

1

**ONLINE SUPPLEMENT**

2    **TRPC6 inhibitor (BI 764198) to reduce risk and severity of ARDS due to COVID-19: a Phase**  
3    **II randomised controlled trial**

4    Lorraine B. Ware, Nima Soleymanlou, Danny F. McAuley, Vicente Estrada, George A. Diaz,

5    Peter LaCamera, Renee Kaste, Wansuk Choi, Abhya Gupta, Tobias Welte

## 6 **Supplementary Methods**

### 7 **Exclusion criteria**

8 The exclusion criteria included: pulmonary oedema/respiratory failure due to cardiogenic  
9 insult; long-term oxygen therapy prior to current hospitalization; a history of cardiac  
10 conditions (myocardial infarction <3 months prior to first dose, unstable angina, and/or a  
11 prolonged QTc interval [as observed on an electrocardiogram or a family history of this]);  
12 received experimental, or off-label usage of, medicinal products as specific treatments for  
13 COVID-19; or any confounding condition.

### 14 **Screening and dosage**

15 Patients who are already hospitalised for COVID-19 were identified and screened. For  
16 patients who met the inclusion criteria, a confirmatory SARS-CoV-2 test (confirmed by  
17 polymerase chain reaction or an approved point-of-care test) was performed during the  
18 screening period (Day -3 to Day 1), after which study medication was administered on Day  
19 1. Efforts were made to minimise the time between patient identification, screening and  
20 treatment initiation. Patients received daily BI 764198 or placebo in the form of an oral  
21 capsule or, only if needed, via nasogastric intubation, following overnight fasting and 1.5  
22 hours prior to breakfast. Dose reductions or down-titrations were not permitted; however,  
23 trial treatment could be restarted following a temporary reason for treatment  
24 discontinuation. Drug administration was in-hospital and overseen by the clinical staff. For  
25 each dose of BI 764198 or placebo administered, the date, time and route (orally or via  
26 nasogastric intubation) was recorded in the electronic care report forms (eCRFs). Any  
27 missed doses were also recorded in the eCRFs.

## 28    **Clinical, physiology and adverse events monitoring**

29    Assessments of concomitant therapy and procedures, hospitalization status, WHO Clinical  
30    Progression Scale, ventilation and oxygen parameters (respiratory rate, fraction of inspired  
31    oxygen [FiO<sub>2</sub>], oxygen saturation [SpO<sub>2</sub>]) and blood gases/partial pressure of oxygen (PaO<sub>2</sub>)  
32    (if captured as part of routine care) were carried out daily until hospital discharge (up to Day  
33    28). All except blood gases/PaO<sub>2</sub> were also carried out during follow-up. Adverse events  
34    (AEs) were recorded daily and by telephone call following discharge from hospital 4 days  
35    after the end of treatment and on Days 15, 29, 60 and 90 (counted from Day 1 of the trial).  
36    Vital status was recorded at each follow-up visit. Follow-up visits were conducted by  
37    telephone calls. For patients that remained hospitalised after the end of the treatment  
38    period, follow-up visits were conducted in hospital until discharge and thereafter by  
39    telephone call. Trial completion was defined as the completion of all follow-up visits.

## 40    **Statistical analysis**

41    The proportions of patients alive and free of mechanical ventilation at Day 29 (primary  
42    endpoint) was analysed using a logistic regression model with covariates of treatment,  
43    severity grade at baseline, age, creatinine at baseline and duration of symptoms before  
44    hospitalization. The logistic regression for the primary endpoint analysis was used for all  
45    other binary endpoints, whereas time-to-event endpoints were analysed using a Cox  
46    regression, which included the same covariates used for the primary endpoint analysis. The  
47    difference in ventilator-free days between BI 764198 and placebo groups was analysed  
48    using ANCOVA model including the same covariates as in the primary endpoint analysis.  
49    Efficacy analyses were performed according to a prespecified analysis plan in all randomized  
50    patients documented to have received at least one dose of trial medication (full analysis

51 set). The intent-to-treat principle was applied to the randomized set, including all observed  
52 data in the primary analysis regardless of treatment discontinuation.

### 53 **Sensitivity and subgroup analyses**

54 A sensitivity analysis was conducted with a logistic regression model including covariates of  
55 treatment, severity grade at baseline, age, creatinine at baseline, D-dimer at baseline, and  
56 duration of symptoms before hospitalisation. Subgroup analysis was performed using  
57 descriptive statistics.

### 58 **Determination of sample size**

59 The proportion of patients assumed to be alive and free of mechanical ventilation at Day 29  
60 in the placebo group is expected to be ~81%. It is assumed that BI 764198 would increase  
61 this proportion by 9% (from 81% to 90%). The probability of observing  $\geq 5\%$  improvement in  
62 the primary endpoint ( $\geq 86\%$  in BI 764198 group as opposed to 81% in placebo group) is 72%  
63 under this assumption with a total of 130 patients (65 patients per group). If there is no  
64 treatment effect (81% in both BI 764198 and placebo group), the probability of observing  
65  $\geq 5\%$  improvement is 22% as depicted in Table E2. As the treatment policy is used to analyse  
66 the primary endpoint, early discontinuation is not considered in the sample size calculation.
