Institute of Radio Engineering and Electronics (IRE),  
Information and Communications University (ICU)**

# Objective

- Provide the simulation result of non-coherent ranging system based on chaotic signal with proposed preamble
  - Show the low cost solution using low rate clocks for non-coherent ranging system
  - It also can be applied to the system based on burst impulse radio

# Chaotic Signal

- Chaotic is flexible enough to change the data rate in a very simple way

OOK, the burst chaotic signaling time can be  
 $T_s = 100 \text{ ns}$ ,  $T_m = 400 \text{ ns} \Rightarrow 2.5 \text{ Mbps}$

And  $T_s$  and  $T_m$  values can be flexibly changed to any specification in case of chaotic signal  
 Ex:  $T_s = 50 \text{ ns}$ ,  $T_m = 200 \text{ ns} \Rightarrow 5.0 \text{ Mbps}$

PPM (Mitsubishi, TDC, I2R, etc)

OOK Wellborn (Freescale)  
 $T_s = 109 \text{ ns}$ ,  $T_m = \sim 218 \text{ ns} \Rightarrow \text{burst rate avg. } 2.3 \text{ MHz}$

# Low Clock Rate Ranging Method

This ranging algorithm can be applied to a system that compare the reference clock and the received waveform or only by comparison of two different rate of clock waveform

**N1, N2, N3** – pulse numbers

$$T_x = (N3 + 0.5 * N2) / f_1 - (N1 + 0.5 * N2) / f_0$$

distance

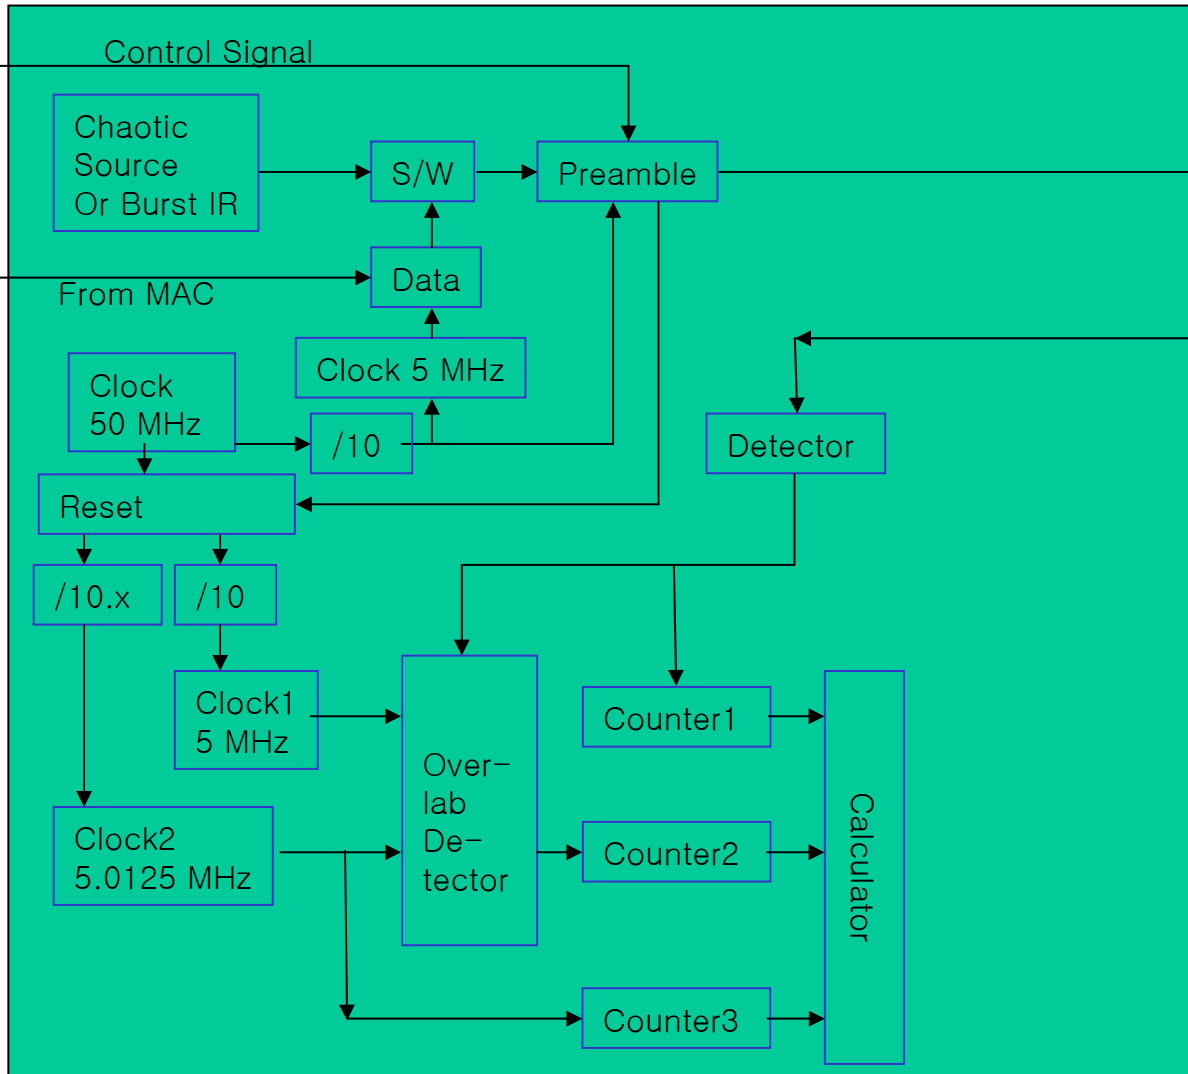

$$S = 0.5 * c * (T_x - \tau_0)$$

$\tau_0$  – retranslation time

Operation time of counters **C<sub>1</sub>, C<sub>2</sub>, C<sub>3</sub>**.

