

Abstracts

Conclusions This analysis indicates that PI is a valid and reliable instrument which can be effectively used to monitor safety conditions at workplaces.

270 HEALTH AND SAFETY EXPERIENCE OF COMMERCIAL JANITORS

¹S Seixas, ¹Simcox, ¹Dominguez, ¹Stover, ²Crain. ¹University of Washington, Seattle, United States of America; ²Portland State University, Portland, United States of America

10.1136/oemed-2013-101717.270

Commercial janitors are an important group of low wage, largely immigrant workers who face significant potential risks at work, and yet have only been minimally studied for occupational injury and illness. Anecdotal reports from a local union representing commercial janitors in the Seattle area suggest pressures on the industry have produced a dramatic increase in workload over the past few years, raising the possibility of increased injury and illness. A cross sectional survey was designed to assess a range of exposures among commercial janitors including both union (n = 275) and non-union (n=75) sectors, and using a group of security guards (n=75) as controls. A novel participatory approach to data collection was developed, utilising workers to recruit subjects and conduct interviews in three languages, using electronic data collection tools linked to an internet-based database. Further, a novel subjective workload scale was adopted, and changes in workload and injury and illness rates over the past three years were assessed. Exposures assessed include general workload, musculoskeletal stressors, chemical use, as well as psychosocial risks such as work stress, safety climate, discriminatory management practices and work-life balance. Outcomes included acute injury, musculoskeletal pain, pulmonary and dermatological symptoms, and sleep disturbance. Initial results indicate a significant increase in workload with 28.5% reporting >7 on a 10 point scale two years ago, up to 35% in the current year. A concomitant increase in injuries was similarly observed. The paper describes the approach to data collection and describes rates of exposure and health and safety outcomes by group. Measures adopted to validate the self-reported conditions are also described.

271 CADMIUM EXPOSURE AND ANEMIA RISK IN AN ELECTROPLATING INDUSTRY AREA WITH METAL CONTAMINATION

¹J H Lee, ¹Chen, ²Chang, ¹Chang, ¹Chuang, ¹Liou, ¹Wang. ¹National Health Research Institutes, Zhuna, Taiwan; ²Department of Information Management, Tzu Hui Institute of Technology, Pingtung, Taiwan

10.1136/oemed-2013-101717.271

Background and Objective Cadmium (Cd) exposure, like Itai-itai disease, may present with erythropoietin (EPO) hypoproduction, and associated erythroid abnormalities. Anemia may be associated with toxic metal (Cd and lead) poisoning with interaction with essential trace elements (iron, zinc, copper) in humans. We aimed at assessing the relationship among erythrocyte parameters (EP), anemia (hemoglobin < 12 g/dL) and blood Cd (B-Cd) among adult residents in an environmentally high-exposed community near electroplating industry area.

Methods A total of 1,062 residents were included through stratified random sampling by three age groups (35–44, 45–54, and

55–64 years) and gender from an electroplating-related metal contaminated area located in central Taiwan during 2002–2005. B-Cd levels were measured by an ELAN 6100 inductively coupled plasma-mass spectrometer (ICP-MS). Multiple logistic regression models were used for test the association between anemia and B-Cd with serum ferritin taken into account.

Results B-Cd levels was negatively associated with the red blood cell (RBC) count, mean cell hemoglobin (MCH), and mean cell hemoglobin concentration (MCHC) (all $p < 0.01$). Odds ratio (OR) of anemia was 2-fold higher (OR = 2.03, $p < 0.05$) for females with elevated B-Cd (> 1.5 µg/L) in logistic regression with adjustment for age, ferritin, estimated glomerular filtration rate, and 2-microglobulin (B2MG). Females with B-Cd > 1.5 µg/L and B2MG > 80 µg/L were associated with the highest risk of anemia (OR = 6.69, $p = 0.001$) as compared to those at lower levels. We observed a positive association between log-scale B-Cd and hemoglobin among female with serum ferritin ≥ 50 µg/L.

