale (from 1 = "Very Bad" to 5 = "Very Good").

Experiences of child abuse. The FRA survey included a set of 11 questions addressing experiences of childhood physical and sexual abuse before the age of 15 (e.g., "did an adult who was 18 years or over hit you very hard so that it hurt?", "did an adult who was 18 years or over expose their genitals to you?"). If any of these questions were answered affirmatively, we considered that the respondent has experienced child abuse during their childhood.

Income. Reported income was measured in each country as household income quartiles (i.e., "below lowest quartile", "between lowest quartile and median", "between median and highest quartile", "above highest quartile").

Erasmushogeschool .

Statistical Analyses

The main purpose of this study was to ensure the measurement equivalence of the physical and sexual violence measures of the FRA survey across the 28 EU member states in order to make appropriate and valid comparisons between these countries. To this end, the psychometric properties (i.e., reliability and validity) and the latent structure of these measures was assessed, and then measurement invariance was tested across the 28 EU countries.

First, the mean, standard deviation, skew, and kurtosis statistics were obtained. The internal consistency of the physical and sexual violence measures in each country was evaluated by computing the Cronbach's α and McDonald's ω, and using the correlation of each item with the rest of its set of questions (i.e., item-test corrected correlation).

Secondly, a confirmatory factor analysis (CFA) was conducted to determine the latent structure of the two IPVAW measures in each country. Two models were compared: a one-factor model, in which all the items loaded onto a single intimate partner violence factor, and a two-factor model, setting one factor for the physical violence items and another one for the sexual violence items. Given the categorical nature of the items, weighted least squares with adjusted means and variances (WLSMV) was used as estimation method.[23] Model fit was evaluated using a combination of fit indices: CFI, TLI, and RMSEA. CFI and TLI values ≥ .95, and RMSEA values ≤ .06 are indicative of good fit.[24 25]

After establishing the factor model, a series of multi-group confirmatory factor analyses (MG-CFA) were carried out, testing three different levels of measurement invariance: configural, metric, and scalar.[12 26] Configural invariance applies the same factor model to all groups (i.e., countries), with no equality constraints for any

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies. Erasmushogeschool .

parameters, ensuring that the same conceptualization of the construct is supported across countries. Metric invariance specifies that the values of the factor loadings are equal across countries, implying that each item is contributing equally and having a similar degree of importance on the factor in all the countries. Scalar invariance holds both factor loadings and item thresholds to be invariant, ensuring that respondents from different countries with the same response pattern on the items will yield the same factor score. If scalar invariance is supported, then the scores on the physical and sexual IPVAW measures can be compared across countries.

To assess which of these invariance levels was best supported by the data, the change in the CFI (ΔCFI) and RMSEA (ΔRMSEA) fit indices was computed, following the general guidelines of Cheung and Rensvold.[27] These guidelines, however, were developed for continuous data, and as Saas, Schmidt and Marsh noted,[28] the interpretation of these fit indices should be taken with caution in the case of categorical data. For this reason, instead of Chen's usual cut-off values for the changes in CFI and RMSEA (i.e., $\Delta CFI \leq .010$ and $\Delta RMSEA \leq .015$),[29] we used the cut-offs values proposed by Meade, Johnson, and Brady: $\Delta CFI \leq .002$ and $\Delta RMSEA \geq -.007$.[30] These cut-offs are more restrictive and tend to perform as well as maximum-likelihood based procedures when the sample size is large and the items are not normally distributed.[28] This approach has also been used to assess the measurement invariance of the set of questions addressing psychological IPVAW in the FRA survey.[18]

Having established an invariant factor model, validity evidence based on relations to other variables was tested using the invariant factor scores of the IPVAW measures. A one-way ANOVA was computed for both physical and sexual violence measures of the FRA survey, testing differences by self-perceived health, experiences of child abuse, and income. These analyses were conducted for the total sample to avoid

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

Erasmushogeschool . Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies.

type I errors. The size effect of the variables was assessed with the partial eta-squared statistic, using values above .01, .06, and .14, as indicative of small, medium, and large size effects, respectively.[31]

Finally, after determining that both physical and sexual IPVAW measures were psychometrically sound and share an invariant latent structure in all EU countries, the factor means of physical and sexual IPVAW were compared across countries conducting a latent means analysis. This procedure is more appropriate and statistically sophisticated than simply computing the average prevalence for each country, as it does not assume that all the items have the same relevance to assess the construct and, moreover, it takes into account all the constraints for the invariant measurement model.[16 17 26] The magnitude of these cross-national comparisons was evaluated using Cohen's *d* statistic, indicating *d* values above .20, .50, and .80, small, medium and large size effects, respectively.[32] This statistic can be used to obtain the Cohen U_3 statistic, which indicates the percentage of cases of one country that is higher than the average of another.[33-35] The Cohen's *d* and U_3 statistics of the comparisons between each pair of countries can be found in the supplementary material (file 1).