# Low Clock Rate Ranging System

Hardware implementation in case of two low rate clock wave form comparison

Clock 5 MHz  
1/4 high, 3/4 low state

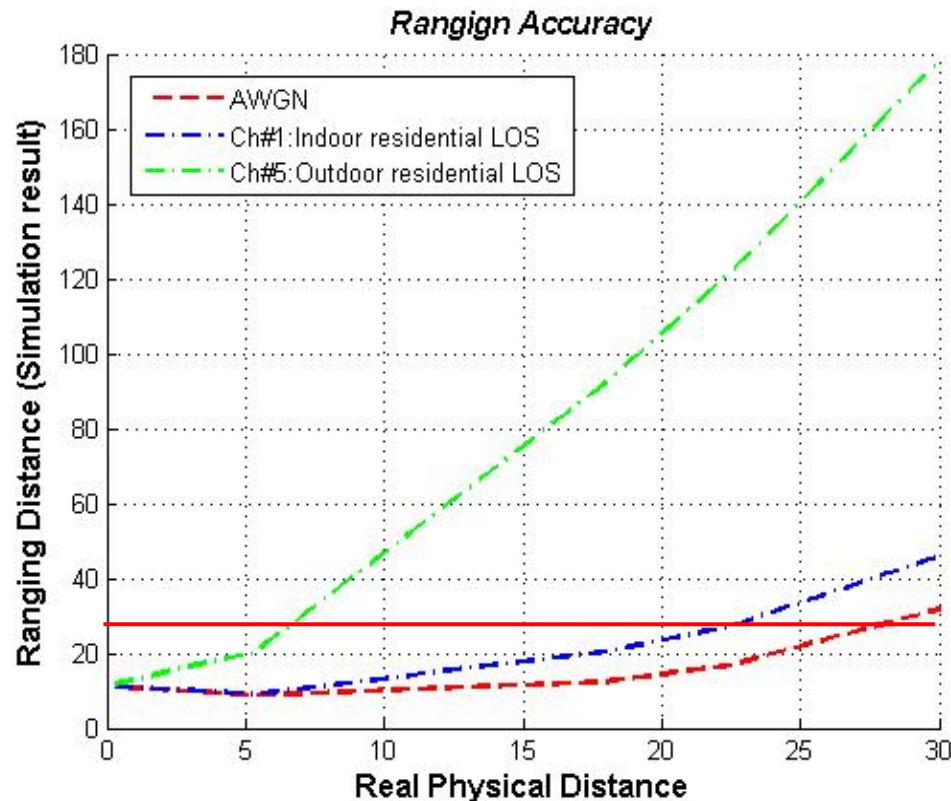

Clock1 5 MHz  
1/4 high, 3/4 low state

Clock2 5.0125 MHz  
1/4 high, 3/4 low state

# Simulation Result

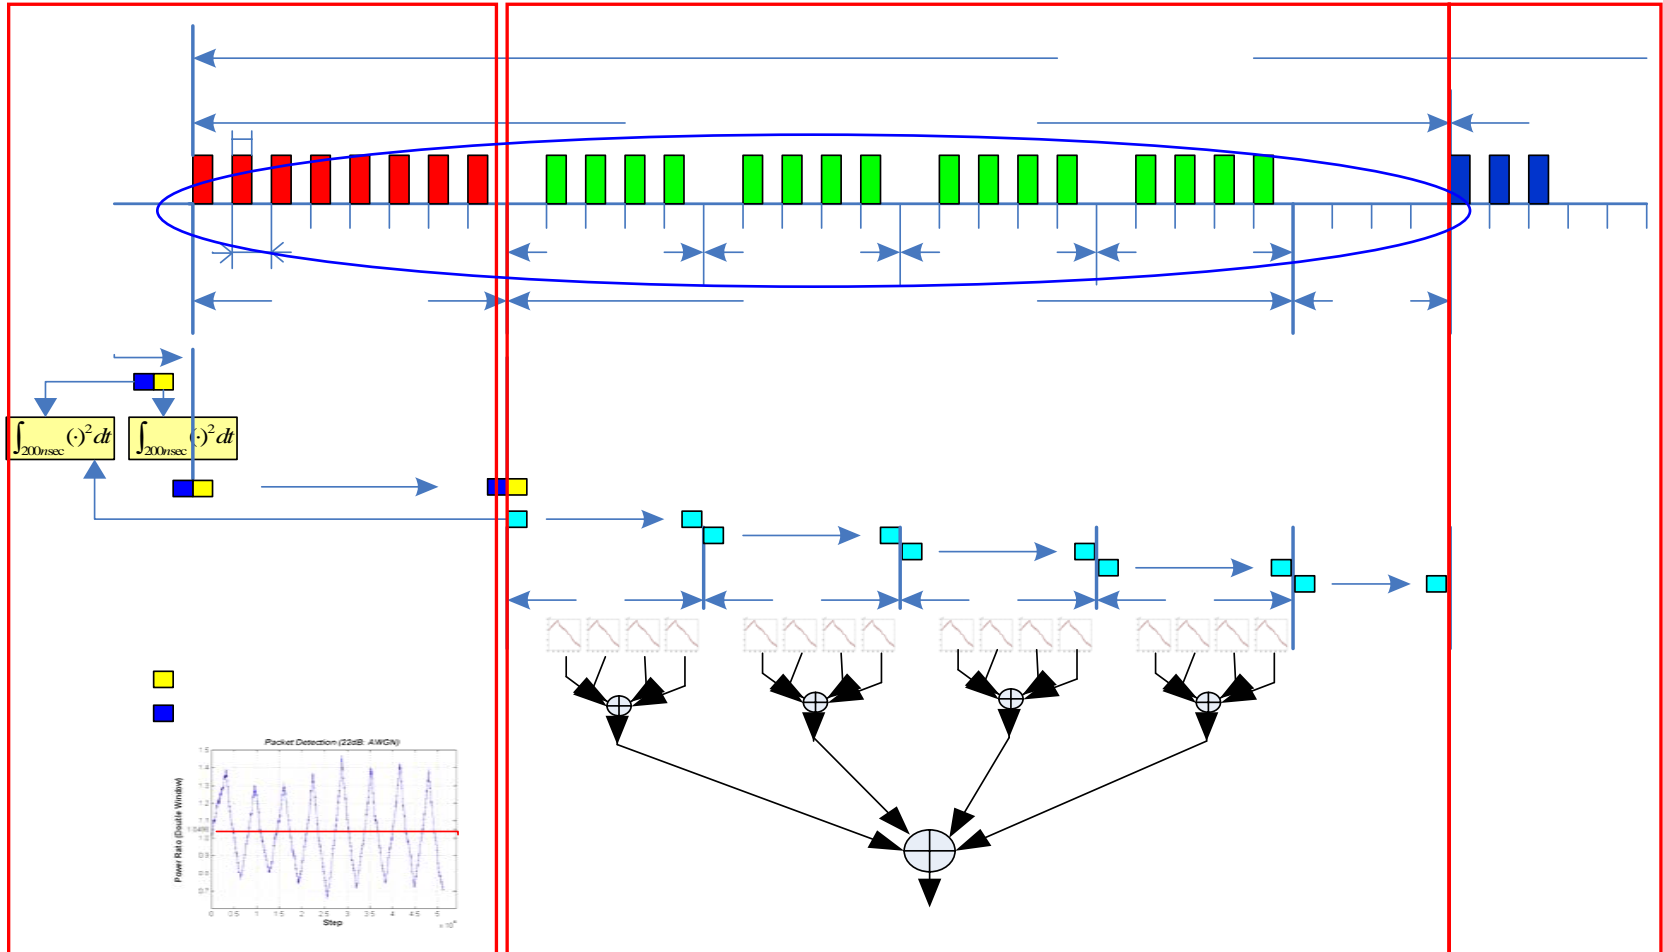

- Simulation result of ranging system using the proposed preamble, detection, double window synchronization, and low rate clock ranging algorithm

# Preamble Used for Simulation

Four bytes preamble structure

**Packet Detection** → **Symbol Synchronization** → **Discernment for SFD**

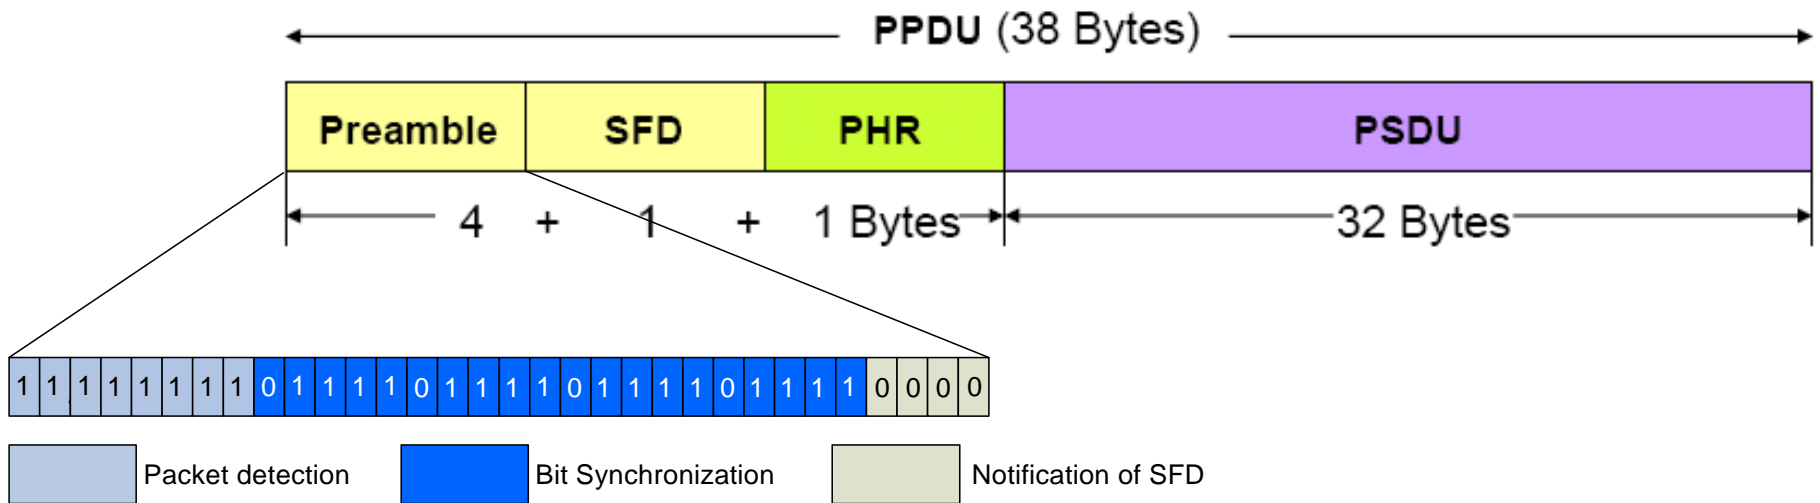

# Back-up Slides

# Preamble

- Proposed preamble consists of packet detection part, symbol synchronization part for non-coherent ranging system

# Preamble Design

- Proposed Preamble Format

- (1) → **Packet Detection Interval: 1 1 1 1 1 1 1 1**

- One Symbol : 2.5MHz → 400ns
- Half Duty Cycle (Adapted into All Preamble Format)
  - 1) Multipath Immunity
  - 2) Efficient Sync.

- (2) → **Symbol Synchronization Interval: 01111 \* 4**

- First 0 : Detected by threshold already decided during the packet detection period

1) **First 0** : Switching Double window into Single Window

→ Symbol Sync.