Conclusions Our findings suggest that low Cd exposure from environmental contamination may have negative impacts on RBC indices, particularly among females. We hypothesised that Cd might induce erythrocyte dysfunction locally on peritubular interstitial cells of renal cortex responsible for EPO production possibly through iron-related oxidative stress. Further studies are needed to elucidate the pathophysiologic mechanism between Cd interacting with body iron on erythropoiesis.

Session: 9. Asbestos and mesothelioma

272 ESTIMATING HEALTH EFFECTS OF ASBESTOS EXPOSURE IN THE CONSTRUCTION INDUSTRY

G Järnholm, B A Englund. Umeå university, Umeå, Sweden

10.1136/oemed-2013-101717.272

Objectives The use of asbestos in the construction industry stopped in mid 1970s in Sweden, but is still in use in some countries. The exposure may vary depending on time, country and occupation. We studied the occurrence of malignant pleural mesothelioma as a marker of asbestos exposure and compared it to the workers own estimation of asbestos exposure.

Methods The incidence of malignant pleural mesothelioma was studied among men in a Swedish cohort (N = 367,568) between 1972 and 2009. They reported the exposure to asbestos in early 1970s during a health examination.

Results Insulators and plumbers had the highest incidences (39 and 16 cases per 100,000 person-years respectively) and constituted 21% of all cases. Electricians and sheet metal workers had and incidence around 10 cases per 100,000 persons-years, while concrete workers and wood workers had an incidence of around 5 cases per 100,000 person-years. The correlation was poor between the incidences and reporting any previous exposure to asbestos among men in these occupations, e.g. in the early 1970s only 7% of the concrete workers but 50% of the wood workers reported any previous exposure to asbestos. The corresponding figure for insulators was 34%.

Conclusions The study shows that construction workers constituted a considerable proportion of the malignant pleural mesotheliomas in Sweden (30–40% in 2000–2009). The analysis indicates that many workers were unaware of their exposure to asbestos. Reports of previous asbestos exposure from workers in this industry are uncertain measures of exposure which is

important in compensation cases. The cause is probably a considerable indirect exposure.

273 THE LATENCY PERIOD OF MESOTHELIOMA AMONG A COHORT OF BRITISH ASBESTOS WORKERS (1978–2005)

G F Frost, Harding. *Health & Safety Laboratory, Buxton, United Kingdom*

10.1136/oemed-2013-101717.273

Objectives To investigate the hypothesis of an inverse relationship between intensity of asbestos exposure and mesothelioma latency among a cohort of asbestos workers in Britain.

Methods The Great Britain (GB) Asbestos Survey recruited asbestos workers attending medical examinations as required under the asbestos regulations in GB. Job details and smoking information were updated at any subsequent examinations. The primary outcome for this analysis was the time from first occupational exposure to asbestos to death with mesothelioma. Univariable and multivariable generalised gamma accelerated failure-time (AFT) models were used to estimate time ratios (TRs). Those who died with mesothelioma between 1978 and 2005 were included in the analysis.

Results After exclusions for missing data, there were 614 workers in the GB Asbestos Survey who died with mesothelioma between 1978 and 2005. Total follow-up time was 9,280 person-years, with a median latency of 22.8 years [95% confidence interval (CI) 16.0–27.2 years]. In the final multivariable AFT model, mesothelioma latency was around 26% longer for females compared to males (TR = 1.26, 95%CI = 1.15–1.37), and 5% shorter for those who died with asbestosis compared to those who did not (TR = 0.95, 95%CI = 0.91–0.99) after adjustment for year of first exposure, age at first exposure, and duration of exposure. There was no evidence of associations between mesothelioma latency and occupation, smoking status and mesothelioma type in either univariable or multivariable analyses.

Conclusions The associations between mesothelioma latency and both sex and presence of asbestosis were in the directions expected if the intensity hypothesis was true. However, there was no evidence that asbestos insulation workers, who tended to experience greater asbestos exposures than other occupations, had shorter latencies than other asbestos workers. Therefore this study did not find sufficient evidence to either support or refute the intensity hypothesis. © Crown Copyright (2012).