Descriptive analyses, internal consistency, and validity analyses were conducted using the statistical package R and the *psych* library.[36 37] CFA and MG-CFA analyses were computed using *Mplus 7*.[38]

Results

Descriptive Analysis and Internal Consistency

Descriptive statistics of the physical and sexual violence measures are presented in Table 2. All the items showed mean values close to zero, and high skew and kurtosis values, especially in the sexual violence measure, indicating that most of the

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

Erasmushogeschool . Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies.

respondents reported having no experience of the episodes described by the items. The corrected item-test correlations were in general high, pointing to a strong relationship between the items and the rest of the questions. Regarding the internal consistency, both measures showed an adequate internal consistency in the complete dataset, with alpha and omega values above.70. Separating the sample by countries yields similar results in both the physical violence and sexual violence measures (ranging, respectively, from α=. 84 in Sweden to α=. 90 in Ireland and Lithuania, and from α = .69 in Slovenia to α = .91 in the Netherlands).

[Insert Table 2]

The items 7 and 9 of the physical violence measure presented an extremely low variance (i.e., "being burned", and "being cut, stabbed or shot"), below 0.01. Given this lack of variability, we decided to remove these items from this measure. As a result, the Cronbach's alpha of the physical violence measure increased to.89 (ranging from α = .84 in Slovenia to α = .92 in Romania and Lithuania), and McDonald's omega increased to .92.

Confirmatory Factor Analysis

Two CFA solutions were tested separately in each country: a one-factor model, assuming that all the items load onto a single IPVAW factor, and a two-factor model, setting one separate factor for the physical and sexual violence items (Table 3). The CFI and TLI indices were excellent for both the one- and two-factor models, with values around .98 and .99 in all 28 EU countries, respectively. However, the residuals for the one-factor model were above the RMSEA ≤ .06 cut-off criterion for a well-fitting model in Belgium, Demark, Finland, France, Germany, Latvia, the Netherlands, Portugal, Sweden, and United Kingdom (the highest was Denmark, with .077, and the closest to the cut-off was Portugal, with .061), whereas in the two-factor model the RMSEA were

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies.
Erasmushogeschool .

below this cut-off (the highest was .031 in Denmark and the lowest, .011 in Poland). For this reason, we kept the two-factor model as the latent structure of the physical and sexual IPVAW measures.

[Insert Table 3]

Measurement Invariance

The analysis of measurement invariance supported the configural, metric, and scalar invariance levels for the physical and sexual violence measures across all EU countries (Table 4). Attending to the fit indices, when the loadings were fixed to have the same value across all countries they did not differ substantially from the configural model (ΔCFI = .002, ΔRMSEA = -.006), supporting the metric invariance level. In the same direction, constraining the item thresholds as well as the item loadings did not substantially reduce the fit of the model (ΔCFI = .002, ΔRMSEA = -.006), indicating that the scalar invariance level could hold.

[Insert Table 4]

The resulting item parameters are displayed in Figure 1. All the items presented high standardized loadings, indicating a strong relationship of the items to the factor. The correlation between factors varies across countries, as the factor covariance matrix was freed in each country. The value for this correlation was around .75 in most of the countries, ranging from .56 in Denmark to .91 in Croatia. The model parameters for all countries can be found in the supplementary material (file 2).

[Insert Figure 1]

Validity evidence based on relations to other variables

The factor scores of the invariant model were used for the validity analyses in all countries. Significant and substantive differences were found in the physical IPVAW scores when self-perceived health ($F(4) = 94.0$, $p < .001$, $\eta^2 = .01$), experiences of child

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies. Erasmushogeschool .

abuse ($F(1) = 984.7$, $p < .001$, $\eta^2 = .03$), and income ($F(1) = 127.3$, $p < .001$, $\eta^2 = .01$) were taken into account, showing that women with higher scores on the physical IPVAW factor had lower self-perceived health levels, lower income and experiences of child abuse.