2) **Next 0** : Reset Memory for next symbol sync. period

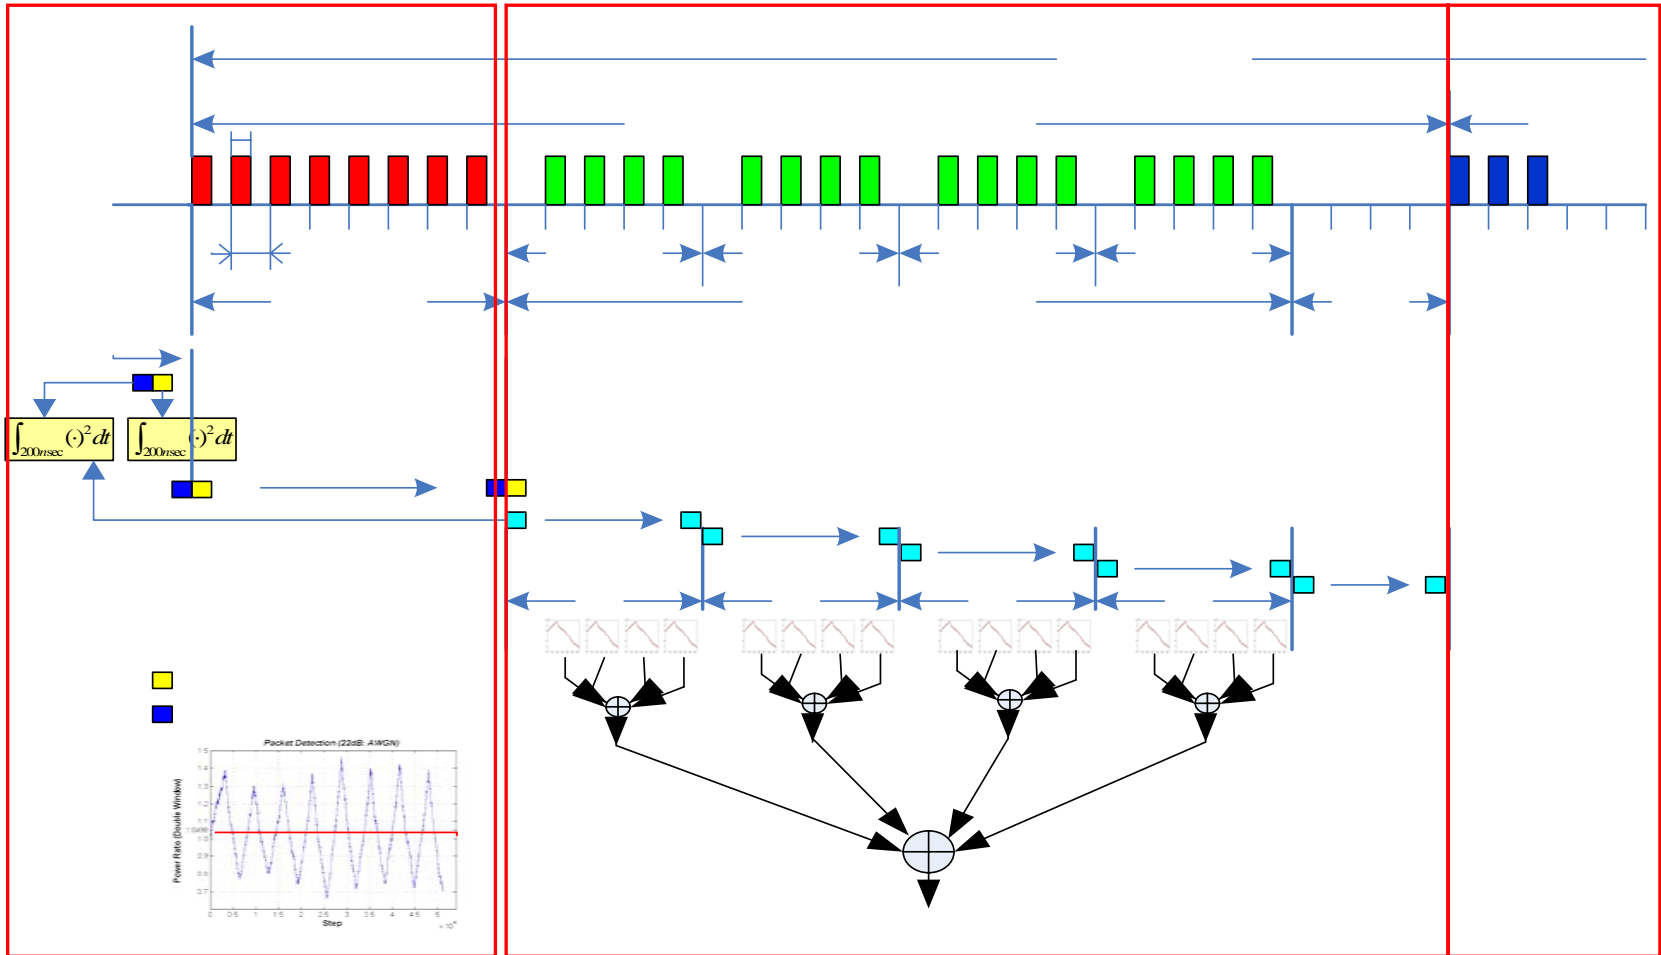

→ 4 Same Period : improve the possibility of detecting the accurate symbol sync.

- (3) → **Discernment for SFD (1 1 1 0 0 1 0 1: 1 byte (IEEE 802.15.4)) : 0000**

- Detected by threshold, same with detecting 0 for symbol sync.