274 BIOMARKERS FOR PLEURAL MESOTHELIOMA IN THE MEXICAN INSTITUTE SOCIAL SECURITY

CINVESTAV. Depto Toxicología, México, DF, Mexico

10.1136/oemed-2013-101717.274

Objective Developing a new diagnostic strategy for Malignant Pleural Mesothelioma measuring soluble proteins in plasma and pleural fluid using ELISA and qRT-PCR.

Methods Case-control study, in which the cases were incident patients with malignant pleural mesothelioma in two hospitals from Mexican Social Security (Neumology and Oncology) and there were 4 controls for each case. A questionnaire was applied for asbestos exposure. ELISA with double antibody was used to

determine the presence of thrombomodulin and mesothelin, using known concentration curves for each one. An statistical descriptive analysis was made as well as logistic regression models and ROC curves.

Results In this study were enrolled 35 cases and 136 controls. The mean concentrations, (SD) and [min-max] in plasma for thrombomodulin were: 10.2 (7) ng/mL [1.6–32.2] for the cases, and 5.4 (5.1) ng/mL [0.78–32.5] for the controls. For mesothelin values were: 104.3 (78.2) ng/mL, [12.2–351.2] for the cases, and 25.2 (3.2) ng/mL, [6.5–330.3] for the controls. Both biomarkers were statistically significant. In the ROC curve for both biomarkers sensibility of 82.3% and specificity of 95.5% were achieved. In the nonconditional logistic regression model, mesothelin and thrombomodulin had an OR = 1.03 (CI: 1.02–1.05) and OR = 1.08 (CI: 1.01–1.16), respectively, adjusted for age and sex.

Conclusions A unique parameter to evaluate a diagnostic test in every situation doesn't exist, but following Sackett and Álvarez-Cáceres guidelines, our two biomarkers have a high specificity (95.5%) and sensibility (82.35%) with a cut-off point, in this sample, ≥83 ng/mL for mesothelin and ≥10.5 ng/mL. Nevertheless we consider that our sample is small and that we also need to control the factors, such as diabetes mellitus, hypercholesterolemia and renal failure, that have influence in the level of both biomarkers.

275 OCCUPATION AND MESOTHELIOMA IN PLEURA AND PERITONEUM IN SWEDEN - UPDATED INCIDENCE FOR MALES AND FEMALES 1961–2009

¹N P Plato, ¹Weiderpass, ¹Sparren, ²Martinsen. ¹Karolinska Institutet, Stockholm, Sweden; ²Cancer Registry of Norway, Oslo, Norway

10.1136/oemed-2013-101717.275

Objectives Mesothelioma incidence increased in Sweden between years 1970 and 2000, and seems to have reached a plateau in the last decade. We used data from the Swedish component of the Nordic Occupational Cancer Study - NOCCA - to study potential occupational exposures other than asbestos that may be associated with mesothelioma occurrence in men and women.

Methods Follow up was done by linkages of the Swedish NOCCA study database, including 53 occupational categories, with the population based Swedish registries (cancer, mortality, total population) from years 1961 to 2009, and matched with the Swedish version of NOCCA-JEM, which include 25 carcinogenic substances with exposure levels for 283 occupations in different employment periods from year 1945 to 1994. Multivariate analysis with 20 years delay for cumulative exposure were done.

Results A total of 4180 incident mesothelioma of the peritoneum and pleura were reported to the Swedish Cancer Registry (1961 - 2009): 26.6% were women. 83.9% were located in the pleura (18% women). We found a significant over risk in mesothelioma in 16 of 53 occupational categories, and a clear gender difference. We observed increased risk of mesothelioma among female textile workers, building cleaners, seamstresses, printers, packers and postal workers. Men had over risks in construction workers, electricians, masons, and insulation workers; the greatest excess risk of pleural mesothelioma was observed among plumbers (SIR 5.1, 95% CI 4.30 to 6.01). In multivariate analysis, controlling for other occupational exposures, significant associations were observed for asbestos exposure and mesothelioma risk.

Conclusion Exposure to asbestos is associated with incidence of mesothelioma in Sweden. There were some occupations