In the case of the sexual IPVAW factor scores, substantive differences were also found in self-perceived health ($F(4) = 82.6$, $p < .001$, $\eta^2 = .01$), experiences of child abuse ($F(1) = 311.4$, $p < .001$, $\eta^2 = .03$), and income ($F(1) = 113.4$, $p < .001$, $\eta^2 = .01$). These differences were in the same direction as in the physical IPVAW, as the women with higher scores on the sexual IPVAW factor presented lower self-perceived health levels, lower income, and experiences of child abuse.

Latent Means Analysis

After determining that the physical and sexual IPVAW measures are psychometrically sound, and after ensuring their measurement equivalence across all EU countries, the means of the physical and sexual violence factors can now be compared by conducting a MG-CFA. Denmark was used as the reference group, as it was one of the countries presenting the highest levels of physical and sexual IPVAW. The factor means for Denmark were fixed to zero and their variances fixed to one. In the rest of the countries these parameters were freely estimated. In this way, the estimated mean parameter of the standardized solution represents the difference in factor means between each country and Denmark. The resulting model presented a very good fit to the data (CFI = .997, TLI = .997, RMSEA = .027 [.026 - .029]). The standardized factor means for each country are displayed in Figures 2 and 3.

[Insert Figure 2]

Although Denmark was the country with the highest levels of physical IPVAW, the differences between this country and Latvia ($z = -0.01$, $p = .850$, $d = 0.01$), Finland

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies. Erasmushogeschool .

(z = -0.04, p = .587, d = 0.04), United Kingdom (z = -0.12, p = .059, d = 0.13), and Sweden (z = -0.12, p = .115, d = 0.12) were negligible, with Cohen's d values below .20. Large substantive differences were found between Denmark and Ireland (z = -0.70, p < .001, d = 0.85), Slovenia (z = -0.75, p < .001, d = 0.84), Spain (z = -0.75, p < .001, d = 0.86), Cyprus (z = -0.77, p < .001, d = 0.94), and Poland (z = -0.79, p < .001, d = 0.96).

It should be noted that the confidence intervals (CI) of the physical IPVAW factor means overlapped between many of the EU countries, indicating no significant differences between them. However, the countries could be grouped according to the confidence intervals. Thus, countries whose factor mean falls within the CI of Latvia showed on average higher levels of physical IPVAW (Denmark, Finland, United Kingdom, and Sweden). On the other hand, countries with factor means falling within the CI of Poland—the country with the lowest factor mean—presented lower levels of physical IPVAW (Ireland, Slovenia, Spain, and Cyprus). The rest of the countries fell somewhere in between, with some countries like Lithuania or the Netherlands closer to the countries with higher levels of physical IPVAW, and others such as Greece or Italy closer to the countries with lower levels.

Regarding the sexual IPVAW measure, the countries with higher latent means in this factor were, along with Denmark, Finland (z = 0.00, p = .986, d = 0.00), Sweden (z = -0.10, p = .537, d = 0.10), Luxembourg (z = -0.31, p = .082, d = 0.34), Bulgaria (z = -0.32, p = .072, d = 0.34), and Slovenia (z = -0.34, p = .130, d = 0.32). Large differences in the sexual IPVAW factor were found between Denmark and Lithuania (z = -0.87, p < .001, d = 1.06), Croatia (z = -0.88, p < .001, d = 1.04), Austria (z = -0.90, p < .001, d = 1.13), Ireland (z = -0.97, p < .001, d = 1.29), Romania (z = -0.98, p < .001, d = 1.24), Poland (z = -1.04, p < .001, d = 1.31), Spain (z = -1.07, p < .001, d = 1.32), Greece (z = -

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies. Erasmushogeschool .

1.08, $p < .001$, $d = 1.39$), Portugal ($z = -1.12$, $p < .001$, $d = 1.43$), and Cyprus ($z = -1.97$, $p < .001$, $d = 1.71$).

[Insert Figure 3]

The CI of the sexual IPVAW factor means were, however, much wider than in the case of physical IPVAW, as this measure is comprised of only four items. As a result, most of the countries' factor means CI greatly overlapped. In this case the CI of Finland was used to group the countries that tend to present higher levels of sexual IPVAW (Denmark, Sweden, Belgium, Luxembourg, United Kingdom, and Slovenia), whereas the CI of Cyprus was used to delimit those countries with lower levels in this factor (Portugal, Greece, Spain, and Poland). The rest of the countries fall into the intermediate area, with some countries such as France and Germany nearer to the countries with higher levels of sexual IPVAW, and others like Romania and Ireland closer to the countries with lower levels of this type of violence. Italy was in the middle of the distribution, and was the only country whose CI did not overlap with the intervals for either Finland or Cyprus.