# Synchronization (Proposed Algorithm)

Packet Detection  $\longrightarrow$  Symbol Synchronization  $\longrightarrow$  Discernment for SFD

# Synchronization (Cont'd)

## Proposed Algorithm (Packet Detection)

### Double Window Method

Two sequential window

(same integration interval: half duty cycle(200ns))

Decision for threshold (COOK Modulation)

→ Ideally, at exact the incoming packet time, the value of the beyond the equation is satisfied

$$\frac{A \text{ Window Integration result}}{B \text{ Window Integration result}} = 1 + SNR$$

Output of the Double Sliding Window

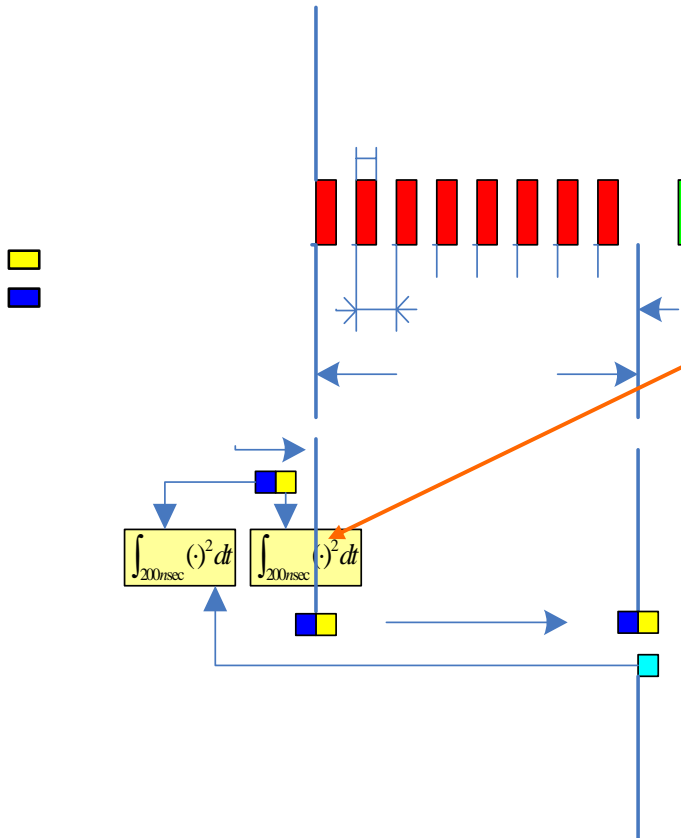

$$m_n = \frac{a_n}{b_n} \quad \text{where } a_n, b_n \text{ are power of sliding window}$$