Comparisons of the physical and sexual IPVAW factor scores can also be made between each pair of countries. For instance, we compare Finland—one of the countries with highest levels of physical and sexual IPVAW—with the Netherlands and Spain—countries with moderate and low levels of both types of IPVAW, respectively. The differences between Finland and the Netherlands were small in the case of physical IPVAW, showing that 59.9% of the Finnish sample had higher values in this factor than the average of the Dutch sample ($d = 0.24$, $U_3 = .595$). Medium differences were found in the case of sexual IPVAW, as 72.6% of the Finnish sample presented higher scores in the sexual IPVAW factor than the average of the Dutch sample ($d = 0.60$, $U_3 = .726$). When Finland is compared to Spain, large differences were found in both factors:

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies. Erasmushogeschool .

79.1% of the Finnish sample presented higher values in the physical IPVAW factor than the average of the Spanish sample (d = 0.81, U_3 = .791), and 90.7% in the case of sexual IPVAW (d = 1.32, U_3 = .907). The comparisons between each pair of countries together with their associated size effect can be found in the supplementary material (file 1).

Discussion

In this measurement invariance study, we conducted a set of analyses to ensure the cross-national comparability of the questions addressing physical and sexual IPVAW used in the FRA survey, and examined how physical and sexual IPVAW levels were distributed across all EU countries.

The first set of analyses aimed to study the psychometric properties (i.e., reliability and validity) of the questions addressing physical and sexual IPVAW across the EU. Our results showed that the measures of the FRA survey were measuring two different constructs: physical and sexual IPVAW. The two factors were related and showed an adequate internal consistency in all EU countries (with α and ω values above .70 in almost all countries). Regarding the validity evidence based on relations with other variables, we found, as expected, that women who reported having experiences of child abuse were more likely to show higher levels of physical and sexual IPVAW. This finding is consistent with previous research showing that women who were victimized in childhood have a higher risk of being victimized during adulthood.[39-44] In addition, we found that the women presenting higher levels of physical and sexual IPVAW also reported lower levels of self-perceived health and income, a well-established finding in the IPVAW literature.[45-49]

The second set of analyses aimed to address the comparability of the physical and sexual IPVAW measures across the 28 EU countries, to rule out the possibility of

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies. Erasmushogeschool .

measurement bias. To do so, a series of MG-CFA analyses were conducted to test and establish measurement invariance. Although previous studies have acknowledged the difficulties in establishing the metric or scalar invariance levels when several groups are used,[14 50 51] we were able to demonstrate scalar invariance (i.e., equal factor loadings and thresholds) across the 28 EU countries. This means that is possible to exclude the country as a biasing variable, which in turn suggest that the respondents conceptualized and interpreted the physical and sexual IPVAW measures included in the FRA survey in a similar way across countries.[52 53] This finding may be due to the type of questions included in the FRA survey, as they are mostly behavioral oriented (e.g., being stabbed, cut, slapped, or being forced into sexual intercourse).

Once an invariant model had been established for the physical and sexual IPVAW measures, we were able to make proper comparisons between countries. Instead of computing the prevalence using the set of questions from the FRA survey, an approach that ignores the latent structure of the IPVAW measures and the magnitude of the contribution of each item to the construct, we conducted a latent means analysis, comparing the factor means of each country.[12 15 16] This is one of the main strengths of this study, and our findings suggest that there were almost no differences between many of the EU countries, since their confidence intervals overlapped considerably, implying that the levels of sexual and physical IPVAW were fairly similar between them. There were, however, substantial differences between the countries with higher levels of physical and sexual IPVAW and those with lower levels. In particular, countries such as Denmark, Finland, Sweden, and United Kingdom showed on average higher levels than countries like Cyprus, Poland, and Spain. These findings are in line with what is known as the Nordic paradox, as Denmark, Finland, and Sweden—countries with the highest

For peer review only - http://bmjopen.bmj.com/site/about/guidelines.xhtml

Erasmushogeschool . Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies.

levels of gender equality in the EU—were among the countries with highest levels of physical and sexual IPVAW.[54 55]

This study has some limitations. First, we used WLSMV as the estimation method for the measurement invariance analysis due to the asymmetrical distribution of the responses to the set of questions included in the FRA survey. According to Sass, Schmitt, and Marsh,[28] the use of fit indices with this method to test measurement invariance could lead to higher rates of Type I errors, assuming an invariant model when actually the instrument is non-invariant. To address this issue, we decided to use the cut-offs proposed by Meade et al. for the CFI and RMSEA,[30] as they are more restrictive than those of Chen.[29] Second, in this case, chi-squared based tests to compare the different levels of measurement invariance could not be used in conjunction with the fit indices, since this statistic is known to be sensitive to large sample sizes. Third, the cross-sectional design of the survey did not allow for testing measurement invariance across different periods of time. Fourth, the wide range of the confidence intervals of the physical and sexual IPVAW factor means suggest that the measures included in the FRA survey could be improved in order to obtain more accurate and reliable estimations of the IPVAW levels, especially in the case of sexual IPVAW. Fifth, self-selection bias is another potential issue, since only a 42% of the respondents agreed initially to be interviewed. This is also reflected in the wide variability in the response rates across the EU countries, with some countries presenting response rates lower than 30% (e.g., Luxembourg, Netherlands, or Sweden), whereas others showed response rates above 60% (e.g., Cyprus, Hungary, or Latvia).[24] Finally, future research could also examine the relationship of physical and sexual IPVAW to other IPVAW measures included in the survey, such as psychological IPVAW, sexual harassment, or stalking behavior.[18]

Taken together, the results of this study showed that the set of questions addressing physical and sexual IPVAW included in the FRA survey can be compared across all EU countries. Although more research is still needed to assess the relevance that the country may have in accounting for the differences of physical and sexual IPVAW across the EU,[56] this study constitutes an important advance towards a more accurate evaluation of cross-national differences in physical and sexual IPVAW, highlighting the importance of testing the measurement equivalence of the instruments used in large socio-demographic surveys in order to make valid cross-national comparisons.

Contributors. MM-F designed the analytic strategy, conducted the statistical analysis and wrote the manuscript. EG conceived the study, supervised the writing of the manuscript, and acquired the funding and the FRA special license. ML supervised the writing of the manuscript, and acquired the funding.

Funding. This research was supported by Grants PSI2017-84764-P (EG, ML), and BES-2015-075576 (MM-F) from the Spanish Ministry of Economy and Competitiveness (http://www.mineco.gob.es/).

Competing interests. None declared.

Ethics approval. The European Union Agency for Fundamental Rights supervised and approved the secondary data analyses conducted in this study, as well as the study design, granting a special license for this purpose (reference number 102577).

Data sharing statement. The data set used for the results presented in this manuscript are available from the UK Data Service (https://www.ukdataservice.ac.uk). The dataset details are the following: Title: European Union Agency for Fundamental Rights:

Table 2. Psychometric properties of the Physical Violence and Sexual Violence measures.

	M	SD	Skew	Kurtosis	$r_{item\text{-}test}$
Physical Violence (Cronbach's α= .87, McDonald's ω = .90)					
Threatened to hurt you physically	0.14	0.35	2.05	2.18	0.70
Pushed you or shoved you	0.16	0.36	1.88	1.53	0.73
Slapped you	0.13	0.33	2.23	2.99	0.73
Thrown a hard object at you	0.06	0.24	3.66	11.43	0.65
Grabbed you or pulled your hair	0.08	0.28	3.03	7.18	0.74
Beat you with a fist or a hard object, or kicked you	0.07	0.25	3.50	10.26	0.72
Burned you	0.01	0.09	11.55	131.34	0.27
Tried to suffocate you or strangle you	0.03	0.18	5.25	25.60	0.53
Cut or stabbed you, or shot at you	0.01	0.09	11.37	127.23	0.29
Beat your head against something	0.04	0.18	5.03	23.32	0.60
Sexual Violence (Cronbach's α= .85, McDonald's ω = .88)					
Forced you into sexual intercourse by holding you down or hurting you in some way	0.04	0.19	4.93	22.34	0.73
Attempted to force you into sexual intercourse by holding you down or hurting you in some way	0.04	0.19	4.94	22.44	0.73
Mad you take part in any form of sexual activity when you did not want to or you were unable to refuse	0.04	0.19	4.94	22.42	0.66
Consented to sexual activity because you were afraid of what your current partner might do if you refused	0.05	0.21	4.28	16.35	0.68

Note: M = Mean; SD = Standard Deviation; $r_{item\text{-}test}$ = corrected item-test correlation. Skew and kurtosis standard error were below .01.