$$a_n = \sum_{m=0}^{M-1} |r_{n-m}|^2$$

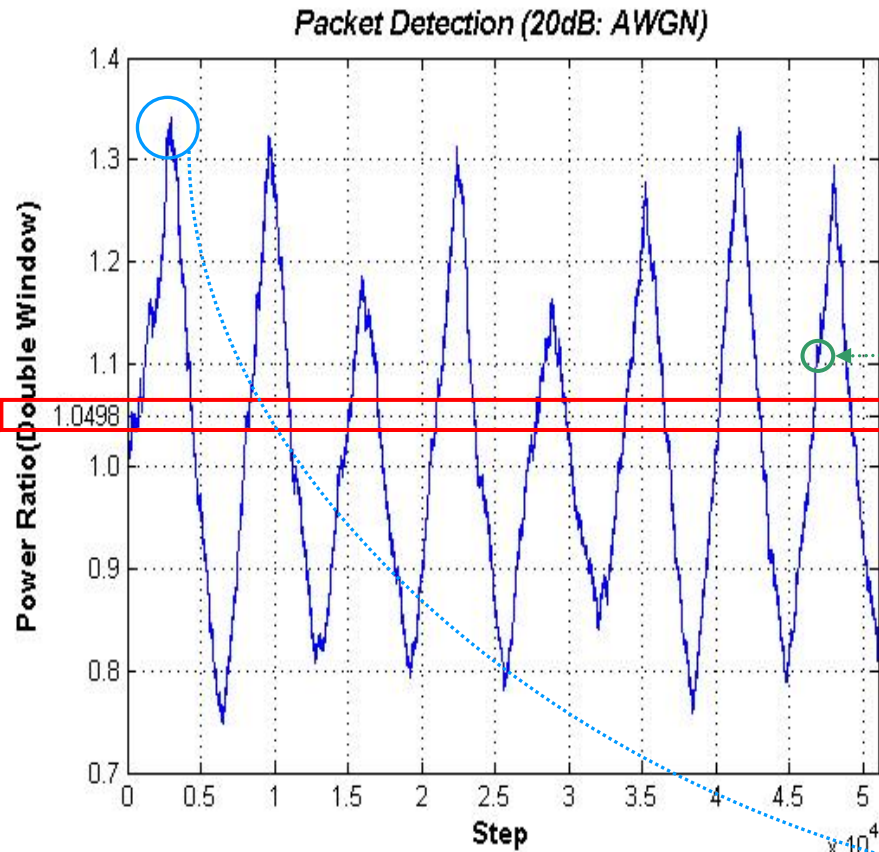

$$b_n = \sum_{l=1}^L |r_{n+l}|^2$$

Threshold

$$\text{threshold} = \frac{\text{mean}(\text{Peak}_{\max}) + 1}{2}$$

# Synchronization (Cont'd)

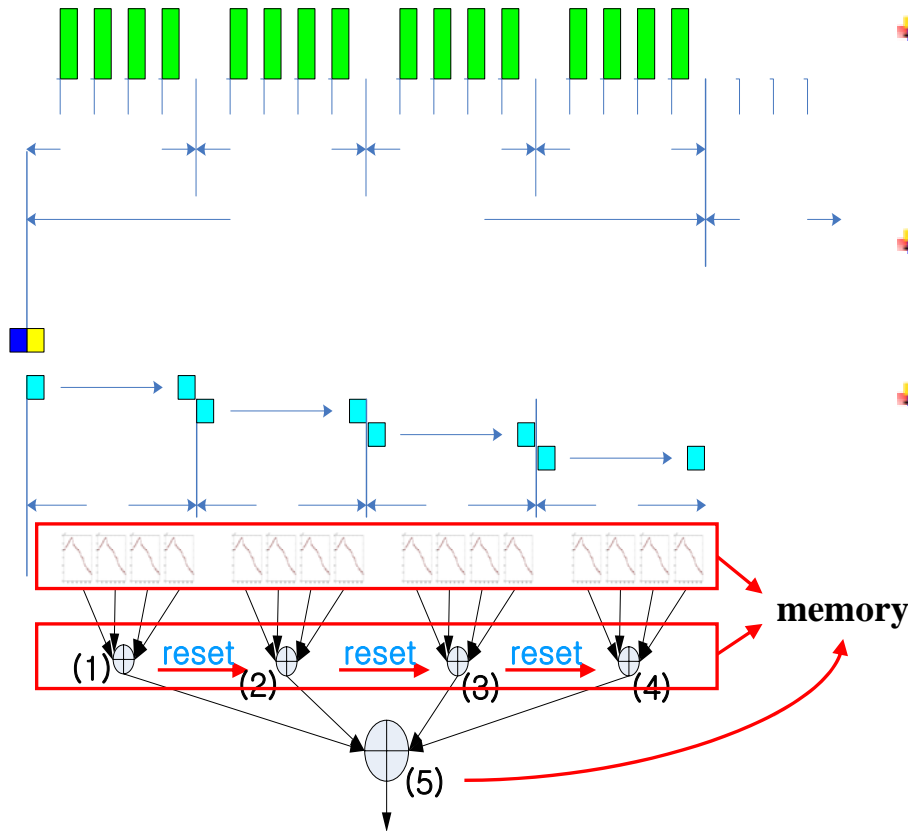

**Threshold: 1.0498**  
**(2.5Mbps, Half Duty Cycle)**

- ✚ All 8 Peak from the Output of Double Sliding Window  
 → Packet Detection Success  
 (Statistically, **20dB** is enough)
  
  - ✚ Soon after detecting the packet by aforementioned packet detection procedure, the last exact point above the threshold is stored in memory for symbol sync. → **Coarse Sync.**
  
  - ✚ After deciding the incoming of the packet, Detecting the first 0 of symbol sync. Composition(20bit)by the threshold (**Coarse Decision**)  
 →  $\frac{\text{Max Pw}(\text{Signal} + \text{Noise})}{\text{Min Pw}(\text{Noise})}$  at fist peak point
- threshold. =  $\frac{\text{Output of Window A}}{\text{Output of Window B}}$

# Synchronization (Cont'd)

## Proposed Algorithm (Symbol Synchronization)

### Single Window Method

#### Why Single Window? (instead of Double Window)

→ No need for the exact threshold w.r.t. different EbNo

→ Half computation complexity

From the previous Threshold, first 0 detection trigger the change of the window from double into single.

#### Two symbol Synchronization Method

1<sup>st</sup> approach (complex method)

- At the coarsely synchronized point, stored during packet detection process, start to preserve all the sliding integration output till detect the next 0 bit.

- Advantage → High accuracy with Chaotic pulse

- Disadvantage → High Memory requirement

# Synchronization (Cont'd)

## Proposed Algorithm (**Symbol Synchronization**)

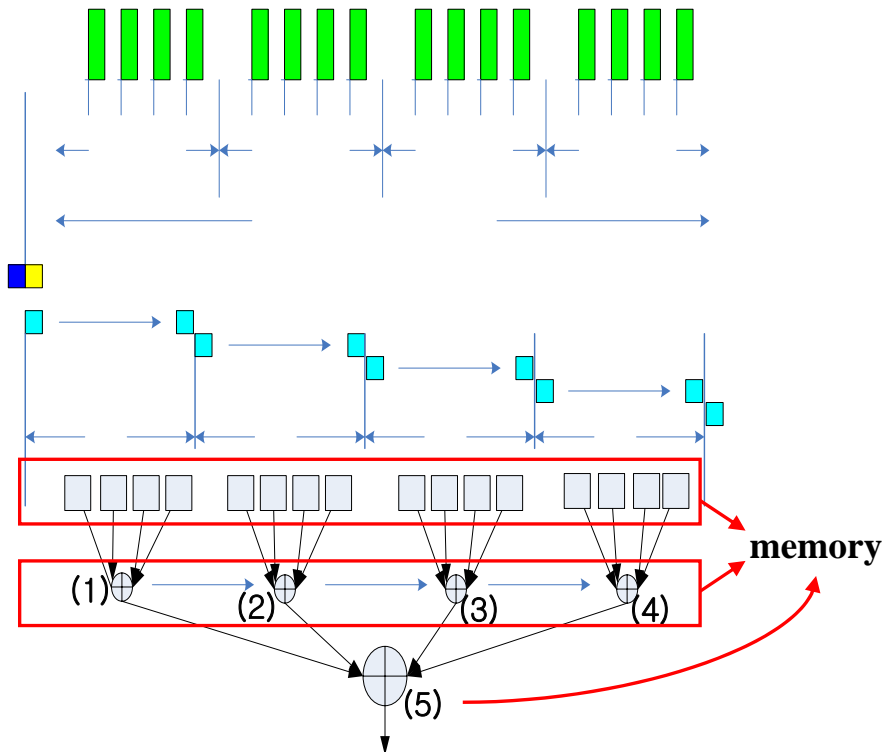

### Single Window Method

#### 2<sup>nd</sup> approach (**Simple** method)

- At the coarsely synchronized point, stored during packet detection process, start to preserve **only distance difference value between the coarse sync. point and max. point** till detect next 0 bit.
- Advantage → low memory requirement
- Disadvantage → less accurate sync. Accuracy (refer to the simulation result)

#### Detecting the next 0 bit (inside the next sync. bit period(5bit)), sum all the value in the memory, send the value into other memory and reset the memory for the next sync. Period

- Keep doing the previous procedure till the last period
- Realizing the end of the sync. Period(4), all four value will be summed and find exact the Symbol sync. Point

# Synchronization (Cont'd)

## Proposed Algorithm (**Discernment for SFD field**)

- ✚ Distinguish the SFD field (**1 1 1 0 0 1 0 1**)
- ✚ Due to the knowledge of the exact start of the symbol, start to detect the next symbol with the same threshold as the symbol synchronization process.
- ✚ As all 4 zero sequence is detected, then receiver know the exact start time of SFD field and prepare for reading the SFD field

# Synchronization

## Simulation Result (AWGN channel)

Synchronization Error(AWGN)

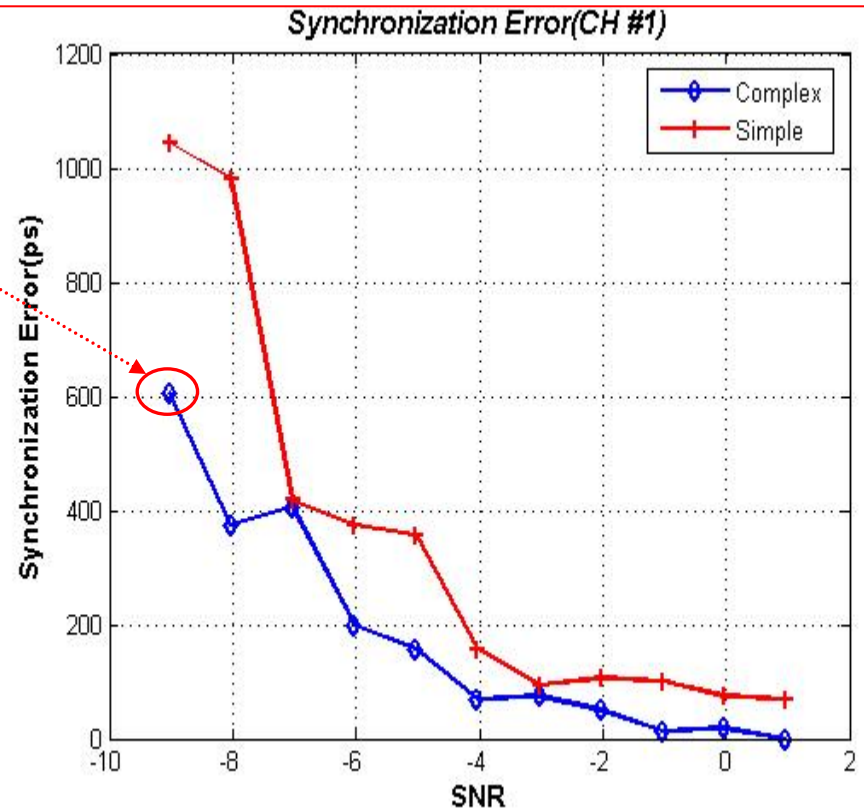

- ✚ EbNo : 20dB~30dB
- ✚ Assumption(Adapted to all result)
  - ✚ Packet Detection failure → Discard that packet
  - ✚ Minimum EbNo for the success of statistically enough possibility of packet detection(1%) → 20dB : Only Chaotic Pulse Case
  - ✚ 10 iteration to improve the statistical reliability
- ✚ Evaluation for two symbol sync. Method.
  - Complex > Simple**
  - Sufficiently reliable for the ranging purpose → **maximum 437 pico.sec** synchronization error in case of complex method → small ranging error