Figure 1. *Multi-group confirmatory factor analysis: scalar invariance model.*
Note: The standardized factor loadings belong to the reference country (i.e., Denmark). As in the standardized solution the factor variances are fixed to 1, there are slight differences in the decimals of the loadings in each country.

Figure 2. *Physical violence latent means across the EU.*
Note: AT: Austria, BE: Belgium, BG: Bulgaria, CY: Cyprus, CZ: Czech Republic, DK: Denmark, EE: Estonia, FI: Finland, FR: France, DE: Germany, EL: Greece, ES: Spain, HR: Croatia, HU: Hungary, IE: Ireland, IT: Italy, LT: Lithuania, LV: Latvia, LU: Luxembourg, MT: Malta, NL: Netherlands, PL: Poland, PT: Portugal, RO: Romania, SE: Sweden, SI: Slovenia, SK: Slovakia, UK: United Kingdom. Denmark is the reference country.

Figure 3. *Sexual violence factor means across the EU.*

STROBE 2007 (v4) Statement—Checklist of items that should be included in reports of *cross-sectional studies*

Section/Topic	Item #	Recommendation	Reported on page #
Title and abstract	1	(*a*) Indicate the study's design with a commonly used term in the title or the abstract	2
		(*b*) Provide in the abstract an informative and balanced summary of what was done and what was found	2
Introduction			
Background/rationale	2	Explain the scientific background and rationale for the investigation being reported	4-5
Objectives	3	State specific objectives, including any prespecified hypotheses	5
Methods			
Study design	4	Present key elements of study design early in the paper	5
Setting	5	Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection	5
Participants	6	(*a*) Give the eligibility criteria, and the sources and methods of selection of participants	6
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable	6-7
Data sources/ measurement	8*	For each variable of interest, give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group	6-7
Bias	9	Describe any efforts to address potential sources of bias	8-10, 12-13
Study size	10	Explain how the study size was arrived at	5
Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen and why	7-10
Statistical methods	12	(*a*) Describe all statistical methods, including those used to control for confounding	7-10
		(*b*) Describe any methods used to examine subgroups and interactions	10, 12
		(*c*) Explain how missing data were addressed	6-7
		(*d*) If applicable, describe analytical methods taking account of sampling strategy	Not applicable
		(*e*) Describe any sensitivity analyses	Not applicable
Results			

For peer review only

.136/bmjopen-2019-032231 on 4 March 2020. Downloaded from http://bmjopen.bmj.com/ on April 25, 2025 at Department GEZ-LTA Erasmushogeschool . d by copyright, including for uses related to text and data mining, AI training, and similar technologies.

Participants	13*	(a) Report numbers of individuals at each stage of study—eg numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow-up, and analysed	5
		(b) Give reasons for non-participation at each stage	5
		(c) Consider use of a flow diagram	Not applicable
Descriptive data	14*	(a) Give characteristics of study participants (eg demographic, clinical, social) and information on exposures and potential confounders	5, 26
		(b) Indicate number of participants with missing data for each variable of interest	5-6
Outcome data	15*	Report numbers of outcome events or summary measures	10, 27
Main results	16	(*a*) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (eg, 95% confidence interval). Make clear which confounders were adjusted for and why they were included	10, 27
		(*b*) Report category boundaries when continuous variables were categorized	13-15
		(*c*) If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period	Not applicable
Other analyses	17	Report other analyses done—eg analyses of subgroups and interactions, and sensitivity analyses	10-12
Discussion			
Key results	18	Summarise key results with reference to study objectives	16-17
Limitations	19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias	18
Interpretation	20	Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of analyses, results from similar studies, and other relevant evidence	18
Generalisability	21	Discuss the generalisability (external validity) of the study results	16
Other information			
Funding	22	Give the source of funding and the role of the funders for the present study and, if applicable, for the original study on which the present article is based	19

*Give information separately for cases and controls in case-control studies and, if applicable, for exposed and unexposed groups in cohort and cross-sectional studies.

Note: An Explanation and Elaboration article discusses each checklist item and gives methodological background and published examples of transparent reporting. The STROBE checklist is best used in conjunction with this article (freely available on the Web sites of PLoS Medicine at http://www.plosmedicine.org/, Annals of Internal Medicine at http://www.annals.org/, and Epidemiology at http://www.epidem.com/). Information on the STROBE Initiative is available at www.strobe-statement.org.