# Synchronization

## Simulation Result (Ch #1: Indoor Residential LOS)

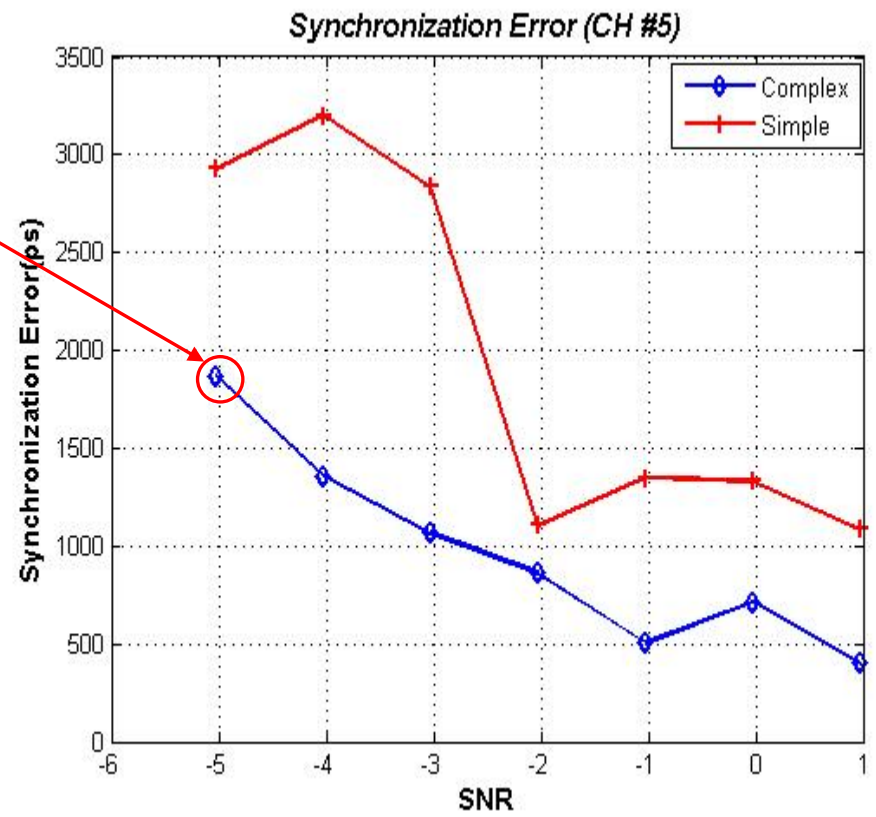

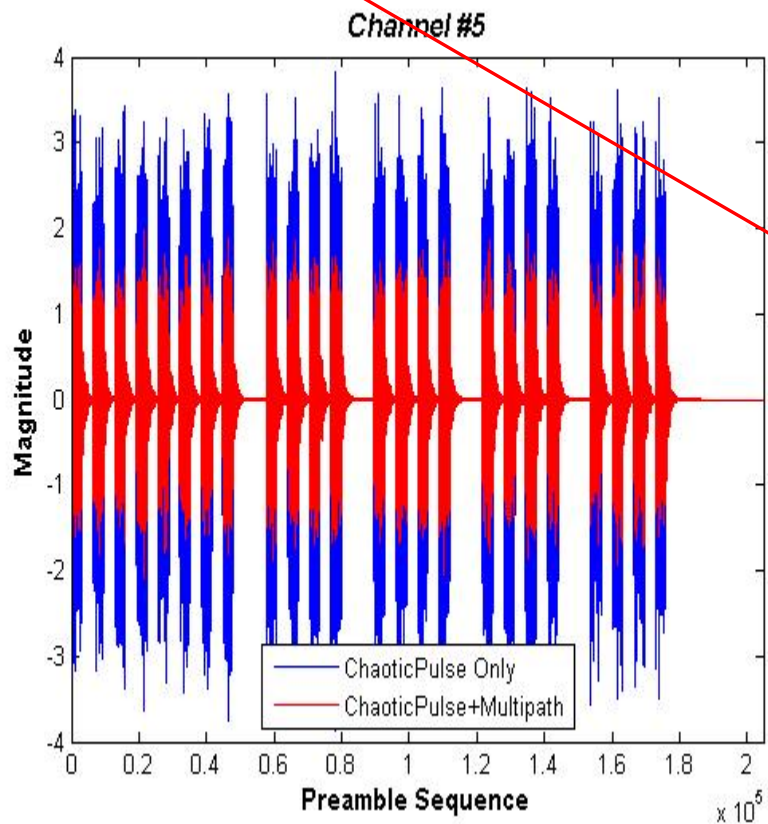

- ✚ Almost the same Sync. Error as the AWGN case (Minimum 20dB requirement for 1% packet detection, same as AWGN)
- ✚ **Max 608 pico. sec** synchronization error in case of complex method

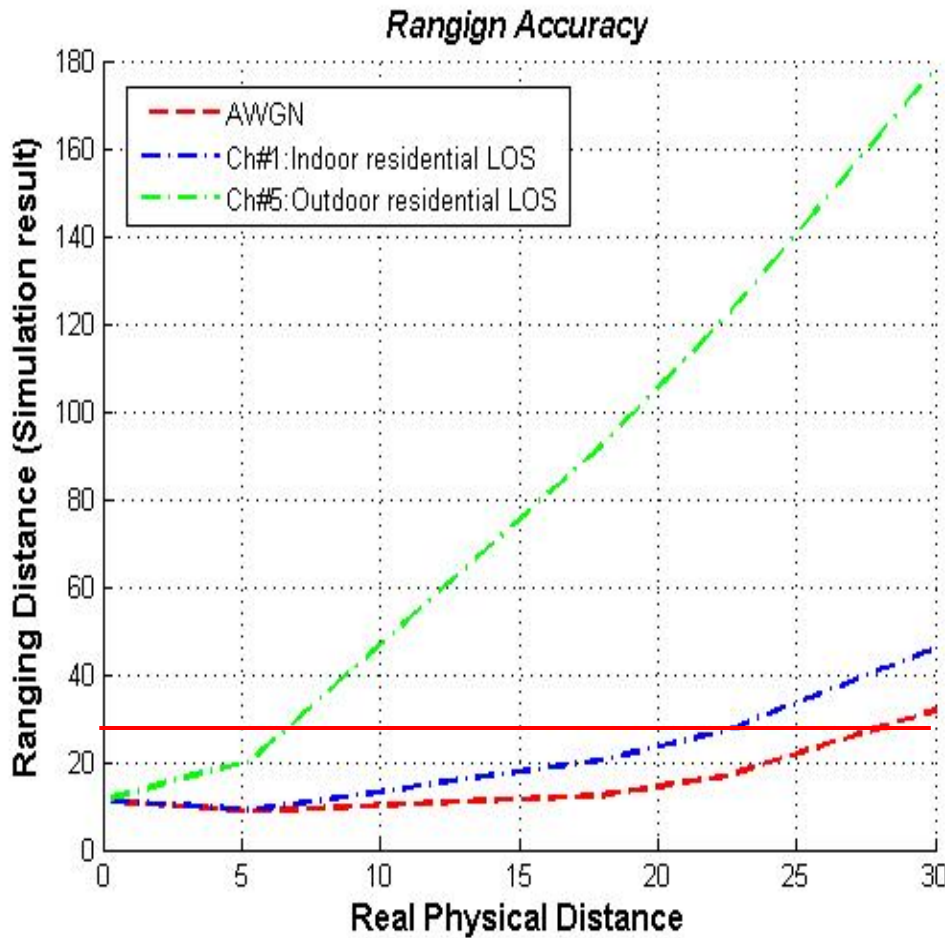

# Synchronization

## Simulation Result (Ch #5: Outdoor Residential LOS)

- ✦ Minimum 24dB requirement for 1% packet detection
- ✦ Max 1803 pico. sec synchronization error in case of complex method

# Ranging Accuracy

## Assumption

- Retransmission time: 50ns
- F1 = 2.5125MHz
- F0 = 2.5MHz
- 0 ~ 20 meter
  - Synch. Error + Ideal Ranging Algorithm Distance Difference
- 20~30 meter
  - Expectation based on the Simulation Error (Not statistically Reliable results)

Technical Requirement  
→ 25 cm
